  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <fileName></fileName>
    <closeFile></closeFile>
  </OpenFile>
</openFiles>
...
</hard>

```

The algorithm is processing data for service provider A100. It returns the following information related to the file name, namely the single File Name in the output related to this service provider and adds its file to the open file list and indicates that it should be closed. (Note that file-per-work-unit is the only known use case where the algorithm will know that it is the last entry for a file and to close itself.)

```

<hard>
...
<fileName>MYFILE_A100_{BC}_{TN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>MYFILE_A100_{BC}_{TN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>

```

Multiple Open Files Example

This example assumes that the file names are defined as per the Managing File Names section above. We'll assume that the algorithm designer chose to not actively close the person information file since there are never more than three files open. Similarly, we'll assume that they chose not to order the data by person type. Here is what is passed in in the middle of the run:

```
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>persons_<personType>_{BN}.txt</value>
  </BatchParm>
  <BatchParm>
    <name>contactFileName</name>
    <value>contacts_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <fileName>persons_P_{BN}.txt</fileName>
    <closeFile></closeFile>
  </OpenFile>
  <OpenFile>
    <fileName>persons_B_{BN}.txt</fileName>
    <closeFile></closeFile>
  </OpenFile>
  <OpenFile>
    <fileName>contacts_{BN}.txt</fileName>
    <closeFile></closeFile>
  </OpenFile>
</openFiles>
...
</hard>
```

An instance of one call to Process Records algorithm that has details for an individual ("P" person type).

```
<fileName>persons_P_{BN}.txt</fileName>
<fileOutput>
  <listValue>
    <SchemaInstance>
      <recordXMLNode>person</recordXMLNode>
      <schemaName>CM-PersonDetail</schemaName>
      <schemaType>FLSS</schemaType>
      <fileName></fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
  <listValue>
    <SchemaInstance>
      <recordXMLNode>person</recordXMLNode>
      <schemaName>CM-AddressDetail</schemaName>
      <schemaType>FLSS</schemaType>
      <fileName></fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
  <listValue>
    <SchemaInstance>
      <recordXMLNode></recordXMLNode>
      <schemaName>CM-ContactDetail</schemaName>
      <schemaType>FLSS</schemaType>
      <fileName>contacts_{BN}.txt</fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
</fileOutput>
```

This XML example illustrates the following points:

- There is an override file name in the fileName element.
- The first two schemas don't have any value in the fileOutput\listValue\SchemaInstance\fileName so they should be written to the file in fileName. Note that these two schemas also include a Record XML Node. That will ensure that if the output is XML format, the data from both of those schemas will be wrapped by the 'person' XML Node. This is not functionality related to this epic. It's just trying to illustrate multiple features.
- The third schema has an entry in fileOutput\listValue\SchemaInstance\fileName . So that data is written to a separate file.

Uploading Records

The base product provides a background process to upload data from a file. The batch control Plug-in Driven File Upload Template (**F1-PDUPL**) may be used as a template. The process includes parameters to configure the file path and file name for file to upload along with other parameters to control how to handle missing files and how to rename the file once processed. Refer to the description of the batch control and its parameters for more information.

This background process requires an algorithm plugged into the plug-in spot **File Upload**. This plug-in is called once for a given file. The batch process opens the file and passes to the algorithm the file reader element. The algorithm associated with the batch control is responsible for using provided APIs to read the content of the file and store the data in appropriate table(s) (for example, an appropriate staging table). The base provided process supports uploading multiple files and may be run mutli-threaded to process multiple files. Each file is processed by one call to the File Upload algorithm and supports a single commit for the records uploaded in a given file.

NOTE: Plug-in scripts written to implement this type of algorithm must use the Groovy script engine version as the APIs are not accessible using the XPath scripting language. Refer to [Additional Coding Options For Server Scripts](#) for more information.

Note that this step in the upload of data is only one part of a typical upload end-to-end process. This step is sometimes referred to in the product as "Process X". The goal of this step is to get records from a file into database records, with minimal validation and processing. The data should be stored in records that are then processed by a second step (often referred to in the product as the "upload" step, for example "Payment Upload"). The second step, independent of the plug-in driven batch process described here, is responsible for validating the data and should be able to be threaded by individual records and have proper error handling for individual records. Note that depending on the type of data being uploaded, the product may already supply appropriate tables that the plug-in driven upload process may populate. These could be staging tables, such as payment upload staging. Or they may be records with business objects that have a lifecycle designed to handle uploaded data, for example Business Flag. In such cases, the product will typically supply out-of-the-box background processes to validate and further process the data and finalize the upload. If the data to upload does not already have a base provided staging table, be sure to work with your implementation team to identify an appropriate table to use for the plug-in driven batch upload. In addition, confirm the design for the second step that is responsible for the detailed validation and finalization of the data.

The product supplies sample algorithms to illustrate calling the supplied APIs for processing different types of source data: comma delimited, fixed position and XML. In every case, the sample data supported by the upload uses 'degree day' information to illustrate the process. The system provides sample target records (based on the Fact maintenance object) in order to illustrate the step to store records based on the input data. Note that only sample plug-in scripts have been provided. No algorithm, algorithm type or batch control is configured to use the sample plug-in scripts. To view the scripts, navigate to the [Script](#) page, search for a Script Type of **Plug-in Script** and Algorithm Entity of **Batch Control - File Upload** and look for the 'Sample' scripts.

Note that the sample plug-in scripts provided by the product are supplied to illustrate use of the provided APIs. They should not be considered a template for how to implement a plug-in script for a real use case. The following highlight some points to consider when designing a file upload algorithm:

- **Error handling / resolution.** The sample plug-in scripts do some basic error handling related to the data to illustrate error handling. However, any errors found in this step require processing of the whole file to stop. As such, this plug-in should only report errors that are not possible to fix, but where the whole file should be rejected. If there are errors that can be adjusted in the data, then the recommendation is to not check for those errors at this step. Rather, this plug-

in should simply populate the appropriate staging tables and let the next step check for validity. As described above, the next step should include the ability to mark individual records in error, allowing for users to fix the data and retry.

- **Target tables.** The sample plug-in scripts use Fact as the target for the resulting insert statements. As mentioned above, the decision of where to store the uploaded data must be carefully considered. There may already be existing tables that are specific to a given use case. If the data being uploaded does not have existing tables to use, review the product to verify what existing tables may be useful, such as Inbound Sync Request or Service Task. Be sure that the tables chosen support error handling, either out-of-the box or via designing an appropriate business object with a lifecycle that supports an error status and the ability to resolve the error. Also note that the Sample Flat File Upload plug-in illustrates a header record / detail record scenario. In this case, the header record is linked to the child record via a CLOB element. This is not the recommended technique. In a real use case, the header record should be linked to the child record via a separate database column to allow for searching.

Configuring a New Process

The following points summarize the steps needed to implement a new file upload background process:

- Verify the details of the data in the upload file and map the data to fields in one or more appropriate tables in the system.
- Design the logic required for reading the record details and identifying each record to properly create the insert statements for storing the data. The sample plug-in scripts provided by the product illustrate using the various APIs available for use. Create a [plug-in script](#) where the algorithm entity is **Batch Control - File Upload**. Create an appropriate algorithm type and algorithm for this plug-in script.
- Create a batch control by duplicating the base template. Plug in the algorithm created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the File Upload algorithm.

How to Re-extract Information

If you need to recreate the records associated with an historical execution of an extract process, you can - simply supply the desired batch number when you request the batch process.

How to Submit Batch Jobs

Most batch jobs are submitted via a batch scheduler. Refer to [Batch Scheduler Integration](#) for information about the integration with the Oracle Scheduler.

Batch jobs may be configured as **Timed**, which means they will automatically be run based on the timer frequency.

You can manually submit your adhoc background processes or submit a special run for one of your scheduled background processes using the online [batch job submission](#) page.

The system provides a [REST web service](#) (using the inbound web service **F1-SubmitJob**) to create a batch job submission request from an external system. Note that no parameter defaulting occurs when submitting a record using a web service. All the desired parameter values must be provided.

How to Track Batch Jobs

You can track batch jobs using the batch process pages, which show the execution status of batch processes. For a specified batch control id and run id, the tree shows each thread, the run-instances of each thread, and any messages (informational, warnings, and errors) that might have occurred during the run.

FASTPATH: For more information, refer to [Tracking Batch Processes](#).

How to Restart Failed Jobs and Processes

Every process in the system can be easily restarted if it fails (after fixing the cause of the failure). All you have to do is resubmit the failed job; the system handles the restart.

Assessing Level of Service

For some background processes, an implementation may wish to supply one or more algorithms that check some conditions to assess whether or not the process is performing as expected. An algorithm could be used to check the performance of the job to see if it is running as efficiently as expected. Or it could analyze the data processed by the background process to assess whether there may be some problem with the quality of the data.

The system provides a Level of Service plug-in spot on [batch control](#) to configure the appropriate algorithms for a given background process, if desired. Each algorithm is expected to return a value to indicate the 'level of service' determined along with a message indicating the reason for the value. The following Level of Service values are supported:

- **Normal.** Indicates that the algorithm did not detect any issues.
- **Warning.** Indicates that the algorithm found some issues that may or may not indicate a problem.
- **Error.** Indicates that the algorithm found some issues that should be investigated.
- **Disabled.** Indicates that the algorithm could not properly execute the level of service logic.

When viewing a [batch control](#) record, if there are any level of service algorithms configured, the logic is executed and the results are displayed. The level of service is also part of the [Health Check](#) service.

Defining Batch Controls

The system is delivered with all necessary batch controls. Implementations may define default values for parameters. In addition, implementations may define their own background processes.

To view background processes, open **Admin > System > Batch Control**.

Use the **Batch Control Query** portal to search for an existing batch control. Once a batch control is selected, you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Background Processing Concepts](#) for more information.

CAUTION: Important! If you introduce a new batch process, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **Batch Process** and **Description** for each batch process.

Owner indicates if this batch control is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a batch control. This information is display-only.

Use the **Detailed Description** to describe the functionality of the batch process in detail.

Enter the **Application Service** that is used to provide security for submission requests for the batch control. The application service must have an Access Mode of **Execute**. Refer to [Granting Access To Batch Submission](#) for more information.

Use **Batch Control Type** to define the batch process as either **Timed** or **Not Timed**. A [Timed batch process](#) will be automatically initialized on a regular basis. A Not Timed process needs to be run manually or through a scheduler.

Use **Batch Control Category** to categorize the process for documentation purposes. The base values provided are as follows:

- **Ad Hoc.** Processes of this type are run on an ad hoc basis, only when needed. For example, if there is a process to do a mass cancel / correction of data, it would only be run when a situation occurs requiring this.
- **Extract.** Extract processes extract information that is interfaced out of the system. Processes of this type typically extract records marked with a given run number. If the requester of the process does not supply a specific run number, the system assumes that the latest run number should be extracted. If you need to re-extract an historical batch, you simply supply the respective run number when you request the batch process.
- **ILM. Information Lifecycle Management** jobs are crawler background processes that are associated with the ILM based storage solution.
- **Monitor.** Processes of this type are processes related to business objects with a lifecycle state that defines [monitor algorithms](#). The monitor process selects records in a given state and executes its algorithms, which may cause the record to transition to another state or may trigger some other logic to occur. Using configuration, the monitor process may target only specific records. Refer to [Monitoring Batch Processes](#) for more information. Note that these types of background processes can be considered a subset of **Process What's Ready**
- **Process What's Ready.** Processes of this type create and update records that are “ready” for processing. The definition of “ready” differs for every process. For example, a payment upload process creates payments for every record that is **pending**. An overdue event monitor activates pending overdue events that have reached their trigger date.
- **Purge.** Processes of this type are used to purge historical records from certain objects that generate a large number of entries and may become unwieldy over time.
- **To Do Entry.** Processes of this type are used to detect a given situation and create or complete a To Do Entry. Refer to [To Do Entries Created by Background Processes](#) for more information.
- **Upgrade.** Processes of this type are typically run only one time and are used to populate data in a table based on information that can be determined elsewhere in the system. These are processes that could have been done through an upgrade script, but perhaps due to data volume or timing, the upgrade logic warranted a separate stand-alone process.
- **Upload.** Processes of this type are used to upload data from a file into the system.
- The following categories are related to the data conversion / migration processes:
 - **Conversion.** Processes of this type are dedicated to converting or migrating data from external applications into the product.
 - **Object Validation.** Processes of this type are dedicated to validate data within objects for conversion or migration purposes.
 - **Referential Integrity.** Processes of this type are dedicated to validate referential integrity within objects for conversion or migration purposes.

NOTE: Additional categories may be introduced by your specific product.

If the batch process is Timed, then the following fields are available:

- **Timer Interval** is the number of seconds between batch process submissions. The system will start the next run this many seconds from the start time of the previous run.
- **User ID** is the ID under which the batch process will run.
- **Email Address** is the Email address to be used for notification if the batch process fails.
- **Timer Active** allows you to temporarily switch off the timer while retaining the other settings for the timed job.
- **Batch Language** is the language associated with the batch process.

Use **Program Type** to define if the batch process program is written in **Java** or **Java (Converted)**, meaning that the program has been converted into Java.

NOTE: **Java (Converted)** program types are not applicable to all products.

Use **Program Name** to define the Java class / program associated with your batch process.

NOTE: View the source. If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadocs](#) viewer.

Level of Service shows the output of the [level of service](#) algorithms for the batch control. If one algorithm is plugged into the Batch Control, the level of service lookup value along with a message indicating the reason for the output value is shown. If multiple algorithms are plugged in, the text **See Results for Details** is displayed. There is an icon provided to expand the details returned by each algorithm. If no level of service algorithm is found, then the value **Disabled** is shown with a message indicating that no algorithm is provided for this batch control.

The **Last Update Timestamp**, **Last Update Instance** and **Next Batch Nbr** are used for audit purposes.

Turn on **Accumulate All Instances** to control how this batch control is displayed in the [Batch Run Tree](#). If checked, the run statistics (i.e., "Records Processed" and "Records in Error") for a thread are to be accumulated from all the instances of the thread. This would include the original thread instance, as well as any restarted instances. If this is not turned on, only the ending (last) thread instance's statistics are used as the thread's statistics. This may be preferred for certain types of batch processes where the accumulation would create inaccurate thread statistics, such as those that process flat files and, therefore, always start at the beginning, even in the case of a restart.

The following fields are default values that are used when a batch job is submitted for the batch control:

- Use **Thread Count** to control whether a background process is run single threaded or in multiple parallel threads. This value defines the total number of threads that have been scheduled.
- Select **Trace Program Start** if you want a message to be written whenever a program is started.
- Select **Trace SQL** if you want a message to be written whenever an SQL statement is executed.
- Use **Override Nbr Records to Commit** to define the default number of records to commit. This is used as the default value for timed jobs as well as online submission of jobs that are not timed.
- Select **Trace Program Exit** if you want a message to be written whenever a program is exited.
- Select **Trace Output** if you want a message to be displayed for special information logged by the background process.

For more information about these fields, see [Batch Job Submission - Main](#)

The parameter collection is used to define additional parameters required for a particular background process. The following fields should be defined for each parameter:

Sequence. Defines the relative position of the parameter.

Parameter Name. The name of the parameter as defined by the background process program.

Description. A description of the parameter.

Detailed Description. A more detailed description of the parameter.

Required. Indicates whether or not this is a required parameter.

Parameter Value. The default value, if applicable. Any value entered here is displayed to a user when submitting a job through online [Batch Submission](#). Users may override the value before submitting the job. This includes resetting the value for an optional parameter. Regardless of how a batch job is submitted, if a value is not supplied for a required parameter, the default value define here, if found, is used. Optional parameters with no value supplied at submission time will not be defaulted to a value defined here. Note that an implementation may define a default value for base provided batch controls.

Security. Indicates whether the system should **Encrypt** the parameter value or not. A value of **Encrypt** means that the parameter value is stored in the database and written to the log files using encryption. In addition, the parameter is written to the log files with asterisks. The setting applies to values entered here as well as in the online [Batch Submission](#). If there is no need to secure the parameter value, use the default setting of **None**.

Owner Indicates if this batch process is owned by the base package or by your implementation (Customer Modification). The system sets the owner to **Customer Modification** when you add a batch process. This information is display-only.

Batch Control - Algorithms

Use this page to maintain a batch control's algorithms. Open this page using **Admin > System > Batch Control** and then navigate to the **Algorithms** tab.

Description of Page

The **Algorithms** grid contains algorithms that control important functions for instances of this batch control. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes the **System Events**.

System Event	Optional / Required	Description
Error Post-Processing	Optional	Algorithms of this type are called if the batch process fails to complete due to an error. Multiple algorithms are allowed and are executed in sequence order. Refer to Error Post-Processing Logic for more information.
File Upload	Optional	Algorithms of this type are only applicable to plug-in driven background processes and are used to upload all records for a file. This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.
Level of Service	Optional	Algorithms of this type are called to determine the Level of Service provided by a batch control. Multiple algorithms are allowed. Refer to Assessing Level of Service for more information.
Post-Processing	Optional	Algorithms of this type are called after all threads are complete. Multiple algorithms are allowed and are executed in sequence order. Refer to Post-Processing Logic for more information.
Process Record	Optional	Algorithms of this type are only applicable to plug-in driven background processes and are used to process a specific record. This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.
Select Records	Optional	Algorithms of this type are only applicable to plug-in driven background processes and are used to define the SQL to use to select the records to process. This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.

NOTE: You can add new system events. Your implementation may want to add additional batch control oriented system events. To do that, add your new values to the customizable lookup field **F1_BATCH_CTRL_SEVT_FLG**.

Defining File Integration Types

This section describes the functionality supported for viewing and maintaining file integration types.

Refer to [Extract Record Processing](#) for an overview of the file integration type functionality provided with [plug-in driven background processes](#).

To view or add a file integration type, open **Admin > Integration > File Integration Type**.

Once a file integration type record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **File Integration Records** zone lists the record definitions for this integration, in hierarchical order. Use the zone actions to add, maintain or view a file integration record. Press the **Record Layout** icon to view a pop-up display of the record's schema.

On-Line Batch Submission

The on-line [batch submission](#) page enables you to request a specific background process to be run. When submitting a background process on-line, you may override standard system parameters and you may be required to supply additional parameters for your specific background process. After submitting your background process, you may use this page to review the status of the submission.

The following topics further describe logic available for on-line submission of background processes.

Batch Submission Creates a Batch Run

When you request a batch job to be submitted from on-line, the execution of the desired background process will result in the creation of a batch run. Just as with background processes executed through your scheduler, you may use the [Batch Run Tree](#) page to view the status of the run, the status of each thread, the run-instances of each thread, and any messages that might have occurred during the run.

NOTE: Your on-line submission record is assigned a status value so that you may know whether your job has been submitted and whether or not it has ended, however, it will not contain any information about the results of the background process itself. You must navigate to the [Batch Run Tree](#) page to view this detail.

Jobs Submitted in the Background

When you save a record on the batch job submission page, the batch job does not get submitted automatically. Rather, it saves a record in the batch job table. A special background process will periodically check this table for pending records and will execute the batch job. This background process will update the status of the batch job submission record so that a user can determine when their job is complete.

NOTE: At installation time, your system administrator will set up this special background process to periodically check for pending records in the batch job submission table. Your administrator will define how often the system will look for pending records in this table.

It should be noted that this special background process only submits one pending batch job submission record at a time. It submits a job and waits for it to end before submitting the next pending job.

NOTE: If you request a batch job to be run multi-threaded, the special background process will submit the job as requested. It will wait for all threads to complete before marking the batch job submission record as **ended**. Refer to [Running Multi-threaded Processes](#) for more information.

Email Notification

If you wish the system to inform you when the background process completes, you may supply your email address. The email you receive will contain details related to the batch job's output; similar to the job results you would see from your batch scheduler.

The email includes information from the product installation to help users that may be working in and submitting background processes in more than one environment.

- It includes the product name and product version for the product in the [installed products](#) list that is marked as the one to display.
- If a domain name message is configured in the [installation messages](#), this information is also included.

NOTE: This assumes that during the installation process, your system administrator configured the system to enable email notification. Your administrator may also override the amount of detail included in the email notification.

NOTE: A batch control parameter may be used to indicate if the email should only be sent in the case of an error or success or both. Refer to [Parameters Supplied to Background Processes](#) for more information.

Running Multi-Threaded Processes

Many of the system background processes may be run multi-threaded. When submitting a background process on-line, you may also run a multi-threaded process. The fields Thread Count and Thread Number on the [batch submission](#) page control the multi-threaded process requests:

- To run a multi-threaded process, indicate the number of threads in **Thread Count** and enter **0** in the **Thread Number**. If a previous run ended with one or more threads in error, a new submission may be created to restart all the threads that were in error. This submission would result in new Batch Thread Instance records added for each thread that previously ended in error. Note that if the previous run was marked to "Do Not Restart", then a new submission will result in a new Batch Run.
- In the situation where a previous run resulted in one or more threads in error, you may use the Thread Number to indicate a specific thread to restart. This is only valid if there is a previous run found that is not marked "Do Not Restart". This will result in a new Batch Thread Instance created for the specific thread in the previous run.
- To run a process as a single thread, enter Thread Count = **1** and Thread Number = **1** (or **0**). This will execute the background process single-threaded.

NOTE: When running a multi-threaded process, the special background process will wait until all threads are complete before marking the batch job submission record as **Ended**.

Batch Jobs May End in Error

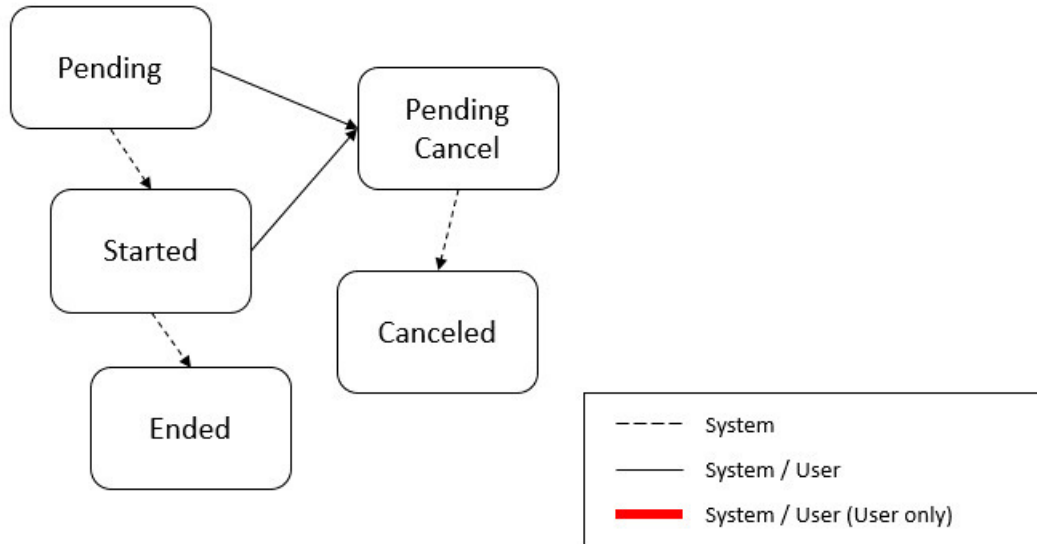

It is possible for your background process to end with an error. When this occurs, your batch job submission record will still be marked as **Ended**. You will need to navigate to the [Batch Run Tree](#) page to determine the status of the batch run.

Submitting Jobs in the Future

If you wish to request a batch job to be submitted in the future, you may do so when creating your batch job submission record by entering a future submission date. The special background process, which looks for pending records in the batch job submission table, will only submit batch jobs that do not have a future submission date.

Lifecycle of a Batch Job Submission

The following diagram illustrates the lifecycle of a batch job submission record.

Pending – Records are created in **Pending** status. Records in this state are put in a queue to be submitted.

Started – Once a pending record has been submitted for processing, its status will be changed to **Started**.

Pending Cancel – Users may request the cancellation of a pending record to prevent the batch job from being submitted. In addition, users may request to cancel a started batch job that was not initiated by DBMS scheduler. The system will look for records in this status and look for batch runs that may need to be canceled for this batch job. Once it is confirmed that any batch runs are stopped, the status changes to **Canceled**.

Ended – When the batch job has finished processing, its status will be changed to **Ended**. Note that records in **Ended** status may have ended in error. Refer to [Batch Jobs May End in Error](#) for more information.

Granting Access To Batch Submission

Every batch control must reference an [application service](#). When you link a batch control to an application service, you are granting all users in the group the ability to submit the associated batch job for execution.

FASTPATH: Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

When the batch control is added to the batch job table, the system checks if both the user submitting the job and the user ID recorded on the batch submission record have access rights. Application security does not apply when viewing a batch control or an associated batch run.

NOTE: Base batch controls will be associated with base owned application services by default. Implementations will need to ensure the appropriate user groups are linked to these application services.

Batch Job Submission - Main

This page allows you to submit a batch job on-line. Navigate to this page using **Menu > Tools > Batch Job Submission**.

Description of Page

The **Batch Job ID** is a system generated random number that identifies a particular submission.

To submit a batch job, choose the **Batch Code** for the process you wish to submit.

The following parameters are provided with each background process:

Thread Number should typically be set to 0. Refer to [Running Multi-threaded Processes](#) for situations where populating a value other than 0 are warranted.

Thread Count is used to control whether a background processes is run single threaded or in multiple parallel threads. It contains the total number of threads that have been scheduled. For example, if the process has been set up to run in 20 parallel threads, each of the 20 instances receives a thread count of 20. Refer to [Running Multi-threaded Processes](#) for more information about populating this field.

NOTE: Not all processes may be run multi-threaded. Refer to the description of a batch control to find out if it runs multi-threaded.

Batch Rerun Number is only used for background processes that download information that belongs to given run number. It should only be supplied if you need to download an historical run (rather than the latest run).

Batch Business Date is only used for background processes that use a date in their processing. In Oracle Utilities Customer Care and Billing, for example, a billing process can use the business date to determine which bill cycles should be downloaded. If this parameter is left blank, the system date is used at the time the background process is executed.

NOTE: Saving a record on this page does not submit the batch job immediately. A special background process will run periodically to find pending records and submit them. Depending on how often the special process checks for pending records and depending on how many other pending records are in the 'queue', there may be a slight lag in submission time. If the desired execution date/time is close to midnight, it is possible that your batch job will run on the day after you submit it. If you have left the business date blank in this case, keep in mind that your business date would be set to the day after you submit the job.

Override Nbr Records To Commit and **Override Max Timeout Minutes**. These parameters are optional and override each background process's Standard Commit Records and Standard Cursor Re-Initiation Minutes. (Each background process's Standard Commit Records / Standard Cursor Re-Initiation Minutes should be documented in the detailed description of the batch control record). Note that Max Timeout Minutes corresponds to the Cursor Re-initiation Minutes.

FASTPATH: Refer to [Parameters Supplied to Background Processes](#) for more information.

User ID is the user ID associated with the run of the background process. It may differ from the user who submitted the batch, as described below. Refer to [Parameters Supplied to Background Processes](#) for more information about the significance of the user id.

NOTE: This field defaults to the id of the current user.

Language is used to access language-specific control table values. For example, error messages are presented in this language code.

If you wish the system to notify you when the batch job is complete, enter your **Email ID**. Refer to [Email Notification](#) for more information.

NOTE: This field defaults to the email address for the current user, if populated on the [user](#) record.

The **Desired Execution Date/Time** defaults to the current date and time. Override this information if you wish the background process to be executed at some future date and time. Refer to [Submitting Jobs in the Future](#) for more information.

The **Batch Job Status** indicates the current status of the batch job. Refer to [Lifecycle of a Batch Job Submission](#) for more information.

The **Submission Method** indicates how the batch job was initiated. Valid methods include:

- **Online** - populated when a user manually creates or manually duplicates a batch job submission.
- **Generated** - populated by algorithms that submit a batch job and by 'initiator' batch jobs that submit other batch jobs.
- **Scheduled** - populated by the DBMS scheduler. Note that for other schedulers, it is not advised to use this value as there may be logic and validation related to records created with this value that may not apply to other schedulers.
- **Timed** - populated by the batch daemon that submits timed batch jobs.
- **Other** - populated when no other value is provided.

Additional values may be added by your implementation. Refer to the lookup **SUBMIT_METH_FLG** for a list of the submission methods supported by your system.

The **Submission User** indicates who initiated the batch job. This value is not populated for timed batch jobs or batch jobs submitted via a scheduler. It is only displayed if the field is populated.

The **Program Name** associated with the batch control code is displayed.

The following trace parameters may also be supplied to a background process and are only used during QA and benchmarking.

- **Trace Program Start** Turn on this switch if you wish a message to be written whenever a program is started.
- **Trace Program Exit** Turn on this switch if you wish a message to be written whenever a program is exited.
- **Trace SQL** Turn on this switch if you wish a message to be written whenever an SQL statement is executed.
- **Trace Output** Turn on this switch if you wish a message to be displayed for special information logged by the background process.

NOTE: The information displayed when the trace output switch is turned on depends on each background process. It is possible that a background process displays no special information for this switch.

NOTE: The location of the output of this trace information is defined by your system administrator at installation time.

If additional parameters have been defined for this background process on the Batch Control page, the **Parameter Name**, **Description**, **Detailed Description** and an indicator of whether or not the parameter is **Required** are displayed.

If a default parameter value is configured on the batch control configuration, that value is shown and may be overridden. Confirm or enter the appropriate **Parameter Value** for each parameter. Note that if the parameter value is configured to be Encrypted on the batch control configuration, the value here will be shown encrypted.

Once you have entered all the desired values, **Save** the record in order to include it in the queue for background processes.

If you wish to duplicate an existing batch job submission record, including all its parameter settings, display the submission record you wish to duplicate and use the **Duplicate and Queue** button. This will create a new Batch Job Submission entry in pending status. The new submission entry will be displayed.

If you wish to cancel a **Pending** or a **Started** record that does not have the **Scheduled** submission method, use the **Cancel** button. The button is disabled for all other status values.

Tracking Batch Processes

The topics in this section cover the tools provided for reviewing the status and performance of batch processes. Refer to [Defining Batch Controls](#) for more information on how batch control codes are defined.

Batch Run Tree

The batch run tree pages show the execution status of a selected batch process. For a specified batch control id and run id, the tree shows each thread, the run-instances of each thread, and any messages (informational, warnings, and errors) that might have occurred during the run.

Batch Run Tree - Main

This page allows you to view the status of a specific execution of a batch job. Navigate to this page using **Menu > Tools > Batch Run Tree**.

Description of Page

Select a **Batch Control** process and **Batch Number** to view information and statistics on the batch run's "threads". The following points should help understand this concept:

- Many batch jobs cannot take advantage of your hardware's processing power when they are run singularly. Rather, you'll find that a large percentage of the CPU and/or disk drives are idle.
- In order to minimize the amount of idle time (and increase the throughput of your batch processes), we allow you to set up your batch processes so that multiple instances of a given batch job are executed at the same time. For example, in Oracle Utilities Customer Care and Billing when you schedule the **billing** process, you can indicate that multiple parallel instances should be executed (rather than just one instance). You'd do this so that the processing burden of creating bills for your customers can be spread over multiple processes.
- We refer to each parallel execution of a batch process as a "thread".
- Statistics and information messages are displayed in respect of each thread. Why? Because each thread is a separate execution and therefore can start and end at different times.

The **Start Date/Time** and **End Date/Time** of the batch run are shown.

The tree includes a node that displays the total number of records processed for the batch run, the total number of records in error for the batch run and the batch run elapsed time. The elapsed time is the longest elapsed time among the batch thread(s). The message is red if there are any records in error. If the application properties file has been configured with the location of the log files and the log files associated with the batch run are still available, the links **Download stdout** and (if applicable) **Download stderr** are visible. Clicking either link allows you to view or save the log files. Note that the logs here are only related to the processing that occurs before the thread execution.

NOTE: Compression. The log files are compressed and include a *.gz extension. Different browsers treat this type of file differently. Some browsers may automatically decompress the file as part of the download and they are viewable in any text viewer by changing the extension to one the text viewer recognizes. However, some browsers download the compressed file and a user will need to unzip the file prior to viewing.

NOTE: Security Access. The 'download' hyperlinks are only visible for users that have security access to the **Download** access mode for the batch run tree application service.

Within each thread, a node appears for each batch instance for the thread. A thread will only have more than one instance in the case of a thread that ended in error where a user subsequently restarted the run. The **Start Date/Time** and **End Date/Time** of the batch run are shown, if populated.

The messages that appear under a thread instance show the start and end times of the execution instance. If errors are detected during the execution of the thread, these error messages may also appear in the tree. Refer to [Processing Errors](#) for information about the types of errors that appear in the batch run tree.

If the background process has been enabled to create [To Do entries for object specific errors](#), information about the To Do entries are displayed in the tree. This information is not displayed for each thread, but rather all the To Do entries created for the batch run are grouped together. The To Do entries are grouped by their status.

If the log files associated with the batch thread are still available, the links **Download stdout** and (if applicable) **Download stderr** are visible. Clicking either link allows you to view or save the log files. The above notes about file compression and security access for downloads applies to these files as well.

Batch Run Tree - Run Control

By default, if a batch process fails, it will restart. This tab allows you to modify the restart status of a failed run.

Navigate to this page using **Menu > Tools > Batch Run Tree** search for the desired batch control and then navigate to the **Run Control** page.

Description of Page

On the main page, you must select a **Batch Control**, **Batch Number**, and **Batch Rerun Number** to view a tree of the batch run. On this page, the following information is displayed:

- **Last Update Timestamp** contains the date and time the most recent batch run started or completed.
- **Batch Business Date** is the business date that was supplied to the background process (this date is used as the "system date" by the process).

Run Status indicates the status of the batch run. Valid values are: **In Progress**, **Error**, and **Complete**.

If the **Run Status** is **Error**, the system will attempt to restart this run when you attempt to execute the **Batch Control**. In most situations, this is exactly what you want to happen. However, there are rare situations where you do not want the system to execute a given batch run (e.g., if this run is somehow corrupt and you cannot correct the data for whatever reasons). If you want the system to skip the execution of a batch run (and proceed to the next run), turn on **Do Not Attempt Restart**.

Batch Day Tracking

The batch day tracking pages provide information to quickly determine the status and performance of the daily batch workload for a selected business date. The portals contain zones to provide details about run status and individual thread performance to assist in detecting data and performance issues with individual batch runs.

Batch Day Dashboard

This portal provides a high level summary of the status, duration and other details of the batch jobs that ran on a given business date. An implementation may introduce additional zones to this portal as needed.

Use **Menu > Dashboards > Batch Day Dashboard** to navigate to the portal.

Batch Runs By Business Day

This zone provides a summary by business date of the number of batch runs completed, in error, and in progress, together with the earliest start time and latest end time of the jobs on that day. The zone is sorted in descending order by business date.

NOTE: For performance reasons, the zone is configured to restrict the number of rows retrieved by the query. The 'Results' number will indicate how many rows have been retrieved. Use the Next and Previous buttons to retrieve additional dates or return to a prior set of dates.

The following filters are provided:

- **Batch Business Date** allows you to select a particular business date.
- **Process Date** allows you to restrict the batch runs included in the summary to those where the processing date is within the start and end dates for the run.
- **Exclude Reruns** allows you to exclude batch reruns from the summary.

NOTE: The values selected in these filters will be applied as hidden filters to the other zones in the portal.

When a specific business date is broadcast from the summary, the following zones will appear as part of the portal's **Main** tab page.

Batch Day By Status

This zone summarizes the batch runs for the business date by their status, displayed in the form of a pie chart. Selecting a specific slice of data on the chart broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action to reset the filter set by this zone.

Batch Day By Category

This zone summarizes the batch runs for the business date by their batch category, displayed in the form of a pie chart. Selecting a specific slice of data on the chart broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action to reset the filter set by this zone.

Batch Jobs Summary

This zone displays details of the individual batch runs for the broadcast business date. The zone is sorted by batch control, batch run number and batch rerun number.

NOTE: For performance reasons, the zone is configured to restrict the number of rows retrieved by the query. The 'Results' number will indicate how many rows have been retrieved. Use the Next and Previous buttons to retrieve additional rows or return to a prior set of rows.

The following filters are provided:

- **Batch Control** allows you to select a particular batch control to review. This filter supports wildcard searching.
- **From Start Date/Time** restricts the batch runs displayed to those where the start date time is on or after this date and time.
- **To Start Date/Time** restricts the batch runs displayed to those where the start date time is on or before this date and time.
- **From End Date/Time** restricts the batch runs displayed to those where the end date time is on or after this date and time.
- **To End Date/Time** restricts the batch runs displayed to those where the end date time is on or before this date and time.
- **Batch Control Type** restricts the batch runs displayed to the selected type.

The following columns are displayed initially:

- **Batch Control** is the batch control ID of the batch run.
- **Description** is the description of the batch control. Click the hyperlink to navigate to the [Batch Run Threads](#) portal.
- **Batch Run** is the run number of the batch job. Click the hyperlink to navigate to the [Batch Run Tree](#).

- **Status** is the status of the batch run.
- **Start Date/Time** is the start time of the run.
- **End Date/Time** is the end time of the run. The current date and time may be displayed if the batch job is still in progress.
- **Duration** is the time taken for the run, formatted as Days:Hours:Minutes:Seconds.
- **Threads** is the total threads for the batch run.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Batch Category** is the category of the batch run.
- **Batch Control Type** is the type of the batch run.
- **Do Not Attempt Restart** indicates whether the run has been marked not to be restarted.
- **Rerun Nbr** is the rerun number of this batch job.

Batch Run Threads

This portal provides details and analysis of the threads for a given batch run. It is accessed via a link from the batch jobs summary zone on the [Batch Day Dashboard](#). An implementation may introduce additional zones to this portal as needed.

The following zones will appear as part of the portal's **Main** tab page

- **Thread Summary.** This zone displays details of the individual threads for the batch run in context. It can be filtered by thread status.
- **Threads by Status.** This zone displays a count of the number of threads by status for the selected batch run, in the form of a pie chart.
- **Threads by Volume.** This zone displays a count of the records processed and records in error for each thread in the selected batch run, in the form of a bar chart.
- **Threads by Elapsed Time.** This zone displays the elapsed time for each thread in the selected batch run, in the form of a horizontal bar chart.
- **Threads by Records Per Second.** This zone displays the number of records processed per second for each thread in the selected batch run, in the form of a horizontal bar chart.

The Big Picture of Requests

Requests enable an implementer to design an ad-hoc batch process using the configuration tools.

An example of such a process might be to send an email to a group of users that summarizes the To Do entries that are assigned to them. This is just one example. The request enables many types of diverse processing.

Request Type Defines Parameters

For each type of process that your implementation wants, you must configure a request type to capture the appropriate parameters needed by the process.

Previewing and Submitting a Request

To submit a new request, go to **Menu > Tools > Request** in add mode. You must select the appropriate request type and then enter the desired parameter values, if applicable.

After entering the parameters, the following actions are possible:

- Click **Save** to submit the request.
- Click **Cancel** to cancel the request.
- Click **Preview** to see a sample of records that satisfy the selection criteria for this request. This information is displayed in a separate map. In addition, the map displays the total number of records that will be processed when the request is submitted. From this map you can click **Save** to submit the request, **Back** to adjust the parameters, or **Cancel** to cancel the request.

When a request is saved, the job is not immediately submitted for real time processing. The record is saved with the status **Pending** and a monitor process for this record's business object is responsible for transitioning the record to **Complete**.

As long as the record is still **Pending**, it may be edited to adjust the parameters. The preview logic described above may be repeated when editing a record.

The actual work of the request, such as generating an email, is performed when transitioning to **Complete** (using an enter processing algorithm for the business object).

To Do Summary Email

The base product includes a sample request process that sends an email to users that have incomplete To Dos older than a specified number of days.

The following configuration tasks are required to use this process:

- Define an Outbound Message Type. The business object usually defined for the Outbound Message Type is **F1-EmailMessage**.
- Define an External System that contains the Outbound Message Type in one of its steps. In the configuration determine if the communication is through SOA, batch, or real-time processing method when sending the email notification. Refer to [Outbound Messages](#) for more information about configuration needed for the different processing methods.
- Create a Request Type that includes the Outbound Message Type and the corresponding External System.
- Create a Request for the created Request Type.

Defining a New Request

To design a new ad-hoc batch job that users can submit via Request, first create a new Request Type business object. The base product BO for request type, **F1-TodoSumEmailTyp**, may be used as a sample.

The business object for the request includes the functionality for selecting the records to process, displaying a preview map for the user to review, and for performing the actual processing. The base product BO for request, **F1-TodoSumEmailReq**, may be used as a sample. The following points highlight the important configuration details for this business object:

- Special BO options are available for request BOs to support the Preview Request functionality.
 - **Request Preview Service Script**. This script retrieves the information that is displayed when a user asks for a preview of a request.
 - **Request Preview Map**. This map displays the preview of a request.

- The enter algorithm plugged into the Complete state is responsible for selecting the records that satisfy the criteria and processing the records accordingly.

Setting Up Request Types

Use the Request Type portal to define the parameters to capture when submitting a request. Open this page using **Admin > General > Request Type**.

This topic describes the base-package zones that appear on the Request Type portal.

Request Type List. The Request Type List zone lists every request type. The following functions are available:

- Click a **broadcast** icon to open other zones that contain more information about the request type.
- Click **Add** in the zone's title bar to add a new request type.

Request Type. The Request Type zone contains display-only information about a request type. This zone appears when a request type has been broadcast from the Request Type List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click **Edit** to start a business process that updates the request type.
- Click **Delete** to start a business process that deletes the request type.
- Click **Deactivate** start a business process that deactivates the request type.
- Click **Duplicate** to start a business process that duplicates the request type.
- State transition buttons are available to transition the request type to an appropriate next state.

Please see the zone's help text for information about this zone's fields.

Maintaining Requests

Use the Request transaction to view and maintain pending or historic requests.

Open this page using **Menu > Tools > Request > Search**. This topic describes the base-package portals and zones on this page.

Request Query. Use the query portal to search for an existing request. Once a request is selected, you are brought to the maintenance portal to view and maintain the selected record.

Request Portal. This portal appears when a request has been selected from the Request Query portal. The following base-package zones appear on this portal:

- **Actions.** This is a standard actions zone.
- **Request.** The Request zone contains display-only information about a request. Please see the zone's help text for information about this zone's fields.
- **Request Log.** This is a standard log zone.

Attachments

Some implementations may require that attachments be available from the application. These attachments can be stored in the Attachment table and then linked to other objects if applicable.

Attachment Overview

The following topics provide additional information regarding attachment functionality.

Attachment Types

The system supports several different attachment content types, for example:

- PDF Document
- Excel Spreadsheet
- Jpeg Image
- Text Document

The attachment data itself may be text or binary. When storing the data in the application however, it is stored as text information only. As a result, the upload of an attachment that is a binary type requires a conversion prior to storing the data. When viewing the attachment, the data is converted again for display.

Each type of attachment is defined using an attachment business object. The business object includes configuration defining the supported file extensions, whether the data is binary or not and the content type that represents the type of data for the attachment.

NOTE: To view the attachment business objects provided with the base product, navigate using **Admin > System > Business Object > Search** and search for business objects related to the Maintenance Object for Attachments (**F1-ATCHMT**).

Owned Attachments

Attachments can be either 'owned' or 'common'. An owned attachment is one that is related to a specific record. For example, the specific test results for a given device can be uploaded and linked to that device or to its test records. These types of attachments are typically uploaded and maintained via the object that owns it.

Common Attachments

Common attachments are ones that are uploaded independent of any transaction in the system. They can be used for general system or company information. Or they can be linked to more than one transaction. For example, instructions for performing a certain type of task can be uploaded as an attachment and linked to a task type where those instructions are relevant. These types of attachments are uploaded and maintained in the central Attachment portal. Objects that may refer to the attachments may link the attachments via characteristics or some other appropriate mechanism.

Emailing Attachments

The system supports a business service that may be used by system processing to send an email. The business service **F1-EmailService** supports receiving the IDs of one or more attachments as input parameters.

Refer to [Sending Email](#) for more information.

External Reference

Attachment records may be added from an external system in which case, the external system could have a reference ID to capture. The attachment allows for including an external reference ID when adding an attachment internally.

Malware Scan

The system provides a plug-in spot where you can configure a step to scan attachment for malware. If an algorithm is provided, it is called every time attachment content is added.

Configuring Your System for Attachments

In order to link attachments to objects in the system, there may be some configuration or implementation required to support the link. It is possible that one or more objects in your product already support attachments out of the box. Consult the product documentation for the specific object for confirmation. For objects in the system that do not support attachments out of the box, the following sections provide some guidelines for enabling support for attachments. Contact product support for more information.

Supporting Common Attachments

The attachments themselves are created / uploaded using the attachment portal. Refer to [Maintaining Attachments](#) for more information.

If your implementation has a use case where one or more common attachments may be linked to an object (and the object does not already support this functionality), the object may need to be extended to capture the attachments.

- If the object includes a characteristic collection, this is a recommended way to capture attachments. A characteristic type should be defined for each type of attachment. The characteristic type should be a foreign key type and should reference the Attachment FK reference. The characteristic entity collection should include the object that the common attachment will be linked to.
- Most characteristic collections are sequence based characteristics and would support multiple entries for the same characteristic types, if multiple attachments are applicable.
- If the object to support the attachments is governed by a business object, the implementation must extend the business object to define one or more appropriate elements used to capture the attachments. If only one attachment of a certain type is allowed, a single flattened characteristic may be used. If multiple attachments of a certain type are allowed, the BO schema may define a “flattened list” exposing the sequence and the characteristic type.
- If the object is maintained on a “fixed page” with a generic characteristic collection, no additional configuration is needed to allow users to link attachments to that object.

Supporting Owned Attachments

When creating an attachment for a specific record, the attachment itself captures the information about the related record, namely its maintenance object code and its primary key. For these types of attachments, no configuration is needed on the related business object to capture the attachments, as was the case with common attachments.

However, it is recommended to configure the user interface of the related object so that the owned attachments can be viewed and maintained from that page. To do this, you may use the generic attachment zone provided by the product: **F1-ATTCHOWN**.

Note that your product may already have support for viewing and maintaining owned attachments on one or more of its base delivered portals.

Configuring Size Limit

The system allows for configuration of a size limit for uploading attachments. This is optional but the recommendation is to set this to a reasonable value so as to limit the ability to upload unreasonably big files. To configure this, navigate to [Feature Configuration](#). Search for an existing feature configuration with the Feature Type **General System Configuration**. If one does not exist, create a feature configuration of this type. Select the **Maximum Attachment Size** option and define an appropriate value.

Defining a New Attachment Type

As mentioned, the product provides support for several content types. If your implementation needs to support attachments for a content type not currently supported, create a new business object copying the configuration of an existing attachment business object.

Configure the following option types for the BO:

- **Binary** indicates whether the attachment data must be converted from binary format. Binary attachments are stored in the database as text, and are then converted back to the original format when retrieved.
- **Content Type** represents the browser's mime type of the attachment.
- **Supported File Extension** specifies the valid file extensions for the content type.

Once the business object is defined, it is ready for use.

Supporting File Name Exceptions

By default, the system prevents attachment file names from having special characters. If there is some reason that an implementation needs to define an attachment with special characters, there is a system property setting that may be configured to relax this validation. Contact your system administrator for support.

Enabling Malware Scan

The product provides a malware scan algorithm in the base product that uses ClamAV. ClamAV itself is not provided as part of the product. To use the base algorithm, your implementation needs to get ClamAV and define system properties for the host and port where ClamAV may be called. The algorithm, called **F1-ATCHM-WS** should be plugged into the [installation options - algorithms](#) collection using the system event **Attachment Malware Scan**

If your implementation wants to use a different algorithm for malware scanning, you may deliver your own algorithm and plug it into the installation algorithm collection.

Maintaining Attachments

This section describes the functionality supported for viewing and maintaining attachments.

Navigate using **Admin > General > Attachment**. You are brought to a query portal with options for searching for common attachments.

Once an attachment has been selected, you are brought to the maintenance portal to view and maintain the selected record.

NOTE: The base search options for the attachments query only support searching for common attachments. Owned attachments may also be viewed on the attachment maintenance portal, but a user may only drill into the attachment maintenance from the maintenance portal of the “owning” entity.

The Attachment zone provides basic information about an attachment, including the ability to upload the file and to view an uploaded file. Viewing an attachment will typically launch a download of the attachment file, following standard browser behavior.

Adding Attachments

Common attachments may be added from the attachments portal (or via the standard menu path). In addition, your product may support attachments associated with specific records (“entity owned attachments”) which may also provide the capability to add attachments.

In both cases, when adding an attachment, you are prompted for the file to upload. Once the file is chosen, the system determines the appropriate business object to associate with the attachment based on the file extension. Typically one and only one business object is found at which point you are prompted to provide the Attachment Name. (Your specific product may also require additional information at this time). Fill in the details and save.

Please note the following:

- If no business object is found for the uploaded file’s file type, an error is issued. This type of file is not currently supported as an attachment.

- If multiple business objects are found, the user must choose the appropriate one. This should be rare.

Monitoring and Analytics

This chapter describes various tools provided in the product to support system monitoring including tools related to reporting, monitoring and analytics.

Reporting Tool Integration

This section describes how to configure your third party reporting tool and how to define your reports in the system to enable users to submit reports online.

The Big Picture Of Reports

The topics in this section describe the approach for designing and defining your system reports. Note that the product includes an out-of-the-box integration with BI Publisher. However it is possible to use the reporting objects to integrate with a different third party tool.

Integration with BI Publisher

Your DBMS, your product, and BI Publisher can work together to produce reports. You may choose to use a different reporting tool, but this may not be a trivial effort. This section provides high-level information about some of the business requirements that are being solved with the reporting solution.

Multi-Language and Localization Support

The integration supports a multi-language implementation and supports different localization settings.:

- All labels, headings and messages are defined using field and message meta-data in the application, which support multiple languages.
- The appropriate font, size, and layout are based on the requested report and the user's language.
- Dates and numbers are formatted as per the user's display profile.
- Currency based numbers are formatted as per the currency definition from the product

Requesting Reports from The System

Although reports are rendered in your reporting tool, users must be able to request ad-hoc reports from within the system (assuming users have the appropriate security access).

- The prompts for the input parameters must be shown in the user's language
- Users should be able to use the standard search facilities to find parameter values
- Plug-ins can be optionally used to cross-validate input parameters
- Application security must authorize ad-hoc report requests

Overview of the Data - BI Publisher

The following diagram provides an overview of where data is stored for your reports for integration with BI Publisher.

Figure 5: Application and BI Publisher

The application contains:

- The application data that appears on your reports.
- The language-specific headings, labels and messages on your reports.
- The layout file name to be used for the report.

BI Publisher contains:

- How your reports look.
- Information about scheduled reports and reports that have already run.

The DBMS contains the SQL used to retrieve the data on your reports (residing in database functions).

NOTE: BI Publisher can be configured to retrieve data via a service call. Because every business object can be read via a service call, elements that reside in an XML based column can be displayed on reports produced using BI Publisher. See your product's *Installation Guide* or *Optional Products Installation Guide* for information on this configuration.

How To Request Reports

A user may request an ad hoc report from within your product:

- A [report submission](#) page enables a user to choose the desired report and enter the parameter values for the report
- The user must be granted security access to the report
- The request is passed to the reporting tool real time. Refer to [Configure The System to Invoke BI Publisher](#) for more information.
- The reporting tool generates the report and displays it in a new browser window

The reporting tools' scheduler creates reports (as per your schedule). This function is entirely within the reporting tool. No scheduling functions reside within your product.

A user can request an ad-hoc report from within the reporting tool. Note, the user's ID must be supplied as a parameter to the report in order for the user's profile to be used to format dates and numbers

Viewing Reports

As described above, ad-hoc reports requested from within your product are displayed immediately after they are generated in a new browser window

If your reporting tools supports it, the [Report History](#) page may be configured to open tool's report execution history page and request a view of this report.

NOTE: The [Report History](#) page currently does not display historical reports for BI Publisher.

Configuring The System To Enable Reports

Configuring BI Publisher Reports

This section contains topics specific about configuring the product to interoperate with BI Publisher.

Configure the System to Invoke BI Publisher Real-time

The base product provides an [installation algorithm](#) plug-in spot called Reporting Tool. This plug-in spot should contain an algorithm that invokes the third party reporting tool real-time.

For BI Publisher, the system provides an algorithm type called **F1-BIPR-INV**, which invokes BI Publisher.

These algorithms rely on information defined in the [Reporting Options](#) table: the reporting server, reporting folder and the user name and password for accessing the reporting tool. The values in the reporting options should have been set up when the system was installed. Contact your system administrator if there are any problems with the values defined on the reporting options.

To use the algorithm types to invoke BI Publisher, perform the following steps:

- Create an [algorithm](#) for the appropriate algorithm type.
- On the [installation options](#), add an entry to the algorithm collection with an algorithm entity of **Reporting Tool** and indicate the algorithm created in the previous step.

Batch Scheduling in BI Publisher

For many of your reports, you probably want the report to be produced on a regular basis according to a scheduler. The reporting solution relies on the BI Publisher software to provide the batch scheduler functionality. Refer to BI Publisher documentation for details about configuring the batch scheduler.

Defining Reporting Options

The reporting options are provided as a mechanism for defining information needed by your reporting solution. The base product uses the reporting options to define information needed to access the reporting tool from within the system using the algorithm defined on the installation option.

Navigate to this page using **Admin > Reporting > Reporting Options**.

Description of page

Reporting Folder defines the shared folder where reports are stored.

Reporting Server From Browser defines the URL of the web application where the reporting tool is installed. For example, using BI Publisher, the format is: `http://<BI Publisher Server>:<port>`.

NOTE: Customize Options. The reporting options are customizable using the Lookup table. This field name is **RPT_OPT_FLG**. The reporting options provided with the system are needed to invoke the reporting tool. If your implementation requires other information to be defined as reporting options, use the lookup table to define additional values for the reporting option flag.

Where Used

This information is used by the reporting tool algorithm on the [installation option](#) to invoke the reporting tool software.

Implementations may use reporting options to record other information needed for their reporting tool.

Defining Report Definitions

For each report supplied by your installation, use the report definition page to define various attributes of the report.

Report Definition - Main

Navigate to this page using **Admin > Reporting > Report Definition**.

CAUTION: Important! If you introduce new report definitions, you must prefix the report code with **CM**. If you do not do this, there is a slight possibility that a future release of the application could introduce a new system report with the name you allocated.

Description of page

Enter an easily recognizable **Report Code** and **Description** for each report. Use the **External Reference ID** to define the identifier for this report in your external reporting tool.

Define an [application service](#) to enable users to request submission of this report online or to view report history for this report. Once you define an application service for each report, use [application security](#) to define which users may access this report.

NOTE: Access Mode. The access mode for application services related to reports must be set to **Submit/View Report**.

If you have more than one parameter defined for your report and you wish to perform cross-validation for more than one parameter, provide an appropriate **Validation Algorithm**.

Enter a **Long Description** to more fully describe the functionality of this report. This information is displayed to the user when attempting to submit the report online or when viewing history for this report.

For BI Publisher, if you want to use one of the sample reports provided by the system, but with a different layout, indicate the layout to use for the report in the **Customer Specific Font/ Layout** field and BI Publisher uses this information instead. The name for base report layout is <report code>_Base. For example, a base layout for CM_TODO is named CM_TODO_Base.

Report Definition - Labels

Navigate to this page using **Admin > Reporting > Report Definition** and go to the **Labels** tab.

NOTE: Company name and logo. Note the company name used as a title in the sample reports is defined as a message on the [installation options](#). For information about installing the company logo, refer to your product's *Installation Guide* or the *Optional Products Installation Guide*.

Description of Page

In order to provide multi-language capability for each report, the labels used for the report must support multiple language definitions. For each label used by your report, indicate a unique **Sequence** and the **Field** used to define the **Label**. The label defined here should be the same label that is defined in your report layout defined in the external reporting tool.

When rendering an image of the report, the external reporting tool retrieves the appropriate label based on the language used for the report.

Report Definition - Parameters

Navigate to this page using **Admin > Reporting > Report Definition** and go to the **Parameters** tab .

Description of Page

The **Parameters** scroll contains one entry for every parameter defined for the report. The following fields display:

Parameter Code is the identifier of the parameter. This must correspond to the parameter definition in the reporting tool.

Required indicates that a value for the parameter must be defined when submitting the report.

Sort Sequence must match the parameter order defined in the reporting tool's report. It is also used when displaying the list of parameters on the [report submission](#) page.

Characteristic Type indicates the characteristic type used to define this parameter.

Default Value is option and if populated is displayed to the user when the report is chosen on the [report submission](#) page.

Description is a brief description of the parameter. This description is used when displaying the parameter on the [report submission](#) page.

Long Description is a detailed description of the parameter. This description is used on the [report submission](#) page when the user requests more information for a given parameter.

Sample Reports Supplied with the Product

Depending on your specific product, there may be sample reports provided that your organization may use as they are or as a starting point for creating a [new report](#). The following sections provide an overview of the sample reports along with instructions on how to use one of the sample reports in your implementation environment.

How to Use a Sample Report Provided with the System

If you would like to use any of the sample reports, you need to perform some steps to be able to execute them in an implementation environment. This section walks you through the steps needed.

Steps Performed at Installation Time

Refer to the *Installation Guide* or *Optional Products Installation Guide* for instructions for setting up and configuring your product and reporting tool to use the sample reports provided with the system. The following steps are described there.

- Setting up the stored procedures used by the sample reports.
- Defining the company title and logo used by the sample reports. Note the company name used as a title in the sample reports is defined as a message on the [installation options](#).
- Defining a user for integration with your product.
- Publishing the sample reports in BI Publisher.

Contact your system administrator to verify that the above steps have occurred.

How To Define A New Report

Use a Sample Report as a Starting Point

- Make a copy of the report and save it in an appropriate directory. Prefix the new report name with **CM**.
- Review the stored procedure(s) used for this report. Refer to the installation guide for information about where the stored procedures should be defined. If you want to change the data that is being accessed, copy the stored procedure, prefixing the new stored procedure with **CM**. Make the appropriate changes in the new version of the stored procedure. Contact your database administrator to find out the procedure for creating a new stored procedure.

NOTE: Performance considerations. When designing a stored procedure, you must consider the performance of the report when executed. Consult your database administrator when designing your database access to ensure that all issues are considered.

NOTE: Defining Messages. The stored procedures provided with the system use messages defined in message category 30. If your new stored procedures require new messages, use message category 90000 or greater, which are reserved for implementations.

- Review the parameters used by the report. Make appropriate changes to the parameters required by the report. This affects how you define your report. Refer to [Designing Parameters](#) for more information.
 - Determine whether or not you require cross validation for your report parameters. If any cross validation is necessary, you should design an appropriate validation algorithm to be executed when requesting a report in your product. Refer to [Designing Validation Algorithms](#) for more information.
-

NOTE: Cross Validation for On-line Submission Only. The cross validation algorithm is only executed for ad-hoc report submissions via your product. If you submit this report through your reporting tool, this algorithm is not executed.

- Review the labels used by the report. Labels and other verbiage are implemented in the sample reports using a reference to the field table in the system. This enables the report to be rendered in the appropriate language for the user. For any new report label you require, you must define a new field entry. Refer to [Designing Labels](#) for more information.
- Review the layout of the report and make any desired changes based on your business needs.

When you have finished designing and coding your new report in your reporting tool, you must do the following in order for it to be usable:

- Publish the report in BI Publisher. Refer to the documentation for this products for details about publishing a report. Refer to [Publishing Reports in BI Publisher](#) for configuration information specific to publishing a report for integration with your product.
- Define the report. Refer to [Designing Your Report Definition](#) for more information.

Publishing Reports in BI Publisher

Please refer to the documentation for BI Publisher for more information about publishing a report in this system. The remaining topics in this section provide information about settings needed to ensure that the report is accessible using BI Publisher.

BI Publisher Database Access

When publishing a report in BI Publisher, you are asked for database logon information. The logon user name and password must be the user name and password that has access to the database functions related to this report in your database.

Verify BI Publisher User Access Rights

To verify the user's access rights to folders in BI Publisher:

- Open the BI Publisher Enterprise Security Center.
- Check that the role for the user has access to the appropriate report folders.

For more information, refer to the "Understanding Users and Roles" section in the Oracle Business Intelligence Publisher User's Guide.

Designing Your Report Definition

When adding a new report, you must define it in the system to allow users to request ad-hoc reports from on-line and to take advantage of the multi-language provisions in the system. The following topics illustrate the steps to take to correctly configure your report definition.

Designing Main Report Definition Values

Refer to field description section of the [report definition](#) main page for information about defining general information about the report.

For the validation algorithm, preliminary steps are required. Refer to [Designing Validation Algorithms](#) for more information.

For the application service, preliminary steps are required. Refer to [Designing Application Services](#) for more information.

Designing Characteristic Types

The parameter tab on the report definition page uses [Characteristic Type](#) to define the report parameters. For each report parameter that you plan to use, you must define a characteristic type.

You do not need a unique characteristic type for each report parameter. For example, if Start Date and End Date are parameters your report, only one **Report Date** characteristic type needs to be defined. This characteristic type would be used on both date parameters.

Each characteristic type to be used as a report parameter must indicate a characteristic entity of **Report**.

To illustrate the characteristic type definitions, let's look at the sample report Tax Payables Analysis. It needs the following parameters: From Date, To Date, GL Account Type Characteristic Type and Account Type value.

NOTE: Account Type Parameters. The tax payables report must find general ledger entries that have posted to a certain distribution code. In order to find the appropriate distribution code, the report expects each distribution code to be defined with a characteristic indicating its GL account type (for example, **Revenue**, **Asset**, etc.) The report needs to know the characteristic type used to define this entry.

To support the required parameters, the following characteristic types are needed.

Char Type	Description	Type	Valid Values	Char Entities
CI_DATE	Date Parameter	Ad-hoc	(Uses validation algorithm to validate proper date entry)	Report
CI_CHTYP	Characteristic Type	FK Reference	CHAR_TYP	Report
CI_GLTY	GL Account Type	Pre-defined	A- Asset, E- Expense, LM- Liability/miscellaneous, LT- Liability/taxes, R-Revenue	Distribution Code, Report

Highlights for some of the above settings:

- We have defined a characteristic type for defining a characteristic type. This is to allow the user to indicate which Char Type on the Distribution Code is used for the GL account type. This is an FK reference type of characteristic.
- The GL account type characteristic type is referenced on both the Distribution Code entity and the report entity.

Designing Parameters

Your report definition parameters collection must define a unique parameter entry for each parameter sent to the reporting tool. The sequence of your parameters must match the sequence defined in your reporting tool.

Continuing with the Tax Payables Analysis report as an example, let's look at the parameter definitions.

Parameter Code	Description	Char Type	Default Value
P_FROM_DT	From Date	CI_DATE	N/A
P_TO_DT	To Date	CI_DATE	N/A
P_CHAR_TYPE	Account Type Characteristic	CI_CHTYP	CI_GLTYP
P_TAX_ACCTY_CHAR	Account Type Char Value for Tax Related GL Account	CI_GLTYP	LT-Liability/taxes

Highlights for some of the above settings:

- The from date and to date parameters use the same characteristic type.
- The characteristic type parameter is defined with a default value pointing to the GL account type characteristic type.
- The GL account type parameter defines the liability/taxes account type as its default value.

NOTE: User Id. The sample reports provided by the system pass the user id as the first parameter passed to the reporting tool. It does not need to be defined in the parameter collection for the report.

Designing Validation Algorithms

When designing your report definition, determine if cross validation should occur for your collection of parameters. In the Tax Payables Analysis report, there are two date parameters. Each date parameter uses the characteristic type validation algorithm to ensure that a valid date is entered. However, perhaps additional validation is needed to ensure that the start date is prior to the end date. To do this, a validation algorithm must be designed and defined on the report definition.

The system provides a sample algorithm **RPTV-DT** that validates that two separate date parameters do not overlap. This algorithm should be used by the Tax Payables Analysis report.

If you identify additional validation algorithm, create a new [algorithm type](#). Create an [algorithm](#) for that algorithm type with the appropriate parameter values. Plug in the new validation algorithm to the appropriate report definition.

Designing Application Services

[Application services](#) are required in order to allow a user to submit a report on-line or to view history for a report. Define an application service for each report and define the user groups that should have submit/view access to this report.

Update [report definition](#) to reference this application service.

Designing Labels

The system supports the rendering of a report in the language of the user. In order to support a report in multiple languages, the verbiage used in the report must be defined in a table that supports multiple languages. Some examples of verbiage in a report include the title, the labels and column headings and text such as "End of Report".

The system uses the [field](#) table to define its labels.

NOTE: Report Definition. This section assumes that your new report in the reporting tool has followed the standard followed in the sample reports and uses references to field names for all verbiage rather than hard-coding text in a single language.

For each label or other type of verbiage used by your report, define a field to store the text used for the verbiage.

- Navigate to the field page using **Admin > System > Field**.
- Enter a unique **Field Name**. This must correspond to the field name used in your report definition in the reporting tool and it must be prefixed with **CM**.
- Define the **Owner** as **Customer Modification**.
- Define the **Data Type** as **Character**.
- **Precision** is a required field, but is not applicable for your report fields. Enter any value here.
- Use the **Description** to define the text that should appear on the report.
- Check the **Work Field** switch. This indicates to the system that the field does not represent a field in the database.

Update the [report definition](#) to define the fields applicable for this report in the **Labels** tab.

If your installation supports multiple languages, you must define the description applicable for each supported language.

Service Health Check

The system provides a plug-in spot on [Installation](#), called Health Check. The algorithms plugged in here are used to check various system conditions and return details to help assess the health of the system.

What Information is Checked?

Each algorithm is responsible for checking one type of health check condition. The condition should be defined as a valid health component type (as defined in the **HEALTH_COMP_FLG** lookup). The algorithm may check conditions across many records (referred to as Health Components) and return a status and details for each health component. For example, if the algorithm is checking the level of service for batch programs in the system, the batch control is the health component in this case. The algorithm should gather the level of service results for each batch program and return the collection of information to the calling program.

The algorithms for the plug-in spot should return the following information for each health component.

- The **Health Component Detail** should be populated with information specific to the object that was checked. For example, if the algorithm is checking batch control level of service, this will have the Batch Control code. In addition, for enabling display for details of each health component type, the algorithm should populate the maintenance object code and primary key field and value details along with the navigation option.
- The **Health Component Status Flag** and **Health Component Status Description** should be populated with a valid status code and description appropriate for the condition being checked. This information could differ based on the health component type as each health component type may have its own unique status values.
- The **Health Component Status Reason** is meant to provide supporting information about the health component's status value. For example, if the component provides an error type of status, this could have the status reason.
- The **Health Component Response** is used to map the status value of the health component to a standard value defined in the lookup **HEALTH_RESPONSE_FLG**. The values are a subset of HTTP response codes. The supported values are **All Checks Successful** (200); **Non-Critical Function Degraded** (203), **No Content** (204) and **One or More Critical Functions Degraded** (500).
- The **Response Details** list is provided for health components that check several conditions as part of the health check. Each condition could return its own status. In this situation, the algorithm should use the response details list to record the individual responses and populate the overall Health Component Status Flag, Description and Reason with summary information. The suggestion is to do the following:
 - Set the status flag and response based on the details of the individual responses. Refer to the batch level of service information below for an example of this logic.

- When the response list is populated, the health check user interface will show the overall Status Reason text along with an icon to expand the details. The suggestion is to populate this field with text like "See Results for Details".

The system provides an algorithm that checks the **Batch Level of Service** health component type. This health component type finds all the batch controls that are configured with at least one [level of service](#) algorithm and invokes the algorithms for each batch control. The business service populates the output for this health service for each batch control as follows:

- The **Health Component Detail** is populated with the Batch Control code and description. In addition, the navigation information for being able to drill into the batch control are provided and used to build the column as hypertext.
- The **Status** is populated based on whether the batch control has one algorithm or multiple. If there is one algorithm, the Level of Service lookup value returned by the algorithm is returned. If there are multiple, the system determines an overall status based on the detailed status values from each algorithm. If any algorithm returns Error, that value is returned. Otherwise, if any return a Warning, that value is returned. Otherwise Normal is returned.
- The **Status Reason** is populated based on whether the batch control has one algorithm or multiple. If there is one algorithm, the expanded text of the status reason returned by the algorithm is returned. If there are multiple, the text from message category / message number 11002 / 22001 is returned (**See Results for Details**)
- The **Response** is populated based on the value of the overall Level of Service status. It is set to **All Checks Successful** (200) when the Level of Service is **Normal** or **Disabled**; **Non-Critical Function Degraded** (203) when the Level of Service is **Warning** and **One or More Critical Functions Degraded** (500) when the Level of Service is **Error**.

How are the Algorithms Called?

These algorithms are called by a business service provided by the product **F1-HealthCheck**.

That service calculates an overall Health Response value based on all the details returned by all the algorithms. The values described above for the **HEALTH_RESPONSE_FLG** are the ones used.

Also note that the system provides [Inbound Web Services](#) for this business service for both SOAP and REST service calls allowing external systems to use a web service to retrieve this information.

Health Check Configuration

To enable your system to display health check information, navigate to the [Installation Options - Algorithms](#) collection and add an entry for the **Health Check** system event for each health check algorithm provided by the product that your product would like to include in your system health check assessment.

Viewing Health Check Results

The product provides a portal that allows a user to view the detailed results of the [health check](#) business service.

Navigate using **Admin > System > Health Check** to view this portal.

The zone on the portal displays the following:

Overall Response is the HTTP response code returned by the business service.

The grid displays the detail of each individual component checked as part of the system health check. Refer to [Service Health Check](#) for more information about the details returned.

Introducing Health Check Conditions

If your implementation would like to check a condition for system health that is not already provided by your product, here are the steps required:

- Define a new value in the Health Component Type lookup (**HEALTH_COMP_FLG**).

- Provide a new algorithm type, plug-in script and algorithm for the Health Check system event that checks the condition that you wish to check. Refer to the [Service Health Check](#) topic for the information that each algorithm should be supplying for the condition. Note that if you follow the pattern of the system delivered Batch Control - Level of Service algorithm, your algorithm may be designed to check conditions across many records of the same type and gather all the results.
- Plug this new algorithm into the [Installation Options - Algorithms](#) collection using the **Health Check** system event.

Measuring Performance

Many implementations need the ability to track and view the performance of key system processes against a defined target level. The framework provides objects to allow an edge product or an implementation to calculate and display performance measures against a desired target for one or more use cases. The topics in this section provide information about what is supplied in the framework and guidelines for implementing a specific use case for batch processes. Your product may supply out of the box support for additional use cases. Refer to your product documentation for more information.

Understanding Performance Targets

The following are examples of use cases that would be well suited for tracking as performance targets:

- Track and view the duration of key batch processes, either individually or as a group, and how they relate to a defined target.
- Monitor used and free space on a database against critical levels.
- Check the performance of individual user interface zones against a defined performance expectation
- Compare the number of web service requests made to an application against a threshold where performance may be of concern.

Framework provides functionality to define and categorize performance targets and link them to objects such as business services, zones and portals. This supports the calculation and display of the metrics against desired results.

In addition, Framework supplies out of the box support for batch process performance targets. Individual edge applications may supply more specific functionality for other use cases, if applicable.

Ideally, users should have the ability to view these performance targets on a dashboard that groups related measures. Framework provides the necessary components to achieve this for batch process performance targets.

The following sections highlight functionality supported for performance targets in the framework. Refer to the edge application product documentation for more details of other supported use cases.

Performance Target Objects Overview

The setup of a performance target involves a unique combination of configuration data and processing logic that calculates and displays a specific measure.

The framework performance target functionality is supported by a combination of inter-related objects, as shown below. Some of these objects will be generic for use in all performance targets while some are specific to a functional area such as batch processes.

- **Maintenance Objects** for capturing performance target types and performance target instances.
- **Extendable Lookups** to define performance target categories and performance target metrics.
- **Business Services** to calculate known metrics for a group of performance targets, such as for batch processes.
- **UI Maps** to interpret the performance calculation results and display them in charts that show the comparison to the target.

- A **Zone** that serves as a template for system duplication to create specific zones related to each performance target. The zone invokes a business service to perform calculations and display performance measures in the related UI map.
- **Business Objects** to capture configuration data for a specific performance target instance and its related objects.
- Functionality to create **Zone instances** for specific performance targets based on the associated template zone.

Each edge application will deliver the following to compliment the objects delivered by the framework:

- **Portals** to group related performance target zones.
- Specific entries for the performance target category **Extendable Lookup** .

The following sections describe the combined use of these objects for performance targets in more detail.

Calculating and Displaying Performance Targets

Performance targets are intended to be displayed in a portal using an explicit object zone. The zone parameters define both the business service used to calculate the performance metrics and the UI map that displays the results. While an individual performance target needs to reference a zone with a unique configuration that calculates a particular metric, those zones will be based on a template zone which defines the core parameters.

Framework provides a base Batch Performance Target Metric Template zone (**F1-PERFBA**) for batch process performance targets. Refer to this zone and its parameters for more information about the batch performance zone configuration and the related business service and UI map.

Performance Target Metrics and Metric Types

The framework supports two types of metrics for performance monitoring:

- **Value based metrics** are used to record results against a specific numeric target.
- **Time based metrics** are used to track the results against a specific date and time target.

The list of valid metrics for a given performance target category and its associated performance target types is maintained using an extendable lookup. Framework uses the base business object Batch Performance Target Metric (**F1-BatchPerfTargetMetric**) to define batch process metric values. Refer to this lookup for the supported batch process metrics.

NOTE: While users are not prevented from adding new values to the lookup, the list is not intended to be extendable as new values will not be recognized by the business service that performs the base batch performance calculation logic.

Your edge product or implementation may supply other extendable lookup business objects for additional performance measurement use cases, if applicable.

Performance Target Categories and Types

There are key configuration details required by all performance targets. These are defined on two related objects.

Performance Target Categories

Target categories define the template zone and security setting for a group of performance measures. The list of valid categories is maintained using an extendable lookup.

The framework product supplies the business object Performance Target Category (**F1-PerformanceTargetCategory**) for this functionality. Refer to the business object description and configuration for more information.

Performance Target Types

Target types define the related performance target business object and the display portal for a group of performance measures. In addition, a target type references a target category which defines the associated zone details.

The framework product supplies the business object Performance Target Type (**F1-PerformanceTargetType**) for this functionality. Refer to the business object description and configuration for more information.

The framework does not deliver any standard type or category values for batch processing performance targets. Refer to your specific edge application products to verify if any standard values are delivered for the batch processes within your applications. Edge applications may also supply standard categories and types for additional performance target use cases.

Performance Targets Define Specific Metrics

Although the types of measures and the business services and UI maps that govern how they are calculated and displayed are defined using separate objects, a **performance target** record defines the additional configuration needed to measure a specific metric and compare the result to a desired value.

There are key configuration details required by all performance target instances. These include a reference to the metric being measured, the desired target value or time, the desired result for the target and the unique zone by which this performance target will be monitored.

NOTE: The performance target maintenance object has a direct foreign key link to the extendable lookup business object and value that define the performance metric. This is an unusual pattern as extendable lookup values are normally recorded only in an object's schema. The pattern has been adopted to allow the description of the metric to be displayed in the performance target maintenance portal.

A given **performance target type** may require additional details for its calculations. For example, the framework batch process performance target defines additional details to restrict the measurement to specific batch processes that have executed within a given time frame. These details are configured on the performance target business object. Refer to the embedded help text on the business objects supplied by the framework and your edge applications for more information.

The **performance target type** also defines the business object to use when creating the resulting performance target record.

Objects Linked to a Performance Target

Some performance measures such as batch process metrics, derive the data for the calculation from objects within the system. The performance target can be linked to one or more related objects to define the specific data sources included in that target metric. For example, when creating a batch process performance target, the framework supports linking specific batch codes to the performance target to indicate the group of batch processes that are included in the measure.

The performance target business object may be configured to allow only relevant objects types to be linked to a performance target record. Refer to the base Batch Performance Target business object (**F1-BatchPerformanceTarget**) for an example.

Creating Performance Target Zones

Once a performance target and its objects have been defined, a unique zone needs to be created to display and monitor the specific target.

The framework functionality for batch performance targets implements the zone creation via the related business object lifecycle. When a performance target is added, status enter plug-ins are responsible for generating the new zone using the template zone and prefix configured on the target category (or the override values) and adding the zone to the portal configured on the target type. When a performance target is inactivated, an enter plug in is responsible for removing the zone from the portal.

NOTE: While the template zone associated with the performance target category may be overridden, the zone generation algorithm makes certain assumptions about the zone type and parameters. In particular, the logic expects to configure a zone parameter that references the performance target code as input to the business service responsible for calculating the metrics.

Refer to the base Batch Performance Target business object (**F1-BatchPerformanceTarget**) for details of the lifecycle and the enter plug-ins responsible for performance target zone creation.

Setting Up Performance Target Configuration

The following topics highlight the general configuration steps required to use performance target functionality. Your particular product or implementation may supply additional functionality to support specific use cases for performance targets. Refer to your product's documentation and the library of business objects supplied for performance target in your system for more information.

Performance Target Category Lookup

Refer to [About Performance Targets](#) for an overview of performance target functionality.

Each Performance Target Type is associated with a unique Performance Target Category. The categories are defined as an extendable lookup.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Performance Target Category** business object. Define values that are appropriate to the categories your implementation is assigning for the performance target types in use. In some cases, an edge application may already have delivered the appropriate performance target category for your use

Refer to the embedded help for more information about configuring this object.

Defining Performance Target Types

Refer to [About Performance Targets](#) for an overview of performance target functionality.

To maintain the performance target types applicable to your product or implementation, open **Admin > Reports > Performance Target Type**.

This is a standard [All-in-One portal](#).

The information captured on the performance target type depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Maintaining Performance Targets

This section describes the functionality supported for viewing and maintaining performance targets.

Refer to [About Performance Targets](#) for an overview of performance target functionality.

Navigate using **Main > Reporting > Performance Target**. This is an [All-in-One portal](#) and includes the standard List and display zones for a performance target.

For information about the data defined on the performance target, refer to embedded help.

Capturing Statistics

The product provides objects to allow for an edge product or an implementation to periodically calculate and capture statistics for one or more use cases. The topics in this section provide information about what is supplied in the framework and guidelines for implementing specific use cases.

Understanding Statistics

There are two objects that work together to capture the statistics related to a given business use case:

- The statistics control record which defines configuration related to capturing statistics. It also defines a category that is used to group similar types of statistics together.
- The statistics snapshot is the record where the actual calculated statistics are captured.

Statistics Control

The statistics control record defines whether or not statistics are automatically calculated and how frequently. In addition, you may control the retention policy of snapshot records. You may indicate that only the most recent snapshot is kept or all snapshot records are kept or that they are retained for a defined number of days.

The system provides a business object for statistics control (**F1-Statistics**) that is expected to be used for most use cases. Its lifecycle includes the support for periodic capturing of statistics snapshot records as well as on demand capture.

Statistics Snapshot

The statistics snapshot object is the object that is responsible for calculating and capturing the statistics details. A separate business object must be defined for each use case. The schema of the business object defines the details that are captured. In addition, it must include an algorithm as an enter plug-in on the **Complete** state that is responsible for capturing statistics.

The system provides a 'root' business object for statistics snapshot (**F1-SnapshotRoot**) which includes the lifecycle that statistics snapshot business objects should follow. No explicit statistics snapshot use case is provided by the Framework. Your specific product may supply some out of the box support for certain use cases, in which case specific statistics snapshot business objects are provided. Refer to your product specific documentation for more information.

Viewing / Reporting Statistics

The product provides the mechanism for defining statistics control and statistics snapshot records and viewing the data in basic format. If your product has provided support for specific use cases, there may also be additional portals used to display the statistics in a meaningful format. For example, the statistics snapshot may be capturing data that can be presented in graphical format. Additionally, if multiple historical statistics snapshot records are retained, a zone may be defined to graph changes over time.

Configuring Your System for Statistics

If your product provides statistics use cases that you are planning to implement, all that you need to do is configure the appropriate statistics control record and define the appropriate configuration for your business requirements. Refer to [Defining and Monitoring Statistics](#) for more information.

If your implementation has identified an additional use case where you would like to capture statistics, the following points highlight the steps needed to configure the system to support the use case.

- Determine whether an additional Statistics Category value is needed. This is captured on the statistics category record. Navigate to the [Lookup](#) page. Search for and select the **STAT_CATEGORY_FLG** field. Review the values and determine if additional values are needed.

- Define a new statistics snapshot BO. This should be a child BO of the base delivered BO (**F1-SnapshotRoot**). Its schema should define elements for the specific information that is captured by the statistics calculations. The schema should be designed in conjunction with an appropriate Enter Status algorithm for the **Complete** that calculates the statistics as appropriate for the business requirement.
- Once the snapshot business object is designed and implemented, configure the appropriate statistics control record.

Defining and Monitoring Statistics

Refer to [Understanding Statistics](#) for an overview of the statistics functionality.

To define and maintain statistics control records and view a list of the current snapshot records, open **Admin > Reporting > Statistics Control**.

This is an [All-in-One portal](#) and includes the standard List and display zones for a statistics control.

For information about the data defined on the statistics control, refer to embedded help.

Statistics Snapshot

If there are any Statistics Snapshot records for the statistics control, the **Statistics Snapshot List** zone displays a list of the most recent records. A user may drill into any of the records to view more detail. You are brought to a maintenance portal where you may view details about the calculated statistics. The information captured will be unique to the particular use case. Refer to the embedded help for more information.

Creating Cube Views

Many implementations require the ability to extract and analyze complex sets of data in a way that is simple to visualize and supports business or organizational decision making. A common model for performing this type of analysis is a multi-dimensional array, often referred to as a data cube. Cube views allow data to be represented in a way that provides the user with multiple perspectives of the results.

Although called a "cube", a cube view can have two, three or a higher number of dimensions. Each dimension represents some attribute in the database and the cells in the data cube represent a measure or value. For example, a cell could contain a count of the number of times that attribute combination occurs in the database, or the minimum, maximum, sum or average value of data related to that attribute. Queries are performed on the cube to retrieve information.

The framework provides objects to support the definition of data cubes and a flexible means of viewing them. The topics in this section provide information about what is supplied in the framework to assist in implementing a cube view. Your product may also supply out of the box support for relevant use cases. Refer to your product documentation for more information.

Understanding Cube Viewer

The framework provides a cube viewer portal which is intended to be used for most implementations of cube views. It supports a number of common actions and data representations.

NOTE: The choice of appropriate menu for the Cube Viewer portal will differ from product to product. Refer to your product specific documentation for more information on how to access the viewer.

The following sections describe the basic concepts and features of the cube viewer.

Cube Viewer Components

The base Cube Viewer interface is comprised of the following main areas:

1. The Toolbar
2. The Settings Area
3. The Filters Area
4. The Views Area

The next topics provide more information about each component.

The Toolbar

The following features are available on the Cube Viewer toolbar.

Settings and Filters Buttons

Click the **Settings** and **Filters** toggle buttons to collapse and expand the respective [Settings](#) or [Filters](#) areas.

Apply Button

Click the **Apply** button to apply any changes to the settings and display the new results in the views.

Details Button

Click the **Details** button to open a dialog box in which additional attributes of the current cube view can be viewed and updated. Refer to [Cube View Details](#) for more information about the attributes displayed.

Cube View Dropdown

Click the **Cube View Dropdown** to open a list of cube views, of the same type as the current view, to which you have access. Selecting a cube view from the list will open that view. Use the search box to search for a view within the list using the cube view description.

Save, Save As and Delete Buttons

Click the **Save** button to save the current settings for the cube view. Click the **Save As** button to create a copy of the current cube view. Click the **Delete** button to delete the current cube view.

Cube View Details

Clicking the **Details** button on the cube viewer **Toolbar** allows you to maintain the following information for the cube view:

- The short **Description** for display in the viewer header and a more **Detailed Description** for capturing additional information about the cube view.
- An **Access Type** of shared, private or public.
- The **Access Group** that defines the group of users with access to the cube view. This field is only visible if the access type is shared.
- A specific **User** who has sole access to the cube view. This field is only visible if the access type is private.
- The **Row Functions** text box in which the functions to be applied to the values across the rows in the data grid are defined. Clicking anywhere in the box will display a list of supported functions to choose from.
- The **Column Functions** text box in which the functions to be applied to the values in the columns in the data grid are defined. Clicking anywhere in the box will display a list of supported functions to choose from.
- An **Inactivate** button. Click this button to deactivate this cube view.

The **Fixed Parameters** for the cube view are displayed but cannot be updated here. Refer to [Configuring Cube Types](#) for more information on cube view parameters.

The Settings Area

The Settings Area contains a number of sections whose inputs control various aspects of the current cube view.

Selection Criteria

Open the **Selection Criteria** section to enter filter values for the user parameters defined on this cube type. User parameters that have been configured as 'Save with Cube View' on the cube type will be saved when the cube view is saved.

Compare

Open the **Compare** section to enter one or more sets of criteria that are used to retrieve data sets for comparison to the data retrieved by the main Selection Criteria. Use the Add and Delete buttons to add or remove a set of criteria. The comparison values will be displayed side by side with the main cube values in the data views. Note that the pseudo dimension **Dataset** must be included as a dimension column in order to display comparison views.

View Options

Open the **View Options** section to access buttons that toggle on and off the display of the supported data view types. The buttons can be used to change the order in which the views are displayed, using drag and drop. Any changes made to the default button settings will be saved when the cube view is saved. Refer to the [Views Area](#) topic for more information on the available data views.

Dimensions

Open the **Dimensions** section to view the list of dimensions defined on this cube type, as well as the pseudo dimension **Dataset** and the date/time filter, if applicable. Use drag and drop to move a dimension into the list of **Columns** or **Rows** displayed in the data views. Moving a dimension into the **Unassigned** list will remove it from the data views.

Format

Click the Edit button on the **Format** section to open a dialog box in which conditional formatting, such as background or text color, can be defined for the values in the data grid. Refer to [Defining Conditional Formatting](#) for more information about the formatting controls.

NOTE: Changes made to the settings will only be reflected in the views when the **Apply** button is pressed, with the exception of the **View Options**, where changes are reflected immediately upon toggling or rearranging the buttons.

Defining Conditional Formatting

Clicking the **Edit** button in the **Format** section of the **Settings** area allows you to define formatting rules for the display of values in the cube view data grid. The rules are based on mathematical expressions or formulas which use the cube view values as variables.

The formulas must be expressed using the field names of the values for the cube, as used in the cube view query zone. A list displaying the **Column Name** and associated **Label** for each value configured in the cube view is provided, to assist in defining the formulas.

The following attributes need to be defined for each rule:

- The **Sequence** defines the order in which the formatting rules are evaluated.
- The **Active** check box indicates whether the rule should be applied or not.
- The **Formula** defines the mathematical expression that is evaluated to determine whether the formatting should be applied. The expression variables should reference the **Column Name** of the value.
- **Format** defines the formats to be applied to cells whose value meets the condition expressed in the formula. The formats include the **Background** and **Text** colors and whether the text should be in **Bold**.
- The **Stop If True** check box indicates whether to stop evaluating the remaining formulas in sequence if this formula evaluates to true.

The Filters Area

The Filters Area provides the ability to select and apply dimension filters to the current view.

The **Tree** section displays a hierarchical view of the dimension values in the current cube view. Clicking a value will cause it to be displayed in the **Filters** section and immediately applies that filter to the data in the currently selected views. To remove a dimension from the filters, click on the value in the **Filters** section.

The **Hierarchical Filtering** icon, , is used to toggle between hierarchical and non-hierarchical selection mode. In hierarchical mode, clicking a dimension value at any level in the tree will automatically populate the filters with the related higher level dimension values. In non-hierarchical mode, only the selected dimension value is added as a filter.

Use the expand and collapse icons, , to quickly expand the tree, one level at a time, below the currently selected dimension value or collapse the entire level.

The Views Area

This section describes the types of views supported by the Cube Viewer.

Data Grid

The **Data Grid** displays the cube view data set in the form of a pivot table. The fields that appear as rows and columns in the table are defined in the **Dimensions** section of the [Settings](#) area. The default aggregation function used for the values is sum. Additional functions can be defined in the details of the cube view. Refer to the description of the **Details** pop-up window in the [Toolbar](#) area for more information.

Raw Data

The **Raw Data** view displays the cube view data set as a flat table.

Line Chart

The **Line Chart** displays cube view data in a chart with a time sequence as the X-axis and value intervals as the Y-axis. Each line corresponds to a specific combination of the selected dimensions. This view is only visible if the cube view includes at least one date/time filter in the selection criteria. If the criteria include more than one date/time field, the first date/time filter in order is chosen for the time sequence.

Bar Chart

The **Bar Chart** also displays cube view data in a chart with a time sequence and value intervals. Each bar corresponds to a specific combination of the selected dimensions. This view is only visible if the cube view includes at least one date/time filter in the selection criteria. If the criteria include more than one date/time field, the first date/time filter in order is chosen for the time sequence.

Cube Configuration Components

Cube views are supported using a number of standard configuration components.

The system provides a business object for cube views (**F1-CubeView**) which is used to capture access controls and the settings, such as user parameter values, for a cube view instance. The business object also defines the portal navigation and the base display UI Map (**F1-CubeViewDisp**) and accompanying display map service script (**F1-CubeViewD**). The display map and service script together drive the functionality supported in the cube viewer.

NOTE: The system also supplies a UI map fragment (**F1-CubeViewProc**) which is used to display a cube view in a process flow panel. Refer to [Process Flows](#) for more information.

The system provides a portal for cube views (**F1CUVWM**) that can be configured on the appropriate menu item or other navigation path for your implementation. The portal is linked to the base cube view zone (**F1-CUBEVIEW**).

In addition, the system supplies a simple query by cube view information (**F1-CUBVIWQ1**) that is the single entry on a base multi-query zone (**F1-CUBVIWQ**). The multi-query zone is not linked to the base portal as the expectation is that implementations will need to create searches tailored to their specific use cases for cube views. The base multi-query provides a quick means of configuring a cube view search while in development mode.

Configuring Cube Types

Cube Types are used to capture the details that define the sourcing of the data for a cube view and parameters that control certain features of the cube viewer. These details include:

- The business service whose associated zone defines the query used to select and filter the data for the cube view.
- The user parameters that correspond to the filters for this cube type's business service and zone.
- The user parameter settings that determine whether a given filter value should be saved with the cube view and whether the value should be populated from global or portal context, if applicable.
- The fixed parameter values to be applied as hidden filters for cube views of this type.
- The results from the business service and zone to be used as dimensions in the cube view and those that are the cube view values.
- The dimension settings that determine the order in which the dimensions are displayed in the data grid, which dimensions are to be used as filters in the cube view and which dimensions are to be included in the cube view tree.
- The values settings that determine the default sequence in which the values are displayed in the data grid.
- The FK Reference used to navigate from the data grid to the underlying source data.

If your product provides business services that support cube views you plan to use, all you need to do is configure the appropriate cube type records. Refer to [Maintaining Cube Types](#) for more information.

If your implementation has identified additional cube views you need for data analysis, you will need to create a zone and business service that use specific techniques for defining the SQL to derive the source data for the view and for mapping the results. Refer to [Cube Type Advanced Topics](#) for more information

Maintaining Cube Types

Refer to [Creating Cube Views](#) for an overview of the cube viewer functionality.

To define and maintain cube type records, open **Admin > Analytics Configuration > Cube Type**.

This is an [All-in-One portal](#) and includes the standard list and display zones for a cube type.

For information about the settings defined on the cube type, refer to [Configuring Cube Types](#) and the embedded help.

Cube Type Advanced Topics

The following topics describe the technical models that need to be followed when creating a new cube type.

Designing Your Cube Type SQL

In order to support the base cube viewer, the SQL used in your cube type data explorer zone needs to be constructed with two main components. The first component creates a view of the data and its dimensions in a form that supports a tree-like structure and allows for the dynamic use of filters. The second component queries the filtered data set to provide the values to be displayed for each dimension.

The first component should contain the following queries:

- A sub-query constructed using a 'with' clause that builds a tree-like view of the cube's dimensions and optionally other columns used in the main SQL. This portion of the SQL must be enclosed within '/*>tree*/' and '/*<tree*/' hints and use the table alias **C_TREE**. The combination of the dimension columns should form a unique 'key' in the **C_TREE** data. Both the 'with' clause and the 'tree' portion within it may contain other supporting sub-queries.
- A sub-query which is the placeholder for filtered queries on the 'tree' data. It must use the table alias **C_FILTER** and take the form 'C_FILTER as (select * from C_TREE where l=1 and ROWNUM <= n)'. The value of 'n' should be set to limit the rows returned to a number that is manageable within the cube viewer.

The second component is the main query that retrieves the measures for the cube view dimensions. This query references **C_FILTER** as the subset of the **C_TREE** and joins with other tables if required to retrieve the numeric values. The first date or date/time result column of the main query (as specified in the zone configuration) designates a time-series column, which forms the time-series 'key' with the dimensions columns.

Defining Your Cube Type Business Service

The business service that identifies the zone for a cube type is also used to provide additional configuration options.

The business service schema should define meaningful element names for the parameters, dimensions and values. It should also define labels for those elements to be used by both the cube type and cube viewer user interfaces. The labels can be derived by mapping the element to a meta-data fields or by using the 'label=' syntax to define a text string directly in the schema definition. The 'required=true' syntax can be used to require a value to be entered for a user parameter on the cube viewer or for a fixed parameter on the cube type.

The user parameter elements are expected to be defined within a group in the schema called 'input' and the fixed parameters within a group called 'hidden'.

Product Use Metrics

The Product Use Metrics portal includes a zone (or zones) that are used to perform a business review of your organization's implementation of the product to confirm licensing / subscription compliance. The information visible on this portal will depend on the product or products installed by your organization.

To view this portal, open **Main > Dashboards > Product Use Metrics**.

For more information about what each zone on the portal is reporting, refer to the embedded help.

External Messages

This section describes mechanisms provided in the product that enable an implementation to configure the system to communicate with an external application.

Incoming Messages

This section provides information about support for incoming messages.

Inbound Web Services

Inbound web service functionality is provided to support receiving web service requests from an external system.

Understanding Inbound Web Services

The system supports communicating with the system via RESTful services or via SOAP services. In both cases, the system uses an object called inbound web service (IWS) to store the configuration. A web service class is used to distinguish whether the IWS is used for REST or SOAP. There is also a distinct business object for each web service class value because there is different configuration for each type of IWS.

For both types of inbound web service, the system supports the configuration of one or more operations per web service. Each operation defines the schema-based object to invoke to perform the desired function. An operation may refer to a Business Service, a Business Object, or a Service Script. If the IWS supports multiple operations, each operation can refer to the same or a completely different schema-based object from other operations within the IWS.

REST APIs may be secured by OAuth client credentials grant in a cloud installation. Refer to the Identity and Access Management chapter in the *Oracle Utilities Cloud Services Administration Guide* for more information.

The following topics provide more information about the different configuration of IWS based on whether it is SOAP or REST.

Inbound REST Web Services

The following topics provide more information about the product's support of REST services using IWS. Note that IWS REST records are marked with a REST engine version of 1.0 or 2.0. Version 2.0 is the version used for new services. Version 1.0 is introduced for backward compatibility. Some of the system behavior differs based on the version of the REST service. The sections below highlight cases where this occurs.

HTTP Method and Parameters

When defining operations for inbound REST web services, the product supports the HTTP methods of Get, Patch, Post, Put, and Delete. Note that the product's support of these various HTTP methods are a means of communicating the purpose of the web service to the outside world. However, the actual behavior of the REST web service is driven by the behavior of the underlying schema based object (business object, business service or service script). For example, you may configure the HTTP Method of "Put" for an operation that references a service script that just retrieves a record. The product is not able to detect this type of discrepancy. Configuration users should carefully consider the correct method to use based on the logic of that service.

For operations that reference a business object, the transaction type must be provided. The REST syntax doesn't support defining the transaction type at runtime. There are some basic validation checks in this case related to the transaction type and the HTTP method. For example, a Get method only makes sense with the Read transaction type.

NOTE: Using the transaction type **Change** requires all values to be passed in. Using the transaction type **Update** allows the web service to pass only the primary key and the values to be updated. All other elements will retain their existing values.

You may additionally define parameters. For each parameter, you define an external reference to the element, which is how this parameter is exposed to the external callers and is defined in the API specification. Each of these parameters is mapped to the XPath of the schema element from the underlying business object, business service or service script. For each parameter, you indicate if it is a **Path** parameter or a **Query** parameter.

- Path parameters are parameters that are part of the endpoint and are required. Each path parameter must be included in the operation's URI component surrounded by curly brackets.

- Query parameters are optional. They are not part of the endpoint but rather are included in the endpoint URL after a question mark, followed by name value pairs.

Refer to the URL section below for examples of path and query parameters in the sample URLs.

URL Composition

When building the endpoint URL for a REST service, there are three main parts that make up the full URL.

- The first part is the one that is environment specific. This will differ for an on premise implementation as compared to a cloud implementation. Both will have the host and the port and then additional components that identify the environment.
- The second part is a hard coded path designated by the product, namely "/rest/apis".

These two parts of the URL are defined in the substitution variable **F1_REST_BASE_URL**. This is defined when initializing your environment. Refer to the Server Administration Guide for more information.

The remaining part of the URL is built dynamically based on configuration for each IWS and its operations. The components are "/ownerURIComponent/resourceCategoryURIComponent/iwsURIComponent/operationURIComponent"

- The owner URI component is taken from the owner flag of the inbound REST web service. A special extendable lookup ([Owner Configuration for REST Services](#)) defines this component for each owner flag.
- Each Inbound REST Web Service must reference a [resource category](#). This category is used to associate related web services to a common category of resources. For multiple IWS records linked to the same resource category, external catalogues can use this information to group together related web services. The resource category is an extendable lookup and the URI component is an attribute of this record.
- Each REST IWS record defines a URI component that serves as an external identifier of this IWS record. The value must be unique within a given owner flag.
- Each operation must define the HTTP Method and optionally a URI component. When defining path parameters, the path parameters must be included in the URI component using curly braces.

In all cases, the URI component must begin with a slash (/).

The following are some examples of the dynamic portion of the URL for a REST service. The last example illustrates the use of a query parameter.

IWS Name URI Component	Owner URI Component	Resource Category URI Component	Operation HTTP Method URI Component	Dynamic URL Component	Run Time Example
c1rateCalculation /rateCalculation	C1 /customer	C1-RATES /rates	Post /	../customer/rates/ rateCalculation/	../customer/rates/ rateCalculation/
w1WorkActivity /workActivity	W1 /asset	W1-WORK /work	Get /{activityId}	../asset/work/ workActivity/ {activityId}	../asset/work/ workActivity/5798165498
w1WorkActivity /workActivity	W1 /asset	W1-WORK /work	Patch /scheduleWindow/ {externalSystem}/ {activityId}/ {windowStartDateTime}	../asset/work/ workActivity/ scheduleWindow/ {externalSystem}/ {activityId}/ {windowStartDateTime}	../asset/work/ workActivity/ scheduleWindow/ MY- COMPANY/5798165498/20190101
CM- AccountActivityHistory	CM /cm	CM-ACCT-INFO /accountInformation	Get /{accountId}	../cm/ accountInformation/ accountActivityHistory/ {accountId}	../cm/ accountInformation/ accountActivityHistory/123456789? activityId=5468976

IWS Name	Owner	Resource Category	Operation HTTP Method	Dynamic URL Component	Run Time Example
URI Component	URI Component	URI Component	URI Component		
/					
accountActivityHistory					

Payload Format

REST services support receiving a request payload in XML or JSON format and returns the payload in either XML or JSON. The default format returned depends on the value of the REST Engine Version.

- Version 2.0 services assume JSON format as the default. The default can be overridden by providing an accept header of **application/XML**.
- Version 1.0 services assume XML format as the default. The default can be overridden by providing an accept header of **application/JSON**.

Root Node for JSON Format

Version 2.0 services with the JSON formatted payload do not accept in the request or return in the response any root node around the payload. The following is an example of the response of a REST call for a version 2.0 service:

```
{
  "batchJobId": "string",
  "requestSuccessful": "string"
}
```

Version 1.0 services with the JSON formatted payload expect a root node in the request and return one in the response. The following is an example of the response of a REST call for a version 1.0 service:

```
{
  "F1CnclBatJob": {
    "batchJobId": "string",
    "requestSuccessful": "string"
  }
}
```

The Open API Specification visible on the inbound web service maintenance page displays the expected format based on the record's REST engine version when viewing the specification.

Data Type Format in JSON

In JSON format, strings are surrounded by quotes and numbers and Boolean data do not have quotes. All services for REST engine version 2.0 follow this standard. Originally services that are REST engine version 1.0 were incorrectly treating numbers and Boolean data as strings and returning the data with quotes. This has been corrected.

To accommodate any integration that may have worked around the behavior for version 1.0 services, the system provides the ability to identify inbound web services that are exceptions to this rule. For any inbound web service identified as an exception, the system continues to treat numbers and Boolean data as strings in JSON responses. To add one or more IWS records to the exception list:

- Go to [Feature Configuration](#).
- Look for an existing feature configuration with the feature type **External Messages**. If one does not exist, create one.
- Add an option for the option type **IWS JSON Data Type Exceptions**.
- In the option value, indicate the IWS record that is an exception. Note that multiple options for the option type may be added. Additionally, the option value supports a comma delimited list.

External Facing Schema

By default the schema of the underlying service (for example, service script, business object or business service) is also the schema for the REST inbound web service operation and acts as both its Request and the Response schema. The product

provides the ability to define an explicit schema for a REST inbound web service (IWS) operation, allowing a user to adjust the schema for an external facing consumer. The IWS operation schema also supports some special configuration that allows additional features to be defined only for the IWS operation schema.

The operation schema supports the following capabilities:

- Declaring whether an element belongs only to the request schema, only to the response schema, both (default) or excluded altogether. This is used to establish a clear separation between request and response schema definitions.
- Assign a different element name to an internal element. This allows the internal service element name to more closely align to internal references to the element, if needed. The external facing element name can be different allowing for a more readable schema.
- Introduce specialized elements that support links and other types of structural standards in a way that does not impact internal service processing.

Refer to [Web Service Schema Nodes and Attributes](#) for more information.

The REST servlet uses the request and response schemas to map elements to and from the internal schema.

NOTE: While the caller should only provide elements defined by the request schema, the application does not filter out extraneous elements. Assumption is that the internal service is designed to ignore such elements. However, only elements defined by the response schema are included in the response.

Dynamic Links

There are use cases where the published API includes a "_self" element that contain the endpoint URL of the GET operation related to the data returned in the response. Additionally, response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).

Syntax is provided in the REST inbound web service operation schema to support building the runtime endpoint URL for the _self and _link elements. Besides dynamically building the static portion of the URL based on the current environment details, it also builds the dynamic portion of the URL, substituting the URL components for the operation and substituting the path parameters. The syntax allows you to define a specific IWS Operation or allows you to reference a maintenance object and at runtime, the system determines the GET operation for the maintenance object and builds the URL accordingly.

Example of the syntax:

```
<_link getOperation="mo:'TO DO ENTRY';pk1:todoEntryId;"/>
```

Example of the runtime endpoint URL:

```
_link: "http://.../common/todos/todoEntries/28937296450934"
```

A GET operation may be associated with a maintenance object to denote that this is the default GET operation for the entity. A **GET Operation** option at the Maintenance Object and Business Object level may be used to override this default. If the entity is not associated with a business object or the latter is not associated with such option then the operation associated with the maintenance object (if any) is used.

Open API Specification Documentation

The following documentation information may be provided for an Inbound Web Service:

- Short and detailed description for each operation.
- Help text may be provided for individual elements. The same text can be shared across multiple elements across all operations of the Inbound Web Service. If an element is not associated with help text then its internal field's label is used instead.
- Sample request and response documents may be provided for each operation.
- Operations may be associated with a sequence number that controls the order in which they appear in the Open API Specification.

NOTE: Detailed descriptions and element related help text are not translated since the published catalogue for base product APIs is in English language only.

Inbound SOAP Web Services

For inbound SOAP web services, by default the system uses the Schema Name to dictate the Request and Response for the service. The API can be overridden with custom formats by specifying Request and Response XSLs to transform into the relevant schema formats. In addition, if desired, the Request and Response Schemas that document the expected message may be provided.

NOTE: The Request and Response Schema fields are not supported in a cloud implementation.

NOTE: The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

In addition, note that for business object based operations, when invoking the web service an action is required. This may be passed into the web service as part of the invocation or alternatively, the action may be defined when configuring the operation using the transaction type.

NOTE: Using the transaction type **Change** requires all values to be passed in. Using the transaction type **Update** allows the web service to pass only the primary key and the values to be updated. All other elements will retain their existing values.

Annotations Used for Security

When preparing to deploy inbound SOAP web services, the security aspects of the service must be decided. The product provides a default security policy that is applied when no other policy is defined: **@Policy(uri="policy:Wssp1.2-2007-Https-BasicAuth.xml", attachToWsdL=true)** which requires HTTP Basic over SSL and a WS-Security Timestamp.

If a different security policy is desired, the following options are available:

- Security policies may be attached to the Inbound Web Service via the Java Enterprise Edition (Java EE) Web Application Server. This allows for multiple policies to be attached as supported by the Java EE Web Application Server. In order to enable this capability, explicit system configuration is required so that the product does not assume the default security policy. See the subsequent bullets for more information.
- Define a system wide security policy using a feature configuration option. Find the [Feature Configuration](#) record for the **External Messages** feature type. (It may need to be defined if it does not exist). Choose the option type **Default security policy** and define an appropriate value. If your implementation wishes for the policies to be attached at the Java EE Web Application Server, define this option type with an option value of **<none>**.
- Attach a security policy to the IWS via a Web Service Annotation. The base product provides annotation types that support the standard WS-Policy (**F1POLICY**) and OWSM Security Policy (**F1-OWSM**). No base annotation is supplied by the product for either annotation type.

If your implementation wishes for the policy of a particular IWS to be attached at the Java EE Web Application Server, define a special annotation for the **F1POLICY** annotation type and configure the **uri** parameter value to **<none>**.

NOTE: Refer to WebLogic documentation for more information on supported security policies.

NOTE: In order to use the OWSM Policy, additional system configuration is necessary. Contact your system administrator to confirm if your implementation supports OWSM.

Inbound SOAP Web Service Deployment

A Inbound SOAP Web Service must be deployed to the Java EE Web Application Server in order for it to be available to the Web Service Clients to access the system. Refer to [Deploying SOAP Web Services](#) for more information.

Deploying XAI Inbound Service via IWS

For implementations using XAI inbound services for external messages, the product recommends moving to the inbound web service mechanism, which uses the Java EE Web Application Server to communicate with the product rather than the XAI servlet.

For XAI inbound services that use the **Business Adapter**, it is straight forward to move to IWS because the configuration is similar. In both cases, the service is configured to reference a business object, business service or service script. The associated WSDL for each record is similar. Changing the interface for the incoming message to use IWS instead of XAI inbound services is similar.

However, for XAI inbound services that use the **Core Adapter**, these services reference an underlying "page service" in the product. For these services, the Request and Response schemas for the XAI inbound service were created using the Schema Editor. In order to support calling an underlying "page service" in IWS, first a [business service](#) must be created to reference the page service (if one doesn't already exist). However, the resulting schema for the business service is different from the Request and Response schemas related to the XAI inbound service. Moving this functionality to IWS using business services requires changes to the format of the incoming messages.

Moving all incoming messages over to use IWS instead of XAI is the product recommendation. However, to aid in implementations that have many integrations in place using the XAI inbound services that use the **Core Adapter** (or any adapter whose message class is **BASEADA**), the product provides the ability to deploy these types of XAI inbound services to the Java EE Web Application Server along with the Inbound Web Services.

To take advantage of this capability, you must define a feature configuration option. Under the **External Messages** feature configuration type, the **Support XAI Services via IWS** is used to indicate if this feature is supported. Setting the value to **true** turns on the feature. If no option is defined for that option type, it is equivalent to setting the value to **false**.

When the system is configured to support XAI services via IWS, the [Inbound SOAP Web Service deployment](#) includes XAI inbound services (that are configured with an Adapter that references the **BASEADA** message class). The deployment portal will also include a zone showing the deployment status of these XAI Inbound Services.

NOTE: There is no support for XAI inbound services via REST, only via inbound SOAP web services.

Configuring Inbound Web Service Options

This topic describes the configuration needed for using inbound web services.

Configuring SOAP Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound SOAP web services.

Technical Configuration

In order to use inbound web services, there are tasks a system administrator must perform.

Refer to the Server Administration Guide for technical details of each of these processes.

Maintaining Web Service Annotation Types

The product provides some base annotation types. Refer to the metadata for more information. If your implementation wishes to define additional annotation types, use the Web Service Annotation Type portal. Open this page using **Admin > External Message > Web Service Annotation Type**.

You are taken to the query portal where you can search for an existing web service annotation type. Once an annotation type is selected, you are brought to the maintenance portal to view and maintain the selected record.

NOTE: Use of custom policies should only be considered if the policies supplied by the Java EE Web Application Server are not sufficient for your implementation's needs.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation type code. Refer to [System Data Naming Convention](#) for more information.

The **Web Service Annotation Type** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

The system supports the ability for an IWS record to refer to multiple policies. In this situation, the annotation type for the policy should include a reference to a parent annotation type so that the system can properly build the array of annotations.

Maintaining Web Service Annotations

If your implementation wishes to define annotations, use the Web Service Annotation portal. Open this page using **Admin > Integration > Web Service Annotation**.

This is a standard [All-in-One portal](#).

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation code. Refer to [System Data Naming Convention](#) for more information.

Maintaining XAI Inbound Services

XAI Inbound Service is a legacy mechanism for exposing system services to external systems as web services. The current supported mechanism for defining web services is [Inbound Web Services](#), which should be used for any new web service.

Some framework based products and existing implementations may have existing XAI inbound services that may need to be viewed. For these services, the product supports deploying them as SOAP inbound web services for execution. Refer to [Deploying XAI Inbound Service via IWS](#).

The following sections describe basic information about the maintenance pages. Note that some of the information is related to legacy functionality that is no longer supported.

XAI Inbound Service - Main

To view an inbound service, open **Admin > XAI > XAI Inbound Service**.

Description of Page

XAI In Service Name is used in the system to identify the service. The service name is also the first XML element after the <Body> element in the XML request/response document. The **XAI Service ID** serves as the primary key.

Owner indicates if this XAI inbound service is owned by the base package or by your implementation (**Customer Modification**). This information is display-only.

The **Adapter** defines the interface with the target application server.

If adapter for this service invokes a system service, then the appropriate **Service Name** is visible.

If adapter is the **Business Adapter** then **Schema Type** and **Schema Name** reference the object to invoke.

Web Service Category is visible if the XAI inbound service is linked to one or more [web service categories](#).

Use the **Description** and **Long Description** to describe the service.

Check the **Active** switch if this service is enabled and available for execution.

Post Error is not applicable.

Trace is not applicable.

Debug is not applicable.

Schema Definitions

NOTE: Request Schema and Response Schema are not applicable to services invoking schema-based objects. They do not appear when the **Business Adapter** is used.

The next two properties define the request and response XML schemas. The schemas are SOAP compatible. The schema XML files are expected to be stored in the Schemas Directory on the Web server running the XAI server.

The **Request Schema** is the XML schema defining the service request. The request sent to the server must adhere to the schema definition.

The **Response Schema** is the XML schema defining the service response. The response generated by the XAI server corresponds to the response schema definition.

The same service may perform several actions on a business object. Use the **Transaction Type** to define the default action performed by a service. The transaction type can be provided when invoking a service, by dynamically specifying a transaction type attribute on the Service element of the XML request. This field may take the following values: **Read, Add, Change, Update, Delete, List** and **Search**.

NOTE: The difference between **Change** and **Update** is that for **Change**, all field values must be passed in with the request. Field values that are not passed in to the request are set to null. For **Update**, you need only pass the primary key field values and the values of the fields to be updated. All other fields retain their existing values.

Services, which perform a Search, may allow searching based on different criteria. When the Transaction Type value is **Search**, use the **Search Type** to define the default search criteria. The possible values are **Main, Alternate1, Alternate2, Alternate3, Alternate4, Alternate5** and **Alternate6**.

NOTE: This is a default definition only and it may be overridden at run time when the service is invoked. To override the search type at run time, you should specify the searchType attribute on the Service element of the XML request.

XSL Transformation Definitions

Sometimes, the XML request document does not conform to the request schema, or the response document expected by the service requestor is not the one generated by the adapter. In such cases the request and/or the response documents must be transformed. The XAI server supports transformation through XSL transformation scripts. Transformation scripts may be applied to the request before it is passed to the adapter or applied to the response document before it is sent to the service requestor.

The **Request XSL** is the name of the XSL transformation to be applied to the request document before processing it. The transformation is usually required when the incoming document does not correspond to the XAI service request schema therefore it has to be transformed before it can be processed by the adapter.

The **Response XSL** is the name of the XSL transformation to be applied to the response document when the requester of the service expects the response to have a different XML document structure than the one defined by the response schema for the service.

Click the **WSDL URL** hyperlink to launch a separate window that contains the WSDL definition for the inbound service. Note that the server name and port number for the URL are built using a setting in the common properties file using the XAI HTTP Caller URL setting.

Configuring REST Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound REST web services.

Owner Configuration Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

When generating the URL for a REST web service, part of the URL is taken from the owner of the Inbound REST Web Service record. The component to add to the URL is defined in this lookup using the URI Component field. The values are provided by the product.

To view the values, navigate to the [Extendable Lookup](#) portal. Search for and select the **Owner Configuration for REST Services** business object.

Resource Category Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

Each Inbound REST Web Service is associated with a Resource Category. The categories are defined as an extendable lookup. The REST URL is built using a component from the IWS record's resource category.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Resource Category** business object. Define values as needed. Typically the category is related to a logical grouping of entities, or maintenance objects, referred to as a 'resource' in REST nomenclature. In some cases, an edge application may have already delivered appropriate resource categories for your use.

Populate the appropriate URI component to include when building the URL for IWS records linked to this resource category.

Maintaining Inbound Web Services

[Inbound Web Services](#) are used to define a specific message that your implementation will receive from an external system and provides configuration needed to process the inbound message.

The product provides support for REST and SOAP services and provides several inbound web services out of the box.

For inbound SOAP web services, by default no annotations are defined for the base inbound web services. You may modify the message options or the annotations for any base IWS record. In addition, you may define additional IWS records for other incoming messages supported by your implementation.

To view an inbound web service, navigate using **Admin > Integration > Inbound Web Service**. You are brought to a query portal with options for searching for inbound web services.

Once an inbound web service has been selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! When adding new records, carefully consider the naming convention of the inbound web service code. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Inbound Web Service.** This zone displays the configuration information for the record and its operations.

- **Operations.** This zone lists the operations defined for the selected inbound web service. The zone is only visible for a REST inbound web service. You may navigate to the Inbound Web Service Operation portal to further describe the operation's web service schema.
- **Help Text Fields.** This zone maintains help text information for fields across all operations of the selected inbound web service. The zone is only visible for a REST inbound web service.

Refer to [Inbound SOAP Web Services](#) for specific information about Operations for SOAP records.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an inbound web service to one or more [web service categories](#).

Maintaining Inbound Web Service Operations

This portal is used to maintain a REST inbound web service operation. You can access the portal from the **Operations** zone on the Inbound Web Service portal for a REST service.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

The following zones may appear as part of the portal's **Main** tab page

- **IWS Operation.** This zone provides information about the selected operation.
- **Schema.** This zone describes the request and response schema as defined by the operation's web service schema. The zone is only visible when an operation schema is explicitly defined.
- **Schema Extensions.** This zone manages web service schema extensions that correspond to extensions made to the operation's internal schema. This zone is only visible if the underlying schema was extended using dynamic data area extension functionality. Each owner that extended the internal schema may provide web service schema information for their extension elements.
- **Options.** This zone lists various options for the operation such as request and response samples. The zone is visible when such options exist for the operation. Note that options are maintained as part of operation record.

The following zones may appear as part of the portal's **References** tab page

- **IWS Operation References.** This zone lists references to the current web service operation. The list includes other inbound web service operation records that reference the current operation via their web service schema. For a GET operation, the list also includes the maintenance object or business object that explicitly references the operation using a **GET Operation** option.

Web Service Schema Nodes and Attributes

A REST inbound web service (IWS) operation invokes a single schema based object, either a Business Object, a Business Service or a Service Script. The object has one schema which by default acts as both the Request and the Response schema. The product provides the ability to define an explicit schema for a web service operation that represents a view of the underlying internal schema for an external facing consumer. Note that the operation schema is a strict view of the internal schema and as such does not introduce structural changes.

While optional, defining an operation schema has the following benefits:

- Declaring the **usage** of an element as to whether it is part of the Request schema, Response schema, both or neither.
- Assigning an **external element name** to an internal element. Useful to avoid cloning of internal services for this purpose only.
- Better management and visibility of **GET operation** references.
- Support HATEOAS style structures outside of the internal schema. This allows for seamless internal processing.
- Providing help text for individual elements.

The following documentation is a complete list of the attributes available to you when constructing an IWS operation schema.

Contents

- [Operation Schema Definition](#)
- [Specialized Elements](#)
- [Open API Specification](#)

Operation Schema Definition

The following attributes defines the external facing operation schema that establishes the request and response schema for the operation.

Mnemonic	Valid Values	Description	Examples
usage=	"REQ"	<p>Indicates that the element should be included in the request schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<code><customerName usage="REQ" /></code>
	"RESP"	<p>Indicates that the element should be included in the response schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<code><customerId usage="RESP" /></code>
	"BOTH"	<p>Indicates that the element should be included in both request and response schema definitions. This is the default value</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<code><customerName usage="BOTH" /></code>
	"EXCL"	<p>Indicates that the element should not be included in either the request or the response schema definitions.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<code><httpMethod usage="EXCL" /></code>
mapTo=	"internal element name"	Maps a web service element to an internal element. By default the internal element name is	<p>Internal schema element:</p> <code><todoPriority .../></code>

Mnemonic	Valid Values	Description	Examples
		<p>assumed to be the same as the web service element name. Use this attribute to assign an external facing element name in the operation schema and map it to a corresponding internal element.</p> <p>Note that this is not an XPath expression but rather a reference to a valid element name that corresponds to the structure of the expanded internal schema.</p> <p>The owner of the element must be the same as the owner of the web service schema. If an operation's underlying schema was extended (using dynamic data area extension) then the extending owner may only reference their elements on their web service schema extension for the operation.</p>	<p>Operation schema element:</p> <pre data-bbox="1141 233 1511 275"><priority mapTo="todoPriority"/></pre>
role=	"FKGP"	<p>Establishes a group structure that represents a foreign key to an entity.</p> <p>The element itself does not exist in the internal schema. It groups together the foreign key value element(s) along with a corresponding _link element that at run time provides the endpoint URL of that entity's GET operation. Consumers of the web service may use the link to get the data for the entity.</p>	<p>Internal schema element:</p> <pre data-bbox="1141 968 1273 989"><user ../></pre> <p>Operation schema group:</p> <pre data-bbox="1141 1047 1622 1152"><user role="FKGP"> <user> <_link getOperation="mo:'USER';pk1:us > </user></pre>
	"COLL"	<p>Establishes a group structure that represents a collection of entities that corresponds to an internal service list.</p> <p>The element itself does not exist in the internal schema. It groups together the internal list mapped to a _data element along with a corresponding _link element that at run time provides the endpoint URL for the collection's GET operation. Consumers of the web service may use the link to get a more detailed set of information for each entity in the list.</p>	<p>Internal schema element:</p> <pre data-bbox="1141 1404 1393 1530"><alerts type="list"> <alert/> <startDate /> <endDate /> <version /> </_data> </alerts></pre> <p>Operation schema group:</p> <pre data-bbox="1141 1589 1500 1757"><alerts role="COLL"> <_link getOperation="... " / > <_data mapTo="alerts"> <version usage="EXCL" / > </_data> </alerts></pre>

Mnemonic	Valid Values	Description	Examples
getOperation=	<p>"expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • mo: '<maintenance object>'; • pk1: '<relative xpath to an element in the internal schema>; • pk2: '...;'; • pk3: '...;'; • pk4: '...;'; • pk5: '...;'; <p>Parameters pk2–5 are required to match the maintenance object's prime key definition.</p>	<p>By default all the elements in the referenced list are included in the operation schema. You may explicitly reference and define attributes for specific elements as needed.</p> <p>Only valid on <code>_self</code> and <code>_link</code> elements. The attribute is used to reference the default GET operation for an entity as defined by its maintenance object or business object.</p> <p>The application determines the GET operation to use as follows:</p> <ul style="list-style-type: none"> • If the entity's business object references an operation using the GET Operation option then it is used. • If the entity's maintenance object references an operation using the GET Operation option then it is used. • If a GET operation is found that references the maintenance object then it is used. <p>If a GET operation cannot be determined for the entity a standard text indicating that a link is not available is returned instead.</p>	<pre><_link getOperation="mo:'TO DO ENTRY';pk: ></pre>
	<p>"expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • iws: '<inbound web service name>'; • operation: '<operation name>'; • parms: [<external reference as defined on the GET operation record>:<relative xpath of an element name in the internal schema that holds the value>; <another external reference name>:<another relative xpath>;...]; 	<p>Only valid on <code>_self</code> and <code>_link</code> elements. The attribute is used to reference a specific GET operation along with the information needed to compose its path parameters.</p>	<pre><_self getOperation="iws:'Fl- ToDoEntry'; operation:'getToDoEntry'; pa [ToDoEntryId:ToDoEntryId;]"/ ></pre>

Specialized Elements

The operation schema definition makes use of specialized element names in the style of the Hypermedia as the Engine of Application State (HATEOAS) standard. These elements should only be defined by the operation schema as they are not relevant to nor should be managed by the internal operation service.

The following list describes each element and how it is used.

Element Name	Description	Examples
<code><_self .../></code>	<p>Response payloads may include a "_self" element that contains the endpoint URL of the GET operation related to the entity returned in the response.</p> <p>This is an optional element and only one may exist in an operation schema.</p> <p>Refer to getOperation= schema definition attributes for more information.</p>	<pre><_self getOperation="mo:'TO DO ENTRY';pk1:ToDoEntry"> </_self></pre>
<code><_link .../></code>	<p>Response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).</p> <p>Refer to role= and getOperation= schema definition attribute for more information.</p>	<pre><_link getOperation="mo:'TO DO ENTRY';pk1:ToDoEntry"> </_link></pre>
<code><_data .../></code>	<p>Provides a standard reference to a list of entities in the internal schema.</p> <p>Refer to role="COLL" schema definition attribute for more information.</p>	<pre><alerts role="COLL"> <_link getOperation="... "/> <_data mapTo="alerts"> </_data> </alerts></pre>

Documentation Attributes

The following attributes provide additional documentation for individual elements that is included as part of the web service's Open API specification.

Mnemonic	Valid Values	Description	Examples
helpText=	"help text field name"	<p>Associates an element with a specific help text record defined for the Inbound Web Service. If the element is included in both request and response schema the same help text is used in both.</p> <p>If this attribute is not specified, and a single Help Text Field record exists for the Field associated with the internal element, that help text record is used. If more than one such Help Text Field record exists the one</p>	<pre><ToDoEntryId usage="BOTH" helpText="TD_ENTRY"> </ToDoEntryId></pre> <p>In this example the inbound web service defines a help text field name "TD_ENTRY" that provides help text for this element. The same help text is included for the element in both request and response schema.</p>

Mnemonic	Valid Values	Description	Examples
		<p>where the help text name is the same as the Field name is used.</p> <p>Note that an internal element is associated with a Field name via the mdField= attributes, if any, else via the mapField= attribute.</p> <p>No valid for _self and _link elements.</p>	
helpTextResponse=	"help text field name"	<p>Associates an element that is included in both request and response schema with a specific help text record to be used in the context of the response schema.</p> <p>Follows same rules as the helpText= attribute.</p>	<pre><todoEntryId usage="BOTH" helpText="TD_ENTRY"></pre> <p>In this example the inbound web service defines the following help text records:</p> <ul style="list-style-type: none"> • Help text field name "TD_ENTRY" describes the element sent in the request schema. • Help text field name "TD_ENTRY_RESP" describes the element populated in the response schema.

Deploying Inbound SOAP Web Services

Once an Inbound SOAP Web Service is defined it is not automatically available to the Web Service Clients to access the system. The Deployment Status and the Active flag (set to true) indicate whether a Web Service is available or not. The last step is to deploy the Inbound SOAP Web Services to the Java EE Web Application Server. This deployment phase has a number of steps that are automatically performed when a deployment is initiated:

- The Web Service files are generated and policies are attached.
- The WSDL is generated with appropriate annotations and enumerations.
- The necessary Java stub code to implement the Web Service in the Java EE Web Application Server is generated and compiled.
- The Web Services are built into a valid Web Application Archive (WAR) file.
- Optionally, the newly created Web Services WAR file is deployed to the Java EE Web Application Server. This can also be done manually for clustered deployments, if desired.

There are two methods available for deploying inbound SOAP web services:

- Deployment at the command line using the **iwdeploy[.sh]** command as outlined in the Server Administration Guide. This method is recommended for native installations and production implementations.
- Deployment using the Inbound Web Service Deployment portal. This method is only supported in development (non-production) environments.

Inbound Web Service Deployment Portal

To use the online Inbound Web Service Deployment portal, navigate using **Admin > Integration > Inbound Web Service Deployment**.

The following sections describe the base zones that are provided on the portal.

Deploy Inbound SOAP Web Services

The Deploy Inbound SOAP Web Services zone provides information about the last deployment. If the region is a development (non-production) region you may use the **Deploy** button to deploy or re-deploy inbound web services. All inbound web services whose Active switch is Yes will be deployed. All whose active switch is No will be undeployed.

NOTE: When an Inbound SOAP Web Service is deployed, the value of its service revision field is captured. Certain changes to configuration will require re-deployment to take effect. When any of the following changes occur, the IWS service revision value is incremented. This will cause the deployment status to show **Needs Deployment**.

- Active switch is changed
- An Annotation is added or removed
- An Operation is added or removed.
- The Operation Name, Schema Type / Schema Name, Request or Response Schema, Request or Response XSL for an Operation is changed.

NOTE: In addition, if the implementation supports XAI services deployed through IWS, the appropriate XAI inbound services will also be deployed or undeployed as required.

Deployment Status

The Deployment Status zone displays a list of inbound SOAP web services in the product, including the deployment status.

The deployment status is determined by comparing the internal Service Revision field on each IWS against the value captured at the time of deployment.

- **Deployed.** Indicates that the IWS has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the IWS has never been deployed or has been deployed but in the meantime, changes have been detected to the configuration that require redeployment.
- **Undeployed.** Indicates that the IWS is marked as inactive and the IWS is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the IWS is marked as inactive but the IWS is found to be deployed at this time.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

NOTE: For cloud installations, the system supports defining the WSDL URI via a substitution value defined for the token URI: @F1_BASE_IWS_URI@. The system will use this value per the functionality described in [URI Substitution](#). When no value is defined, the system uses a default URL, which is the appropriate URL for on-premise installations.

Use the broadcast button adjacent to any of the inbound web services listed in the zone to view the details of the IWS record. This causes the **Inbound Web Service** zone to appear. It is the same zone that appears on the [Inbound Web Service](#) maintenance portal.

XAI Inbound Service Deployment Status

The XAI Inbound Service Deployment Status zone is only visible if the feature configuration option **Support XAI Services via IWS** is configured on the **External Messages** feature type or if the system detects that there are XAI inbound services that have been deployed. (The latter condition is checked for the case where an implementation has XAI inbound services deployed and then chooses to discontinue using this functionality. After changing the feature configuration option to false, one more deployment is required to "undeploy" the XAI services.) The zone displays a list of XAI inbound services in the product that are related to page services. Refer to [Deploying XAI Inbound Service via IWS](#) for more information.

The deployment status is determined by comparing the record's Version field against the value captured at the time of deployment.

- **Deployed.** Indicates that the XAI inbound service has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the XAI inbound service has not been deployed or has been deployed but in the meantime, changes have been detected to the configuration.
- **Undeployed.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** and the XAI inbound service is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** but the XAI inbound service is found to be deployed at this time.

XAI inbound service does not have the equivalent of a Service Revision field that inbound web service has, which is only incremented when changes are made to the record that impact deployment. For XAI inbound service, the version number on the record is used. This field is incremented when any changes are made, even ones that may not impact deployment. As a result, some XAI Inbound Services may indicate "Needs Deployment" in cases where a redeployment may not be necessary. The recommendation when this occurs is to simply Deploy again to be safe.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

Guaranteed Delivery

There are alternatives for sending messages to the system besides using inbound web services. An external system may be able to send messages to the system in a generic manner where a new web service does not need to be defined for every new type of message. These types of messages may provide a payload (the message) and the service script or business service to invoke. An example of this type of communication is a message sent from a mobile application using RESTful operations.

The external system may have no mechanism for retrying failed messages. For this situation, the product provides an algorithm that may be used to capture incoming messages that should 'guarantee delivery'. A servlet processing this type of message may invoke the [installation algorithm](#) - Guaranteed Delivery, passing the details of the message and an indication if a response should be returned. The algorithm is responsible for storing the message information in a table so that it can be subsequently processed.

Outgoing Messages

"Outgoing messages" is the term used to describe messages that are initiated by our system and sent to an external system. Messages may be sent real time or near real time. The system provides the following mechanisms for communicating messages to external systems.

- **Outbound Messages.** This method allows implementers to use configurable business objects to define the message format and to use scripts to build the message. If sent near real-time the message is posted to the outbound message table waiting for Oracle Service Bus to poll the records, apply the XSL and route the message. If sent real time, the message dispatcher routes the message immediately.
- **Web Service Adapters.** Using a web service adapter, an implementation can consume a WSDL from an external system and create an "adapter" record that references the URL of the external system and creates appropriate request and response data areas to expose the payload information in a format understood by configuration tools. A script may then be written to build the request information and initiate a real-time web service call from within the system.
- **Send Email.** The system supplies a dedicated business service that may be used to send an email real-time from within the application.

All these methods are described in more detail in the following sections.

Outbound Messages

Outbound messages provide functionality for routing XML messages to an external system real-time or in near real time. In addition the functionality supports collecting related messages into a batch to then be sent to an external system as a consolidate XML message.

For each outbound message that your implementation must initiate you define a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, you define the fields that make up the XML source field. These are the fields that make up the basis for the XML message (prior to any XSL transformation).

Each outbound message requires the definition of its schema by creating a business object whose schema describes the information that is provided to the external system. An XSL transformation may then be performed when routing the message to an external system.

For each external system that may receive this message, you configure the appropriate message XSL and routing information.

Because the outbound message type is associated with a business object, your implementation can easily create outbound message records from a script using the **Invoke business object** step type. Such a script would do the following:

- Determine the appropriate [outbound message type](#) and [external system](#) based on business rules
- Access the data needed to populate the message detail
- Populate the fields in the schema and use the **Invoke business object** script step type for the outbound message type's business object to store the outbound message.
- The resulting outbound message ID is returned to the script and the scriptwriter may choose to design a subsequent step to store that ID as an audit on the record that initiated this message.

The following topics provide more information about functionality supported by outbound messages.

Polling Outbound Messages Using OSB

If the outbound message that needs to be sent to an external system can be sent as an asynchronous message (in 'near real time'), the process initiating the outbound message should create a record in the outbound message staging table. Oracle Service Bus (OSB), is the recommended tool to use to process outbound messages in near real-time.

Outbound messages that should be processed by OSB should be configured with a processing method defined as **SOA** for the external system / outbound message type. No other information is required for defining outbound message types that are processed by OSB.

For the OSB part of the processing, the product provides a custom transport: OUAF Outbound Message that may be used by an implementation to define messages to process and how to process them. This transport processes outbound messages in order of the priority defined on the outbound message type.

This section provides an overview of steps required to develop OSB integrations for outbound messages created by your product.

Before developing OSB integrations, a developer should be familiar with OSB development such as creating proxy services, business services, and message flow/routing. These terms are defined as follows:

Proxy Service: In OSB, a Proxy Service is the entity that processes a given type of message and routes it to a Business Service. A separate proxy service should be defined for each type of outbound message. If a given outbound message type may be routed to different external systems, it is the responsibility of the proxy service to query the external system defined on the outbound message and invoke the appropriate business service (see below). If any transformation is required prior to routing a message to a business service, it is the proxy service's responsibility to perform the transformation.

Business Service: In OSB, a Business Service is an entity that receives a message from OSB and routes it to the appropriate destination. This should not be confused with the Business Service object provided in the product in the configuration tools.

FASTPATH: Refer to the technical reference paper *OSB Integration* for more information.

Batch Message Processing

Your implementation may be required to send messages to the same destination as a single XML file with multiple messages include. The following points describe this logic:

- The individual messages that should be grouped together must have a processing method of **batch** on the external system / outbound message type record. The appropriate batch code that is responsible for grouping the messages must also be provided.
- A separate "consolidated message" outbound message type should be configured for the external system with a processing method of **SOA**.
- When outbound message records are created for the individual messages, the batch code and current batch run number are stamped on the record.
- When the batch process runs it is responsible for building the XML file that is a collection of the individual messages. This batch process should include the following steps:
 - Format appropriate header information for the collection of messages
 - Apply the individual message XSL to each message before including the message
 - Insert a new outbound message for the external system with the "consolidated message" outbound message type.
- The consolidated message is ready to be processed by Oracle Service Bus.

NOTE: No process provided. The system does not supply any sample batch job that does the above logic.

Real Time Messages

The system supports the ability to make web service calls, i.e. sending real time messages, to an external system.

The system supports special functionality for sending an Email message real-time. Refer to [Sending Email](#) for more information.

For other types of real-time messages, the system also uses outbound message type and external system configuration to format and route the message. When defining the configuration for real time messages, an additional step is required to define the mechanism for routing the message using a message sender. The system supports routing messages via HTTP and via JMS. Note that for HTTP routing, the system also supports sending the message using a JSON format.

Just like near real-time messages, initiating a real-time outbound message may also be done from a script. When a real time message is added, the system immediately routes it to the external system. If the external system provided a response message back, the system captures the response on the outbound message. If the outbound message type for the external system is associated with a response XSL it is applied to transform the response. In this case the system captures the raw response as well on the outbound message. Note that the outbound message BO should be configured to capture a response XML in its schema.

Any error (that can be trapped) causes the outbound message to be in a state of **Error**. It is the responsibility of the calling process to check upon the state of the outbound message and take a programmatic action. When the outbound message state is changed back to **Pending** the message will be retried.

The base package provides two business services: Outbound Message Dispatcher (**F1-OutmsgDispatcher**) and Outbound Message Mediator (**F1-OutmsgMediator**) that further facilitate making web service calls. Both business services are similar, allowing the calling script to configure the following behavior (with differences noted):

- Whether or not exceptions encountered while sending the message are trapped. Trapping errors allows the calling script to interrogate any errors encountered and take some other programmatic action.

- Whether or not the sent message is persisted as an actual outbound message record.
 - If a persisted message is desired, the recommendation is to use the Outbound Message Dispatcher. This business service creates the message using standard BO processing, relying on the outbound message logic to route the message and store the record. The message is routed after the BO pre-processing algorithm and after the record is persisted but before the BO post-processing and audit plug-ins are executed. If you need to send the outbound message ID as part of the message, refer to [Capturing the Outbound Message ID in the Message](#) for more information.
 - If the message should not be persisted, then the recommendation is to use the Outbound Message Mediator. As mentioned, the Outbound Message Dispatcher creates the outbound message record, relying on the outbound message logic to route the message. If it should not be persisted, it is subsequently deleted. In contrast the Outbound Message Mediator executes the BO pre-processing algorithms and then routes the message explicitly without creating a message record. It is more efficient for scenarios that don't require persistence. Note that the Outbound Message Mediator also supports persistence, but it does so by creating the records without using BO processing. This is not recommended. The Dispatcher is the better option if persistence is desired.

Refer to the descriptions of the two business services for more information.

Designing the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system. The configuration walks you through the steps to configure a single external system and all its messages.

Define the Outbound Message Business Object and Type

The product supplies many outbound message Business Objects along with Outbound Message Types for out of the box functionality.

In addition, implementations may need to define configuration for custom outbound messages. For each outbound message that must be sent to an external system, create a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, your implementation defines the elements that make up the XML Source field (XML_SOURCE). These are the elements that are the basis for the XML message. XSL transformations may be applied to this XML source to produce the XML message.

If your integration is real-time and a response is expected, the Outbound Message business object should also map to the XML Response field (XML_RESPONSE).

- You may decide to capture the response as is and define the element as “raw”. For example

```
<responseDetail mapXML="XML_RESPONSE" type="raw"/>
```

In this scenario, a Response XSL may or may not be needed.

- Alternatively, if the details of the response are needed, you may define specific elements for the response. For this option, depending on how the integration is designed, a Response XSL may be needed to transform the response into the expected XML format.

Once you have your business object and schema, define an [outbound message type](#) for each unique outbound message.

Referencing an XSL

The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

Capturing the Outbound Message ID in the Message

If your integration would like to use the system generated Outbound Message ID as a unique identifier with the external system, the following configuration is needed:

- Define an element within the XML Source that should be populated with the system generated outbound message.
- Configure a BO Option on the outbound message's business object using the Option Type **Outbound Message ID XPath** and set the Option Value to the XPath of the element defined to capture the ID.

NOTE: This functionality is only applicable if the outbound message is persisted.

Support for Dynamic URLs

The product supports the ability to build a dynamic URLs. These are cases where the URL requires information determined at runtime. This is supported with a combination of BO schema definition, URL configuration and appropriate code when creating the outbound message. The following points highlight the steps needed to support this functionality.

- When defining the [Message Sender's](#) URL, use the syntax **\${pathParms}** in the location of the URL where runtime information must be inserted. For example: **http://[SERVER_NAME]:1000/rest/services/\${pathParms}**
- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes elements for **pathParms** and **queryParms**.
- In the code that creates the outbound message, populate the **pathParms** and if applicable **queryParms** elements with the appropriate information. The system will build the URL by plugging in the **pathParms** element value followed by a question mark, followed by the **queryParms** element value into the **\${pathParms}** location in the URL.

The following is an example of run time values.

```
<dynamicConfiguration>
  <pathParms>job/1234</pathParms>
  <queryParms>firstName=John&lastName=Doe</queryParms>
</dynamicConfiguration>
```

Add SOAP Header Parameters at Runtime

The product supports the ability to add SOAP header parameters to an external message at runtime. The following points highlight the steps needed to support this functionality.

- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes the element **soapHeaders** .
- In the code that creates the outbound message, populate the **soapHeaders** element with the self contained XML to add to the SOAP header section of the outgoing SOAP request.

Real-Time Message Configuration

Messages are routed to an external system real-time using the outbound message dispatcher or using the real-time send email business service. The system supports routing messages using HTTP and routing messages using JMS. In addition, there is a special type of message sender used for sending emails. The following sections highlights the supported real-time communication and the configuration needed for each.

Email Messages

For sending emails, the following configuration is needed:

- Define a [message sender](#) configured for email. Senders of this type should be configured with the **RTEMAILSNDR** class. The sender context is used to configure the connection information for the connecting to the SMTP server.

- This sender may be defined as the default email sender on the [message option](#) table. Alternatively, the message sender can be provided to the business service as input. Refer to [Sending Email](#) for more information.

Outbound Messages

For other outbound messages that are routed using the real-time outbound message dispatcher, a [message sender](#) must be configured to define how to route the message. The following points highlight more detail related to this configuration.

Determine the communication mechanism prior to configuring the sender.

- When routing the message using JMS, the following configuration must be defined
 - Define an appropriate [JNDI Server](#) that indicates where the JMS resources are located.
 - Define a [JMS Connection](#) to define additional configuration needed for the connection.
 - Define the [JMS Queue](#) or [JMS Topic](#) to define the queue or topic to use.
- When communicating using a JSON format, determine the method to use to convert the XML to JSON. The desired method is driven by how the request should be sent.
 - If choosing the **Base JSON Conversion** method, if XSL transformation needs to be applied prior to the conversion to JSON, then the target XML Request Schema must be defined (using a data area) so that the conversion logic knows the format of the XML it is converting. The XSL is applied to the outbound message's XML Source, resulting in the defined XML Request Schema, which is then converted to JSON. If XSL transformation is not required, then the outbound message's XML Source is converted to JSON.
 - If choosing the **Rootless JSON Conversion** method, the group element mapped to the XML source field is removed by the conversion, resulting in a rootless JSON request document.
 - If the XML source on the outbound message can be converted to JSON using an XSL, then the **XSL Transformation** method may be chosen.
 - You may also choose to convert the XML Source to JSON via the **Standard API Conversion** method (using a Jettison library). With this method, an XSL may optionally be provided. The conversion will be performed on the transformed XML.
 - For the response, if the outbound message BO defines detailed elements for the XML Response field, then the JSON should be converted to this format.
 - If your conversion method is **Base JSON Conversion**, then if the JSON response cannot be converted directly to the XML Response elements on the outbound message BO, then define a Response Schema (data area) that represents the results for the base JSON conversion. In addition, define an XSL that can transform the response from the converted XML to the XML format expected on the BO.
 - If your conversion method is **Rootless JSON Conversion**, the response document is assumed to be rootless. The group element mapped to the XML response field is added by the conversion process, resulting in a well formed XML response document.
 - If the conversion method is **Standard API Conversion** or **XSL Transformation**, the standard API is used to convert JSON to XML. An XSL may be defined to convert the response to the XML Response if needed.
 - If the outbound message BO defines a "raw" element to capture the response, then a response schema and XSL are not necessary. In this case, the system will perform a JSON to XML conversion using the **Standard API Conversion** method (regardless of the conversion method defined) and the result is captured in the XML response.
- For HTTP senders including JSON senders, the system provides the following support for sending messages secured by OAuth authentication:
 - Using Oracle Web Services Manager (OWSM). The system provides a pre-configured set of policies for OAuth (**F1-OAUTH**) using a special extendable lookup. Note that the values of this policy set defines a specific CSF key repository that the implementation should use for capturing its CSF keys. In addition, there is a substitution value defined for the token URI: @F1_OAUTH2_URI@. Configure the appropriate URI for this implementation as

described in [URI Substitution](#). By default the system does not support additional policy sets to be defined. If your implementation requires a different policy set, contact support.

- You may provide OAuth related settings as part of the [message sender](#) configuration for a REST API.

Define a [message sender](#) configured for each appropriate routing method. The invocation type should be configured as **Real-time**. For routing via HTTP, use the **RTHTTPSNDR** - HTTP sender class. For routing via HTTP with SOAP format automatically applied, use the **SOAPSNDR** - HTTP SOAP sender class. For routing via HTTP using JSON format, use the **RTJSONSNDR** - JSON sender class. For routing via JMS, use the **RTJMSQSNDR** - JMS queue sender class or **RTJMSTSNDR** - JMS topic sender class and configure the JMS Connection and JMS Queue or JMS Topic. Use the sender context to configure the required values for connecting to the appropriate destination.

NOTE: Refer to [Support for Dynamic URLs](#) for configuration needed to support dynamic URLs when sending an outbound message. There is specific configuration expected when defining the URL on the Sender in order to support dynamic URLs.

Configure the [external system](#) / outbound message type collection. The processing method defined for the external system / outbound message type must be **Real-time**.

Define the External System and Configure the Messages

Define an [external system](#) and configure the valid outgoing messages and their method of communication (processing method). Refer to [Outbound Messages](#) for more information.

Outbound Message Schema Validation

The outbound messages that are generated by the system should be well formed and valid so that they do not cause any issues in the external system. To ensure this validity you may configure the system to validate messages before they are routed to their destination. Note that the validation is applied just before communication with the sender and therefore after any Request XSL has been applied.

- Define a directory where the valid W3C schemas are located using the Message option **Outbound Message Schema Location**.
- Each [external system](#) message must indicate the appropriate W3C schema to use for validation.

You may turn on or off this validation checking using the Message option **Schema Validation Flag**.

This feature is not supported for cloud implementations.

Configuring the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system.

JNDI Server

If using JMS to communicate outbound messages, define a new JNDI Server. Open **Admin > Integration > JNDI Server**.

Description of Page

Enter a unique **JNDI Server** and **Description**.

Indicate the Provider URL to indicate the location of the JNDI server. A variable may be used in place of all or part of the URL. The variable must be predefined in the substitution variable property file. The value here should enclose the variable name with @. Refer to [Referencing URIs](#) for more information.

Indicate the **Initial Context Factory**, which is a Java class name used by the JNDI server provider to create JNDI context objects.

JMS Connection

To define a JMS Connection, open **Admin > Integration > JMS Connection**.

Description of Page

Enter a unique **JMS Connection** and **Description**.

Indicate the **JNDI Server** to be used. Refer to [JNDI Server](#) for more information.

Use the **JNDI Connection Factory** to indicate the lookup keyword in the JNDI server used to locate the JMS connection.

Where Used

JMS Queue

To define your JMS Queue values, open **Admin > Integration > JMS Queue**.

Description of Page

Enter a unique **JMS Queue** and **Description**.

Enter the **Queue Name** as defined in the JNDI server. This is the JNDI lookup name identifying the queue.

Use the **Target Client Flag** to indicate whether or not the target client is **JMS** or **MQ**.

Select the **JNDI Server** where the queue is defined. Refer to [JNDI Server](#) for more information.

JMS Topic

To define your JMS Topic values, open **Admin > Integration > JMS Topic**.

Description of Page

Enter a unique **JMS Topic** and **Description**.

Select the **JNDI Server** where the topic is defined. Refer to [JNDI Server](#) for more information.

Enter the **Topic Name** as defined in the JNDI server. This is the JNDI lookup name identifying the topic.

Message Sender

The topics in this section describe the maintenance of a message sender

Message Sender - Main

To define a new sender, open **Admin > Integration > Message Sender**.

Description of Page

Enter a unique **Message Sender** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the message sender code. Refer to [System Data Naming Convention](#) for more information.

Set **Invocation Type** to **Real-time**.

Indicate the **Message Class** for this sender, which indicates the method used to route the message. The valid sender classes are as follows:

Message Class	Description
RTEMAILSNDNR	Email sender.
RTHTTPSNDR	HTTP sender.
RTJMSQSNDNR	JMS queue sender.
RTJMSTSNDNR	JMS topic sender.
RTJSONSNDR	HTTP JSON sender.
SOAPSNDNR	HTTP SOAP sender.

Indicate whether or not this sender is currently **Active**.

For JMS related senders, indicate whether the **MSG Encoding** is **ANSI message encoding** or **UTF-8 message encoding**. (Note that for all other types of senders, the Character Encoding context type is used to configure encoding.)

If the Message Class is one that connects to a JMS Queue or JMS Topic, indicate the appropriate **JMS Connection**

FASTPATH: Refer to [JMS Connection](#) for more information.

If the Message Class is one that connects to a JMS queue, indicate the name of the **JMS Queue** to define where the message is to be sent.

FASTPATH: Refer to [JMS Queue](#) for more information.

If the Message Class is one that connects to a JMS topic, indicate the name of the **JMS Topic** to define where the message is to be sent.

FASTPATH: Refer to [JMS Topic](#) for more information.

Message Sender - Context

The sender may require context information to define additional information needed by the system to successfully send outgoing messages. Open **Admin > Integration > Message Sender** and navigate to the **Context** page.

Description of Page

Define the **Context Type** and **Context Value**, which contain parameters for senders when more information is required. See below for the supported context values for different types of senders.

Email Sender Context

The email sender is used by the business service that [sends email messages real-time](#).

An email sender must point to the Message Class **RTHTTPSNDR**. In addition, the following context records should be defined for senders of this type.

Context Type	Description
SMTP Host name	The SMTP server host name.
SMTP Username	The user ID used to access the SMTP server.
SMTP Password	The password used to access the SMTP server.
Response Time Out	The amount of time the system should wait for a real time response.

HTTP Sender

An HTTP sender is one that sends messages to an HTTP server using the HTTP protocol. HTTP senders should reference a Message Class of **RTHTTPSNDR**, **RTJSONSNDR** or **SOAPSNDNR**.

Various parameters are required to establish a session with the target HTTP server. You specify these parameters by defining a collection of context values for the sender. A set of context types related to HTTP variables is provided with the product. The following section describes the context types and where appropriate, indicates valid values.

Before defining the HTTP sender, you need to find out how the HTTP server on the other side expects to receive the request, and in particular, to answer the following questions:

- What is the address of the HTTP server?
- Is the HTTP server using a POST or GET HTTP method?
- If the server is using POST, how are message contents passed? Does it use an HTTP FORM or does it pass the data in the body of an XML message?

Context Type	Description	Values
HTTP URL1 - URL9	<p>Used to construct the URL of the target HTTP server.</p> <p>Since the URL may be long and complex, you can break it into smaller parts, each defined by a separate context record. The full URL is built by concatenating the values in URL1 through URL9.</p> <p>You may use substitution variables when entering values for URL parts. Note that the substitution string @XMLMSG@ may be used for GET calls if an XSL has been applied to convert the message into HTTP GET parameters. It is useful if the HTTP Form is not applicable to the type of message.</p> <p>Refer to Support for Dynamic URLs for configuration needed to support dynamic URLs when sending an outbound message.</p>	
HTTP Method	<p>The HTTP method used to send the message.</p> <p>NOTE: The SOAP sender message class SOAPSNDR only supports the POST method.</p>	POST or GET
HTTP Transport Method	<p>Specifies the type of the message. You can either send the message or send and wait for a response.</p>	Send or sendReceive
HTTP Form Data	<p>Used when the message is in the format of an HTML Form (Content-Type: application/x-www-form-urlencoded).</p> <p>This context specifies the form parameters (data) that should be passed in the HTTP message. Since a form may have multiple parameters, you should add a context record for each form parameter.</p> <p>The value of a form parameter takes the format of x=y where x is the form parameter name and y is its value.</p> <p>If y contains the string @XMLMSG@ (case sensitive) then this string is replaced by</p>	

Context Type	Description	Values
	<p>the content of the service response XML message. The @XMLMSG@ string can be used in the HTTP Form Data or in the HTTP URL, but not in both.</p> <p>If a context record of this type is defined for a sender, the sender uses the HTML Form message format to send the message even if @XMLMSG@ is not specified in one of the context records.</p> <p>If a context record of this type is not defined for a sender, then the XML is sent with <code>Content-Type: text/plain</code>. When using POST it is put in the HTTP message body.</p> <p>Always required when using the GET method. If you are using the GET method and do not specify a Form Data context record, no message is transferred to the HTTP server.</p> <p>You may use substitution variables when entering values for Form Data.</p>	
HTTP Login User	The HTTP server may require authentication. Add a context record of this type to specify the login user to use.	
HTTP Login Password	The HTTP server may require authentication. Add a context record of this type to specify the login password to use.	
HTTP Header	<p>Sometimes the HTTP server on the other side may require the addition of HTTP headers to the message.</p> <p>For each HTTP header that has to be specified you should add a context record with a value having the following format <code>x:y</code> where <code>x</code> is the header name and <code>y</code> is the value for the header</p>	
HTTP Time Out	Indicates the amount of time to wait for a connection to be established with the remote system.	
Character Encoding	Indicates if the message should be encoded. The sender will add to the HTTP's content type header the string <code>; charset=x</code> where <code>x</code> is the value of this context and when sending the message it will encode the data in that encoding.	UTF-8 or UTF-16
Response Time Out	The amount of time the system should wait for the remote system to send a response.	
Sender Security Type	Indicate the desired security type to apply. (Note that additional security types are applicable only to the SOAP Sender. See below for more information.)	BASIC (HTTP Basic), TEXT (Username Token plain text), DIGEST - Username Token Digest, OWSM - OAuth Security via OWSM, OAUTH - OAuth Security.

OWSM Policy Set	Applicable only if the Sender Security Type is OWSM . Defines the policy set to apply.	Enter a valid value for the extendable lookup Set of Policies (F1-SetOfPolicies). The product provides the value F1-OAUTH that may be used here.
OAuth Grant Type	Applicable only if the Sender Security Type is OAUTH . Defines the OAuth specification method for acquiring an access token.	client_credentials
OAuth Access Token URL	Used to construct the URL of the target authorization server. You may use substitution variables to construct the URL.	
OAuth Client ID	The generated identifier for the current application in the external system's authorization server.	
OAuth Client Secret	The secret paired with the OAuth Client ID as provided by the external system's authorization server.	
OAuth Key Ring	Defines the key ring used to store the OAuth Client ID and secret provided by the external system's authorization server. If a key ring is specified, the OAuth Client ID and OAuth Client Secret context entries are not allowed.	
OAuth REST API Scope	The authorization level granted by the end point.	
OAuth Token Request Details in Body	By default, the authorization token request includes the Client ID and Secret information in the message header. This context type may be used to indicate that this information should be sent in the body of the request instead.	Set this to 'Y' to send the Client ID and Secret information as part of the body of the authorization token request.

Real-time HTTP Sender

The following context type is only applicable to senders with the **RTHTTPSNDR** message class.

Context Type	Description
Content Type	Populate a value here to override the Content-Type attribute in the HTTP header, which defaults to text/xml .

SOAP Sender

A SOAP sender is an HTTP sender that automatically adds support for the SOAP format. For this type of sender (message class of **SOAPSNDR**), besides the context values listed above, the following context entries may also be supplied.

Context Type	Description	Values
Message Namespace URI	Used to indicate a specific namespace to be included in messages for this sender. Note that this value is used only when the External Message link to this sender is configured with	

Context Type	Description	Values
	a Namespace Option of Configured on Sender .	
SOAP Insert Timestamp	Indicate whether a timestamp should be added. Default value is 'N'.	Y or N
SOAP Expiration Delay (in seconds)	Indicate an expiration delay to add to the timestamp. The default value is 60.	
Sender Security Type	Additional security types are supported for SOAP senders for specific third party integrations.	CIM - Uses an appropriate namespace and adds security information in the SOAP header specific to Landis+Gyr, MS_V30 - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v3.0, MS_V41R - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v4.1, ITRON - Uses appropriate SOAP header information security information in the SOAP header specific to Itron.

NOTE: Refer to [Add SOAP Header Parameters at Runtime](#) for information about dynamically including SOAP Header parameters when sending a message.

JMS Sender

A JMS sender is one that sends messages to a JMS queue or JMS topic. JMS senders should reference a Message Class of **RTJMSQSNDR** or **RTJMSTSNDR**, respectively.

The following parameters are used to connect to the JMS resource.

Context Type	Description	Values
JMS Message Type (Bytes(Y)/Text(N))	Indicates whether the data is sent as a bytes message or as a text message.	Y or N
JMS User Name	Enter the user name to connect to the JMS resource.	
JMS User Password	Enter the password to use to connect to the JMS resource.	
JMS Header	If JMS header values are required for the message, use this context type. For each JMS header that has to be specified, add a context record with a value having the following format x:y where x is the header name and y is the value.	

Defining Outbound Message Types

Refer to [Outbound Messages](#) for an overview of this functionality.

Use this page to define basic information about an outbound message type. Open this page using **Admin > Integration > Outbound Message Type**. You are brought to a query portal with options for searching for outbound message types.

NOTE: This page is not available if the **External Message** module is [turned off](#).

Once an outbound message type has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Outbound Message Type** zone provides basic information about an outbound message type. Besides the code and description, the outbound message type captures the outbound message business object and the relative priority of the outbound message. The priority is only applicable if the [outbound message is processed using OSB](#). In addition, if the outbound message type is linked to any web service categories, they are displayed.

CAUTION: Important! When adding new records, carefully consider the naming convention of the outbound message type code. Refer to [System Data Naming Convention](#) for more information.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an outbound message type to one or more [web service categories](#).

The **External System Links** zone is visible if the outbound message type is linked to any external systems.

External Systems

Use this page to define an external system and define the configuration for communication between your system and the external system.

External System - Main

Open this page using **Admin > Integration > External System**.

NOTE: This page is not available if both the **External Message** and the **Open Market Interchange** modules are [turned off](#).

Description of Page

Enter a unique **External System** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the external system code. Refer to [System Data Naming Convention](#) for more information.

Use the field **Our Name In Their System** to specify the identity of your organization (i.e., your external system identifier) in the external system.

NOTE: The workflow process profile and notification download profile are only applicable to products that support workflow and notification. They are not visible in the product if the **Open Market Interchange** module is [turned off](#).

If this external system sends inbound communications through notification upload staging, the type of workflow process that is created is controlled by the sender's **W/F (Workflow) Process Profile**.

If you send notifications to this external system, select a **Notification DL (download) Profile** that is used to define the configuration of the outgoing messages.

NOTE: The remaining fields are not visible if the **External Message** module is [turned off](#).

Set **Usage** to **Template External System** for external systems whose outbound message type configuration is inherited by other external systems.

If the outbound message type configuration should be inherited from a template external system, define the **Template External System**. If this field is specified, the outbound message type collection displays the data defined for the template system as display-only.

The **Outbound Message Type** accordion contains an entry for every type of outbound message defined for this external system. For each type of outbound message identify its **Outbound Message Type**.

Define the **Processing Method** for messages of this type. Valid values are **Batch**, **Real-time**, **SOA** and **XAI**.

Define an appropriate **Message Sender** if the processing method is **XAI** or **Real-time**.

Namespace Option is used when your message should include a namespace in the resulting XML. The valid options are **Standard Namespace** and **Configured on Sender**. If the value is Standard Namespace, the system will generate a namespace for the resulting WSDL with the following value: **http://ouaf.oracle.com/outbound/AAA_BBB**, where AAA is the external system code and BBB is the outbound message type code. If the value is Configured on Sender, then the value of the namespace is taken from the sender context with context type **Message Namespace URI**.

Define an appropriate **Batch Control** if the processing method is **Batch**.

If the message sender is one with a message class of **RTJSONSNDR**, indicate the **JSON Conversion Method**. The valid values are **Base JSON Conversion**, **Standard API Conversion** and **XSL Transformation**. Refer to [Real Time Message Configuration](#) for more information about these methods and the additional configuration that may be applicable.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Request Schema** is enabled. Populate a data area that defines the schema for the XML format to convert the outbound message's BO schema to prior to performing the JSON conversion. Refer to [Real Time Message Configuration](#) for more information.

The **Message XSL** is the schema used to transform information from the format produced by the system to a format understood by the sender, who receives a message of this type. This is not applicable for Processing Method of **SOA**. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

Enter the file name of the appropriate **W3C Schema** if you want to validate the message built for outbound messages for this external system / outbound message type prior to being routed to their destination. Refer to [Outbound Message Schema Validation](#) for more information. This is not applicable for Processing Method of **SOA**. This feature is not available for cloud implementations.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Response Schema** is enabled. Populate a data area that defines the schema for the XML format that the JSON message is initially converted to. The XML is then converted to BO XML. Refer to [Real Time Message Configuration](#) for more information.

Response XSL will only be displayed when the processing method is **Real-time**. Refer to [Real Time Messages](#) for more information on how it is used. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

External System - Template Use

If you are viewing an external system whose usage is a **Template External System**, use this page to view the other external systems that reference this one. Open this page using **Admin > Integration > External System** and then navigate to the **Template Use** tab.

Description of Page

The tree shows every external system that references this external system as its template.

Message Option

The Message Option page defines various system settings used by the system when processing external messages.

To define options for your environment, open **Admin > Integration > Message Option**.

Description of Page

The following options are supported.

Option	Description	Option Name
Default Email Sender	This is the default Message Sender used for sending e-mails when no explicit Message Sender is specified.	defaultEmailSender
Default User	The default user is used by the system to access your product when no other user is explicitly specified.	defaultUser
Email Attachment File Location	This is the default location of e-mail attachment files. If not specified, the e-mail service provided with the product assumes a full path is provided with each attachment file.	emailAttachmentFileLocation
Email XSL File Location	This is the default location of e-mail XSL files. If not specified, the e-mail service provided with the product assumes a full path is provided to an XSL file as part of an e-mail request.	emailXSLFileLocation
Messages Language	The default language to use for the messages.	language
Outbound Message Schema Location	Enter the full path of the virtual directory where valid W3C schemas are stored if your implementation wants to validate outbound message schemas . For example: http://localhost/cisxai/schemas.	xaiOuboundSchemaLoc
Schema Validation Flag	Enter Y to turn on schema validation for outbound messages . Enter N to turn this off.	xaiSchemaValidationCheck

Note that the following options are no longer applicable.

Option

To Do Type for Inbound JMS Message Errors

To Do Type for Outbound Message Errors

XSD Compliance

Managing Outbound Messages

Use this page to view information about outbound messages.

Outbound Message - Main

Open this page using **Menu > Integration > Outbound Message**.

Description of Page

Outbound Message ID is the system-assigned unique identifier of the outbound message. These values only appear after the outbound message is added to the database.

The **Processing Method** indicates whether this record will be processed by a **Batch** extract process or **Real-time**. (The value of **XAI** is no longer supported). The value defined on the external system / outbound message type collection populates this value.

When records are created with a processing method of **Batch**, the system sets Extract to **Can Be Extracted**. Change the value to **Not to be extracted** if there is some reason that processing should be held for this record.

For records with a processing method of **Batch**, **Batch Control** indicates the process that will extract this record. This value is populated based on the on the external system / outbound message type's value. **Batch Number** indicates in which batch run this record was extracted or will be extracted.

The **Retry Count** is no longer applicable..

The **Creation Date** indicates the date that this record was created.

The status is no longer applicable.

Outbound Message - Message

Use this page to view the XML source used to build an outbound message. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Message** tab.

Description of Page

The **XML Source** is displayed.

If a message XSL is defined on the external system / outbound message type record linked to this outbound message, the **Show XML** button is enabled. Click this button to view the XML that is a result of applying the Message XSL to the XML source.

Outbound Message - Response

Use this page to display the XML response. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Response** tab.

Description of Page

The **XML Response** and optionally the **XML Raw Response** is displayed.

XML Response displays the response data from the system called by the real-time message. If a response XSL is defined on the external system / outbound message type record linked to this outbound message, a transform is performed and the XML Raw Response displays the original, unchanged response.

Web Service Adapters

The base product provides a configuration object called Web Service Adapter that is used to help build configuration objects to allow for functionality in the system to initiate a web service call from within the system. A Web Service Adapter provides the following functionality:

- WSDL (web service description language) import. An implementer can use the WSDL import functionality to read the details of a WSDL into the system
- Internal API generation. The system generates internal data areas that have two main purposes: they provide the API for custom code to define the appropriate input and they provide output data for the web service call using Oracle Utilities Application Framework schema language. In addition, the web service dispatcher uses element mapping defined in the data areas to transform the internal XML into the structure expected by the external system as described in the WSDL.
- Defines the URL needed to perform the web service call at runtime.

Understanding Web Service Adapters

The following topics describe the system functionality in more detail.

Importing a WSDL

Configuring a Web Service Adapter starts by identifying the WSDL (the web service description language document used to define the interface) that will be provided by the external system. The following steps describe the base product functionality provided to allow a user to import a WSDL.

- Navigate to the **Web Service Adapter** page in add mode and select the appropriate base business object.
- Enter a meaningful Web Service Name and appropriate descriptions.
- Provide the URL of the given WSDL.

- Click **Import** to retrieve the details of the WSDL. The system then parses the WSDL details and populates the WSDL Service Name, WSDL Source, WSDL Port, URL and a list of Operations (methods) defined in the WSDL.
- Determine which Operations should be **active** based on the business requirements for invoking this web service. **Active** operations are those that the implementation is planning to invoke from the system. These require appropriate request and response data areas generated for them. The following section provides more information about that.
- Specify the appropriate Security Type to configure the type of security to use when invoking this web service.
- Click Save.

At this point, a web service adapter record is created in pending status. The next step is to generate the request and response data areas for the operations configured as active.

Generating Request and Response Data Areas

Each **active** operation for the web service adapter requires a pair of data areas, request and response, that represent the request and response XML messages for the operation.

The base product provides steps to generate the data areas as follows:

- As described in the Importing a WSDL section above, the operations listed in the WSDL are generated for the web service adapter and the implementer should indicate which operation to activate.
- After saving the **pending** web service adapter, the display lists all the active operations and for each one includes a **Generate** button.
- After clicking **Generate** for an operation, a window appears where the names of the new Request and Response Data Areas may be defined. Click **Save** to generate the data areas.

The generated data areas provide the API for the implementer to use when implementing the web service call in an appropriate algorithm or service in the system. The data areas contain the appropriate mapping from the elements that the implementer works within the code that invokes the web services and the WSDL definitions.

To facilitate generating the request and response data areas, the base product invokes a special business service used to create the appropriate mapping. The business service is defined as a BO option on the Web Service Adapter business object. This allows an implementation to provide a custom business service to further enhance the request and response mapping where appropriate.

NOTE:

Generated data areas. It is possible to edit and modify the generated data areas after they are created. An implementer can change element names or remove unneeded elements if desired. Manually changing the generated data areas must be done only when absolutely necessary. This is because the system is not able to validate manual changes and issues with the data areas would only be detected at run time.

Activating Web Service Adapters

The business objects provided by the base package for web service adapters include a simple lifecycle of **Pending** and **Active**. Configure the web service adapter and its data areas while in **Pending** status and activate it when it is ready to be implemented in the appropriate system functionality.

Invoking Web Services

To make a call to a web service using a web service adapter, the system has provided a Web Service Dispatcher business service (**F1-InvokeWebService**) to submit a web service call. The calling program is responsible for retrieving all the information to correctly populate the request data required by the web service call before invoking the business service.

NOTE:

Refer to the detailed description of the business service for more information.

Limitations

The following points highlight limitations associated with the types of web services that the system supports:

- It is possible for one WSDL document to contain definitions for several web services. The system currently supports only one port or service per WSDL document.
- It is possible for a WSDL to support multiple message patterns. The system currently supports only request / response.

Setting Up Web Service Adapters

Use the Web Service Adapter portal to define the configuration needed to communicate with an external system using a web service call. Open this page using **Admin > Integration > Web Service Adapter**. You are brought to a query portal with options for searching for web service adapters.

Once a web service adapter has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Adapter** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

FASTPATH: Refer to [Understanding Web Service Adapters](#) for information about common web service adapter functionality.

Sending Email

The framework provides the ability to initiate an email from within the system. The following topics highlight the functionality available.

- Sending email "real time" using a specific business service. The framework provides a business service **F1-EmailService** that supports sending an email. The schema supports elements for all the information required to create an email real time. The SMTP information (host, user name and password) may be provided or may be defined on a message sender, that may be provided as input. In addition, the business service supports using a default message sender defined as a [message option](#). Review the business service schema for information about the input elements.

NOTE: Retry setting. An option in the system properties file allows your implementation to configure the number of times to retry (if any) if the SMTP server is unavailable. Refer to the server administration guide for more information.

- The business service supports sending attachments. The may either reference attachments from the file system (file name and content ID) or reference attachment records captured in the system's attachment table. Note that attachments in the file system are not supported in a cloud implementation.

NOTE: Validating attachments. If a Validate Email Attachment algorithm is plugged into the [installation record](#), it is called to validate the attachments supplied, if applicable.

- Using an outbound message to send an email. This option allows for different variations as described in [Outbound Messages](#).
 - Some emails may be created en masse (for example a large group of emails routed to users for a given set of To Do entries). In this case, the records can be created in the staging table for processing using OSB.
 - Messages may still be sent real time using one of two business services described in [Real Time Messages](#). This option is an alternative to the dedicated email service described above when aspects of the outbound message functionality

are needed, such as the ability to instantiate a record as an audit or to include additional logic via BO plug-ins as part of sending the email.

Web Service Category

The product provides the ability to categorize web services that are defined in the system. The term web services refers to Outbound Message Types, Inbound Web Services, and for those implementations where they are applicable, XAI Inbound Services.

A given web service may be linked to more than one category. The product supplies web service categories and most base delivered web services are configured with appropriate categories. Implementations may define new categories and may link custom web services to base delivered categories or to custom categories. In addition, implementations may link additional categories to base delivered web services. However, implementations may not remove base delivered web services from base delivered categories.

If your implementation uses the [Integration Cloud Service Catalog](#), the integration provides the categories for each web service that is sent to the catalog.

The web service category portal supports adding and removing web services from the category. In addition, the [Outbound Message Type](#) portal and [Inbound Web Service](#) portal each provide a page action button to **Add to Category**.

Defining Web Service Categories

Refer to [Web Service Category](#) for an overview of this functionality.

Use this page to define basic information about a web service category. Open this page using **Admin > Integration > Web Service Category**. You are brought to a query portal with options for searching for web service categories.

NOTE: This page is not available if the **External Message** module is [turned off](#).

Once a web service category has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Category** zone provides basic information about a web service category.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service category code. Refer to [System Data Naming Convention](#) for more information.

Once a web service category exists, an **Add Web Services** zone is provided to find and select web services to link to the web service category.

When viewing a category that already has web services linked to it, they are visible in the zone **Included Web Services**. This zone allows a user to remove a customer owned web service from the list.

JMS Message Browser

The JMS Message Browser portal allows you to select a JMS queue and view messages currently in the queue.

In order for a JMS queue to be available on the portal, a [message sender](#) must be defined that is configured for the appropriate JMS queue with the credentials to connect to the queue.

- If your organization sends real-time outgoing messages to a JMS queue, this configuration would exist as per the details in [Real-Time Message Configuration](#).
- If inbound web service messages are routed to the system via a JMS queue, no configuration is needed in the system. However, if you would like to view the messages in the queue in the JMS message browser portal, configuration for the JMS queues as described for outgoing messages is required.

Navigate to the portal using **Main > Integration > JMS Message Browser**.

The JMS Senders zone provides a list of configured message senders eligible for selection.

The JMS Message List zone is visible for the JMS Sender broadcast from the first zone. This zone supports selecting one or more records to delete from the queue. Use the message selector to limit the results to messages that satisfy the message selector. This uses standard JMS API message selector functionality. Refer to the zone embedded help for information about the supported syntax.

The JMS Message Details zone displays a message broadcast from the list zone.

Oracle Integration Cloud Catalog

Oracle Integration Cloud (OIC) is an offering that serves as integration infrastructure for Oracle cloud solutions. The product provides an adapter for OIC to streamline integration between your edge application and OIC.

The product provides a mechanism (referred to as an adapter) for OIC to retrieve the REST catalog and another to retrieve the SOAP catalog from a given product. The expectation is that a given implementation would use either REST or SOAP and not both, but for those implementations that do support both classes of web services, OIC can retrieve both catalogs.

For the SOAP catalog, the adapter retrieves the name, the source system, the WSDL location and namespace for each web service.

For the REST catalog, the adapter retrieves the name, the source system and the OpenAPI specification for each web service.

It is possible that not every web service supported by an edge product is managed by OIC. In order to only include the appropriate web services in the adapter, configuration is needed to identify which web services to include.

The web service catalog is used to identify the records that should be retrieved by the adapter. Separate catalogs exist for REST and for SOAP

- For SOAP inbound messages, the system supports both the use of [inbound web services](#) and XAI inbound services that are [deployed via IWS](#). Each IWS or XAI inbound service that should be included in the catalog must be flagged in the SOAP catalog. Note that only [deployed](#) services are returned to the catalogue.
- For REST inbound messages, each IWS that should be included in the catalog must be flagged in the REST catalog.
- For outbound message, the system requires the creation of an External System that includes each outbound message type that the external system receives. For outbound messages that are integrated through OIC, the external system itself will represent OIC. Rather than identifying each outbound message type to include in the catalog, only the external system needs to be flagged. The adapter will return web service information for all the outbound message types configured for the external system. If an implementation supports both REST and SOAP, separate external systems should be created to separately group the REST and SOAP outbound messages.

NOTE: The subordinate catalog functionality is no longer applicable and will be removed in a future release.

FASTPATH: Refer to [Maintaining the Web Service Catalog](#) for more information.

Web Service Catalog Configuration

The topics in this section describe the configuration needed in your edge application to integrate with OIC.

Web Service Catalog Master Configuration

The **Service Catalog Configuration** ([master configuration](#)) record defines several system wide settings related to integrating with the service catalog.

It includes configuration for the WSDL base URL for the SOAP catalog. Note that this element supports the functionality described in [Referencing URIs](#). Note that for the REST catalog, the system will use the URL defined in the substitution variable **F1_OPEN_API_BASE_URL**

The subordinate server section is no longer applicable and will be removed in a future release.

For more information about specific fields in the master configuration, refer to the embedded help.

Maintaining the Web Service Catalog

Refer to [Oracle Integration Cloud Catalog](#) for an overview of web service catalog functionality.

To add or remove services that are reported to the OIC catalog, navigate to the portal using **Admin > Integration > Web Service Catalog**.

The Catalog by Class zone provides the list of classes (REST and SOAP). Broadcast the web service class that you want to work with.

The Catalog zone provides a list of services that are currently in the catalog based on the web service class chosen. Users may use this zone to remove services from the catalog.

The Candidate Services zone provides a list of external systems and inbound web services that are not currently linked to the catalog. Users may use this zone to add services to the catalog. The inbound web services will be limited to those with the same web service class as the one broadcast. All external systems are shown regardless of the web service class because there is no web service class configuration on external systems.. The expectation is that implementers will create the external system to include either only REST or only SOAP services and will know which external system to include in which catalog. For the SOAP web service class, if XAI inbound services are applicable, they are also visible.

NOTE: For inbound SOAP web services and XAI inbound services, they may be selected for the SOAP catalog at any time. However, only [deployed](#) services are returned to the catalog by the OIC adapter.

XAI Documentation Note

The XAI functionality is legacy functionality and not recommended for new implementations. The help topics are no longer provided.

Integrations

This chapter provides high level information about product integrations supported for all products that use Oracle Utilities Application Framework.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts to help navigate the user to the appropriate target portal or page and to make provided parameter values available for use on the portal or page.

NOTE: This technique may also be used within the product to launch a new browser tab from within the application when it's important to maintain the current screen. For example, launching the GIS Viewer in Oracle Utilities Work and Asset Management by creating a new browser tab.

To do this, parameters are added to the application URL by appending a question mark (?) to the end and using the syntax "key=value". If you require more than one parameter, use an ampersand (&) to separate each key=value pair. There are

several predefined parameter key values recognized by the application. In addition, specific parameters understood by the script may be provided. The following list highlights the predefined parameters.

- **location=<navigation key>** - If the exact page to launch is known, the navigation key value of that page can be part of the URL using 'location='. For example, if an approval process has sent an email to a user to approve an adjustment, the link configured in the email may include the adjustment's navigation key.
- **script=<BPA script name>** - In almost every use case, a script is needed to help navigate to the correct page and display the correct information. Even if a location is known and provided in the URL, if there is context data provided as a parameter, it is the responsibility of a script to move that parameter data from the URL into the page data model, so that the page can access the information and display the correct record. In cases where the target page is dynamic based on information provided by parameters, the script may be used to determine what page to launch.
- **portal=true** - When using the location parameter where the target page is a portal page and passing context data, use this parameter. This allows the system to know that the parameter data must be pushed into portal context.
- **initNav=false** - By default, if a script is provided but the location attribute is not provided, the system navigates to the user's home page prior to executing the script. If the script itself includes a step to navigate to a target page as one of its initial steps, the navigation to the home page is unnecessary and may degrade performance. This optional attribute may be included in the URL to bypass the home page.

NOTE: The system still requires a page to be launched for technical reasons. A blank portal with no zones is used for this purpose. Users may see this portal (called **Launching Application**) briefly before the navigation initiated by the script. In addition, this is the portal that the user will remain on if there are any errors in the script or if the script does not navigate anywhere.

- **minDashboard=true** - This option minimizes the dashboard area as part of launching the application. (The user will be able to maximize the dashboard themselves if needed). You would use this option to potentially improve the speed at which the application is launched. Whether this is useful will depend on the use case. If the reason for launching the application is to bring the user to a specific record to view details about that record, the dashboard may be providing valuable information about the record. In this case, it may be correct to display the dashboard by default (and not include this parameter in the URL). On the other hand if the use case is that a user is already in the application and clicks a link that opens a new browser tab to show the user specific detail about a chosen record, while keeping the original page open on the first tab, the dashboard may contain the same information already visible on the original tab. In this case, minimizing the dashboard may be beneficial.

For example, the following URL illustrates launching the script **CM-StopAutoPay** for a given account, assuming the application URL for launching the system is `http://system-server:1234/cis.jsp`:

- **`http://system-server:1234/cis.jsp?script=CM-StopAutoPay&ACCT_ID=1234512345&location=accountMaint`**

It doesn't matter in which order the parameters are provided. The system processes them in the correct order. For example, the following examples are processed by the system in the same way:

- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&script=CM-StopAutoPay&location=accountMaint`**
- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&location=accountMaint&script=CM-StopAutoPay`**

These parameters are kept in a common area accessible by any script for the duration of the session. To use these parameters on a script you may reference the corresponding **%PARM-<name> global variables**. In this example, after the system is launched any script may have access to the above account ID parameter value by means of the **%PARM-ACCT_ID** global variable. Also note, these parameters are also loaded into temporary storage (to continue the example, there would also be a temporary storage variable called **ACCT_ID** that holds the passed value).

Determining the Application URL

When building the link from within application logic, the service script **F1-EnviURL** may be used to retrieve and build the application URL information.

Navigate to a Given Record's Maintenance Portal

The product provides a script **F1-GotoPrtl** (Navigate to portal for an MO and key values) that may be used for any use case that simply navigates to the maintenance page for a given record and displays that record. This script is only applicable to records that are governed by a business object (and define a navigation option as a BO option). It requires the parameters **mo=** with the maintenance object code of the record and the parameters **pkValue1=** through **pkValue5=** for providing the key values. It looks up the appropriate portal navigation option from the record's BO, populates keys into the 'page data model' and navigates to the portal.

It is also recommended to include the **initNav=false** attribute when building a URL with this script. The example below navigates to the appropriate Migration Data Set portal for the given ID's business object.

- <http://system-server:1234/cis.jsp?script=F1-GotoPrtl&pkValue1=1234512345&mo=F1-MIGRDS&initNav=false>

LDAP Integration

Organizations commonly use a Lightweight Directory Access Protocol (LDAP) security repository as a source of security credentials. The system provides support for importing users and groups from an external LDAP repository into the product to populate Users and User Groups in the system. Once imported, all user and group functions are available. You can resynchronize your LDAP users and groups at any time.

NOTE: Import only. The system currently supports importing LDAP information. Exporting users and groups from the system to LDAP is not provided.

NOTE: Additional configuration. When importing new users and / or groups, additional configuration is needed in the base product. For example, after importing a new user group and its users, the user group configuration should be updated to define the valid application services for the user group. After importing a new user, additional configuration may be needed on the user such as valid To Do Roles, valid Home Page, etc.

FASTPATH: Refer to [Defining Security and User Options](#) for more information about the application security and what it controls.

This section the functionality provided in the framework application that supports LDAP. Refer to the *LDAP Integration* technical reference paper for more information about typical steps related to the full integration.

LDAP Integration Overview

This topic provides a high level overview of the integration process.

At a high level, the base product provides a process to import user group and / or user definitions from and LDAP repository. This is a one way integration.

- When importing a user, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user group, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user, its user group links will be updated as per the information in the import file. In addition, if there are any user groups linked to the user that are not found in the system, they will be added (however, the other users linked to that group in the LDAP repository will not be added as part of this step).
- When importing a user group, its user links will be updated as per the information in the import file. In addition, if there are any users linked to the user group that are not found system, they will be added (however, the other user groups linked to that user in the LDAP repository will not be added as part of this step).

- The import will not cause any deletions of the User or User Group to occur.

A Batch Process Initiates the Import

A batch process is used to initiate the import of information from the LDAP repository. **F1-LDAP** may be submitted ad hoc or may be set up in a scheduler to periodically re-sync the information from the LDAP repository into the application.

The batch process uses parameters to define how to connect to the LDAP repository. In addition, parameters are used to indicate which user or group is being imported.

Adjusting Data to Import

The system provides several mechanisms for adjusting data that is being added to the system:

- There is an **LDAP Import Preprocess** algorithm plug-in spot on the [installation](#) record. Algorithms plugged in here are called by the batch process prior to the add or update of any records. It may be used to make adjustments to the data before doing updates in the application.
- Specifically for creating or updating Users, the **F1-IDMUser** business object is used to add and create the user. The standard BO Preprocessing algorithm plug-in spot may be used to adjust data prior to creation.
- The LDAP mapping file supports some attributes to perform simple modifications to data.
 - The **transform** attribute supports values to truncate values or to convert data to upper case.
 - The **autoGenerate** attribute is specific to the User ID field. Setting this to true will trigger code that will automatically populate the User ID based on the user's name. Refer to [LDAP Mapping](#) for more information.

Performing Additional Processing After Import

The system provides a plug-in spot on the [installation](#) record called **LDAP Import**. Algorithms plugged into this spot are called after users or user groups have been added or updated. It may be used to perform any extra processing that may need to be executed.

In addition, for any additional processing related to the creation or update of a User, the standard [Business Object plug-ins](#) may be used for the **F1-IDMUser** business object which the LDAP batch process uses to create or update users.

Configuring LDAP Integration

To interface the LDAP based security repository with the authorization component of the Oracle Utilities Application Framework product the following must be performed:

- The location and port number of the LDAP based security repository must be defined to in the JNDI Server.
- The LDAP based security repository must be mapped to the Oracle Utilities Application Framework security model. This mapping is expressed as an XML file containing the LDAP query, rules and defaults used in the transformation.
- The mapping file must be configured on the **F1-LDAP** batch job.

Define the JNDI Server

The first step in the configuration process is to define the location of the LDAP based security repository server so that the interface can connect to the physical attributes of the interface. This is done by creating a [JNDI Server](#).

NOTE: The LDAP server is strictly not a JDNI source but is treated as a JNDI source for the integration.

Enter a reasonable JNDI Server name and description.

Populate the **Provider URL** using the format **ldap://<hostname>:<portnumber>** where **<hostname>** is the host of the LDAP server and **<portnumber>** is the port used for the interface.

For the **Initial Context Factory**, the interface uses the standard `com.sun.jndi.ldap.LdapCtxFactory` provided with java for the LDAP interface. If your vendor supplies a custom context factory it may be used. Refer to the documentation provided with your LDAP based security repository for further information.

Define Mapping

The critical component of the interface is a file that describes the mapping between the LDAP based security repository and the system's security model. This file contains the mapping, rules and queries used by the LDAP batch program to provide the interface. The LDAP batch job includes the reference to the mapping file as a parameter. Refer to [LDAP Mapping](#) for more information on defining the mapping file.

Configure LDAP Batch Process

At this point, many parameters for the **F1-LDAP batch control** can be updated with system wide configuration.

- JDNI Server, User and Password may all be configured appropriately. Note that it is recommended that the **Security** setting for the Password be set to **Encrypt**.
- The **LDAP Configuration File** should be populated with the name and location of the LDAP Mapping file.
- If the LDAP service has any limitation to the number of objects that may be imported, configure the **LDAP Query Page Size** parameter to enable querying.

NOTE: Group and User Parameters. The assumption is that the Group or User input parameters are specific to a given import request and as such would not be populated as part of a configuration step.

NOTE: L2 Cache. The LDAP Import batch process requires the L2 Cache to be disabled since it needs to perform some updates in the outside of the worker threads. Any environment using LDAP Import must set `spl.runtime.batch.L2CacheMode=OFF` in the `threadpoolworker.properties` file. It is recommended to run the LDAP import in its own dedicated threadpoolworker.

LDAP Mapping

An LDAP repository consists of multiple entries. Each entry represents an object in the directory that is identified by a Distinguished Name (DN) and may contain one or more attributes. In a typical LDAP repository there is usually an entry for users and an entry for groups. The connection between users and groups may be implemented in two different ways:

- The users belonging to a group are defined in a special multiple-value attribute on the Group entry.
- The groups to which a user belongs are defined in a special multiple-value attribute on the User entry.

The mapping between LDAP security objects and base security objects is stored in an XML document that can be processed by the LDAP import batch job. As part of setting up your system for LDAP import, you need to define this mapping. The base package provides a sample mapping file called `ldapdef.xml` that can be used as a starting point and changed per your business requirements and your particular LDAP repository.

Once you have defined the mapping XML document, this is configured as a parameter in the **F1-LDAP** batch job.

The XML structure:

- The **LDAPEntry** element maps the LDAP entries to system objects (User or Group). The mapping file must contain one and only one LDAPEntry element for User and one for Group.
- The **LDAPCDXAttrMapping** element within the LDAPEntry element maps attributes in the LDAP entry to attributes in the system object.
- The **LDAPEntryLinks** element describes objects linked to the LDAP entry. When mapping the user entity you need to describe how the groups the user belongs to are retrieved. When mapping the group entity you need to describe how the users contained in the group are retrieved.

The following table describes the attributes to define for each element.

Element	Attribute	Description
LDAPEntry	name	The name of the LDAP entry: - Group - User
	baseDN	The base distinguished name in LDAP for this entry.
	cdxEntity	The name of the base product entity to which the LDAP entry is mapped: - Group - User
	searchFilter	An LDAP search filter that is used to locate LDAP entries. A %searchParm % string in that filter is replaced by the value from the user or group parameter from the F1-LDAP batch job submission.
	Scope	Sets the scope of the search. Valid values are: - onelevel (the value normally used) - subtree
LDAPCDXAttrMapping	ldapAttr	The name of the LDAP attribute to be mapped. Note that this may be referenced more than once to allow one LDAP element to map to multiple base product elements. For example, if an email address should be used both for the Login ID and the Email Address.
	cdxName	The name of the base product attribute to be mapped. For User, this is the element within the F1-IDMUser business object. For Group, this is either the 'group' or the 'description'.
	default	The default value that will be assigned to the element referenced in the cdxName attribute when one of the following occurs: - The LDAP attribute contains a null or empty value - The LDAP attribute does not exist or is not specified. Default values are applied only when creating a new entity and are not applied to updated entities.
	autoGenerate	Set this to true in order to turn on auto generation of the user ID. If this is true, the system will define the user id as <first initial of first name>+<last name> all uppercase, to a maximum of 8 digits. If an existing user is found for the generated ID, a number will replace the eight digit (or be appended to the end). The system will increment the number until a unique ID is found.
	transform	Use this attribute to indicate if a transformation of the data should occur. Valid values: uppercase truncate . Note that this attribute should not be used in conjunction with the autoGenerate attribute.
LDAPEntryLink	linkedToLDAPEntity	The name of the linked entity (User or Group). Use User when describing the Group entity. Use Group when describing the User entity.
	linkingLDAPAttr	The multiple-value attribute name on the LDAP entity that contains the linked entity.
	linkingSearchFilter	The search filter to be applied to retrieve the list of linked objects, for example: (&!(objectClass=group)(memberOf=%attr%)) The search filter may contain the string % attr % that acts as a substitution string and is replaced at run time by the value of the attribute named "attr" of the imported entity. If the LDAP entry you are describing is a Group and the string is %name%, it is replaced by the value of the "name" attribute of the group you are importing. If the LDAP entry you are describing is a User and the string is %dn%, it is replaced by the "dn" attribute of the User you are importing.
	linkingSearchScope	Sets the scope of the search. Valid values are: - onelevel (the value normally used) - subtree

Sample Mapping

The following XML describes a sample mapping. The example makes the following assumptions:

- The base product attribute **displayProfileCode** is defaulted to "NORTHAM" when adding a new user.
- The LDAP Group entry contains the list of users belonging to the group in the **departmentNumber** attribute.
- The groups to which a user belongs are retrieved by applying a search filter.

```
<LDAPEntries>
  <LDAPEntry name=" User" baseDN="ou=people,dc=example,dc=com" cdxEntity="
  user" searchFilter=" (&(objectClass=inetOrgPerson)(uid=%searchParm%))">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="uid" cdxName=" user" />
      <LDAPCDXAttrMapping ldapAttr="cn" cdxName="externalUserId" />
      <LDAPCDXAttrMapping cdxName="language" default=" ENG" />
      <LDAPCDXAttrMapping ldapAttr="givenName" cdxName="firstName"/>
      <LDAPCDXAttrMapping ldapAttr="sn" cdxName=" lastName"/>
      <LDAPCDXAttrMapping cdxName="displayProfileCode" default="NORTHAM" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge1" default="30" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge2" default="90" />
      <LDAPCDXAttrMapping cdxName="userEnable" default="ENBL" />
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="Group" linkingLDAPAttr="departmentNumber" />
    </LDAPEntryLinks>
  </LDAPEntry>
  <LDAPEntry name="Group" baseDN="ou=people,dc=example,dc=com" cdxEntity="
  Group" searchFilter=" (&(objectClass=organizationalUnit)(ou=%searchParm%))">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="name" cdxName="Group" />
      <LDAPCDXAttrMapping ldapAttr="description" cdxName=" Description" default="Unknown" />
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="User" linkingSearchFilter="
      (&(objectClass=inetOrgPerson)(departmentNumber=%distinguishedName%))"
      linkingSearchScope="onelevel" />
    </LDAPEntryLinks>
  </LDAPEntry>
</LDAPEntries>
```

Oracle Identity Manager Integration

The *Oracle Identity Manager* product allows a site to centralize their user definitions and password rules to manage and deploy across the enterprise set of products. When an employee joins an organization, changes their name or departs an organization their security presence across an enterprise must be appropriately managed. Oracle Identity Manager allows for users to be provision and managed in a central location.

An integration is provided to allow the ability to create, maintain and remove users in the identity management product and sync those changes to the users defined in the application. The following sections provide additional details about the integration with respect to configuration steps required in an Oracle Utilities Application Framework based product. For more information about the configuration required in the identity management product, refer to the *Identity Management Suite Integration* technical reference paper.

In order to use this functionality, [feature configuration](#) options for the **External Messages** feature type must be configured.

- Set option type **Support SPML Deployment in IWS** to **true**.
- Set option type **Default SPML service security policy** to an appropriate value per your implementation rules.

Template User Functionality

The user object in this product captures configuration used to control access but also preferences. The identify management product allows for extending the configuration to capture user configuration that is specific to this product. However, it does

not support providing searches or dropdowns to select valid values. For example, to define the user's Home Page requires the reference to a navigation option. To set up your business process such that the home page is configured when defining the user in the identity management product dictates that the security user types in the correct navigation option reference.

On the other hand, to define a minimal amount of user information in the identity management product may result in a two step process for defining users: first define them in the identity management product with the basic authentication details and setting system defaults for some important fields, then after submitting the new user to be added to this product, navigate to the [user](#) page in this product and fill in all the configuration that is specific to this product.

The product provides support for defining a template user that can facilitate the definition of users and reduce some of the challenges listed above. The concept is as follows:

- Define a template user for each broad category of users in the system. For example, Oracle Utilities Mobile Workforce Management may define the following template users: Dispatcher, Mobile Worker, System Administrator and Contractor. Each user would define the typical configuration for users of that type including the home page, the user groups, the To Do roles, the portal preferences, etc.
- When extending the configuration in the identity manager product, simply map the information that is unique to a user and in addition, define a field for the template user. For example, you may choose to only capture the Name (first and last), Email address and User IDs for the user along with its Template User (which is mapped to a user characteristic). Additional fields may be included for capture in the identity management product when defining new users as per an implementation's business needs. For example, if the organization covers multiple time zones, perhaps it is easier to define the user's time zone when defining the user in the identity management product.
- When the new user is uploaded to the system, the interface uses the user BO **F1-IDMUser** to create the user. The BO includes a preprocessing algorithm that looks for the existence of a template user (sent as a characteristic of type **F1-TMUSR**). All the information from the template user will be copied onto the new user record except for the information passed in from the identity manager. The template user is captured on the newly created user via a characteristic for information / audit purposes.
- Once the new user is created, its configuration can now be adjusted, if applicable. Note that the template user is only a tool used when adding a user. Updates to the template user will not "ripple" to all the other users that were created based on this template.

Configuring Template Users

Before configuring template users, all the administrative control tables that are part of User configuration must be defined, including time zones, display profiles, To Do roles, data access roles and user groups.

The next step is to define the user configuration for your system users. During this exercise, you will find that you have broad categories of users. But you will also see that within a given category of user there may be variations in the user privileges and preferences. For example, perhaps there are supervisors within the Mobile Worker role that have more security privileges than a typical Mobile Worker. In addition, there may be variations based on the attributes of the users themselves. For example, maybe your organization exists in multiple time zones and some of your workers are in one time zone and some are in the other.

At this point your security users that are designing their user provisioning procedures must decide the following:

- What information about a new user will be captured in the identity system (besides the expected information like Name, Email and the User IDs)? For example, for the case of multiple time zones, maybe the best solution is to capture the time zone when defining the user.

What information is defined on the template user and how many template users should be created to reduce the need for manual steps or additional data captured in the identity management system? In the case of multiple time zones, proliferating the template users to have one set for one time zone and another set for the other time zone may not make sense since this is one field that is different. However it may be reasonable to create additional templates in the case of variations in the levels of privileges for workers of a different category. So rather than template users for Dispatcher, Mobile Worker, System Administrator and Contractor, your organization may have template users for Dispatcher, Mobile Worker, Mobile Worker (Supervisor), System Administrator, Contractor (Short Term) and Contractor (Long Term).

What information is must be configured one the User record in the application after the user is added? If only a small number of users have a variation from other users, it may be that the easiest way to deal with those variations is to simply update those user records manually. Using the above examples:

- If your organization covers 2 time zones but only a small group of people work in one of the time zones whereas the bulk of the users are in the other time zone, the simplest procedure may be to define the template users for the main time zone and use that for the creation of all users. Then for the small group of users in the separate time zone, navigate to the User page to adjust the time zone after the record is added.
- If only a small number of Mobile Workers are supervisors with separate privileges, rather than defining a special template user for those type of workers, the simpler procedure may be to use the Mobile Worker template and then navigate to the User page to add the additional privileges to the supervisor users after the record is added.

To create a template user, navigate using **Admin > Security > User**.

- Define a User ID that will become the template user reference in the identity management system.
- Be sure to choose a **User Type** of **Template User**.
- Define all the information that should be copied onto a new user that references this user as a template user. Note that **Bookmarks** are not included in the data that is copied from a template user.

NOTE: There is configuration needed in Oracle Identity Management to capture the template user and any other information that the implementation has chosen to define in the identity management product when provisioning a new user. Refer to the *Identity Management Suite Integration* technical reference paper for more information.

User Redirection

The product allows an implementation to support the ability for a customer to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal (Digital Self Service), to see exactly what the end customer is seeing/experiencing.

When the request for the CSR to view the customer information is received, the following steps occur:

- The security server for the customer facing portal is contacted to obtain a temporary grant code.
- The redirection response returns the grant code and the URL of the target customer facing portal.
- The browser redirects to the user to this URL with the grant code, which is further authenticated and automatically exchanged for an authorization token, allowing the CSR to log in.

Standard security measures with private/public key encryption using JSON Web Tokens (JWT) ensures that only the implementation's enterprise application is allowed to communicate with the implementation's customer facing portal server. The system also provides a plug-in spot to allow for additional information, such as the customer's name and email address, to be included in the call to the security server.

This feature works in conjunction with functionality provided by the enterprise customer application. Refer to the documentation for that product for information about how this feature is supported.

NOTE: The product has been designed to potentially support other types of redirection besides the mentioned use case by adding another entry in the Redirection Target lookup (F1_REDIRECTION_TARGET_FLG). However, the internally provided services work specifically for the Digital Self Service use case. There is no guarantee that they would work for a different redirection use case. Please contact product support if your implementation would like to implement a different redirection scenario.

Redirection Security Context Plug-in

The product supports a plug-in spot to allow for the system to populate additional keys and values to add to the JWT (JSON Web Token) when calling the external security service.

In addition, the product provides an Extendable Lookup BO **Redirection Security Context (F1-RedirectionSecurityContext)** to define the key mnemonic values. For an enterprise product or implementation to populate additional keys, use the extendable lookup to define the key mnemonics. Then provide an algorithm that uses the available information about the customer and populates the security context keys and values by determining the related data in the system.

Master Configuration

The master configuration **Redirection Targets Configuration (F1-RedirectionTargetsConfig)** defines the information needed to contact the security server to obtain a grant code. It also defines the redirection URL.

Build an Anchor Hyperlink

The service script **Return a Hyperlink to the Redirect Servlet for a given Target (F1TargetLink)** is provided to allow for a link to be placed on a UI map or in a zone to initiate the redirection request. Refer to the service script detailed description in the metadata for more information.

Batch Scheduler Integration

The Oracle Database includes an enterprise wide scheduler to simplify the scheduling of background processes. The scheduler is implemented by the *DBMS_SCHEDULER* package. The product provides an integration with the Oracle Scheduler to facilitate scheduling background processes shipped with the product.

At a high level, the integration with the Oracle DBMS Scheduler supports the following entities:

- **DBMS Program.** A program should be defined for each Batch Control that needs to be scheduled by the DBMS scheduler. A program would typically invoke a batch job, but it could be configured to set certain options instead.
- **DBMS Chain.** A Chain defines a series of steps with dependency rules between them. A step references a program, with the program performing the actual work for that step. A rule is attached to each step to identify its dependent steps and the condition for when that step should be executed. For example, in a chain consisting of STEP_A and STEP_B, where STEP_B can only start if STEP_A was successful, the rule for STEP_B to start would specify a condition of "STEP_A SUCCEEDED".
- **DBMS Schedule.** A predefined frequency for jobs that need to be run periodically, for example, nightly jobs.
- **DBMS Job.** Defines a plan to perform a specific program or a chain periodically on a specific schedule or ad-hoc.

The product provides a set of business services to maintain these entities as well as submit jobs, manage submissions and report on past submissions. Refer to business services that start with the prefix "F1-DBMS" for more information.

NOTE: For details on the integration, refer to the *Server Administration Guide* which contains the API. In addition, refer to the technical reference paper *Oracle Scheduler Integration* that provides guidelines for using this integration.

Data Synchronization

Your implementation may need to communicate certain data to external systems. This may be part of a data warehousing requirement or an integration effort. The synchronization process has two main parts. First, the change to the data must be detected and captured. Once that is accomplished, the next step is to manage the communication of that change to the external systems involved. The changes must be captured in chronological order so as to avoid systems going out of sync.

Understanding Data Synchronization

The product supports various options for managing an ongoing synchronization of an entity to an external system. While each integration involves unique business rules, in many cases the process is quite similar and involves the following overall steps:

- When an entity is added, changed or deleted logic determines whether the change is eligible for synchronization and if so a sync request record is initiated to manage the synchronization process. The base product uses the **Audit** plug-in spot on the maintenance object to allow for such logic to be performed when a change is detected to a record for that MO. The framework calls the algorithm defined on this plug-in spot in the event a change to the MO has been detected. Refer to the description of the plug-in spot on [Maintenance Object - Algorithms](#) for more information about when this plug-in is called.
- The processing of the sync request is deferred to batch so that the communication with the external system does not impact the updating transaction. It also ensures that the data being shared with the external system is fully committed to the database.
- When processed, sync request logic manages the following aspects of the process:
 - Determines whether the synchronization is still needed and if not discards the request.
 - Prepares the outbound message with the entity's synchronization details and sends it to the external system.
 - Manages errors and retry attempts as needed.

The following sections describe the various data synchronization options supported by the product.

Accumulative Data Synchronization

The product supports a data synchronization method by which several changes made to an entity may be accumulated and sent together as a single message to the external system.

The following points describe the functionality at a high level:

- When an entity is added, changed or deleted, a snapshot of the entity's data from before the change is captured on one or more sync requests, one for each external system the data needs to be interfaced to. The before-update snapshot is used as a base line for detecting all changes made since then at the time of sending the message to the external system.
- Sync requests are processed by the next monitor batch process.
- The processing of the sync request typically involves business rules that compare the before-update snapshot with the current content of the entity to detect all change made. If changes were made, logic may decide to proceed with the sending the synchronization message otherwise the request is discarded. These rules are also responsible for handling any errors encountered while communicating with the external system and manage retry attempts as needed.

This functionality is supported by logic supplied in the base business object Sync Request (**F1-SyncRequest**). Note that each edge application delivers an appropriate child business object for this BO for each specific synch scenario supported in that product. Some of the functionality below is accomplished using configuration on the parent BO delivered by the framework while other functionality may be delivered by the child BO. In addition, there may be more complex use cases supported by your specific product integration. Refer to your specific application's library of Sync Request business object along with the documentation related to your specific product integration for more information.

The following sections describe key aspects of this data synchronization approach.

Capturing the Change

The base product provides a change data capture (MO Audit) algorithm **F1-GCHG-CDCP** that may be used by maintenance objects that need to be synchronized by this method. This algorithm creates a Sync Request record for the changed record, capturing the MO code and the primary key, if it doesn't find an existing sync request for the same record (and the same business object) in the initial state. The sync request business object used is the one defined in the **Sync Request BO** option on the MO for the record that was changed. If more than one such option exists then multiple sync requests are created.

Your specific product may also introduce additional Audit algorithms to cater for more sophisticated examples.

When creating the sync request record, typically the Sync Request BO will have a pre-processing plug-in that captures a snapshot of the record's data prior to its change. This will be used in subsequent steps to verify that the external system needs to be notified of the change.

Confirming that a Sync is Needed

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

NOTE: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, records are added to the sync request table throughout the day but all are processed together. The MO audit algorithm ensures that a new sync request is not created if a Pending record already exists for a given MO / PK combination (for the same business object). However, it is possible that a record for that MO / PK exists in a subsequent “non-final” (such as **Awaiting Acknowledgement**). This state includes a monitor algorithm to check for that condition and to skip transitioning if another record exists. This is done to ensure that the existing record is fully processed before this new record is processed.
- The next state of the lifecycle is **Determine if Sync Needed**. This step uses an algorithm to take a snapshot (called the ‘final snapshot’) of the data and compare it against the initial snapshot taken when the record was created. Based on the logic of the algorithm, it may decide to proceed (transition to **Send Request** or to discontinue (transition to **Discarded**.

Communicating to the External System

Once it is confirmed that the sync should occur, a message must be sent to the external system. The following points highlight the basic functionality.

- An algorithm linked to the **Send Request** state. The expectation is that this algorithm creates an outbound message that routes the information to the external system appropriately. The algorithm must determine the external system and outbound message type to use. Business objects for Sync Request support BO options to define the external system and outbound message type to use for this algorithm.
- Once the outbound message is triggered, the record transitions to the **Awaiting Acknowledgement** status. This state is used to hold the sync request from further state transitions until an acknowledgement is received from the external system. Note that this step relies on implementation of a response mechanism from the external system. It is recommended to implement a response as this helps control the chronological flow of information. The product supplies the business service **F1-UpdateSyncRequest** that transitions the sync request to either the next default state (in this case the **Synchronized** state) if a positive acknowledgement is received; or the state associated with the Rejection transition condition (in this case the **Error** state) if a negative acknowledgement is received. In addition, this state may be configured with a monitor algorithm that detects that a timeout limit has been reached.
- For records that enter the **Error** state, it is recommended to configure an algorithm that creates a To Do entry to alert someone of the problem. Refer to the integration documentation for more information. The state is already preconfigured with an algorithm to complete To Dos when exiting the state.
- The final state **Synchronized** is used to mark the successful synchronizations. However, for more complicated use cases, this state may be used to trigger some additional action. Refer to the documentation for your specific product integration for more information.

Generic Data Synchronization

The product supports a generic data synchronization method by which each change to an eligible entity triggers a synchronization flow that communicates details about the entity to one or more external systems.

The following points describe the functionality at a high level:

- The integration of a specific entity (maintenance object) and an external system is enabled and configured using a **Data Synchronization Control** (F1-DataSyncControl) extendable lookup record.
- Rules supporting the integration reside in a **synchronization script** referenced on the control record.

- When an entity is added, changed or deleted, a sync request may be initiated for each integration according to business rules defined by the corresponding synchronization script.
- Sync requests are processed by the next monitor batch process.
- When the sync request is processed, data is synchronized to the external system according to business rules defined by the corresponding synchronization script.

This functionality is supported by logic supplied in the base business object Generic Data Sync Request (**F1-GenericDataSync**). This business object does not need to be extended to support specific integration rules as these rules reside in the synchronization script associated with each integration's data synchronization control record.

The following sections describe key aspects of this data synchronization approach.

Data Synchronization Control

The **Data Synchronization Control** (F1-DataSyncControl) extendable lookup defines the configuration needed to support an ongoing data synchronization of an entity to an external system. The configuration defines the entity's maintenance object, the external system it is synchronized with and references a synchronization script that manages the specific synchronization rules for this integration. An integration is considered enabled when its corresponding control record is in active status.

The data synchronization script is called in the following modes:

- When the entity is added, changed or deleted, the script is called in **Check** mode to determine whether a sync request should be created for the changed entity and a specific external system.
- When the sync request is processed, the script is called in **Process** mode to prepare and send the outbound message to the external system. Alternatively the script may request to discard the request or indicate that it should be processed later. The latter may be used when there is a need to wait until certain conditions are met before sending the message to the external system.

Note that the configuration for a maintenance object and a specific external system may be overridden by another configuration defined with a higher sequence number.

Confirming that a Sync is Needed

The base product provides a change data capture (MO Audit) algorithm **FIONGDATASYN** that may be used by maintenance objects that need to be synchronized by this method. The algorithm consults the synchronization script associated with each active integration control record configured for the entity as to whether the external system needs to be notified for this change. Once confirmed, the algorithm creates a Sync Request record for the changed record, capturing its MO code and the primary key, along with the corresponding external system.

Note that the decision as to whether to create a sync request or not is controlled by the integration specific synchronization script while the creation of the sync request is the responsibility of the audit algorithm. As such, the same sync request BO is used for all integrations, with no provision for capturing integration specific details.

It is recommended to design the synchronization script to only approve the creation of a synchronization request when it is needed. This prevents unnecessary creation of sync requests that would otherwise be discarded when eventually processed.

Managing the Synchronization Process

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

NOTE: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, the changes that triggered the request are fully committed before being communicated to an external system.

- When the sync request record is processed, a monitor algorithm calls the synchronization script associated with the corresponding integration's control record to manage the synchronization process. The synchronization script may indicate either of the following:
 - The request is not yet ready to be processed, i.e. it should remain in its current status and get processed again by the next batch run.
 - The request should be canceled. This indication results in the transition of the record to the **Canceled** status.
 - The request was successfully processed. The synchronization script has prepared the outbound message and routed the information to the external system appropriately. This indication results in the transition of the record to the **Sent** status.
- If an error occurs while processing the request, a To Do Entry is raised to capture the error details and the record is set to the **Error** status. Retry processing of the sync request continues with each batch process until the request is either sent or canceled.

Communicating to the External System

Typically the communication with an external system is finalized when the message is successfully sent and successfully processed by the external system. Depending on the specific integration, the message may not be processed right away by the external system but rather queued and processed later. In this situation, the sync request may need to be further acknowledged as successfully processed (set to the **Acknowledged** status) upon an explicit response mechanism from the external system. The product supplies the web service **F1-UpdateAndTransitionSyncRequest** that may be used to process such acknowledgements.

Maintaining Sync Requests

The system provides a Sync Request portal that is used to view the in progress or completed sync request records.

The menu location of the portal depends on your specific edge product. It may be in a Data Synchronization menu or perhaps in the Batch menu. You are brought to a query portal with options for searching. The options may differ based on your specific product.

Once a sync request has been selected, you are brought to the maintenance portal to view and maintain the selected record.

An **Actions** zone may appear to display specific actions. Alternatively, the actions may be displayed directly in the display area of the **Sync Request** zone.

The **Sync Request** zone provides basic information about the sync request record.

Depending on your specific product additional zones may appear.

Operational Analytics

The framework provides several building blocks and tools that the edge applications may use to implement analytic reports directly from the operational application using Oracle Utilities Analytics Visualization product (referred to in this section as the analytics visualization product). The following sections provide more information about this functionality.

Understanding Operational Analytics

The following sections describe the type of configuration supported in your product to integrate with the analytics visualization product. Refer to the Oracle Utilities Analytics Visualization documentation for more information.

Direct Data Access

The analytics visualization product's canvases report directly off of the operational system (with the exception of batch run analytics) thus eliminating the need of an ETL process. Selected tables and views have been designated as dimensions and facts for the purpose of generating the Start Schemas used by these canvases.

Batch Run Analytics

There is a high volume of batch run data in the operational system that changes frequently and is recorded in a complex set of relationships. The product provides snapshot tables to capture only the batch run and thread data required for analytics. Using these tables for batch subject areas both improves performance and supports extracting the data for upload to other environments.

The snapshot tables are populated in increments. The **Batch Run Analytics Snapshot Update** and the **Batch Thread Analytics Snapshot Update** processes are run on an ongoing basis; each snapshot update selects only the batch runs and threads not yet included in the snapshot. Parameters are supplied to restrict the selected data to a range of months, to support the initial uptake of data. It is recommended that batch run data is updated before the batch thread data, as only threads with corresponding records in the batch run snapshot will be added. Refer to batch controls **F1BRANSN** and **F1BTANSN** for more information.

The **Batch Run Analytics Data Export** and **Batch Thread Analytics Data Export** processes are provided to extract the batch data in increments for upload to other environments. These processes assume that a **Data Export Control** exists for each of the snapshot maintenance objects, to capture the date of the previous extract as a reference point for selecting the next set of records. Refer to batch controls **F1BRANEX** and **F1BTANEX** for more information.

NOTE: As at this time, the analytics views have not been amended to reference the batch snapshot tables. The batch processes **F1BRANSN** and **F1BTANSN** are provided to allow the tables to be populated ahead of the introduction of new batch views in a future release.

Calendar and Time Dimensions

Analytic reports rely on calendar and time dimensions to support various hierarchical grouping by date and time.

The Calendar dimension provides a level-based definition of the standard calendar and fiscal calendar in a flattened representation that is commonly used in data warehouses. This is necessary to enabling customers to group by calendar week, months, quarter and fiscal calendar period, quarter and fiscal year etc. Note that fiscal information about a specific date is optional and sourced from your edge application specific accounting calendar

In the same way, the Time dimension provides a level-based definition of each minute in a day, supporting reports that group by hours, AM/PM etc.

NOTE: Calendar dimension records are generated by a batch process; one record for each date in a specified period of time. You need to run the **Generate Calendar Dimension** batch process on an ongoing basis to cover the standard and accounting calendar days needed to support your business. Refer to **F1-BICDD** batch control for more information.

NOTE: Time dimension records are also generated by a batch process; one record for each minute in a day. You need to run the **Generate Time Dimension** batch process once to generate all the records. Refer to **F1-BITMD** batch control for more information.

Bucket Configuration

The analytics visualization product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

Analytics Attribute Mapping

The product supports mapping of characteristics to user defined fields associated with dimensions in the analytics visualization product. Each characteristic table that is associated with a dimension table is provided with pre-generated user defined fields identified by unique column sequence numbers in the analytics visualization product. The mapping of characteristics to dimension user defined fields is maintained directly on the dimension portal. You may also review these mappings using the [Analytics Attribute Mapping](#) portal.

Logical Dimension

The Element Name of a foreign key field to a dimension represents a distinct logical version of the dimension. This allows for different logical dimensions to be based on the same dimension table. For example, a "Location" dimension may be referenced as a "Main Location" on one fact and also as an "Alternate Location" on the same or other fact. While both elements refer to the same dimension as foreign keys, each represent a distinct logical dimension via their element names. In the same way, while each date field is implicitly considered as a foreign key to the Calendar dimension, each distinct element name establishes a unique logical dimension. For example, a "Start Date" element name and an "End Date" element name are distinct logical dimensions of the underlying Calendar dimension.

Some logical dimensions may represent an aggregated or summarized form of another logical dimension. They are also known as "shrunk" dimensions. For example, the "Calendar Month Dimension" view is an aggregated dimension of the Calendar dimension. Establishing a link between a summarized dimension and its detailed dimension allows the analytics visualization tool to drill from one fact to another for performance reasons when they are indirectly linked via the same logical dimension but at different aggregation levels. For example, "Fact A" represents daily records and "Fact B" aggregates the same measures at a monthly level. Associating the "month" field in "Fact B", which is a foreign key to the "Calendar Month Dimension" view, with the logical dimension name of the "date" field in "Fact A" allows analytic queries to use "Fact B" for queries at the monthly level or above which perform better than performing them on the more granular "Fact A".

Analytics Configuration

Depending on which product or products you have installed, there may be some configuration needed for the analytics visualization product. Refer to [Defining Analytics Options](#) for more information.

Calendar and Time Dimensions

This portal is used to view generated calendar and time dimension records.

Refer to [Understanding Operational Analytics](#) for an overview of operational analytic functionality.

Navigate using **Admin > Analytics > Calendar and Time Dimensions**.

The following zones may appear as part of the portal's **Main** tab page:

- **Calendar Dimension.** This zone lists most recent calendar dimension records. You may filter the list to review records generated up to a specific date.
- **Calendar Date.** This zone provides information about a selected calendar date.
- **Time Dimension.** This zone lists all time dimension records.

Maintaining Bucket Configurations

Several key performance indicators in the analytics product look at measurement values (for example: the age of an asset or the age of debt) classified into a number of pre-defined groups also known as buckets. The overall metric can then be reported by the different buckets and allow various analyses.

For example, the age of an asset can be classified into the following buckets:

- Less than 6 Months
- 6-12 Months
- One Year and Older

The age of debt, also known as arrears can be classified onto the following buckets:

- 0-30 Days
- 30-60 Days
- 60-90 Days
- 90+ Days

The definition of the buckets is extracted to the Business Intelligence data warehouse, to be used as dimensions.

Bucket Definition Considerations

Each type of bucket is defined using a bucket configuration Business Object. The bucket definition considerations and/or rules will vary based on the bucket configuration business object used. The business objects available are driven by your specific product. For a list of available bucket configurations business objects, navigate to the business object page and view the business objects for the Bucket Configuration maintenance object.

Setting Up Bucket Configurations

To maintain the bucket ranges for the bucket configuration(s) applicable to your product, open **Admin > Analytics Configuration > Bucket Configuration**.

You are taken to the query portal where you can search for an existing bucket configuration. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

NOTE: Your specific product may also include an Analytics Configuration portal that displays the list of existing and potential bucket configuration records, allowing you to drill into this page to view the record in detail.

The **Bucket Configuration** zone provides basic information about the bucket configuration.

For more information about the elements supported refer to the zone's help or to the relevant analytics integration documentation for your product.

Defining Analytics Options

Refer to [Understanding Operational Analytics](#) for an overview of the operational analytics functionality.

Your specific product may require some system wide configuration to be defined when using operational analytics.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Analytics Options** business object.

Use the embedded help to review information about the options to define.

Defining Analytics Tables

This portal is used to search for Analytics Table definitions. An Analytics Table record exists for each table or view in the operational system that represent dimension and fact tables in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a record has been selected you are brought to its maintenance portal to view and maintain the selected record.

Defining Analytics Dimensions

This portal is used to maintain metadata for Analytics Dimension tables. A dimension record exists for each table in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a dimension record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected dimension record.
- **Fields.** This zone lists all the fields that define the dimension table. Fields may be selected from the dimension's underlying operation table using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this dimension references via foreign key constraints.
- **Referenced By.** This zone lists dimension and fact tables that reference this dimension via foreign key constraints.
- **Characteristic Mapping.** This zone manages characteristic mapping extensions for the dimension. Refer to [analytics attribute mapping](#) for more information.
- **Excluded Fields.** This zone lists fields from the dimension's operational table that are not included in the dimension table.

NOTE: The ability to introduce custom analytics dimensions is currently not supported.

Defining Analytics Facts

This portal is used to maintain metadata for Analytics Fact tables. A fact record exists for each table or view in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a fact record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected fact record.
- **Fields.** This zone lists all the fields that define the fact table. Fields may be selected from the fact's underlying operation table or view using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this fact references via foreign key constraints.
- **Excluded Fields.** This zone lists fields from the fact's operational table or view that are not included in the fact table.

NOTE: The ability to introduce custom analytics facts is currently not supported.

Defining Analytics Attribute Mapping

This portal maps extensions to user defined fields provided for tables associated with an analytics dimension table that capture well defined extension data. A common example of this type of data are characteristics.

These mappings may be directly maintained on the operational [Analytics Dimension](#) portal. Refer to [Understanding Operational Analytics](#) for more information.

If your system is integrated with the Oracle Utilities Analytics product refer to [Understanding Analytics Integration](#) for more information about ETL based characteristic mapping.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Attribute Mapping**. You are brought to a query portal with options for searching for a specific mapping record. Once a record has been selected you are brought to the this portal to review the information for the selected record.

The **Analytics Attribute Mapping** zone on the portal's **Main** tab page provides information about the mapping record.

NOTE: For characteristic mapping, only **Adhoc** and **Pre-defined** characteristic types are supported.

NOTE: For the product provides support for identifier mapping for operational analytics in this release but only the metadata definition is supported. The support for these types of attributes in the operational analytics product is in a future release.

Analytics Integration

The framework provides several building blocks and tools that the edge applications may use to implement integration with the Oracle Utilities Analytics product (referred to in this section as the analytics product). The following sections provide more information about this functionality.

Understanding Analytics Integration

The following sections describe the type of configuration supported in your product to integrate with the analytics product. Refer to the Oracle Utilities Analytics documentation for more information.

Master Configuration

Edge applications that include an integration to the analytics product typically include a master configuration record that captures information needed for the extract, load and transformation step, such as extract parameters. These records are provided by the specific edge products and may be viewed and maintained on the [master configuration](#) portal.

Note that your specific edge application may deliver an **Analytics Configuration** portal that displays the information from the master configuration record along with other analytics related configuration.

Bucket Configuration

The analytics product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

ETL Based Characteristic Mapping

The product provides objects to allow mapping configuration of characteristics in the product to user defined fields on dimensions in the analytics product. The mapping is used by the extract process to populate target user defined columns with corresponding characteristic data.

This type of mapping relies on configuration in the Allowed Target Dimensions [extendable lookup](#). The extendable lookup is used to define each Target Table in the analytics product that has one or more user defined fields that may be populated with characteristic values. It also defines the valid characteristic entities that may act as the source for the characteristic data.

NOTE: The framework does not provide any values in this lookup, but edge products that support mapping provide values in this lookup. Please refer to your specific product's integration chapter and refer to the Oracle Utilities Analytics documentation for more information.

Refer to [Defining Analytics Attribute Mapping](#) for more information.

Change Data Capture Using Sync Request

Depending on the specific edge application and version you are using, there may be components of the integration that use Sync Request for the change data capture step. If that functionality applies to your implementation, the following points highlight how to get more information:

- Refer to the administration guide for Oracle Utilities Analytics to confirm if your product integration is using Sync Request for any change data capture functionality.
- Review the Sync Request Business Objects provided by your product for analytics integration.
- Refer to [Data Synchronization](#) for a high level understanding of the process.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems.

Understanding Business Flags

The following is an example of a use case for business flags. Imagine that DataRaker highlights potential theft of service at a certain location. That product may initiate a business flag alert to various products owned by the implementation with a recognized "standard name" for the business flag, such as "TAMPER".

- If Oracle Utilities Meter Data Management receives this business flag, it may initiate a service investigation monitor.
- If Oracle Utilities Mobile Workforce Management receives this business flag, it may initiate a service investigation activity.
- If Oracle Utilities Customer Care and Billing receives this business flag, it may initiate a hold on billing for that location.

Note that the framework product supplies basic functionality to support logic that is common to all edge applications that implement business flag functionality. However it is the individual edge applications that supply more specific functionality (business objects and algorithms) for specific use cases, if applicable.

The following sections highlight functionality supported for business flags in the framework. Refer to the edge application product documentation for more details for supported use cases.

Standard Name

To ensure that Business Flags are universally understood across all edge applications and to simplify integration each Business Flag will have a Standard Name. This is a name that is used by all the products when sending information to each other. That way, if DataRaker product sends Oracle Utilities Meter Data Management a "TAMPER" business flag, it should result in the same functionality as when Utilities Customer Care and Billing sends a "TAMPER" business flag.

Standard Names are defined using an extendable lookup. In addition to common extendable lookup fields, the standard name also references a category and a class. The lookup also supports defining one or more external names, for cases where information is communicated from an external system that does not send the expected Standard Name.

The framework delivers the class values but does not deliver any standard names or category values. Refer to your specific edge application products to verify if any standard names or categories are delivered. Your implementation may configure appropriate standard names and categories based on your business rules.

Business Flag Type Defines Behavior for a Standard Name

Although the definition of the business flag standard names should be universally understood by the various integrated products that support them, each individual product defines what should occur when a business flag with a given standard name is created. This is configured using a business flag type. Only one active business flag type may exist for a given standard name. Business flags that are received from an external system will define the standard name, but will not have knowledge of the specific business flag types defined. The business flag type is determined based on the standard name.

The business flag type defines the business object to use when creating the resulting business flag record. The business object defines the lifecycle of a resulting business flag record.

Business Flag Type Algorithms

The business flag type includes support for algorithms. This allows for an implementation to define a common business object that may be used for different business flag types (if a common lifecycle is followed) but allow for different functionality to kick in depending on the business flag type.

The product supplies a plug-in spot for **Additional Processing** that may be invoked by a business flag that enters the Additional Processing state. Refer to your product's library of business objects to determine if there is an Additional Processing state that supports calling algorithms on the business flag type.

Objects Linked to a Business Flag

There are two types of links between an object in the system and a given business flag.

Affected Entity

Each business flag is associated with a single record in the system that is considered the "affected entity" or the entity that the business flag is associated with. The affected entity is defined by the specific business objects designed for the use cases supported by your edge product. For example, many utility base products may configure service point as the affected entity for its business flag use cases. Each business flag created is linked to a specific service point. Linking a specific entity to each business flag allows for algorithms to trigger functionality for that entity such as an investigation order. In addition, algorithms may be implemented in other business process areas that look for the existence of a business flag and act accordingly.

Related Objects

The business flag supports linking one or more related objects to a business flag to make it easier to trigger functionality or for impacted business processes to look for business flags. For example, when creating a business flag for a given service point, it may be useful to link all the accounts that are currently linked to the service point. Then, if an account oriented process should check for a business flag, it can look directly for a business flag linked to the account in its related object.

Impacted Business Process

The product supplies support for associating one or more impacted business processes to a business flag type. This configuration is used when functionality for that business process is impacted in some way based on the existence of a business flag of a given type. For example, maybe some process is put on hold when a certain type of business flag exists.

Note that configuring a business process on business flag type is not enough to trigger any impact on that business process when a business flag exists. There must also be some logic implemented in the business process functionality itself that knows to look for a business flag for a given record that is configured to impact the business process.

The definition of the business process is at the discretion of the edge application that supplies functionality to support this. For example, the business process could be defined as something broad such as “billing” or could be something more granular such as “billing estimation”. The system supplies an extendable lookup to use for configuring the supported business processes. Refer to the values of the business process extendable lookup in your edge application or to the edge application specific Business Flag documentation for more information about supported business processes.

Dates

A business flag supports two dates: a Business Flag Date/Time and a Business Flag **End** Date/Time

- The business flag date / time is required for all business flags. For some types of business flags only one date is needed.
- For business flags that have a start and end period, the business flag date/time acts as the start date and the other field is the end date.

For a business flag that has a date range, it may be important for functionality implemented for [impacted business processes](#). How the process treats the date will depend on its functionality.

- For some processes, the business flag is essentially expired after the end date has passed. This applies to impacted processes that are only looking at the current status of data in the system. For example, collection processing could be held if there is a business flag currently in effect (where the current date is within the date range). It would never look at historical business flags.
- For some processes where historical data may be relevant, a business flag effective during that same historical period may impact the process. For example if a business flag denotes an outage event for a given time period, perhaps estimated consumption should never be calculated for that time period.

Note that because business flags have a status, the design for the lifecycle of the business objects for the above effective dated use cases must carefully consider the states. For business flags that are considered expired after the end date passes, the BO lifecycle may be designed to transition to a final state after that date such that the record is no longer included in active processing. For business flags that continue to impact processing for a historic period, the BO lifecycle may be designed to remain in a non-final state such that it is clear that the record is still applicable.

Creating Business Flags

Business flags may be created in a system for one of the following reasons:

- A message is received from an external system that initiates the creation of a business flag. In this case, logic in the external system has detected some situation that this product is being alerted about.
- Business logic in this product detects a situation that should be investigated or should act as a flag. In this scenario, there may not be any integration needed depending on the business rules.
- Business logic in this product detects a situation that another integrated product should be alerted about. In this scenario, the business flag record is used to send out information to the integrated product.
- A user manually creates a business flag based on knowledge of the affected entity. For example, a customer service representative may create a business flag as a result of contact with the customer.

Creating a Business Flag from a Web Service

The system supplies both a REST and SOAP inbound web service that may be used for an external system to initiate (or update) a business flag. The REST service is **F1-BusinessInsights**. The SOAP service is **F1-BusinessFlagSync**. In both cases, the web service invokes a "driver" service script whose ultimate responsibility is to determine the appropriate Business Flag Type based on the standard name or external standard name, and therefore the appropriate business object for

the new business flag. Because different products may have different logic related to creating a business flag, the service script calls another service script linked to the maintenance object using the Business Flag Sync MO option.

The "driver" service script includes a "contextData" group, which in turn references the data area **F1-BusinessFlagContext**. This data area is to allow for an external system to provide additional information for a given business flag use case. For any integration that requires additional information to be passed in from the external system, a separate data area should be used to define the additional elements; and that data area should refer to **F1-BusinessFlagContext** as its extended data area.

The framework does not supply a Business Flag Sync service script, however individual edge applications supply a service script based on the use cases it supports out of the box.

NOTE: For products that are continuing to use XAI for external messages, the product also includes an XAI inbound service for the same Business Flag Sync Driver service script. Note that the product recommendation is to discontinue use of XAI and use [inbound web services](#) instead.

Error Handling

If there is a problem in trying to create a business flag based on incoming information, the Business Flag Sync Driver service script creates a special business flag record using the Business Flag Error Business Object. This is also configured on the maintenance object as an option. The framework product supplies the business object Business Flag Error (**F1-BusinessFlagError**) for this functionality. Refer to the business object description and configuration for more information.

Confidence

There may be use cases where a condition is suspected, but not confirmed. The originating system should be able to assign a "confidence" level to the business flag.

For example, Oracle Utilities Analytics Insights or other machine learning platforms will aggregate and analyze large amounts of data to identify potential insights that need investigation. These platforms can initiate a business flag with a **Suspected** confidence.

An application receiving this business flag may adjust the confidence to either **Confirmed** or **Rejected**.

- Setting the confidence to **Confirmed** is the equivalent of a true positive.
- Setting the confidence to **Rejected** is the equivalent of a false positive.

Note that the application that receives a business flag is responsible for acting on the value based on business rules. Any updates to the confidence can be communicated to the other products that received the same business flag, if desired.

Additionally, creating a business flag in the application with a confidence of **Missed** provides a way to denote a missed insight. This is the equivalent of a false negative.

Because a utility implementation may have multiple applications installed that support business flags, the following guidelines are suggested for designing where the confidence flag should be updated.

- If Oracle Utilities Service Order Management is implemented, it has the responsibility of updating the confidence flag and communicating the update to other products.
- Otherwise, the assumption is that Oracle Utilities Customer Care and Billing owns field work orchestration and that it will have the responsibility for updating the confidence flag and communicating the update to other products.

No product logic is provided to enforce the above suggestions, however, the business objects supplied by the different edge applications will support the recommended implementation.

Business Flag Updates from External System

When the product that is responsible for updating the Confidence flag makes a change, it should initiate an outbound message to alert other products. On the receiving side, the same inbound web service and Business Flag Sync service script is responsible for the update. Refer to [Creating Business Flags](#) for more information.

Setting Up Business Flag Configuration

The following topics highlight the general configuration steps required to use business flag functionality. Your specific product may supply additional functionality to support specific use cases for business flags. Refer to your specific product's documentation and the library of business objects supplied for Business Flag in your product for more information.

Standard Name Category Characteristic Type

Define one or more categories for grouping your standard names into logical business groupings.

Navigate to the [Characteristic Type](#) page. Search for and select the Business Flag Category characteristic type (**F1–BUSFC**).

Define desired category values and descriptions to be used for the standard names.

Standard Name Lookup

Navigate to the [Extendable Lookup](#) portal. Search for and select the **External Insights Standard Name** business object.

Define values that are recognized in the external systems that your implementation is receiving business flag details from.

Define a **Category** for the standard name that is appropriate for your product. Note that the category does not have to be in sync with standard name definitions in external products.

Select a **Class** for the standard name that is appropriate for its usage.

Refer to the embedded help for more information about configuring this object.

Business Process Lookup

If your specific product supports configuring business processes that may be impacted by the existence of a business flag, they are defined as an extendable lookup.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Business Process** business object.

Integration Configuration

The following points highlight configuration required to support receiving business flag information from an external source:

- Define a record for each [External System](#) that the product may be receiving business flag records from. This should be a value known by the external system and provided when new business flags are sent to this product.

When this product should initiate business flag information to be sent to an external system, configure one or more [Outbound Message Type](#) records. For each one, update the External System to configure how each outbound message type is communicated to the external system.

Defining Business Flag Types

Refer to [About Business Flags](#) for an overview of business flag functionality.

To maintain the business flag types applicable to your product, open **Admin > Integration > Business Flag Type**.

This is a standard [All-in-One portal](#).

The information captured on the business flag type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Business Flags

This section describes the functionality supported for viewing and maintaining business flags.

Refer to [About Business Flags](#) for an overview of business flag functionality.

Navigate using **Main > Integration > Business Flags**. You are brought to a query portal with options for searching for business flags.

Once a business flag record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Business Flag** zone provides basic information about a business flag. Refer to the embedded help for more information.

Market Transaction Management

This section describes various entities and aspects involved in the configuration and maintenance of market transactions. The framework product supplies basic functionality to support the objects related to market transaction management. However more specific functionality (business objects and algorithms) for specific use cases are supplied by the edge applications.

Understanding Market Transaction Management

Several objects are provided to support market transaction management.

- **Market Message Type.** This object is used to define the different types of market messages, both inbound and outbound and to define the appropriate market message Business Object to use when creating objects of this type.
- **Inbound Market Message.** This object captures the instance of a market message received from an external source.
- **Outbound Market Message.** This object captures the instance of a market message that will initiate a message to an external source.
- **Market Process Type.** This object is used to define configuration related to processes that may be initiated to support steps that should be execute to support an inbound or an outbound market message. It defines the market process Business Object to use when creating market processes of this type. It may also define one or more market process event business objects to initiate events that are generated to support steps within the market process.
- **Market Process.** This object captures the instance of a market process that may be created to carry out business logic related to a specific inbound or an outbound market message.
- **Market Process Event.** This object is used to orchestrate individual events that may occur to support steps in a given market process.
- **Market Configuration.** This object may be used to capture configuration needed to support market transactions. Each type of configuration should use a Business Object to define what information needs to be captured. Each type of configuration may define up to five key fields that may be used to uniquely identify an individual configuration instance.

Configuring Market Transaction Management

The following sections describe market transaction management configuration options.

Defining Market Configurations

Each market configuration is used to define one or more options for a given type of configuration (based on a delivered business object).

The product defines a generic set of portals, described here, that may be used to define any type of market configuration. However, it may be that your implementation includes more specific configuration portals for certain types of market configurations.

Open this page using **Admin > Market Transaction Management > Market Configuration**.

You are brought to the **Market Configuration Query** where you need to search for the market configuration (i.e., its business object).

Once you have found the appropriate market configuration, select the value and you are brought to a standard [All-in-One](#) portal that lists the existing values for the market configuration. The standard actions for an All-in-One portal are available here.

Defining Market Message Types

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Message Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market message type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Defining Market Process Types

This page is used to define market process types which control behavior of the resulting market processes and the valid market process events that could be triggered as a market process progresses through its lifecycle.

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Process Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market process type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Market Transactions

The following sections describe various pages available to view and work on market transactions.

Maintaining Market Processes

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Process**. You are brought to a query portal with options for searching for market processes.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Related Processes

This zone displays market processes that are linked to this market process using the explicit related process table. The market processes linked here are marked either as a parent, a child or a sibling market process.

Other Related Objects

This zone displays market process events linked to this market process. In addition, the zone displays any miscellaneous objects that are linked to the market process in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Maintaining Market Process Events

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

You can view this page when drilling into a market process event from the [Market Process](#) related objects tab.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process Event** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes a zone that displays all entries in the market process event's related object collection.

Maintaining Market Messages

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Message**. You are brought to a query portal with options for searching for market messages. Both inbound market messages and outbound market messages may be queried here.

Once a market message record has been selected, you are brought to the appropriate maintenance portal (inbound market message or outbound market message) to view and maintain the selected record. The inbound market message portal and the outbound market message portal have similar portal tabs and zones.

The **Market Message** zone provides basic information about the market message. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Other Related Objects

This zone displays any miscellaneous objects that are linked to the inbound / outbound market message in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Content Migration Assistant (CMA)

This chapter describes the Content Migration Assistant (CMA), a facility to enable the export of data from one environment to another.

CAUTION: This chapter is intended for users responsible for creating environments for testing.

Understanding CMA

The Content Migration Assistant (CMA) provides implementers with a flexible, extensible facility for migrating data from one environment to another (e.g., from a development environment to a production environment). Data is exported from the source system to a file. The file can then be checked in to a version control system for reuse, or can be immediately imported into the target system and applied.

NOTE: As used in this chapter, *source* systems are those on which export-related activities are conducted and *target* systems are those on which migration updates are to occur.

The following points highlight some common use cases for using this tool:

- Seeding a newly created environment with configuration data. For example, if you are creating test environments, you can import configuration data from a development environment. In this case, you will probably set up a "copy all configuration" type of migration. Another use case is if you want to troubleshoot an issue in production, you may want to copy all production configuration to a test environment.
- Updating an existing test environment with new configuration or updates to configuration from a development environment. In this case your set of objects will be more targeted and you are doing more of an incremental migration.
- Promoting tested configuration to your production environment.
- Migrating selected master and transaction entities from one environment to another for testing purposes.

Here are key aspects of the import process that apply to all cases:

- When records exist in both the target and the source, the CMA tool will fully **replace** the object with the version from the source. Special consideration should therefore be given to records whose **primary key is system generated** to ensure the correct entity is being replaced.
- While typically the source version of an object is applied directly onto the target environment, CMA does provide a way to [Adjust Imported Data](#).
- The import process **does not handle deletion** of records in the target environment. When importing records from a source environment to a target environment, the import process for the migrated records is able to identify objects to add and objects to change. There is no mechanism for indicating that records in the target environment should be deleted. The absence of those records in the import is not enough because the migration may be only importing a subset to add or update. If data on the target system must be deleted, users must delete the records in the target accordingly. Note that CMA does orchestrate the deletion of child rows of an object as a result of a comparison. This is only applicable to child records that are owned by the implementation.

Configuration steps are mainly used to define the data to migrate at the source system but also involve tasks to be performed at the target environment. Note that the products provide base delivered configuration that may be used as is or used as a template for building more specific configuration for a given implementation. At a high level, configuration tasks involve the following entities:

- System wide settings are defined in the **Migration Assistant Configuration** master configuration record.
- Each type of record that may be copied requires a **Migration Plan**. The migration plan is used to identify the maintenance object (MO) for the record (using a business object) and allows for instructions to specify related records that may be included in the migration.
- A **Migration Request** is used to define the data to include in a given migration export.

Refer to [CMA Configuration](#) for more information.

Once you have a migration request defined to include desired data to export, the next steps are to export from the current environment and import to the target.

- The **Export** process includes all the steps needed to select records to be exported from the source environment and create the export file. For more information, refer to [Exporting a Migration](#).
- The file created by the export, which is a BINARY file, needs to be transferred from the export directory to the import directory. The transfer needs to be done in such a way as to preserve the file structure. Refer to [Additional Migration Considerations](#) for more information.
- The **Import** processes include all the steps needed to read an imported file, compare the data in the file to the data in the target, review the proposed changes and apply the updates. For more information, refer to [Importing and Applying a Migration](#).

The topics in this section provide a general understanding of the Content Migration Assistant (CMA) tool.

Types of Migrations

The Content Migration Assistant is used for two general types of migrations: wholesale and targeted. The following topics provide some additional information about these concepts.

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administrative data from one environment to another. For example, a wholesale migration might be used when migrating administrative data from a development or test environment to a production environment.

A wholesale migration may be comprised of one or more migration requests that in total include all the administrative data to move. Migration plans used in wholesale migrations may be designed to omit subordinate instructions related to explicit foreign keys that are identified through constraints as they are not needed, assuming that the data they are referring to will also be included in the migration.

With the ability to group migration requests, the expectation is that implementations follow these guidelines:

- Multiple migration requests using the Criteria-based or Entity List migration request classes are used to group information logically together to allow for more reuse.
- A Group migration request is used for the export. This allows for one data set to export and one data set on the import side, simplifying the process. Note that depending on the amount of data, this may be a large import set to process. An implementation may find it easier to create multiple migration requests that break down the process into several steps.

You should consider that the framework product provides base migration requests and your specific edge product may provide base migration requests as well that may or may not include framework migration plans. Using the product provided migration requests is beneficial with respect to maintenance. As features are added to the product (including new administrative maintenance objects), any impact on CMA should be included in the product owned migration requests. If your implementation introduces new custom administrative maintenance objects that should be included in CMA, then custom migration plans and a custom migration request should be added. Your implementation can build a Group migration request that includes the base migration request and your custom migration requests to have a consolidated export.

NOTE: Refer to [Framework Provided Migration Objects](#) for information about migration requests provided in the framework product. Refer to your specific product's documentation for information about additional base provided migration requests.

Targeted Migrations

A targeted migration refers to migrating a specific subset of data from one environment to another. Migration plans used in targeted migrations are designed to be self-sufficient and include all necessary subordinate instructions needed to ensure that the exported entity can be imported without encountering referential integrity errors. With this type of migrations, any relationship explicitly excluded from the migration plan assumes the related entity already exists in the target environment. Examples of targeted migrations include:

- Migration of a new portal, its zones, and its application service.
- Migration of all outbound message types.
- Migration of selected accounts and their related master and transactional entities to a lower environment for testing purposes.

Migrating Configuration Data

A main use of CMA is to migrate configuration data, where the source environment is considered a kind of system of record and the target environment is getting updates based on changes to the source environment. Alternatively you may be seeding a new environment. The expectation is that the target record is updated to look like the source record.

Configuration data may include a mixture of records that have an owner flag and ones that do not. The comparison step of the import process will generate appropriate insert or update SQL statements for the following data found in the export:

- Configuration data in a maintenance object with no owner flag. This is purely implementation data.
- Configuration data in a maintenance object with owner flag, where the owner is **Customer Modification**. For example, implementer-specific business objects.
- Configuration data in a maintenance object with owner flag, where the main record is owned by the product but where a child record exists with an owner of **Customer Modification**. For example, implementer-specific algorithms added to a base owned business object.

- Customizable fields in a record that is owned by the product. For example, the priority of a based owned To Do type.

Migrating Business Data

CMA may be used to perform a targeted migration of selected master entities and their related transactional data from one environment to another. For example, migrating a subset of accounts and their related data for testing purposes.

The following points highlight key differences between business data and configuration data that call for special considerations when designing your business data migrations:

- Migration of business data typically involves a much higher number of records in a data set compared with a configuration-only data set. While there is no explicit limit to the size of a data set, some reasonable limit has to be assumed.
- Having large sets of entities depend on relatively few entities in the same data set significantly slows the import process. This situation occurs when mixing configuration data, master data and high volume transaction data in a single migration. We therefore recommend designing separate migrations for these data classes. Refer to the **Reduce Dependency Between Migration Objects** section below for more information.
- All business entities have a system generated key. Refer to [Data with System Generated Primary Keys](#) for more information.

The following sections expand on topics and concepts related to business data migration.

Reduce Dependency Between Migration Objects

CMA leverages the application's referential integrity and business rules to ensure entities remain compliant and valid when imported into another environment. These rules are there to prevent an entity from being imported when any of the entities it references do not exist in the target environment. When both the referencing entity and the entity it references are part of the same data set they establish a **dependency** that dictates the sequence in which these entities should be processed in order to be successfully imported. Note that the tool supports even the more complex and rare situations wherein the dependency between entities is cyclical, i.e. entity A (directly or indirectly) refers to entity B while entity B (directly or indirectly) refers back to entity A, for which sequential processing is not enough to guarantee a successful import.

The tool uses foreign key relationships between entities in the same data set to identify sets of dependent entities and group them into separate migration transaction records. Note that these foreign keys are defined in the application's **data model** repository and not at the database level for greater flexibility. The larger the migration transaction the more complex the process is to successfully import all its objects. So while the tool is designed to support all types of dependencies (sequential and cyclical), handling very large sets of dependent objects may incur a significant performance cost.

While configuration entities tend to be highly inter-dependent, the total number of entities that comprise the entire set of configuration objects is relatively small. Therefore, the impact on performance such dependencies have when importing a configuration-only data set is negligible. On the other hand, configuration entities tend to be referenced on many master and transaction entities as they control many aspects of the latter's business rules. As such, mixing configuration and business

data in the same data set is likely to form extremely large sets of business entities that dependent on a small number of configuration entities. It is therefore strongly recommended to import or set up configuration data in the target environment prior to importing business data into it.

In a similar way, some transactional data tends to be of a much higher volume compared to the master data entities they reference. Here too, it is strongly recommend to migrate master data entities prior to their high volume related transactional data. For example, many interval measurement records (transaction data) reference the same measuring component (master data). Migrating a large volume of measurement data along with their measurement component would result in a very large migration transaction that may take long to import. Importing the measurement components prior to migrating their interval measurements will eliminate unnecessary dependencies within the measurements only data set and significantly improve the performance of the overall process.

Reasonable Data Volume

The overall volume of all business entities to migrate in a single data set should be reasonably sized. For example, importing several hundreds of accounts and their related master and transactional data is considered a reasonable size. Migrating too much data may reach physical and performance limitations of the tool.

You may use any supported migration request methods for describing the entities to export. If you opt for an Entity List migration request, consider using the [Collect Entity](#) dashboard zone to build the list of entities as you browse them on their respective portals.

Single Source of Data

CMA uses an entity's prime key to determine if it is new to the target environment and therefore should be added or refers to an existing record and therefore needs to be replaced with the new version. All business entities have system generated keys, which are environment specific. It is therefore possible to have different entities in separate environments having the same prime key. When migrating entities whose keys are system generated, it is strongly recommended to migrate data to a target environment from a single source environment and avoid creating such entities in the target environment using the application. This practice ensures that prime keys for an imported entity are always in sync with their source environment. Refer to [Data with System Generated Primary Keys](#) for more information and considerations.

No Deletion

CMA does not handle deletion of entities of any kind, whether they are configuration or business entities. If a test needs to be repeated using an initial snapshot of the data, you should restore your target environment to a backup taken before test data was imported and import the latest version of the test data. If there is no need to delete previously imported entities, you may keep reloading test data from a single source environment as needed.

Bulk Import Mode

By default, the import process creates a migration object for each imported entity. This allows for granular reporting and error handling at the entity level. When importing a high volume data set of business entities, this granular management has a performance toll. In this situation, you may want to use the **Bulk Import** option on the migration data set import request. In this mode, a single migration object record is created for multiple entities of the same maintenance object. In the same way, a single migration transaction record is created for multiple logical transaction groups. Using this option reduces the migration object management effort throughout the process and thus results in better performance.

Note that each entity is still individually compared and validated, as in regular import processing, but if one entity is invalid the entire migration object is not applied hence impacting all entities grouped together with it. Bulk import mode is useful when importing a large set of data from a validated data source such that almost no errors are anticipated.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Insert Only Mode

By default, the comparison step of the import process needs to determine whether the imported entity is new and therefore should be added, represents a change to an existing entity and should be updated or the entity is unchanged. When importing a high volume data set of business entities that are all new to the current environment, this check is time consuming and can be avoided. In this situation, you may use the **Insert Only** option on the migration data set import request to indicate that all imported entities are assumed to be new additions to the current environment. By doing so, the import process avoids unnecessary steps to determine whether the entity should be added or updated and thus contributes to a faster import process.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Separate Batch Processes for Managing Business Migration Objects

By default, the same import related batch processes manage configuration and business data migrations. Typically, business data migrations involve high volume of records compared to much lighter configuration data sets. Processing them together by the same batch process may slow down the performance of configuration migrations, preventing them from completing faster and more frequently. The issue mainly affects test-like environments where mixed data class migrations are more common: configuration data is imported from a lower environment and large test data is imported from a higher environment. You may adjust the base product's configuration in such environments to benefit from separating the import processes for configuration and business data.

Note that the ability to separate import processes applies to migration objects only because of their volume. Migration data set and transaction records are of low volume and as such remain managed by the same batch processes.

Designated batch processes are provided for importing migration objects containing business data but they are not used by default:

- F1-MGOPB - Migration Object Monitor (Business)
- F1-MGOAB - Migration Object Monitor (Business) - Apply

Follow these steps to use these separate designated batch processes for business data:

- Update the **Migration Object Business Data** (F1-MigrObjectBus) business object to reference the business data related batch controls on the following statuses:
 - **Pending, Error Applying, Needs Review** - Migration Object Monitor (Business) - F1-MGOPB
 - **Approved** - Migration Object Monitor (Business) - Apply - F1-MGOAB
- If your organization uses event driven job submissions for CMA batch processes then refer to [Running Batch Jobs](#) for additional configuration steps.

Data with System Generated Primary Keys

For records with system generated keys, there is an issue if the target environment already has a record with the same key but doesn't represent the same record. The tool shouldn't be just updating that target record with the view of the source in case this will break foreign key relationships that exist in the target.

The tool provides support for administrative data with system-generated primary keys. The logic relies on the maintenance object to use a method that looks at other attributes of the record (considered a "logical key") to detect whether the record being migrated already exists in the target region or not. The examples in this section are based on the Attachment maintenance object. Common attachments are considered administrative data. The attachment MO uses the file name and the creation date as the "logical key".

Imagine a common attachment for the "standard rate codes" file exists in a source region with the key 123456789. The table below highlights possible situations at the target region and actions supported in CMA.

Scenario	Target Situation	Action	Comments
1	No matching record	Record can be added with key 123456789.	
2	Record exists with key 123456789 and logic confirms that it is also the "standard rate codes" attachment.	Record can be updated.	
3	Record exists with key 123456789, but logic detects that it is not the "standard rate codes" attachment.	Record is not updated. An error is issued.	The system cannot update this record because it's not the right attachment record.
4	The system detects that another attachment record exists for the "standard rate codes" attachment with a different ID.	Record is not updated. An error is issued.	Assumption is that the record was created directly in the target or was copied from a different source.

The use cases described in scenarios 3 and 4 above would require key mapping to keep track of the id from the source to the id in the target so that any other records from the source that reference this key as a foreign key would be updated as part of the migration. This functionality is not supported.

Scenarios 1 and 2 above are supported for maintenance objects that use the method to detect the logical key.

NOTE: If a maintenance object with a system generated key does not supply a method to detect the logical key, CMA will update an existing record with the same ID. For maintenance objects in the framework that provide this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about support for data with system generated keys.

The product recommends that an implementation establishes a migration strategy such that records with system generated keys are always created in the same region and always follow a standard migration path for promoting the data from this source region to other regions. Following this strategy, you would minimize or eliminate the possibility that a record for the same logical key is created in multiple places such that different IDs would be generated as described by scenario 4 above.

MOs with a Mixture of Administration and Non-Administration Data

There are some MOs that contain a mixture of master or transaction data and administrative data. The Attachment is an example of this. The product supports common attachments and owned attachments. Owned attachments are records that are specific to its owner. The owner could be master or transaction data and its attachments are therefore considered master or transaction data. Owned attachments are not candidates for migration using CMA. Common attachments on the other hand are considered administrative data and may be candidates for migration using CMA. For these use cases, an implementation may follow the suggested strategy of only creating the administrative data in one region so that IDs for common attachments are not reused. However, it is reasonable and expected that owned attachments are being created in the target region and may receive a system generated key that matches the key of a common attachment from the source region.

To try to minimize this issue, the system includes special logic to be used by any MO that may contain administrative data mixed in with master or transaction data. This special logic generates the key of an administrative record with a zero (0) in the middle of the key and ensures that the keys for master and transaction data do not include a zero in this spot. For maintenance objects in the framework that use this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about additional maintenance objects that may be in this category.

Importing Data that References a User

Although the tool supports copying users from one environment to another, the assumption is that it will be more common for implementations to define their valid users for each environment separately. In fact, the default CMA configuration for copying security configuration assumes that users are not being copied.

There may be times were a record is being copied from one environment to another where a user is referenced on the record but that user is not valid in the target environment. For example, if a batch control is configured as Timed with a user referenced, if this batch control is copied to another environment, what should happen if that user is not found? You may not want that user defined in the target environment. To handle this, the product provides support for a Default User that you can define in the [migration assistant configuration](#). If this default user is configured then any time the CMA import

process recognizes that a record references a User and the user does not exist in the target environment, it updates the record to instead refer to the default user.

NOTE: Please note that if you are trying to copy entities that includes valid users, you should ensure that all the users are copied to the target environment first. Otherwise, the entity will be updated to refer to the default user, which may not be your intention.

NOTE: If you copy records that reference a User within an XML field or CLOB, the CMA input tool is not able to detect that. A pre-compare algorithm is recommended if this use case exists in your implementation.

Additional Considerations

The following sections describe some additional considerations for CMA.

File Transfer Considerations

When moving the export file between systems, use the binary transfer option of whatever tool you use to move the file so that line-end characters are not converted from Linux-style to Windows-style or vice versa.

It is recommended to avoid using 'txt' for the export file's extension (defined in the [master configuration](#)). That file extension by default implies a non-binary file and tools that perform file transfer may treat this as a non-binary file unless explicitly stated. The recommendation is to define 'cma' as the extension. This is not a recognized file extension and most file transfer tools will transfer the file as is.

Note that if the file gets converted, there are two likely outcomes - either a numeric conversion error, or a buffer under-run error may be received when attempting to import the file.

Multi-Language Environment Considerations

If your implementation uses a language other than English, it means that migrated administration objects may have multiple language rows (because English is always enabled). There are some important points with respect to multiple languages and CMA:

- As described in [User Language](#), there are steps to follow when supporting an additional language. The steps outlined in that topic highlight that for system data, translation of the strings may be provided via a language pack provided by the product or may be the responsibility of your implementation. In either case, this effort is non-trivial and will have its own established plan. The expectation is that the translation of the system data is applied for each region at your implementation site. CMA should not be used to create a new language in a target region.
- For administrative / control data that your implementation develops as part of your project, the expectation is that descriptions for your supported language are entered in the region that is considered the source region used to promote changes to regions in the "chain". For example, control data is entered in a development region and promoted to a test with the supported language enabled in both regions.
- What if you export data from a region with more languages enabled than your target? This scenario is perhaps a case where the source region is a type of test or playpen region where the additional language is enabled for other purposes. In this case, if the language code doesn't exist at all in the target region, the import will produce an error given that the code is invalid. If the language code exists but is not enabled, this will cause the extra language rows to be inserted in the target region, but will not cause any issues. They are simply ignored.
- What if you export data from a region with fewer languages enabled than your target? In this situation, the import process will only create language rows for the languages that were copied from the source. It will not automatically create language rows in the target as part of the import. For this situation, the recommendation is to run the **New Language** batch program (**F1-LANG**) that creates any missing language entries.

Versions and CMA

This topic addresses two separate version related topics with respect to using CMA between two environments.

- Different versions of the application
- Different CMA file format versions

Different Versions of the Product

CMA was developed with the main requirement of copying data between two environments that are on the same version of the product. For example, copying configuration data from a development environment to a test environment on the same product version.

In general, there isn't anything about how CMA functions that would limit your ability to copy data between two different versions of the product. However, it's possible that your product has enhanced the functionality of a specific object to add or remove columns or change the type of data captured in those columns or has change validation around how data should be captured.

Our products follow strict standards for upgrading clients to ensure backward compatibility. Upgrade scripts in the blueprint process know what was changed from one release to another and update the data accordingly where applicable. When using CMA to move data from one version of the product to another, you are bypassing these upgrade scripts. It means your data is not being adjusted as expected. It's not recommended unless you are certain that the data of an object from one version is compatible in the other version. The following points highlight this in more detail.

- For objects whose structure and rules have not changed between the two versions, there should be no issues.
- For objects that have changed between the two versions, there are scenarios that may cause additional steps.
 - If the target environment is a later version and includes a new optional column on an object that was not present in the source, the import should go through without any issues.
 - If the target environment is a later version and includes a new required column on an object that was not present in the source, a 'pre-compare' algorithm could be used to populate the new required value. Your implementation can provide this algorithm to populate the data according to your business rules.
 - If the target environment is an earlier version than the source, we cannot guarantee that there won't be specific issues encountered with specific objects.

File Format Version

If your implementation has decided that you are going to use CMA across product versions, given all the cautions described in the previous section, this section provides information on the rare case where CMA has a change in who it writes the export file.

When creating the export file, the format of the file is specific and the CMA import step knows how to read the file. It is rare, but there are times when the product makes an enhancement to CMA that requires a change in the structure of the export file at which point the 'version' of the CMA file is incremented.

The CMA file format version has no impact to migrations that are exported and then imported into the same version of Oracle Utilities Application Framework. However, if your implementation has different environments on different versions of the product where the CMA file format is also different, then the system has functionality to cater for these differences.

- If you are exporting data from a lower file format version to a higher file format version, there is nothing special that you need to do. The export step captures the file format version and the import step reads this information and processes the file accordingly.
- If you are exporting data from a higher file format version and the product currently supports exporting to a lower file format version, at export time you are prompted for the earlier file format version. You may indicate that you want the earlier file format version when creating the migration data export.

NOTE: The product supports exporting to an earlier file format version for a reasonable amount of time, but not in perpetuity. If you don't see any option in the user interface to export to an earlier file format, it means that it is not supported in that release.

CMA Configuration

The following sections describe tasks required for CMA configuration.

Master Configuration - Migration Assistant

The **Migration Assistant Configuration** record defines system wide configuration used in both the source environment and the target environment.

As described in [Importing Data that References a User](#), if you have records being imported that may reference a user does not exist (and shouldn't exist) in the target environment, define a Default User here.

In both the source environment and the target environment, the system needs to know the location of the export directory and the import directory along with the expected file suffix. For these fields, implementations may also rely on the system defaults. If no Migration Assistant Configuration record is found, the system assumes that there is an entry defined in the system's substitution variable list for **F1_CMA_FILES**. Further it defaults the values as follows:

- Export directory is the value for this variable plus "**\export**".
- Import directory is the value of this variable plus "**\import**".
- File suffix is set to **cma**

Refer to [Referencing URIs](#) for more information about the substitution variable list.

For additional information about specific fields in the master configuration, refer to the embedded help.

NOTE: This record can be updated at any time to change details. The new configuration takes effect on all subsequent exports and imports.

Migration Plans

A migration plan defines one or more types of objects that are eligible for migration. It is essentially a set of instructions describing how the data to be exported is structured, allowing objects to be migrated together as a logical unit to ensure consistency and completeness.

The migration plan is always related to a given maintenance object, defined using its primary instruction. Multiple migration plans may exist for a given maintenance object if there are different requirements for migrating records in that MO under different circumstances. For each migration plan, you decide if additional data should be included as part of an object using subordinate instructions. For example, when copying a single algorithm type, should the system only copy that algorithm type record, or should it also copy all its algorithms and its related script (if applicable)? Refer to [Types of Migrations](#) for more information.

The following topics describe defining a migration plan as well as other topics for a migration plan.

Defining a Migration Plan

To view or define a migration plan, navigate using **Admin > Implementation Tools > Migration Plan**.

Use the **Migration Plan Query** portal to search for an existing migration plan. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! If you introduce a new migration plan, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following points provide information about defining **Instructions** for a migration plan.

The **Instruction Sequence** uniquely identifies the instruction. The recommendation is to use increments of 10 to allow insertion of other instructions in the future.

Select **Primary** for the first **Instruction Type**. All migration plans must contain one and only one primary instruction. All subsequent instructions require a **Subordinate** instruction type. In this case, the **Parent Instruction Sequence** must be entered. This number, used to maintain the defined relationships in the exported data, must match an instruction sequence number at a higher level in the hierarchy.

The instruction **Description** provides a business description of the instruction.

Select a **Business Object (BO)** to define the type of object from which data will be derived.

NOTE: Though BOs are specified in each instruction, it's important to understand that each BO is used only for filtering purposes. The migrated data set comprises the complete contents of the *maintenance object* that the business object structure is defined against. For a more detailed explanation of this, see [Understanding the BO Filtering Process](#).

NOTE: Refer to [Identifying Tables to Exclude From Migrations](#) for information about defining child tables to always exclude from a migration.

Traversal Criteria is used to define the relationship between each of the objects in a migration plan. The system provides three options to define how the child object is connected to the parent object so the system knows how to traverse from one object to another. **Traversal Criteria Type** options are **Constraint**, **SQL** and **XPath**. The following points explain each option:

- **Constraint** allows you to select a table constraint that represents a given record's relationship to another record in the system via a foreign key constraint defined in the meta-data. If **Constraint** is selected, the following additional fields are enabled:
 - **Constraint ID** is a unique identifier for the constraint. The search will show the valid table constraints for the MO of the instruction's BO and the MO of the parent instruction's BO.
 - **Constraint Owner** is used to define the owner of the constraint. This is populated automatically when selecting a constraint from the search.
- **SQL** lets you specify SQL join criteria between the parent instruction's object and the child object in the **SQL Traversal Criteria**. The syntax of the the traversal criteria is a WHERE clause (without including the word WHERE). When referring to a field on the parent instruction's object, use the syntax `#PARENT.TABLE_NAME.FIELD_NAME`. When referring to a field on the current instruction's object, use the syntax `#THIS.TABLE_NAME.FIELD_NAME`. For example, the following statement is used on a migration plan for Business Object, where the parent instruction is the BO and the subordinate instruction is used to reference the UI Map that is referred to as a BO option with the option type "F1DU":

```
#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_FLG = 'F1DU' AND @trim(#THIS.F1_MAP.MAP_CD) = @trim(#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_VAL).
```
- The **XPath** option lets you apply syntax in an XPath expression referencing elements in the instructions' referenced business objects. This is entered in the **XPath Traversal Criteria**. For example, the display map collection statement in the SQL example noted above would be written as follows in XPath: `#this/mapCd = #parent/businessObjectOption/businessObjectOptionValue AND #parent/businessObjectOption/businessObjectOptionType = 'F1DU'`. This technique allows foreign key references that are mapped inside an XML column to be referenced.

NOTE: The #parent expressions may access elements that are stored in an XML column and described using mapXML and mdField. However, the #this expressions must refer to fields available in the business object using the mapField reference.

Defining **Next Migration Plan** provides the ability to indicate that in addition to copying the object defined in the instruction, any additional instructions included in that referenced migration plan will also be included in an export.

The **Algorithms** grid contains algorithms associated with each instruction. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the Sequence in which they should execute.

System Event	Optional / Required	Description
Pre-Compare	Optional	Algorithms of this type may be used to adjust the data after it is moved to the target system. These may only be defined on the primary instruction. Refer to Adjusting Imported Data for more information.
Import	Optional	Algorithms of this type are no longer supported.

Understanding the BO Filtering Process

Migration plan instructions require the definition of a business object to provide CMA with information about the record related to the instruction.

If the business object is the physical business object for the maintenance object, then CMA assumes that the instruction applies to all records that satisfy the traversal criteria. CMA recognizes the physical BO by comparing the BO to the value defined in the maintenance object option. If the business object defined is not the physical BO, then CMA will limit the records in the instruction to those that explicitly reference this BO or reference a child of this BO as its [identifying BO](#) value. (In other words, this BO must be in the parentage hierarchy of the records to be included in the instruction.)

NOTE: Unlike Bundling, CMA does not use the BO schema to drive what data is copied for a given record. The BO is only used as a filtering mechanism for selecting records. Refer to [Identifying Tables to Exclude from Migration](#) for information about how to ensure a child table is not included in a migration.

For example, if you define a migration plan for Master Configuration and use the physical business object for the instruction (**F1-MstCfgPhysicalBO**) then all master configuration records are considered for the instruction. If instead the business object you define is Migration Assistant Configuration (**F1-MigrationAssistantConfig**) then only the record related to this business object is included in the instruction.

Migration Plans for Objects with XML-Embedded Links

When migrating objects where foreign key references are captured in the object's XML based field, subordinate instructions are needed to define the foreign key references in order for CMA to understand the relationships. This is in contrast to direct foreign keys where CMA can determine the relationships using constraints. The instructions provide two purposes. Defining instructions ensures that the related objects are included in the migration, if appropriate. If you know that the related objects are included because of other criteria, the instructions allow CMA to group related objects into transactions. This helps in the apply process at import time to ensure that related objects are grouped together. However, the apply process includes iterative steps to try to overcome dependencies like this so defining the instructions is not critical for this purpose.

The following are options for creating migration plans with XML-embedded links:

- One option is to use the specific logical (business) BO in the primary instruction to define the object you are copying. With this option, the subordinate instructions may use XPath criteria to define the related foreign key. When this approach is used, a separate Migration Plan must be created for each logical BO. (Refer to [Understanding the BO Filtering Process](#) for more information.) This option would only be used in isolated cases.
- Another option is to create a migration plan that uses the Physical BO as the primary instruction, and then include a subordinate instruction for the real logical BO, using SQL Traversal to join the object to itself by its primary key. Note that with this technique, the records that reference the logical BO will still only be included in the export file once. At this point further subordinate instructions may use XPath notation to define the foreign key data. Using the physical BO as the primary instruction ensures that all records in the MO are considered. The subordinate instructions with the logical BO and XPath notations will only apply to the records that are applicable to that BO. This option is useful for MOs that have a small number of logical business objects with disparate foreign keys.
- Another option is to use the physical BO in the primary instruction and use raw SQLs in the subordinate instruction's traversal criteria to identify the foreign keys using substring commands. A separate Subordinate Instruction is needed for each SQL corresponding to each element occurrence. Using this technique has the same advantages of the previous in that all records for the MO are included in the migration. However, this technique may be useful for maintenance objects with a larger number of business objects expected where each has one or more foreign keys. It's especially useful if many business objects reference the same foreign key. Then only one instruction is required for that foreign key. Note that a single migration plan may use this technique and the XPath technique for different elements.

A migration request may have multiple migration plans for the same maintenance object. That allows for some flexibility and long term maintainability in that the above techniques may be used in multiple migration plans. Consider the following example:

- A product provides base business objects with foreign keys defined in the XML field and provides the appropriate migration plan with instructions. An implementation extends this business object or perhaps creates their own business object for the same maintenance object and includes different additional foreign keys in the XML. Rather than duplicating the base migration plan and adding additional instructions for the additional foreign keys, the implementation can create a second migration plan for the MO with the additional foreign keys defined. A migration request should be defined to include both migration plans. In this case if the implementation has only one custom BO, they can choose to use the custom BO as the primary instruction as described above in the first option.

Defining a Migration Request

Migration Requests are used to define the data to be included in a migration. To view or define a migration request, navigate using **Admin > Implementation Tools > Migration Request**.

Use the **Migration Request Query** portal to search for an existing migration request. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

There are three types or classes of migration request. The system provides a base business object for each along with a migration request class, which matches the business object. The subsequent sections provide more information about each class of migration request.

Note that all migration requests support defining a Category, which allows implementers to categorize the migration request.

In addition, all classes of migration request include the following zones:

- **Migration Request** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Referencing Migration Requests** This zone is only visible if the displayed migration request is included in a Group migration request. It lists each group migration request that includes it.

Other zones may appear for specific classes of migration requests. See the following sections for more information.

Criteria-based

This type of migration request defines a set of migration plans to be logically included together as part of a migration. For each migration plan, selection criteria is defined to indicate which records for each MO should be included. Selection may be defined using SQL, an algorithm or explicit primary key values.

- For selection using SQL Statement, refer to the embedded help for examples.
- For selection using Algorithm, the algorithms that are eligible to be plugged in here are those valid for the **Migration Request - Select** system event.
- For selection using Specific Keys, the primary key (1 through 5) must be explicitly specified. Multiple rows are allowed.

Entity List

This type of migration request allows the user to choose explicit MO / prime keys. The MOs that are eligible are those that are configured with a **Default Migration Plan** option. Although the user is managing MO / PKs, the migration instructions are still defined with a migration plan. The system maps the migration instructions in a similar way to a **Criteria-based** migration requests that use a Specific Key selection type. Note however that it will create a separate migration instruction for each MO / PK combination. It does not try to group all PKs for the same MO / migration under one migration instruction.

For this type of migration request, a user adds a migration request record with its description and other main information. Then, a special zone **Add Entities** is provided to find and select records based on a selected maintenance object and add to the migration request. The user is prompted to provide a reference and comments, if desired. If the category selected is one that requires a reference, then this will be validated. Alternatively, you may also use the [Collect Entity](#) dashboard zone to add specific entities as you review them on their respective maintenance portals.

When maintaining a migration request with existing entities, they are visible in the zone **Migration Request Entities** . This zone allows a user to remove the entity from the list.

Group

This type of migration request points to other migration requests. This allows you to define separate migration requests that represent logical groupings of migration plan instructions for ease of maintenance, but to combine all the separate migration requests into a single "grouped" migration request for streamlined export / import purposes.

The CMA export process will build an extract that includes the union of all the objects that qualify for the export and group them together based on their relationships.

Identifying Tables to Exclude From Migrations

Some maintenance objects that are eligible to be migrated may include child tables that should not be included in the migration. For example, if an object includes log tables, the entries in the log should reflect the actions on the object in that system, and will be different between the source system and the target system. If you have a custom Maintenance Object that includes tables you don't wish to migrate (such as a log table), use the **Non-Migrated Table** option on the MO to specify this table. All child records for this table will also be ignored during migration.

Another use case to consider is a child "many-to-many" table that connects two administrative objects and exists in the maintenance object of both tables. The child table may be in both MOs for convenience sake, but it may be that one MO is considered more of a "driver" object and the other more of a subordinate. If you are doing a migration where you want to copy a subset of objects, you may want to only copy the driver object and its children and their data but not their children. For example, a To Do Type includes a collection of valid To Do Roles and in turn the To Do Role refers to its To Do Types. If an implementation wants to copy a single To Do and include all its related information, including its To Do Roles, it does not want the migration of each To Do Role to in turn copy all its To Do Types (and their data).

NOTE: The MO option must be set in both the Source and Target systems for a given MO.

Configuring Custom Objects for Migration

During the implementation and extension of the product, new custom administrative maintenance objects may be introduced. If your implementation would like to migrate records in those maintenance objects using the Content Migration Assistant, additional steps must be performed, which are highlighted in the following sections.

Physical Business Object

As described in [Understanding the BO Filtering Process](#), the migration plan requires a business object for its instruction. The business object is used to identify the records eligible for inclusion in the migration. Assuming your custom tables use one or more "logical" business objects for their processing, your implementation must decide if these business objects are appropriate for use by the migration plans, or if a physical BO is warranted. If so, [create an appropriate physical BO](#).

Review MO Option Configuration

The following points highlight maintenance object (MO) configuration that should be reviewed or updated to support CMA:

- If a physical BO was created (above), link it to the MO as an option using the appropriate option type.
- Be sure that your MO defines an appropriate [FK Reference](#) and includes an Option on the MO that identifies the FK Reference. This is used by various portals and zones for CMA when showing detail about records being imported into the target region. Also be sure that this FK reference defines an Information program.
- As described in [Identifying Tables to Exclude From Migrations](#), an MO option is used to identify child tables for an MO that should never be included in a migration. If your custom maintenance object includes a standard Log table, then the recommendation is to list that table as an excluded table. Depending on the specific design of the maintenance object, there may be other child tables to define.

Characteristic Type Configuration

The CMA import process will attempt to create a log record for any administrative object that includes a log table. If your implementation has introduced any custom administrative tables that you plan to include in a migration request and it includes a log table, you must, to ensure that the log creation is successful, add your log table as a valid characteristic entity to the characteristic type **F1-MGO** (Migration Object).

Navigate to [Characteristic Type](#) and select the characteristic type **F1-MGO**. Navigate to the **Characteristic Entity** tab and add a row to include the characteristic entity for your custom maintenance object's log table.

Standard CMA Configuration

Create one or more migration plans for the new object, depending on the type of data in the maintenance object and the types of migrations you envision:

- If you have implemented only one "logical" business object used to define the data in the MO, then a single migration plan that references the this BO (or the maybe the MO's physical BO) is appropriate.
- If you have implemented more than one "logical" business object, would the data for multiple business objects get copied together? Then perhaps a single migration plan that references the MO's physical BO is appropriate.
- Are there additional foreign keys defined using mapXML in the business object(s) for the MO? If so, then it is recommended to include sub-instructions to define the links. At this point, if multiple "logical" BOs exist, your implementation may choose to define all the additional elements in the same migration plan or choose to define separate migration plans for each logical BO.
- Your implementation may decide to define more than one migration plan for the same type of record based on the types of migrations you plan to include. For example, you may decide to include a migration plan that copies only the records in this maintenance object. You may decide to define another migration plan that copies the records in this MO along

with related records in another MO (for a special type of migration). Having said that, be sure to design the migration plan with reuse in mind to minimize maintenance efforts.

In order to support **Entity List** migration request, a default migration plan must be defined as an option on the maintenance object. This should be a single migration plan that supports all types of business objects for the MO.

If your implementation has a template migration request to use for migrations, include the new migration plan(s) as appropriate.

CAUTION: Important! New migration plans and migration requests should follow naming conventions. Refer to [System Data Naming Convention](#) for more information.

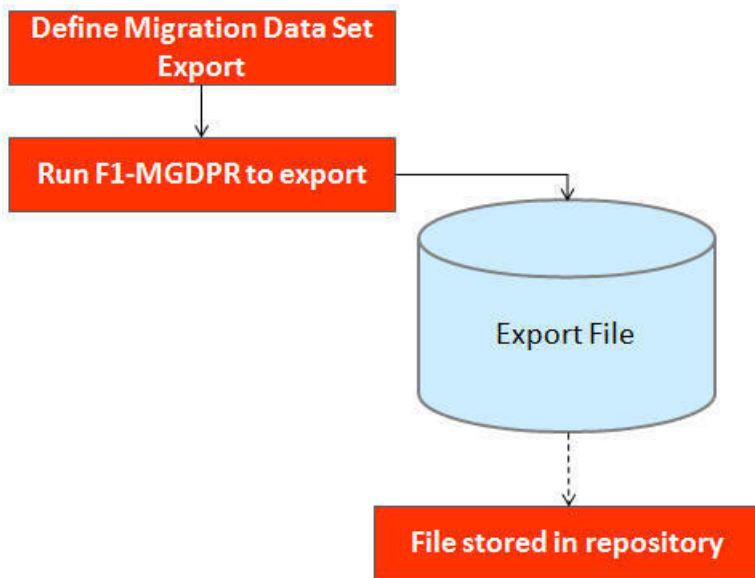

The CMA Execution Process

The following diagram illustrates a high-level view of the Content Migration Assistant execution process. The subprocesses illustrated here are described in more detail in the following sections.

Exporting a Migration

The migration export process begins in the source environment by defining a **Migration Data Set Export**, which specifies a defined **Migration Request** and provides a file name and description for the export file. After the data set is defined and saved, the **Migration Data Set Export Monitor** batch job can be submitted generate the export file. The lifecycle of the Migration Data Set Export business object includes algorithms that select the appropriate records according to the migration request, determine dependencies between records to build groupings of related objects and create the export file.

The following topics provide more detail about this process.

Migration Data Set Export

To migrate data from one region to another, define a **Migration Data Set Export**. This establishes the export file name and identifies the migration request.

To view an existing migration data set export, navigate using **Admin > Implementation Tools > Migration Data Set Export**. Use the query criteria to locate the desired data set.

Note that you can also initiate the creation of an export data set from the [Migration Request](#) portal using the **Export** button.

The export requires the name of an existing **Migration Request**.

Enter a unique **File Name** for the export. Do not use spaces in the name, and do not enter the file extension or a path. The output location and file extension of the intended export file, which should appear in the **Export Directory** and **File Suffix** labels, are defined as described in the topic [Migration Assistant Configuration](#).

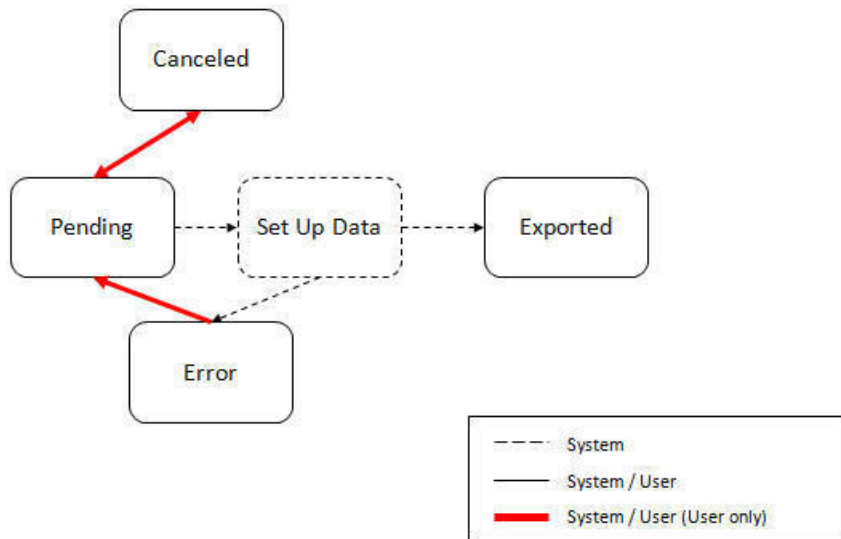

Enter an **Export Description** to provide information about the purpose of the export. Note that this field is not language enabled.

The **Source Environment Reference** is for information purposes. It should be populated with text that provides a meaningful description of the source environment. The default value is the URL of the source environment.

The **Migration File Version** is only visible if the product currently supports creating a file in an earlier [file format version](#). If this element is visible and you are planning to import the file in a target environment that uses an older migration file format version, indicate the lower file format version that you wish the export to use.

Export Lifecycle

The following diagram describes the lifecycle of a Migration Data Set Export (data set).

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- A user may choose to temporarily **Cancel** a pending data set to prevent it from being processed. The user can later return it to the Pending state when desired.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Export Monitor** (F1-MGDPR) selects pending records and transitions them to **Set up data**. Refer to [Running Batch Jobs](#) for more information.
- Set up data is a transitory state that includes the algorithm that does the work of determining the objects to include in the export and group related objects together into a transaction. If everything is successful, the export file is written to the appropriate file location and the record transitions to **Exported**. If an error is detected, the process stops and the record transitions to **Error**.
- If a record is in error and it is possible to correct the error, the record may be transitioned back to Pending to try again.

When the process is marked as **Exported**, the export file can be imported into the target system.

NOTE: The export process creates a file, providing the benefits of having a standalone file. It can be stored in a version control system for audit purposes or provided to others for import purposes.

CAUTION: Under no circumstances should exported data files be edited manually. Doing so could cause data corruption when the file content is applied to the target environment.

NOTE: The export functionality is supported using the business object **Migration Data Set Export** (F1-MigrDataSetExport). The expectation is that implementations will use the delivered base business object and its logic and will have no reason to implement a custom business object for the CMA export process.

Importing and Applying a Migration

The import process is broken down into four general steps: Import, Compare, Approve, Apply. The following points provide an overview of the steps.

- **Import.** The first step covers importing the file and creating appropriate Migration Import records in the target environment to facilitate the subsequent steps.

- **Compare.** The compare step reviews each object that is in the import file and compares the object in the import against the equivalent record in the target environment. The comparison step results in noting which objects are unchanged, which are new (and the appropriate SQL to insert them) and which objects are changed (and the appropriate SQL to update them). Based on user configuration at import time, the objects that qualify for the import may be in a state that requires review or may be pre-approved.
- **Approve.** Once the comparison is complete, the user should review the results. There may be records marked for review. All of these records must be approved or rejected before the import can proceed. Users may choose to suppress individual SQL statements for a given object that is approved. When the user is satisfied with the results of the comparison and has completed the review, the import is marked to proceed to the Apply step. Optionally, a migration import may be configured to automatically apply.
- **Apply.** This is the final step and is the step where the records in the target environment are added or updated. Because of potential high volumes of data and because of possible dependencies between records, this step supports two levels of attempting to apply the records. There is an apply step at the object level and an apply step at the transaction level. This will be described in more detail below.

Import Step

The import process starts with verifying the import directory configured as described in the following topic [Master Configuration - Migration Assistant](#) and ensuring that the exported file is located in that directory. Then, in the target environment, a **Migration Data Set Import** record should be created. The user indicates the file name.

In addition, the user decides what the default status should be for resulting objects.

- The **Default Status for Add** sets the default status for objects that are determined to be *new* during the import comparison process. The default is to automatically set new objects to **Approved** status. Other options are to set any new objects to **Rejected** or **Needs Review** status.
- The **Default Status for Change** sets the default status for objects that are determined to be *changed* during the import comparison process. As with new objects, the default for changed objects is **Approved**, with **Rejected** or **Needs Review** options available.

The user may also configure the **Automatically Apply** flag to **Yes**. This allows for use cases where the migration is repetitive and has been tested and the user feels that there is no need for manual approval. Note that when configuring this setting, neither of the Default Status values may be set to **Needs Review** and at least one must be set to **Approved**.

The file to import contains a list of all the objects included in the export. Any objects that the export step determined to be related have been grouped into “transactions”. Once the Migration Data Set Import is created, the next step is for the system to read in the file and create Migration Transactions and Migration Objects.

By default, the import step creates a Migration Object for each entity in the file. When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. If at least one of the entities included in the migration object record is new and the remaining ones are either new or unchanged then the **Default Status for Add** setting applies to it. If at least one included entity is determined to be changed then the **Default Status for Change** applies to the record. Refer to [bulk import mode](#) for more information.

The following is a portion of the Migration Data Set Import lifecycle as it pertains to the import step.

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Import Monitor** (F1-MGDIM) selects pending records and transitions them to **Ready to Compare**. Refer to [Import Process Summary](#) and [Running Batch Jobs](#) for more information.

The Ready to Compare state has an algorithm that is responsible for reading the related import file and creating the migration transactions and migration objects. The data set remains in this state until the comparison step is complete.

NOTE: A user may choose to **Cancel** a data set. Refer to [Cancelling a Data Set](#) for more information.

The following diagram highlights the relationships of the resulting migration import records.

The migration transaction and migration object each have their own lifecycle that will help manage the subsequent compare and apply steps. At the end of the import step, the status values of the three types of records are as follows:

- Migration Data Set Import is in the **Ready to Compare** state.
- Migration Transaction is in the **Pending** state.
- Migration Object is in the **Pending** state.

NOTE: The import functionality is supported using business objects supplied by the base product. The expectation is that implementations will use the delivered base business objects and their logic and will have no reason to implement a custom business objects for the CMA import process. The base business objects are **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Compare Step

The import step results in the creation of one or more migration objects. Typically, one migration record is created for each record selected in the export based on the export's migration request and its configuration. Related objects are grouped together in migration transactions.

When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. Refer to [bulk import mode](#) for more information.

The next step in the import process is the Comparison step. In this step, the data captured by the import file for each object is compared to the view of that object in the target environment.

To cater for a possible large volume of objects, the comparison is done via a batch monitor. To aide in performance of the process, the monitor is performed on the migration objects so that it can be run multi-threaded. Once the objects are

finished with the comparison, the migration transactions and the migration data set should be updated with an appropriate overall status before continuing to the next step. As a result, the comparison actually requires three steps: Migration Object Comparison, Migration Transaction Status Update and Migration Data Set Export Status Update. The steps are explained in detail in the following sections.

NOTE: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Migration Object Compare

This is the main step of the comparison. The **Migration Object Monitor** (F1-MGOPR) selects pending migration object records and transitions them to **Comparing**. This is a transitory state that includes the algorithm that does the work of comparing. There are various possible outcomes that could occur based on the logic in the algorithm. The following diagram illustrates a portion of the migration object lifecycle that pertains to comparison.

NOTE:

When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)** process (F1-MGOPB) works in the same way to compare business migration objects.

The following points describe the lifecycle.

- When **Pending** records are selected by the monitor batch job, it transitions to **Comparing**. If the migration object refers to one or more pre-compare algorithms, they are executed to [adjust the data prior to comparison](#). Then algorithm will determine the appropriate next state by comparing the source data to the target data.
- Entity related notes:
 - If the record in the migration object is found in the target environment and the data is exactly the same, the record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If the record in the migration object is found in the target environment and the data is different, the algorithm sets the object action value to **Change** and generates the appropriate SQL to be used later in the Apply step to update the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Change setting captured on the Data Set.

- If the record in the migration object is not found in the target environment, the algorithm sets the object action value to **Add** and generates the appropriate SQL to be used later in the Apply step to insert the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Add setting captured on the Data Set.
- When the import is performed in **bulk mode** each included entity is compared separately but the overall status of the record is set as follows:
 - If all included entities are unchanged then the migration object record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If all included entities are either unchanged or changed then the object action value is set to **Change**, corresponding SQLs are generated for the changed entities only and the migration object transitions based on the Default Status For Change setting captured on the Data Set.
 - If all included entities are either unchanged or new then the object action value is set to **Add**, corresponding SQLs are generated for the new entities only and the migration object transitions based on the Default Status For Add setting captured on the Data Set.
 - If some of the included entities are new and some changed then the object action value is set to **Mixed Actions**, corresponding SQLs are generated for the each entity and the migration object transitions based on the Default Status For Change setting captured on the Data Set.
- If there is any issue with attempting to parse the object data from the import, the record transitions to **Error Comparing**.
- If there is any reason that the imported object is not valid for import, the record transitions to **Cannot Apply**. The log will be updated with the error that caused the record to transition to this state. An example is that perhaps the record was exported in a different version of the product and has additional elements that are not recognized in this version.

NOTE: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Transaction Status Update

After the import step, the migration transaction remains in the Pending state until all its objects have completed the comparison step. At that point, the status of the transactions should be updated based on the results of their objects. The **Migration Transaction Monitor** (F1-MGTPR) selects pending migration transaction records and runs its monitor algorithms. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates a portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Pending.

- If any related migration object is in the Error Comparing state, the transaction transitions to **Error Comparing**.
- If all related migration objects are in the Unchanged state, the transaction transitions to **Unchanged**.
- Otherwise, the transaction transitions to **Ready to Apply**. This means that at least one object is in an “apply-able” state.

The transaction remains in the **Ready to Apply** state until a user has approved the data set to move to the Apply step and the transaction's related objects have attempted to apply themselves. This is described in more detail below.

NOTE: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Data Set Import Status Update

Once all the objects and all transactions have been updated via the previous two steps, the migration data set export must be updated based on the results of their transactions. The **Migration Data Set Import Monitor** (F1-MGDIM) selects Ready to Compare data sets and runs its monitor algorithms. Note that this is the same monitor process that is used to select Pending data sets. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates the portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Ready to Compare.

- If any related migration transactions is in the Error Comparing state, the data set transitions to **Error**.
- If all related migration transactions are in the Unchanged state, the data set transitions to **Unchanged**.
- Otherwise, the transaction transitions to **Awaiting Approval**. This means that there are no errors and at least one object is in an “apply-able” state.

The data set remains in the **Awaiting Approval** state until a user decides that the data set and all its records are ready to progress to the Apply step.

NOTE: A user can choose to cancel a data set at any time while it is in progress. Refer to [Cancelling a Data Set](#) for more information.

Approval Step

Once the comparison is complete and the data set transitions to the Awaiting Approval state, a user needs to progress the data set to **Apply Objects** to trigger the Apply step. The following points describe steps a user may take during the approval step.

- If the data set configuration for the Default State for Add and Change was set to **Approved**, then any migration object that is determined to be eligible for the Apply step will be in the Approved state. In this situation, a user may want to review the data set and its transactions and objects to see verify that the results make sense. At that time, the user is able to move an object to Needs Review or Rejected as appropriate.
- If the data set configuration for the Default State for Add and Change was set to **Needs Review** for either option, then each migration object in the Needs Review state must be reviewed and the user must either Reject or Approve each object before moving to the Apply step.

- If the data set configuration for the Default State for Add and Change was set to **Rejected** for either option, the assumption is that the rejected records don't need to be reviewed. But if a user finds a rejected record that shouldn't be rejected, it may be transitioned to Approved (or Needs Review) as appropriate.

A user has the option to mark one or more SQLs within a migration object to be suppressed. In this case, if the migration object is approved, then only the SQLs that are not marked as Suppressed will be applied. This option is useful when importing a record that has many child records. It may be that the user wants to only include a subset of the child records. This may be done by suppressing the child records that should not be included.

Once the user is comfortable with the data set's results and no more objects are in the Needs Review state, the user should transition the record to **Apply Objects**. This will initiate the Apply step.

Alternatively, if the Automatically Apply flag was set to **Yes** when creating the import record, the import data set will progress from **Awaiting Approval** to **Apply Objects**. Refer to [Import Process Summary](#) for more information.

NOTE: Refer to [Maintaining Import Data](#) for details about the pages provided to help the user review a data set and its transactions and objects to help in the approval step.

NOTE: A user can choose to cancel a data set at any time while it is in progress.

Apply Step

The apply step is the step where records in the target environment are added or updated. Like the comparison step, the apply step is actually multiple steps to optimally handle high volume and dependencies between records as smoothly as possible.

NOTE: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Before explaining the apply steps in detail, the following points highlight the type of data that may be included in a given data set.

1. Records that have no foreign keys and therefore no dependencies on other records. Examples: Message, Display Profile.
2. Records that have foreign keys that may already be in the target. Examples: Algorithms for existing algorithm types, To Do Roles for existing To Do Types.
3. Records that have foreign keys that are new records but also part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: Script-based Algorithm Type where the script is also in the migration.
4. Records that have foreign keys that are new records but also part of the migration. CMA did not detect the relationship. This may occur if the referenced foreign key is in a XML or parameter column and the migration plan did not include an instruction to explicitly define the relationship. Example, a Zone that references a visibility script.
5. Records that have circular references where both records are new and are part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: plug-in Script for a BO plug-in spot. The script references the BO and the BO references an algorithm for the script's algorithm type. Another example is when the same record is maintained by multiple maintenance objects and therefore exists in multiple migration objects.

To handle high volume data, the first step in the apply process is to perform the apply logic at the migration object level via a multi-threaded batch job. This should result in all records in categories 1 and 2 above being applied successfully.

For records in categories 3 and 4 above, if a record with a foreign key is added or updated before its related record, the validation will fail. However, if the related record is added first and then the record referring to it is added, validation will pass. The tool handles these dependencies as follows:

- Dependency between master and transaction entities is typically hierarchical and in most cases straight-forward. The tool leverages that knowledge to orchestrate the processing of objects in an optimal way that follows their dependency order

as much as possible. Note that relationship between entities could be complex and this approach does not eliminate all processing order related errors but rather significantly reduce them.

- Dependency between configuration entities is more complex and inter-twined and therefore migration objects are not ordered, i.e. the multi-threaded batch process may not process records in the desired order.
- To overcome the potential issue of processing order related errors, the Apply step has special functionality, described in detail below.

For records in category 5 above, the circular reference will mean that the apply process at the object level will not successfully add or update these records. The apply process at the transaction level will cover these records. This is described in detail below.

Apply Objects

Once the Data Set is in the state of **Apply Objects**, the **Migration Object Monitor - Apply** process (F1-MGOAP) runs to attempt to apply the objects.

NOTE:

When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)- Apply** process (F1-MGOAB) works in the same way to apply business migration objects.

The background process in conjunction with the Apply algorithm have special functionality to ensure records in categories 3 and 4 (above) successfully apply during this step:

- The **Migration Object Monitor - Apply** process is a special one that continually re-selects records in the **Approved** state until there are no more eligible records to process.
- When an error is received in the Apply Object algorithm, the algorithm increments an "iteration count" on the migration object record. If the iteration count does not exceed a maximum count (noted in the algorithm), the object remains in the **Approved** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum defined in the algorithm, the record transitions to the **Error Applying** state.

NOTE: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish.

The following diagram is the portion of the migration object lifecycle that pertains to the Apply step.

At the completion of the Apply monitor process, typically the objects will be in the **Applied** state or the **Error Applying** state. The records in the Error Applying state are in that state for one of two reasons.

- They are in category 5 described above where the records have a circular reference with another record. For this scenario, the Apply Transactions step described below should successfully apply the records.
- There is some other error that is unrelated to the records in the current migration. In this case, manual intervention may be required. Refer to the [Resolving Errors](#) section below for more information.

As shown in the diagram, the Apply Objects algorithm may also detect a reason that the object cannot be applied. This may occur if the object in the target environment has been updated since the comparison step, making the SQL captured at that point no longer applicable. If this occurs, after the current migration is fully applied, the original file may be imported again, and new comparisons can be generated and applied.

Apply Transactions

Ideally, after the Apply Objects step, all the objects are **Applied** or are in **Error Applying** due to the "circular reference" situation. The typical next step is to turn over responsibility to the transactions. The migration transactions can then attempt to apply their objects in bulk.

In order to ensure that multiple background processes are not trying to select migration objects to run the Apply step, the Transactions are only eligible to attempt to "apply my objects" if the Data Set is in the **Apply Transactions** state.

A monitor algorithm (executed by the data set monitor batch process) on the Apply Objects state checks to see if all migration objects are no longer **Approved** or the count of records in **Error Applying** does not exceed a configured limit. If so, it automatically transitions the record to the **Apply Transactions** state.

If the number of objects in **Error Applying** exceeds a configured limit, the monitor algorithm does not automatically transition the record. In that case, a user must determine if the large number of errors can be resolved or manually transition to **Apply Transactions** (despite the large number of errors). The [Resolving Errors](#) section below describes alternative steps that the user may take if there are errors.

Once the Data Set is in the state of **Apply Transactions**, the **Migration Transaction Monitor - Apply** process (F1-MGTAP) runs. It attempts to apply the transaction's objects. If no migration objects are in error, the migration transaction simply transitions to **Applied**. If any of the migration objects are in **Error Applying**, the background process and the Apply algorithm have special functionality to try to overcome dependencies in migrated objects:

- The Apply algorithm selects all migration objects in error and performs all their SQL, then validates all the records. If there are objects in the transaction with circular references, they should pass validation at this point.
- Because there may still be some dependencies across transactions, similar error handling described in the Apply Objects step occurs here. When an error is received in the Apply Transaction's Object algorithm for any of the objects in the transaction, the algorithm increments an "iteration count" on the migration transaction record. If the iteration count does not exceed a maximum count (noted in the algorithm), the transaction remains in the **Ready to Apply** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum, the record transitions to the **Error Applying** state. Note that if any objects in the transaction are in error, none of the objects are applied. They all remain in error.
- The **Migration Transaction Monitor - Apply** process is a special one that continually re-selects records in the **Ready to Apply** state until there are no more eligible records to process.

NOTE: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish, erasing the benefit of the iteration processing.

The following diagram is the portion of the migration transaction lifecycle that pertains to the Apply step illustrating the points above.

If at the end of the transaction level Apply process there are transactions in error (and therefore there are still objects in error), a user must review the errors and determine how to fix them. Refer to the [Resolving Errors](#) section below for more information.

Resolving Errors

As mentioned in the previous sections, errors may be received after the Apply Objects process runs. If the number of records in error is below a certain limit (and the data set monitor batch job is submitted to execute the monitor algorithms) the system will automatically transition the data set to the **Apply Transactions**. If the monitor batch job is not run or if the number of objects in error exceeds a certain limit, a user must make the decision after viewing the errors in the Objects in Error zone on the [Migration Data Set Import](#) portal.

- If the errors appear to be dependency related, the user can decide to let the "transactions apply their objects" and transition the data set to **Apply Transactions**, described above.
- If the errors appear to be related to an outside issue that can be manually resolved, the user may choose to fix the issue and redo the Apply Objects step.
- The user may also decide to reject one or more objects to remove them from the migration.

After the Apply Transactions step, if there are still errors, a user must review the records and determine how to proceed. Errors are visible in the **Transactions in Error** zone on the [Migration Data Set Import](#) portal.

- The user may decide to reject one or more objects to remove them from the migration.
- The user may manually resolve an issue external to the migration and then decide to do one of the following:
 - Redo the **Apply Objects** step. This is recommended if there are a large number of Objects still in error and not a large number of dependencies expected. The benefits of running the Apply Objects multi-threaded will ensure that the process runs efficiently.
 - Redo the **Apply Transactions** step.

Because the objects and transactions are in Error Applying, in order to "retry" the Apply step after manually fixing an error, the system needs to move the records back to the state that allows them to be picked up by the appropriate Apply process. For migration objects, records need to be moved back to **Approved**. For migration transactions, records need to be moved back to **Ready to Apply**. The following points describe the Retry logic for migration objects.

- If a user decides to **Retry Objects** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Objects** state. At this point the Migration Object monitor must be run.
- The monitor on the **Error Applying** state for the objects detects that the data set is in the state of **Retry Objects** and that triggers the transition back to **Approved**.
- The next step is to transition the data set from **Retry Objects** to **Apply Objects**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the objects are eligible to be picked up by the object level Apply process.

Analogous logic exists for the migration transactions.

- If a user decides to **Retry Transactions** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Transactions** state. At this point the Migration Transaction monitor must be run.
- The monitor on the **Error Applying** state for the transactions detects that the data set is in the state of **Retry Transactions** and that triggers the transition back to **Ready to Apply**.
- The next step is to transition the data set from **Retry Transactions** to **Apply Transactions**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the transactions are eligible to be picked up by the transaction level Apply process.

The retry logic may also occur when transitioning between the Apply Objects and Apply Transactions depending on whether or not there are errors. The following scenario highlights this point.

- After the **Apply Objects** step there are objects in **Error Applying**. The data set transitions to **Apply Transactions** and the Apply step is done at the transaction level.
- After the **Apply Transactions** step there are transactions in **Error Applying**.
- User chooses to try to apply objects again (by clicking **Retry Objects**). The steps outlined above for retrying objects are followed at this point.
- After the apply objects, user may choose to retry objects again (after fixing errors if applicable).
- At some point the user will transition to **Apply Transactions** again. If there are transactions in **Error Applying**, the system will automatically transition the data set to **Retry Transactions** and the steps outlined above for retry transactions are followed.

Finalize Apply Step

Once all the migration objects for a migration transaction are in a final state (**Applied**, **Rejected** or **Cannot Apply**), the migration transaction transitions to the **Applied** state. Once all the migration transactions are in the **Applied** state, the Migration Data Set record transitions to the **Completed** and the import is complete.

NOTE: To review the full lifecycle for each record, refer to the Business Object - Summary tab in the application metadata for the base business objects **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Adjusting Data Prior to Comparing

There are reasons that the data you are importing requires some adjustment before applying it in the target environment. In such cases, an algorithm plugged into the [migration plan](#) primary instruction may be used to adjust the data when importing. This algorithm is executed by the comparison algorithm before any comparison is performed. Algorithms of this system event receive the view of the source record (being imported) and the view of the existing record in the target region, if it exists. The data is provided using the physical BO of the migration plan's maintenance object. The algorithm may make changes and pass a new view of the record that should be used for the comparison. This system event supports multiple algorithms that are executed in sequence. Each algorithm receives the original record's data, the target record's data (if applicable) and the 'new' view of the data (as populated by previous algorithms, if any). The final 'new' view of the data is used for the object comparison. The system includes the algorithms linked to the primary instruction of the migration

plan from the source environment. If the system finds any additional pre-compare algorithms linked to the migration plan's primary instruction in the target system, those algorithms are also executed.

FASTPATH: Refer to [Base Business Objects](#) for more information about physical BOs.

Some examples of records that may require import algorithms.

- Batch Control references its next batch sequence number along with snapshot information like the last run date / time. This information is only relevant with respect to its environment. The instruction for a batch control can include an algorithm to not overwrite the batch sequence number when copying a batch control.
- Some products include administrative objects that reference a master data object. Master data objects are not copied as part of CMA. An import algorithm may be used to adjust the referenced master data foreign key when importing, for example to reset it (or not overwrite when updating). If the algorithm knows how to find the appropriate master data record to link, that may also be included.
- If you are importing data that from a source environment on a lower version, if the object you are importing has been enhanced in the latest release with a new required field, you may need to provide an algorithm to populate data in that field.

Note that it is possible to use the algorithm to "reset" the source data as a way of indicating that the record should not be imported. For these situations, the migration object comparison step will transition the record to **Unchanged** and will use an object action value of **Canceled**. (Note that object action is a simple lookup value. The record is not transitioned to the **Canceled** BO state as to reserve that status for user initiated cancellations of the object or one of its parent records). This technique not expected to be used often because ideally using appropriate selection criteria at export time should ensure that the only records exported are those that should be imported.

NOTE: Legacy 'Import' system event. The system originally provided an Import system event / plug-in spot. The purpose of algorithms for this plug-in spot were similar in that they were meant to adjust imported data prior to adding or updating. The algorithms were executed in the Apply step. The logic does not allow for easily interacting with the record using a BO. This makes it difficult to use a plug-in script as the plug-in type. In addition, it is difficult to update elements in an XML column. The support for the plug-in spot will be removed in a future release. Algorithms to adjust the data should be using the pre-compare system event.

Import Process Summary

The following table summarizes the steps required to complete the import process from start to finish. Note that this section **only a summary** and assumes that you are familiar with the details described in the previous sections. It highlights what steps are manual and what steps are performed by a batch monitor process. For each step, the table highlights the Next Action sequence that would occur. For the Apply steps, there are two parts where multiple next actions are possible based on whether there are errors and the user's decision on how to resolve the error. Refer to [Resolving Errors](#) for more information. The possible next actions have the same sequence with a letter following the sequence highlighting the action to take based on the results of the previous step.

NOTE: When running the Apply batch jobs, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.

Also note that a sequence and action marked in bold is considered the "normal path".

When using [separate batch processes for business data](#) any reference to a migration object monitor batch process applies also to the business data related batch controls.

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
Import	10	Create Import record	Manual	Migration Data Set Import - Add		Migration Data Set Import - Pending	11
	11	Import file	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Ready to Compare Migration Transaction - Pending Migration Object - Pending	20
Compare	20	Migration Object Compare	Batch		F1-MGOPR - Migration Object Monitor [When using separate business data processes submit also F1-MGOPB (Migration Object Monitor (Business))]	Migration Object - Approved, Needs Review, Rejected, Unchanged or Error Comparing	21
	21	Migration Transaction status update	Batch		F1-MGTPR - Migration Transaction Monitor	Migration Transaction - Ready to Apply, Unchanged or Error Comparing	22
	22	Migration Data Set Import status update	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Awaiting Approval, Apply Objects (if configured for Automatic Apply), Unchanged or Error	30
Approval	30	Review comparison results, approve / reject as needed (This step is skipped if the data set is configured for Automatic Apply)	Manual	Migration Data Set Import, drill in to the Transactions / Objects as necessary.		Migration Object - Approved or Rejected (no records should be in Needs Review) Migration Data Set Import - Apply Objects	40
Apply	40	Apply Objects	Batch		F1-MGOAP - Migration Object Monitor - Apply [When using separate business data processes submit also	Migration Object - Applied or Error Applying	41 Appropriate next action is based on error review, if applicable.

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
					F1-MGOAB (Migration Object Monitor (Business) - Apply)]		
	41a	Migration Data Set Import status update - auto transition to Apply Transactions. Only applicable if the number of migration objects in Error Applying is below a threshold	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Transactions	42
	41b	Migration Data Set Import status update - manual transition to Apply Transactions. Occurs if user reviews errors and determines that they may be resolved in the Apply Transaction step.	Manual	Migration Data Set Import - click Apply Transactions			
		System detects that all the transactions are in the Ready to Apply state and proceeds to the Apply Transactions state.				Migration Data Set Import - Apply Transactions	42
		System detects that there are transactions in the Error Applying state and transitions instead to the Retry Transactions state.				Migration Data Set Import - Retry Transactions	45
	41c	Migration Data Set Import status update - manual transition to Retry Objects. Occurs if user reviews errors and decides to fix an external error and wants	Manual	Migration Data Set Import - click Retry Objects		Migration Data Set Import - Retry Objects	44

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
		to try the batch level Apply again at the object level.					
	42	Apply Transactions	Batch		F1-MGTAP - Migration Transaction Monitor - Apply	Migration Transaction - Applied or Error Applying Migration Object - Applied or Error Applying	43 Appropriate next action is based on error review, if applicable.
	43a	Migration Data Set Import status update - auto transition to Completed Applicable if all transactions are Applied	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Completed.	N/A
	43b	Migration Data Set Import status update - manual transition to Retry Objects. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Object level.	Manual	Migration Data Set Import - click Retry Objects		Migration Data Set Import - Retry Objects	44
	43c	Migration Data Set Import status update - manual transition to Retry Transactions. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Transaction level.	Manual	Migration Data Set Import - click Retry Transactions		Migration Data Set Import - Retry Transactions	45
	44	Migration Objects status update from Error Applying back to Approved. Occurs if user chose to Retry Objects.	Batch		F1-MGOPR - Migration Object Monitor [When using separate business data processes submit also F1-MGOPB (Migration	Migration Object - Approved	

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
					Object Monitor (Business))]		
		Migration Data Set Import status update from Retry Objects to Apply Objects	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Objects	40
	45	Migration Transactions status update from Error Applying back to Ready to Apply. Occurs if user chose to Retry Transactions or if the user transitions to Apply Transactions and the system detects that there are Transactions in the Error Applying state.	Batch		F1-MGTPR - Migration Transaction Monitor	Migration Transaction - Ready to Apply	42
		Migration Data Set Import status update from Retry Objects to Apply Objects	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Transactions	42

The following table summarizes the batch monitor jobs that are used in the import process. You can see that there are special monitor processes for the Apply step for both the Object and Transaction. However, for all other states that have monitor logic, the standard monitor process for that MO is used.

Batch Control	Description	Comments
F1-MGDIM	Migration Data Set Import Monitor	Processes data set records in the following states: <ul style="list-style-type: none"> • Pending • Ready to Compare • Apply Objects • Retry Objects • Apply Transactions • Retry Transactions
F1-MGTPR	Migration Transaction Monitor (Deferred)	Processes transaction records in the following states: <ul style="list-style-type: none"> • Pending • Error Applying
F1-MGTAP	Migration Transaction Monitor - Apply	Processes transaction records in the Ready to Apply state where the data set is in the Apply Transactions or Canceled state. <p>NOTE: Be sure to set the number of threads to a number that does not exceed the</p>

Batch Control	Description	Comments
		number of threads supported by the thread pool worker.
F1-MGOPR	Migration Object Monitor	Processes object records in the following states: <ul style="list-style-type: none"> • Pending • Needs Review (check for Data Set cancellation) • Error Applying
F1-MGOPB	Migration Object Monitor (Business) Applicable only when separate business data processing is enabled.	Similar to F1-MGOPR (Migration Object Monitor) but restricted to business data migration objects.
F1-MGOAP	Migration Object Monitor - Apply	Processes object records in the Approved state where the data set is in the Apply Objects or Canceled state. NOTE: Be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.
F1-MGOAB	Migration Object Monitor (Business) - Apply Applicable only when separate business data processing is enabled.	Similar to F1-MGOAP (Migration Object Monitor - Apply) but restricted to business data migration objects.

Refer to [Running Batch Jobs](#) for more information about managing the batch jobs, including ways to automate the above steps.

Canceling a Data Set

A user may choose to **Cancel** a data set to prevent it from being processed at any point during the process.

If related migration transactions or migration objects have already been created, they will not be canceled as part of the data set getting canceled (due to possible high volumes of related records). They will be canceled the next time an appropriate monitor batch process runs. The child records checks to see if the data set has been canceled prior to any state transition.

Additional Note Regarding Imports

The following points describe miscellaneous comments related to Migration Import.

- CMA relies on the fact that database referential integrity constraints are not in place, and that the SQL statements can be run in any order within the transaction. Any archiving solution that requires referential integrity constraints (such as Information Lifecycle Management) would not be possible on this data. Given that CMA migrations comprise administrative data and not transactional data, this should be a reasonable exception.
- The validation that is performed is only via the **Page Validate** service. BO validation algorithms are not executed. Page validation does not include validation of the business object against the schema (for example, for required fields, field sizes, etc.).
- If multiple migration requests are exported at the same time, on the import side, you should consider importing, reviewing, and applying an entire file/data set before moving on to the next one. The reason is that if objects are included in more than one file, two sets of "inserts" will be generated, but only the first will succeed. The second will cause the object to transition to "Cannot Apply". If instead you wait until the first file is completed before importing the second, the second data set will not generate any SQL for the object, since it has already been inserted. It's a matter of efficiency: If you first import all files and then try to apply all, you'll have to identify the duplicated object as an error and then mark the object as rejected before applying the transaction. This may also be avoided by using a Group migration request to include all objects in one file rather than multiple files.

- The system provides an algorithm to purge "unchanged" migration objects for a given migration data set. This may be plugged in as a BO exit algorithm on the **Ready to Compare** state for the Migration Data Set Import business object (**F1-MigrDataSetImport**).

The following points describe miscellaneous comments related to importing a business data set in [bulk mode](#).

- The number of entities included in each migration object is captured on the migration object record.
- The comparison step only generates SQLs for new or changed entities. SQLs are not generated for unchanged entities.
- Searching for migration objects based on their included entities is only supported for entities that were determined as new or changed. In other words, this type of search by included entities is only possible after the comparison step is performed.

Caching Considerations

There are two important caching considerations when using CMA to migrate administrative data.

- The "apply" batch processes update data. As described in [Batch Cache](#), if any batch job is updating data marked as "cached for batch" it must be run in a special thread pool. Contact your system administrator and ask for the name of a thread pool that has turned off caching. This thread pool name must be entered in the batch controls used for CMA processing in the **Thread Pool Name** parameter.
- After a successful migration, the target region now has new administrative data which needs to be part of various caches. It is recommended to flush the server cache (which will trigger a 'global' flush of the cache). If the thread pool workers in the target region are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing.

FASTPATH: Refer to [Caching Overview](#) for more information.

FASTPATH: Refer to [Running Batch Jobs](#) for more information about running CMA batch jobs.

Maintaining Import Data

This section describes the portals provided to add, view and maintain migration import data.

Migration Data Set Import

Use the Migration Data Set Import portal to view and maintain migration data set import records. Refer to [Importing and Applying a Migration](#) for an overview of the import process.

Navigate using **Admin > Implementation Tools > Migration Data Set Import**. You are brought to a query portal with options for searching for import data sets. In addition, the query provides an option to specifically search for data sets that have either objects in error or transactions in error. Once a data set has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are visible on the **Main** tab:

- **Migration Data Set Import.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current data set across the various statuses.

The following zones are visible on the **Transactions** tab:

- **Migration Data Set Transactions in Error.** This zone is only visible if there are transactions for this data set in a non-final state that have errors. It indicates the error for each transaction. A user may use this zone to review errors

after the monitor batch job to apply transactions completes. The errors received when attempting to apply objects at the transaction level may differ from those received when attempting to apply objects at the object level. A transaction log is created for each object error received and these exceptions are shown in this zone.

NOTE: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Transactions.** This zone is visible once the [Import Step](#) has occurred and lists all the transactions that are related to the data set. To see more information about a specific migration transaction, click the hypertext for its ID. This brings you to the [Migration Transaction](#) portal.

The following zones are visible on the **Objects** tab:

- **Migration Data Set Objects in Error.** This zone is only visible if there are objects for this data set in a non-final status that have errors. It indicates the error for each object. A user may use this zone to review errors after the monitor batch job to apply objects completes. Using the error information shown, the user can choose to drill into the record to transition it to **Error Applying** or choose to manually fix the cause of the errors and click **Retry Objects**. The user may also choose to select one or more records to **Reject**.

NOTE: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Impacted Object Summary.** This zone is visible once the [Import Step](#) has occurred and lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.

Migration Transaction Portal

This page appears after drilling into a specific migration transaction from the migration data set portal or from the migration object portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The following zones are visible on the main tab:

- **Migration Transaction.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Migration Transaction Objects.** This zone lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current transaction across the various statuses.

Migration Object Portal

This page appears after drilling into a specific migration object from the migration data set portal or from the migration transaction portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The **Migration Object** zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.

The **Migration Object - List of SQL Statements** zone lists the SQL statements that have been generated as a result of the comparison step. A check mark in the Suppressed checkbox indicates that the SQL for that row will not be applied during the apply step.

The **Migration Object - Algorithms** zone displays any pre-compare algorithms that are associated with the migration plan for this migration object.

Running Batch Jobs

There are several batch jobs that are part of the CMA process, especially the import step (which are highlighted in [Import Process Summary](#)). And in some cases, a single batch jobs may process multiple states in the same business object lifecycle. Implementations must decide the best way to manage the batch job submission depending on how they plan to work.

- **Batch scheduler.** If an implementation wishes to put these batch jobs in the batch scheduler, a given job may need to be included several times to manage progressing the records to completion.
- **Timed Batches.** The batch controls can be configured as timed batches so that they run every N minutes based on the setting. This allows for the batch jobs to run periodically and process whatever is ready. A user doesn't have to manually submit a batch request. Navigate to the [Batch Control](#) page and select the appropriate batch controls. For each one, change the Batch Control Type to **Timed**. Fill in the additional information that appears for timed batches.
- **Event Driven.** The system provides BO enter plug-in algorithms and batch control post processing plug-in algorithms that automatically submit the appropriate next batch job for that step in the process. This allows for as much automation as possible for the steps that don't require user input. Note that configuration is required because the BOs / batch controls are not configured for this scenario by default. The following table highlights the BO and status where an algorithm may be plugged in and the name of the algorithm to use.

Business Object	Status	Algorithm
Migration Data Set Export	Pending	F1-MGDPR-SJ (Submit Migration Data Set Export Monitor).
Migration Data Set Import	Pending	F1-MGDIM-SJ (Submit Migration Data Set Import Monitor).
	Ready To Compare, Retry Objects	F1-MGOPR-SJ (Submit Migration Object Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOPRB-SJ (Submit Migration Object Monitor (Business)).
	Apply Objects	F1-MGOAP-SJ (Submit Migration Object Apply Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOAPB-SJ (Submit Migration Object Monitor (Business)).
	Apply Transactions	F1-MGTAP-SJ (Submit Migration Transaction Apply Monitor).
	Retry Transactions	F1-MGTPR-SJ (Submit Migration Transaction Monitor).

The following table highlights the batch controls where an algorithm may be plugged in and the name of the algorithm to use.

Batch Control	Algorithm
F1-MGTPR (Migration Transaction Monitor)	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGTAP (Migration Transaction Monitor - Apply)	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGOAP (Migration Object Monitor - Apply) When using separate batch processes for business data update also this batch control:	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGOAB (Migration Object Monitor (Business) - Apply)	
F1-MGOPR (Migration Object Monitor) When using separate batch processes for business data update also this batch control:	F1-MGTPR-NJ (Submit Migration Transaction Monitor).

- **Manual submission.** The user managing the CMA import process submits the appropriate batch jobs on demand when a particular step is ready. Navigate to [Batch Job Submission](#), select the appropriate batch control and fill in the parameters as needed.

Note that for the CMA batch processes used to migrate administrative data, there are multiple important caching considerations. Refer to [Caching Considerations](#) for more information.

CAUTION: Be sure that the Thread Count set when submitting the batch job does not exceed the number supported by the thread pool. Otherwise the extra threads will wait until the supported number of threads are finished, possibly resulting in a large number of errors in the Apply steps.

Refer to the parameter descriptions in the batch control metadata for more information about filling in the parameters.

For additional details on submission controls, refer to the topic [Batch Job Submission - Main](#) in the Batch Jobs section.

CMA Reference

This section provides additional reference information.

Framework-Provided Migration Configuration

This topic describes special information relating to migration objects provided for use by CMA in the product. Additional objects may be provided by your specific product. Any special information for objects is provided separately in each product's documentation.

The following points highlight some information about Framework-provided migration requests. Navigate to the migration request page in the application to view the details of all provided objects.

- Several base migration requests are supplied to logically group system and administrative tables. For example, there is a migration request for Framework System Configuration **F1-SystemConfig** where most system configuration objects are included. There is another one provided for CMA related configuration objects.
- The system supplies a group migration request **F1-FrameworkConfig** (Framework Configuration), which includes several other migration requests. The expectation is that this migration request includes all the typical objects that are included in a wholesale migration. Your specific product may include this migration request into its own group migration request to support a wholesale migration of all the framework and product administrative tables. An implementation may choose to build a custom group migration request. In this case, review the various migration requests provided by base to see if any may be included as components for the custom migration request. Then any new migration plans added to the base migration request in future releases are automatically included in future migrations.
- There are several different security related migration requests that include different combinations of migration plans to support multiple possible business requirements related to security migration. Note that the security migration request included in the above mentioned group migration request is the one that does not include users. If your implementation wants to copy users to a target environment, refer to [Importing Data that References a User](#) for some considerations.

NOTE: Refer to your specific product's CMA documentation for its recommendation on which migration requests to use for a full migration of framework and product administrative tables.

The following points highlight some information about the Framework-provided migration plans. Navigate to the migration plan page in the application to view the details of all provided objects.

- Fields and characteristic types are not migrated with an object (like a business object or a data area) unless specifically indicated.

- The **Application Service** used by an object is migrated only if it is CM-owned.
- The **Batch Control** object optionally references a User (for 'timed' batches). Refer to [Importing Data that References a User](#) for some considerations about copying the user. Also note that when running a batch job, snapshot information is captured on the batch control. Updates like this increment the version number. If a batch control record is part of the migration and the comparison step has detected a change to the batch control, the Apply step will error out for this batch control if a batch job is submitted between the compare and apply step.

NOTE: CMA batch controls that are part of the import step are executing and as such, the system does not include these records in a migration. If your implementation changes default parameters for any of the batch controls, the recommendation is to manually make those changes to the target region.

- The base migration plans for MO and BO include instructions to copy option types that use foreign key references to refer to other objects. Note that the data stored in the options are not validated, so defining these instructions is not required when doing wholesale migrations. However, including subordinate instructions for foreign key references is useful for targeted migrations to ensure that the related data is included in the migration. If you add additional MO or BO option types that use foreign keys and you want to support targeted migrations, you must create custom migration plans and requests for MO and BO, respectively to include these referenced objects in the migration plan. Note that you do not need to duplicate the instructions in the base migration plans. You may define the additional migration plans to only have the additional custom option types. When submitting a migration request for MO or BO you must include both the base migration plans and the custom migration plans in the request.
- For scripts, schema-based objects and zones, the migration plans provided by the product migrate, through constraints, some of the typical associated data with them. However, data specified through alternate formats (such as through **Edit Data** steps in scripts, referenced in schemas for schema-based objects, or data from mnemonics in zone parameters, etc.) are not identified and combined in the same transaction. The iterative processing functionality of the import step should resolve any timing issues that may result in validation errors for these types of objects.
- There are two migration plans for **Scripts**. The migration plan **F1-ScriptOnly** migrates just the script and its **Application Service** (provided the Application Service is CM-owned). The migration plan **F1-Script** includes most related objects, but does not migrate any objects referenced in the edit data area steps. It does not move the **Function** maintenance object. It may be included in any appropriate custom targeted migration request where scripts and related data should be migrated.
- If your implementation includes a **Feature Configuration** setting for the **F1_DBCONINFO** entry that will be included in a migration request, be sure that the import user on the target region has the appropriate security rights to this entry (**Administrator** access mode for the Feature Configuration application service (**CILTWSDP**)).
- The common attachments in the Attachment maintenance object may be considered administrative data to include in a migration. Because this MO has a system generated key, as described in [Administrative Data with System Generated Primary Keys](#), it uses a logical key of the file name and the creation date to determine if the record exists in the target environment. In addition, this MO contains administrative data (common attachments) and non-administrative data (owned attachments). To try to minimize the possibility of key "collision", new common attachments receive a generated key that includes a zero in the middle whereas owned attachments receive a generated key that does not have a zero in the middle.
- The Menu maintenance object has a user defined key, however, its menu lines and menu items have system generated keys. To avoid the possibility of overriding a menu line or menu item incorrectly, the menu MO will check the menu line's menu name in the source and target to be sure they match and will check the menu item's menu line in the source and target to be sure they match otherwise an error will be issued in the comparison step.
- For the system messages, the product provides three different migration plans.
 - Message Category and its Messages (F1-MessageCategory). This migration plan is included in the **F1-SystemConfig** migration request.
 - Message Category (F1-MessageCategoryOnly). This migration plan is provided to support a targeted migration where an implementation has created a custom message category and wants to move it but doesn't want to move all its messages.

- Message (F1-Message). This migration plan is provided to support a targeted migration where only specific messages within a message category should be migrated.
- For lookup values, the product provides two different migration plans.
 - Lookup Field and its Values (F1-Lookup). This migration plan is included in the **F1-SystemConfig** migration request.
 - Lookup Value (F1-LookupValue). This migration plan is provided to support a targeted migration where only specific lookup values within a lookup field should be migrated.
- There are some system data objects where no information in a base delivered record may be modified by an implementation. For these records, the base delivered migration requests include selection criteria to only select CM-owned records (because the base records will always exist in the target region assuming both regions have the same release). An example is Algorithm Type. The **F1-SystemConfig** migration request only includes CM-owned algorithm types. However, many system data objects support custom changes to one or more fields, for example the Zone object allows an implementation to override the zone text or certain parameters. Other system data objects support custom additions to a collection. For example, the Maintenance Object allows an implementation to add algorithms or options. For the migration plans related to these system data objects, all records are included in the base delivered migration requests to allow for any customized configuration to be migrated. It means that during the Import / Compare step many base delivered objects that are not customized will be marked **Unchanged**.
- Many of the integration related maintenance objects that include references to environment-specific data, such as Message Senders. This data should be migrated with extreme care. When appropriate, consider taking advantage of URI substitution. Refer to [Referencing URIs](#) for more information.

Facts

Fact is an optional configuration tool for simple workflow-type business messages or tasks. The base package does not provide a dedicated Fact user interface because fact is generic by design. Implementations configure their own user interface to visualize the desired custom business process. The topics in this section describe the generic Fact entity and how it can be customized.

Fact Is A Generic Entity

The Fact maintenance object is a generic entity that can be configured to represent custom entities and support automated workflows for a variety of applications. Each fact references a business object to describe the type of entity it is. A status column on the fact may be used to capture its current state in the processing lifecycle controlled by its business object.

The maintenance object also supports a standard characteristic collection as well as a CLOB element to capture additional information.

Fact's Business Object Controls Everything

A fact's business object controls its contents, lifecycle and various other business rules:

- Its schema defines where each piece of information resides on the physical Fact maintenance object.
- It may define a lifecycle for all fact instances of this type to follow. Each fact must exist in a valid state as per its business object's lifecycle definition.
- It may define validation and other business rules to control the behavior of facts of this type.

FASTPATH: For more information about business objects, refer to [The Big Picture of Business Objects](#).

Fact Supports A Log

The Fact maintenance object supports a log. Any significant event related to a Fact may be recorded on its log. The system automatically records a log record when the fact is created and when it transitions into a new state. In addition, any custom process or manual user activity can add log entries.

FASTPATH:

Refer to [State Transitions Are Audited](#) for more information on logging.

Conversion

This section describes the overall conversion process and the tools provided to support it.

Understanding The Conversion Process

When you're ready to convert data from your legacy system, you will have analyzed your processing requirements according to your business and organizational needs and set up the control tables accordingly. After the control tables are set up, you are ready to load data into the system from your legacy system.

There are two table owners in the system database. We refer to the first owner as **staging** and the second owner as **production**. The staging owner is linked to the tables into which you insert your pre-validated data. The production owner is linked to the tables used by your production system.

NOTE: It's important to notice that **control tables exist only in production**. In staging, they exist as views to the production schema. Refer to [Multiple Owners In A Single Database](#) for more information about table ownership.

The conversion effort involves several steps as illustrated in the following diagram:

The following points briefly outline each of the above tasks:

- **Load Legacy Data.** During this step, your legacy data is loaded into the system. Notice that you are not migrating this data directly into production. Rather, your rows are loaded into tables that are identical to the production tables; they just have a different owner. Mapping legacy data into the system is probably the most challenging part of the conversion process because the system is a normalized database (and most legacy applications are not).
- **Validate Staging.** During this step, the system validates the data you loaded into the staging tables. Note that validation rules validate your staging data using the control tables that have been set up in production.
- **Assign Production Keys.** During this step, the system allocates random, clustered keys to the rows in the staging database.
- **XML Resolution.** During this step, the system resolves legacy keys that may be mapped to an XML storage field with new values that were assigned in the key assignment step.
- **Insert Rows Into Production.** During this step, the system populates your production tables with rows from the staging. When the rows are inserted, their prime keys and foreign keys are reassigned using the data populated in the key assignment and XML resolution steps.
- **Validate Production.** During this step, you rerun the object validation processes, but this time against production. We recommend performing this step to confirm that the insertion programs have executed successfully.

NOTE: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

This section further discusses concepts and guidelines related to the conversion process.

Conversion Entities

Conversion is enabled for selected master and transaction maintenance objects. In the same way, only a subset of a maintenance object's tables are enabled for conversion.

The following is provided for each maintenance object that supports conversion:

- An [entity validation](#) batch control. This batch process validates data in staging and can also be run to validate data in production.
- A [key assignment](#) batch control for each **table** that is eligible for conversion and has a system-generated key.
- An [XML resolution](#) batch control if the maintenance object has at least one table that includes an XML storage field.
- An [insertion to production](#) batch control for every **table** of the maintenance object that is eligible for conversion.

You may review the conversion configuration provided for an entity and more using the [Conversion Entity Dashboard](#) portal.

Conversion Steps

The following sections provide more details about the steps in the conversion process.

NOTE: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

Load Legacy Data Into Staging Tables

This section provides some high level discussion about mapping and loading legacy data to the system's staging tables.

Mass Load Utility

Unless in a Cloud installation, you can use any method you prefer to load data from your legacy application. However, we recommend that you investigate your database's mass load utility (as opposed to using insert statements) as the mechanism to load the staging tables. In addition, we strongly recommend that you disable the indexes on these tables before populating these tables and then enable the indexes after populating these tables.

NOTE: In a Cloud installation, refer to the "Data Conversion Support for Cloud Implementations" for more information about the various tools provided to support database related conversion tasks.

Populating Keys

Some tables in the staging database have keys that are system-assigned random numbers. Special consideration should be given when populating these keys. Refer to [A Note About Keys](#) for more information on how to properly populate these tables. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields.

Populating Characteristic Tables

There are many maintenance objects that include a characteristic table used to capture miscellaneous information about the object. Most of these tables include an indexed column used when searching by characteristic value called Search Characteristic Value. During conversion and depending on the type of characteristic, this column must be populated as follows:

- **Predefined.** Populate search characteristic value with the contents of the characteristic value column converted to upper case.

- **Ad hoc.** Populate search characteristic value with the first 50 bytes of the ad hoc characteristic value column converted to upper case.
- **Foreign key.** Populate search characteristic value by concatenating the values of each foreign key characteristic value column to a maximum of 50 bytes.

Validate Information In The Staging Tables

During the first validation step, the system validates the data you loaded into the staging tables. This section provides some high level discussion about the validation process.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion must be validated using its respective entity validation conversion batch process. These are classic background processes that can also be run against production data.

These processes are multi-threaded and have no dependency on other processes.

Validation Mode

By default, each entity is fully validated for schema as well as entity validation rules, at the maintenance object and business object level. The batch process performs the same business rules that are used to validate data added by users in your production system. You may restrict the batch process to perform schema validation only or entity validation rules only using a batch parameter. This may be useful in identifying common data issues in preliminary runs.

Random Sample Mode

By default all records are selected for validation. The "Process Every Nth" batch parameter allows you execute this process in a random-sample mode to highlight pervasive errors. In this mode, you are actually telling the batch process to validate every N records.

We strongly recommend validating each entity in the following steps:

- Execute the validation batch process in random-sample mode.
- Review and correct the errors. Note, you can use the base package's transactions to correct an error if the error isn't so egregious that it prevents the object from being displayed on the browser.
- After all pervasive errors have been corrected; re-execute each object's validation batch process in all-instances mode to highlight elusive, one-off errors.

Reported Errors

Errors encountered during validation are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the validation process using the [Conversion Entity Dashboard](#) portal.

Recommendations To Speed Up Validation

The following points describe ways to accelerate the execution of the validation process:

- Ensure that statistics are recalculated after data has been inserted into the staging tables.
- Execute the process multi threaded.
- Execute shorter running validation processes (e.g., less records) first so that the error data can be analyzed while other processes are busy running.
- Remember that validation can be run in random-sample mode. We recommend running these batch processes using a large sample value for this parameter until the pervasive problems have been rectified.

NOTE: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Another use for these programs

In addition to validating your objects after conversion or an upgrade, the validation programs have another use. Say for example, you want to experiment with changing the validation of a business entity and you want to determine the impact of this new validation on your existing records. You could change the validation and then run that entity’s validation batch process- it will produce errors for each record that fails the new validation.

Allocate Production Keys

During the key assignment step, the system assigns a new key for each legacy key for a table that its prime-key requires a system-generated random key. The conversion process allocates new prime keys to take advantage of the system's parallel processing and data-clustering techniques in the production system (these techniques are dependent on randomly assigned, clustered keys).

The topics in this section provides some high level discussion about the key assignment process and describe the background processes used to assign production keys to the staging data.

The Old Key / New Key Table

It's important to understand that the system does not overwrite the prime-keys on the rows in the staging database, as this is a very expensive IO transaction. Rather, a series of tables exist that hold each row's old key and the new key that will be assigned to it when the row is [transferred into the production database](#). We refer to these tables as the "old key / new key" tables.

The convention "<1st letter of owner flag>K_<table_name>" is used to denote the old key / new key table name. For example, the old key / new key table for CI_ACCT is called CK_ACCT.

The insertion batch process that transfers the rows into the production database use the new key for the main record of the key along with any other record where this key is a foreign key. In the same way, the XML resolution process resolves conversion foreign keys residing in XML storage fields and replaces them with their corresponding new keys from these table.

A Batch Process Per Table

A key assignment batch process is provided for each table that has a system-generated key and belongs to a maintenance objects that is eligible for conversion. The batch process is responsible for populating the corresponding old key / new key table (i.e., you don't have to populate these tables). These processes are single threaded. Refer to a table’s corresponding key assignment batch process for more information.

Key Assignment Dependencies

Most tables with system-generated keys do not inherit part of their key from another table’s key. Their corresponding key assignment batch process have no dependencies and can therefore be executed in any order you please.

Some tables inherit part of their key from another table’s key. Key assignment batch processes for such tables must be executed in key inheritance order. In other words, the key assignment process for a table should be run after the process that generates keys for the entity it depend on. The [Conversion Entity Dashboard](#) portal displays key inheritance dependency information if any exist for a conversion entity.

NOTE:

You may run multiple key assignment batch process in parallel as long as they are independent with respect to key inheritance.

Iterative Conversions

Rather than perform a "big bang" conversion (one where all records of an entity are populated at once), some implementations have the opportunity to go live on subsets of their entity base. If this describes your implementation, please be aware that the system takes into account the existing prime keys in the production database before it allocates a new key value. This means when you convert the next subset of customers, you can be assured of getting clean and unique keys.

Key assignment logic creates the initial values of keys by a manipulation of the sequential row number, starting from 1. After any conversion run, a subsequent conversion run will start with that row number again at 1, and the possibility of duplicate keys being assigned will be higher. The key assignment batch process allows you to specify a starting value for that row number. The purpose of this parameter is to increase the value of row number by the given value, and minimize the chance of duplicate key assignment. This parameter is only used if you are performing conversions where data already exists in the tables in the production database.

Run Type

Key assignment is performed in two steps:

- **Initial Key Generation.** The system allocates new keys to the rows in the staging tables (i.e., it populates the respective old key / new key table).
- **Duplicate Key Resolution.** The system reassigns keys that are duplicates compared to production.

By default, both steps are performed at the same run but you have the option to run them separately by indicating which step to run via a batch parameter. The proper use of this parameter will greatly speed up the key assignment step as described under **Recommendations To Speed Up Key Generation** section.

Recommendations To Speed Up Key Generation

The following points describe ways to accelerate the execution of the key generation programs.

- For a non-Cloud installation:
 - Make the size of your rollback segments large. The exact size is dependent on the number of rows involved in your conversion. Our research has shown that processing 7 million rows generates roughly 3GB of rollback information.
 - Setup the rollback segment(s) to about 10GB with auto extend to a maximum size of 20GB to determine the high water mark
 - A next extent value on the order of 100M should be used.
 - Make sure to turn off all small rollback segments (otherwise Oracle will use them rather than the large rollback segments described above).
 - After the key assignment programs execute, you can reclaim the space by:
 - Keep a low value for the "minimum extent" parameter for the rollback.
 - Shrink the rollback segments and the underlying data files at the end of the large batch jobs.
- Compute statistics on the old key / new key tables after every 50% increase in table size. Key generation is performed in tiers or steps because of the inheritance dependency between some tables and their keys. Although key generation for the inheritance dependency tier currently being processed is performed by means of set-based SQL, computation of statistics between tiers will allow the database to compute the optimum access path to the keys being inherited from the previous tier's generation run.
- Optimal use of the **Run Type** batch parameter.
 - Before any key assignments, alter both the "old key" F1_CX_ID index and the "new key" CI_ID index on the old key / new key tables to be unusable.
 - Run all key assignment batch processes in tiers, submitting each job to only perform the **Initial Key Generation** step.

- Rebuild the indexes on the old key / new key tables. Rebuilding the indexes using both the PARALLEL and NOLOGGING parameters will speed the index creation process. Statistics should be computed for these indexes.
- Run all key assignment batch processes in the current tier that were previously run in initial key generation mode, to perform the **Duplicate Key Resolution** step. This will reassign all duplicate keys.

NOTE: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

XML Resolution

Most system-generated foreign keys are stored in physical fields and characteristic tables and as such their legacy value is replaced with its corresponding new key as part of the insertion to production process. Rarely, maintenance objects may store system-generated foreign keys in an XML storage field, i.e. a field defined with the data type of CLOB or XML. This step is only applicable to such maintenance objects.

During this step, the system resolves convertible system-generated foreign keys that may reside in XML storage fields you may have loaded into the staging tables. This section provides some high level discussion about the XML resolution process.

The XML Resolution Table

It's important to understand that the system does not overwrite the prime-keys on the XML storage fields in the staging database, as this is a very expensive IO transaction. Rather, a corresponding XML resolution table exists for each table that defines an XML resolution field to capture each row's resolved XML storage content, i.e. the content with all the old keys replaced with the new assigned keys.

The convention "<1st letter of owner flag>R_<table_name>" is used to denote the XML resolution table name.

The [insertion](#) batch process that transfers the rows into the production database replaces each XML storage field with its resolved value from the corresponding XML resolution table.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion and support XML storage fields is provided with an XML resolution batch process. These batch processes must be run to resolves foreign keys that may reside in these XML storage fields.

These processes are multi-threaded and must be executed after the key assignment step has completed and before inserting data to production.

XML Resolution Eligibility

Not all maintenance objects that support XML storage fields actually store convertible system-generated foreign keys in their XML storage field. If none of the business objects associated with the maintenance object involve mapping of such foreign keys to an XML storage field then XML resolution is not needed for any row in the maintenance object. The XML resolution batch process detects such situation and completes right away without storing any rows in any of the maintenance object's XML resolution tables.

NOTE: If the XML resolution batch process detects that the maintenance object is eligible, the maintenance object must reference a physical BO. If a product delivered business object supports system-generated foreign keys in an XML storage field, the product should be supplying a physical BO. If your implementation has system-generated foreign keys in an XML storage field in a custom business object for a maintenance object where the product has not supplied a physical BO, you must [create a physical BO](#) and link it to the maintenance object.

Only Resolved Values Are Captured

XML storage fields typically store large amounts of data. To avoid capturing the same XML content redundantly, the system only stores values in the resolved XML storage fields if the resolved value is different than the original value, i.e. at least one key was resolved.

If for a given record the resolved XML content is the same as the original content then the following rules apply:

- If this is the primary table of the maintenance object a record is inserted into its corresponding XML resolution table for that record with no value in the XML storage field.
- If this is a child table of the maintenance object then no record is inserted into the corresponding XML resolution for that record.

Reported Errors

Errors encountered during XML resolution are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the XML resolution process using the “Validation Error Summary” page.

Insert Production Data

The topics in this section describe the background processes used to populate the production database with the information in the staging database.

A Batch Process Per Table

An insert to production batch process is provided for each table of a maintenance objects that is eligible for conversion.

The batch process is responsible for transferring to production all the rows from the staging table while replacing all references to old keys with their corresponding new keys as follows:

- Keys residing in prime keys, foreign key fields and characteristics are resolved using the corresponding [old key / new key](#) tables.
- Keys residing in generic foreign key reference tables where each row represents a reference to an entity’s maintenance object and prime key values are also resolved using the corresponding [old key / new key](#) tables. Note that all entities referenced this way must either be convertible or view of production. A reference to an entity that is explicitly marked as not convertible is not supported as it cannot be resolved.
- Keys residing in XML storage fields are resolved using the corresponding [XML resolution](#) tables.

NOTE: Foreign keys residing in any other form of storage are not resolved. For example, any references stored in raw elements, log records, or any other field that is not used as an XML storage field.

All insertion batch processes are independent and may run concurrently. Also note, all insertion batch processes can be run in many parallel threads as described in the next section (in order to speed execution).

Recommendations To Speed Up Insertion

The following points describe ways to accelerate the execution of the insertion batch processes:

- Before running the first insertion batch process:
 - Rebuild the index on the prime key on the old key / new key table.
 - Re-analyze the statistics on the old key / new key table.
 - Alter all indexes on the production tables being inserted into to be unusable.

- After the insertion programs have populated production data, rebuild the indexes and compute statistics for these tables.

NOTE: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Validate Production

During this step, you rerun the [object validation batch processes](#), but this time in production. We recommend rerunning these batch processes to confirm that the insertion batch processes have executed successfully. We recommend running these batches in random sample mode (e.g., validate every 1000th object) rather than conducting a full validation in order to save time. However, if you have time, you should run these processes in full validation mode (to validate every object).

A Note About Keys

The prime keys of the tables in the staging database are either system-assigned random numbers or they aren't. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields. Every table whose prime key is a system-assigned random number has a related table that manages its keys; we refer to these secondary tables as "key tables".

The following points provide more information about the key tables:

- Key tables are used by programs that allocate new keys. For example, before a new key is allocated, the key assignment program checks the corresponding key table to see if it exists.
- Key tables only have two columns:
 - The key of the object.
 - An environment ID. The environment ID identifies the database in which the object resides.
- Key tables are named the same as their primary table with a suffix of "_K". For example: The key table for CI_ACCT is CI_ACCT_K.
- The key table for a table whose prime key is a system-assigned is defined on its table definition record.
- When you populate rows in tables with system-assigned keys, you must also populate a row in the related key table. For example, if you insert a row into CI_ACCT, you must also insert a row into CI_ACCT_K. The environment ID of these rows must be the same as the environment ID on this database's [installation record](#).
- When you populate rows in tables that reference this record as a foreign key, you must use the appropriate key to ensure the proper data relationships. For example, if you insert a row in CI_SA for the above account, the ACCT_ID column must contain the temporary account key.
- When you insert rows into your staging database, the keys do not have to be random, system-assigned numbers. They just have to be unique. A later process, [Allocate Production Keys](#), will allocate random, system-assigned keys prior to production being populated.

Multiple Owners In A Single Database

The conversion process relies on the following table owner configuration in the system database:

- The production owner is linked to the tables used by your production system. These tables have an owner ID of CISADM.
- The staging owner is linked to the tables into which you insert your pre-validated data. These tables have an owner ID of CISSTG.

The staging owner schema is almost identical to the production schema, with the following exceptions:

- Control tables are not actual tables in staging but rather views to the corresponding tables in production.

- Conversion specific tables designed solely to support the conversion process exist only in the staging schema. For example, tables that manage key assignment and XML resolution.

This section provides some high level concepts related to these table owners.

Validation Always Uses Production Control Data

When the validation batch processes run against your staging data, they validate the staging data against the production control tables (and insert errors into the staging error table). This means that the SQL statements that access / update entities needs to use the staging owner whereas the SQL statements that access control tables need to use the production owner. But notice that when these same validation batch processes run against production, the SQL statements will never access the staging owner. Rather, they all point at the production owner.

This is accomplished as follows:

- A separate application server must exist for each owner. Each application server points at a specific database user ID.

NOTE: In a Cloud installation, the application server may only point to a specific database user ID at any point in time. Refer to the “Data Conversion Support for Cloud Implementations” for more information about switching owners.

- The database user ID associated with the staging owner uses CISSTG as the owner for the master and transaction tables, but it uses CISADM as the owner of the production control tables.
- The database user ID associated with the production owner uses CISADM as the owner for all tables.

You may wonder why we went to this trouble. There are several reasons:

- We wanted to reuse the validation logic that exists in the programs that validate your production data. In order to achieve this, these programs must sometimes point at the staging owner, and other times they must point at the production owner (and this must be transparent to the programs otherwise two sets of SQL would be necessary).
- We wanted to let you use the application to look at and correct staging data. This can be accomplished by creating an application server that points at your staging database with the ownership characteristics described above.
- We wanted the validation programs to be able to validate your production data (in addition to your staging data). Why would you want to validate production data if only clean data can be added to production? Consider the following scenarios:
 - After an upgrade, you might want to validate your production data to ensure your pre-existing user-exit logic still works.
 - You may want to conduct an experiment of the ramifications of changing your validation logic. To do this, you could make a temporary change to user exit logic (in production) and then run the validation jobs on a random sample basis.
 - You forget to run a validation program before populating production and you want to see the damage. If you follow the instructions in this document, this should never happen. However, accidents happen. And if they do, at least there's a way to determine the ramifications.

Only Validation Can Work In Both Owners

While the redirection of owner ID's is a useful technique for the validation batch processes, it cannot be used by the key assignment and production insert batch processes? Why, because these processes have to access the same tables but with different owners at the same time. They also need to reference conversion specific tables that do not exist in production. For example, the batch process that inserts rows into a table in production must select rows from the staging version of that table, resolve keys from the conversion old key / new key mapping tables and insert the resolved records into the production version of that same table

This is accomplished as follows:

- In staging, a view to production exists for each eligible to conversion table. These views have hard-coded the database owner to point to production. For example, there is a view called CX_PER that points at person table in production.

- The key assignment and insertion programs use these views whenever then need to access production data.

Conversion Entity Dashboard

This portal provides an overview of a maintenance object's conversion configuration along with information related to its current status and progress within the overall conversion process.

Refer to [Understanding Conversion](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Conversion Entity Query**. You are brought to a query portal with options for searching for a specific maintenance object that is eligible for conversion. Once a maintenance object has been selected you are brought to the conversion entity dashboard portal to review the information for the selected record.

The following zones may appear as part of the portal's **Main** tab page.

- **Tables.** This zone provides information about tables that belong to the maintenance object and are marked as eligible for conversion.
- **Batch Controls.** This zone lists the conversion batch controls defined for the maintenance object in the order they should be executed within the conversion process along with current execution details if any.
- **Error Summary.** This zone provides a summary of all conversion errors related to the maintenance object.
- **Duplicate Keys.** This zone lists duplicate legacy keys that need to be resolved by the key assignment conversion process.

The **Errors** tab page provides a query zone that allows you to review conversion errors related to the maintenance object by various criteria.

Data Export

This section describes concepts and tools related to the various types of data export methods supported by the product.

Understanding Data Export

The application supports the following classes of export methods for a maintenance object:

- **Generalized.** This method may be used for maintenance objects that are low to medium in volume and update activity. Most maintenance objects are eligible for this method.
- **Specialized.** This method should be used for maintenance objects that are high in volume or very frequently updated.

This section discusses concepts and guidelines related to data export features.

Generalized Data Export

The generalized data export method provides a file-based export of data in JSON format. Exporting the data of a maintenance object using this method involves an initial export of the entity's entire data followed by an ongoing export of changes as they are made over time. These processes are illustrated in the following diagram:

The overall process involves the following steps:

- Enable entities for export in the [Generalized Export Dashboard](#) portal. You may enable many entities at once. This step also allows you to enable ongoing export of these entities.
- Submit the Generalized Initial Export Initiator (**F1-GEXPI**) batch process to export the current content of all enabled entities. This step submits a separate batch process for each entity you have enabled for export.
- Schedule the Generalized Ongoing Export (**F1-GEEXO**) batch process to run periodically.

The following sections further discuss concepts and guidelines related to the generalized data export method.

Eligibility

While most entities are eligible for generalized data export, not all of them are. Here are a few of the common reasons for that:

- The entity manages extremely high volume of data. Tracking changes to such entity would double the volume of managed data and impact overall performance.
- The entity is updated very frequently. Tracking these events may impact overall performance.
- The entity is used by the product's infrastructure and operational processes. These entities are maintained differently and cannot be subject to the generalized data export methods.

By default a maintenance object is eligible for the generalized data export method unless explicitly marked otherwise by the **Data Export Class** option. The option may be used to mark an entity as either not allowed for any type of export or allowed for a [specialized](#) export only. The lack of such explicit option means the maintenance object is eligible for the generalized export.

CAUTION: If an entity is explicitly marked as not eligible for generalized data export there is a good reason for that and its configuration should not be changed.

One Method Fits All

The generalized data export method is designed to accommodate many eligible maintenance objects in a generic way that must also take performance considerations into account. For this reason this method does not support entity specific filtering options nor custom rules of any kind.

The following rules apply to all entities that may be exported using this method:

- Entire data is exported.

- All fields on all tables that belong to the maintenance object are exported except for “key” and “log” tables if any.
- Maintenance object log tables typically do not contain useful business information and as such are omitted from export for performance and data volume reasons. However, there are entities for which log records provide analytical value. When applicable, use the **Export Log Tables** option to explicitly include log tables for a specific maintenance object.
- Same data structure and format is used for all entities. Refer to the **Record Format** section for more information.
- Data is exported to files only. Refer to the **Export To Files Only** section for more information.
- All changes are captured. It is not possible to exclude some changes from being tracked for ongoing export based on custom business rules.
- When data changes, a full snapshot of the data related to that entity is exported to avoid heavy data merging on the target side.
- When the entity is deleted, only the primary key of the entity is exported along with an indication that it is deleted.

NOTE: Export is not supported for entities that rely on the logical time zone functionality. This type of definition is not commonly used and includes maintenance objects that at least one of their fields is defined as stored in **Logical Standard Time**.

Export To Files Only

The immediate destination of both initial and ongoing export processes are files in a customer specified location. In a Cloud installation files are created in a customer owned Object Storage.

Based on your business requirements you may further consume these files by downstream applications such as data lakes etc.

Enabling Data Export

To enable data export for an eligible maintenance object a **Data Export Control** record needs to be created. The record keeps an indication of whether the initial export for the maintenance object has been completed or not and whether changes made to the entity should be tracked and exported on an ongoing basis. A designated portal allows you to enable the generalized data export for many maintenance objects at once as well as monitor their current export status at a glance. Refer to [Generalized Export Dashboard](#) portal for more information.

CAUTION: Enabling and disabling entities for export should only be made via the Generalized Export Dashboard or the Data Export Control portals to ensure the configuration is valid and complete.

CAUTION: When applicable, ongoing data export should be enabled before submitting the initial export batch process for the entity. This ensures that changes made during the initial export are properly tracked.

Ongoing export options are cached in various online and batch caches. In order for these options to take effect and track entity changes made by any online or batch process, the various caches must be properly flushed when these options are changed. Using the designated portals to enable entities for export triggers a 'global' flush of the caches. If the batch thread pool workers are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing. Refer to [Caching Overview](#) for more information.

Initial Data Export

Each maintenance object that is eligible for the generalized data export method is associated with an initial data export batch control that is referenced on the maintenance object using the **Export Batch Control** option. The same common batch program is used by all these batch controls to export the entire data of an entity to files. The process is multi-threaded and

produces one file per thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

Instead of manually submitting the generalized initial export batch process for each maintenance object you have enabled for export, submit the **F1-GEXPI** Generalized Initial Export Initiator batch process to automatically submit them all at once.

The initial export process for each maintenance object updates the corresponding data export control record for the maintenance object to indicate that the process has started and updates it again upon completion. This allows you to view the overall status of the initial export across all enabled entities on the [Generalized Export Dashboard](#) portal.

Note that the initiator batch process only submits batch processes for enabled maintenance objects that according to their data export control record their initial export has not started yet. If you need to export one or more entities again, reset the initial export status indication on their data export control records and submit the initiator batch process again.

The initial export file name is constructed as follows:

```
INIT_EXPORT[_file prefix(optional)]_[maintenance object]_[batch run]_[thread]_[thread count]_[timestamp]
[_file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows `_2`.

Refer to any of the individual generalized initial export batch controls and the initiator batch control for more information.

Restricting Initial Export By Date

By default, the Initial Data Export batch process exports the entire data for an entity. In some situations, typically around high volume historical data, there may be a need to restrict the export to more recent data, for example the last few months of data.

The initial export batch process supports an optional batch parameter **Restrict By Date** that can be used to limit the scope of data to export. The parameter references a date field and a requested time frame in terms of number of days prior to business date. Refer to the **F1-GEIXP** Generalized Initial Export Template batch control for more information.

CAUTION: Excluding records from export should be carefully considered as this may result in data discrepancies when the excluded data is referenced on other exported entities.

NOTE: The option is only applicable to specific entities that have a qualifying reference date and the time frame for export may vary for each customer. Therefore, the new parameter is not added to any base product Initial Export batch control aside of the template batch control for documentation purposes. You may clone the base product batch control for a specific entity and add the parameter as per your business needs.

Ongoing Data Export

Data changes are tracked by the Capture Change for Ongoing Export (**F1-MO-REGCHN**) Maintenance Object Audit algorithm. The algorithm records the prime key of a changed entity in a designated **Data Export Update** table that serves as a queue of changed entities to export. The queue is later on consumed by the ongoing data export batch process.

NOTE: The Maintenance Object Audit plug-in spot is capable of tracking changes made to the entity by any layer of the application. Making changes using direct SQL would bypass this mechanism and therefore should be avoided.

The audit rule is added to a maintenance object when the ongoing data export option on its corresponding data export control record is enabled. In the same way the audit rule is removed from the maintenance object when the ongoing export option is disabled.

NOTE: The ongoing export option has to be enabled on the data export control record for the entity before it is initially exported. This ensures changes made while the initial export process is in progress are not missed.

Unlike the initial export batch process that requires a batch control to be defined for each eligible maintenance object, a single batch process is used to export ongoing changes made to all entities.

The following describes the ongoing export batch process at a high level:

- All changes queued in the Data Export Update table are exported to a designated ongoing export file. Refer to the **Managing a Large Backlog** section for more information.
- A full snapshot of the data related to the changed entity is exported to avoid heavy data merging on the target side.
- Once exported, records are deleted from the Data Export Update table.

The process is multi-threaded and a separate file is produced for each thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

NOTE: It is important to schedule the ongoing export batch process to run frequently enough to avoid accumulating a high volume of records in the Data Export Update table. The smaller the table is kept the faster it is for the change data capture mechanism to add records to it.

The ongoing export file name is constructed as follows:

```
INC_EXPORT_[batch run]_[thread]_[thread count]_[timestamp]_[file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows _2.

Refer to Generalized Ongoing Export (**F1-GEEEXO**) batch control for more information.

File Size

The initial export batch process produces a single file per thread by default. For some high volume entities this may result in files that are too large to manage. To produce multiple and smaller files for a specific entity, limit the number of records written to each file by setting the corresponding parameter on the initial export batch control defined for the entity. The same parameter may be provided when submitting the Initial Export Initiator batch process, in which case the initiator value is used only when a corresponding value has not been defined on the entity's specific batch control record.

In the same way, the ongoing export batch process produces a single file per thread by default. To produce multiple and smaller files, limit the number of records written to each file by setting the corresponding parameter on the batch control.

To avoid the creation of too many files by a single batch run, the system sets a maximum limit of around 500 files per run. When the requested number of records per file is determined to cause the number of generated files to exceed the system limit, the actual value used is adjusted to meet the system limit.

Managing a Large Backlog

When a large backlog of changes accumulates in the ongoing export queue for some reason, the next batch takes longer to export which delays the downstream import step. A better option is for the backlog to be cleared in smaller "chunks", allowing the downstream process to import them as they are made available.

You may limit the number of records the batch process exports using the **Thread Processing Limit** batch parameter. When specified, the number of records exported by each thread is capped by the specified limit, leaving the remaining records to be consumed by subsequent batch runs. Instead of waiting for the next scheduled batch run, a new batch process may be automatically submitted, if explicitly requested to do so using the **Automatic Backlog Clearance** batch parameter.

It is important to ensure that the backlog clears gradually and that the queue resumes its normal size in a timely manner. The processing limit must therefore be set with an appropriate value that would promote proper clearance of the queue. To do so, at least 20% of the queue, and no less than 100,000 records, must be consumed by each batch run across all threads. If the specified limit does not meet the minimum clearance requirement then the processing limit is adjusted accordingly.

Record Format

Data is fetched and exported directly from the database in bulk read operations for performance reasons. For that reason, the structure used does not reflect the logical data model of the entity but rather its physical list of tables. Data for a given instance is organized by tables followed by rows in each table and for each row its list of fields in JSON format.

The following describes the format and structure used:

```
{
  "OBJ": "<mo name>",
  "TIMESTAMP": "<export time in ISO format for example 2019-07-25T11:06:04.740615Z>",
  "PK1": "<mo pk1 value>",
  "PK2": "<mo pk2 value if any>", # PK2-5 should only be included when applicable
  "PK3": "<mo pk3 value if any>",
  "PK4": "<mo pk4 value if any>",
  "PK5": "<mo pk5 value if any>",
  "DELETED": true, # should only be included when the entity is deleted
  "DATA":
  {
    "<MO table name 1>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>},...
    ],
    "<MO table name 2>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ],...
    "<MO table name n>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ]
  }
}
```

Notes about field values and formats:

- All fields for a row are included even when the field is empty or null.
- All string values are trimmed of excess trailing spaces but if a field is empty it exported as an empty string "" and not null.
- An empty array is used for a table node when no records exists for the entity in the table.
- Date/time information is converted to UTC time zone and exported in ISO format for example 2019-07-25T11:06:04.740615Z.
- Deletes have an explicit indicator in the header.

Order of Consuming Files

It is important to apply all the initial export files for a maintenance object before applying ongoing change files to ensure data consistency.

The following is a recommended procedure for consuming generalized data export files:

- Apply all initial data export files before ongoing export files.
- Apply initial files for a maintenance object in run number order.
- Apply ongoing export files in run number order.
- If a new initial export is available the file consumption procedure should be changed temporarily as follows:
 - Stop consumption of ongoing export files.

- Apply the new initial export files.
- Resume consumption of ongoing export files.

Recover from a Lost Ongoing Export File

The ongoing export batch process keeps a backup of all entity keys, that were exported on a specific batch run, in a designated backup table. In rare situations where an ongoing export file is deleted or becomes corrupted before it gets processed, the backup table may be used to identify the missing changes and export them again.

Use the Restore Generalized Export Keys (**F1-GERST**) batch process to recover from this situation. The process identifies the entities that were exported during a specified batch run and adds them back to the ongoing changes queue from the backup table. The entities would then be exported again when the next ongoing export runs. This method does not restore the exact content of the original file that was lost as it cannot be reproduced. Instead, the process ensures that the entities that were included in the lost file would be exported again.

NOTE: Backup records follow a weekly retention policy for performance reasons. They are meant to support near future situations of file recovery and are not an historical change data capture log.

Specialized Data Export

Several performance considerations are called for when exporting the data of a high volume entity or an entity that is updated in extremely high frequency. The generalized method does not fit such entities and a specific batch process is designed for each, aiming to achieve an optimal export method for the entity. The initial run of the process exports the entity's existing data while subsequent runs of the same process exports data incrementally, i.e. it exports records that were added or updated since the previous run based a timestamp field. The overall process is illustrated in the following diagram:

The following sections further discuss concepts and guidelines related to the specialized data export method.

A Specific Process For Each Entity

A maintenance object that is designed to be exported using the specialized method is explicitly marked as such by the **Data Export Class** option and its specific batch process is defined using the **Export Batch Control** option.

All specialized batch processes are designed to export the data in a CSV format as it produces smaller files in size compared to more verbose formats. Refer to each batch process for more information about specific export considerations and parameters.

Enabling Data Export

To enable data export for a maintenance object a specialized type of [Data Export Control](#) record needs to be created. The record serves as an indication that such entity should be exported and keeps track of the date and time through which data has been exported so far, allowing subsequent export run to only export incremental changes.

Incremental Data Export

The specialized export method tracks changes incrementally from prior export run and does not use a change data capture mechanism. It therefore relies on a timestamp field on the primary table of the maintenance object to indicate when data was added or changed. Only entities that were added or changed since the previous export run are exported with each subsequent run. The date and time through which data has been exported is recorded for each maintenance object on its corresponding Data Export Control record.

Order of Consuming Files

Specialized data export files should be consumed in run number order to ensure a consistent and chronological uptake of data.

Defining Data Export Control

This portal is used to maintain Data Export Control records. These records capture your organization's export settings and current export state for a selected maintenance object. For a generalized export it keeps an indication as to whether the initial export for the maintenance object has been completed or not and whether changes made to the maintenance should be tracked and exported on an ongoing basis. For a specialized data export it keeps the date/time through which data was exported.

Refer to [Understanding Data Export](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Data Export Control**. You are brought to a query portal with options for searching for a specific record. Once a data export control record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Data Export Control** zone provides information about the selected record.

Generalized Export Dashboard

The number of maintenance objects that are eligible for generalized export is large. This portal allows you to easily select and enable export for many eligible entities at once as well as review the current export state of those already enabled at a glance.

Refer to [Generalized Data Export](#) for more information about the generalized data export method.

You can access the portal from the **Admin Menu > Implementation Tools > Generalized Export Dashboard**.

The following zones may appear as part of the portal's **Main** tab page.

- **Export Entities.** This zone lists entities for which generalized data export control settings have already been set.
- **Eligible Entities.** This zone lists entities that are eligible for the generalized data export method and for which such settings have not yet been set.

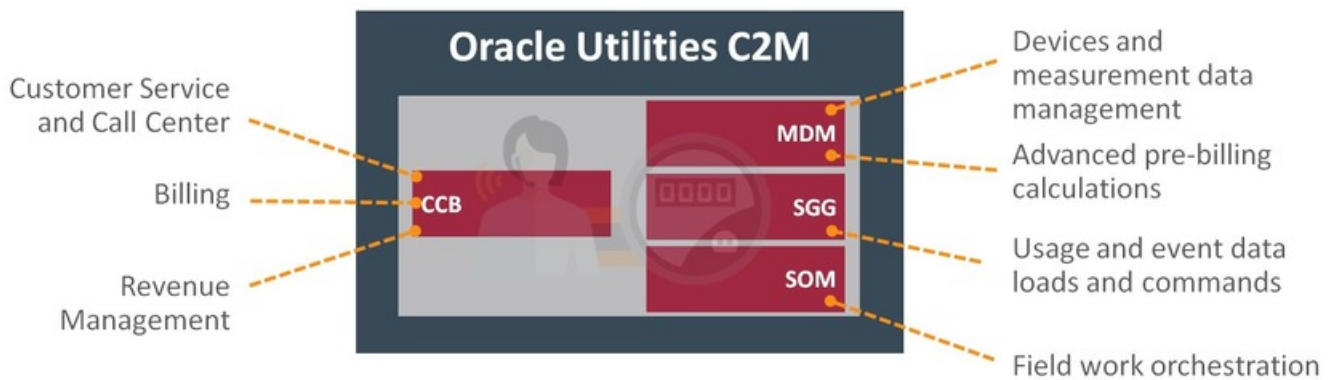

Customer to Meter Administrative User Guide

Customer to Meter Overview

Customer to Meter Overview

Oracle Utilities Customer to Meter is a next generation customer service and billing application that incorporates a modern meter data management system. This system is designed to scale with mass smart meter volumes while handling the complexity associated with a utility's processes across multiple types of service, operating divisions, and jurisdictions. The new application components allow for traditional scalar meter functionality that is equivalent to prior versions of Oracle Utilities Customer Care and Billing; so, it can accommodate the many types of utility environments, and evolve with the business to include more advanced digital requirements.

The roles for each application area in Oracle Utilities Customer to Meter are defined as follows:

The application components have internal integration for master, admin, and transactional data. The primary transactions between them are for bill determinant processing with MDM and service order processing with SOM. These transactional processes can be initiated by the CCB solution, or from other external systems.

In addition, Oracle Utilities Customer To Meter can also include asset management functionality via Oracle Utilities Operational Device Management which provides the ability to handle large volumes of assets and to manage the receipt, installation, maintenance, tracking and removal of those assets.

Best Practices

Performance Recommendations

Partitioning and Data Removal

- Implement Partitioning:** Partitioning is essential to manage the large amounts of data coming into Meter Data Management. Customers will have significant performance problems without partitioning. Partitioning is required for good performance and to organize the data so old data can easily be dropped from the database. Customers need historic partitions (for conversion and replacement reads) and future partitions.
 - Cloud Implementations: Customers should run 'Add Partition' jobs, **F1-ILMAD** and F1-ILMSV (for sub-partitions, if needed) on a regular basis to ensure that new partitions are created regularly.
 - On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* for partitioning guidelines for on-premises implementations.
- Implement Compression:** Compression is essential to reduce the size of the database. For standard hardware we recommend Advanced Compression. For engineered systems that use Oracle Exadata, we highly recommend HCC (Hybrid Columnar Compression) this reduces the overall database by approximately 50%.
 - Cloud Implementations: Customers should use the “ILM Automation – Non-Measurement Compression” (F1-ILMNC) batch process to will change the compression level from Advanced to Hybrid Columnar for non-Measurement data at least two months old, which can result in significant disk space savings. Use the following

parameters when running this batch process: Owner, MO (optional), DOP (Degree of Parallelism), Estimated Time Limit (How long job can run until it will not compress another partition). In larger databases this can run for several days a month.

- On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* for compression guidelines for on-premises implementations.
- **Setup Information Lifecycle Management (ILM):** – The Information Lifecycle Management processes mark items eligible to be removed and update partitions to segregate the data that can be removed. Customers need to define the “ILM Configuration” default retention periods (via the ILM Master Configuration). The retention period should be defined for all ILM objects. Important note, completed IMDs (Initial Measurement Data records) are no longer needed and can be removed shortly after being imported. Removing IMDs after 3 months will reduce the compressed DB by about 50%. There will be savings from other ILM objects too - including Activities and To Do Entries .ILM Crawlers are provided for low volume transactions. High Volume transactions are marked as eligible for archiving automatically.
- Cloud Implementations: Run the ILM Crawlers Batch Job (batch controls by object) and once the data is aged request Cloud Operations to move the partitions to Object Storage.
- On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* and [Information Lifecycle Management](#) for ILM guidelines for on-premises implementations.

Device Channels to Process

Oracle does not recommend customer process all channels of data that Meter Data Management can derive.

- Oracle does not recommend utilities hard-code devices with time of use periods (e.g.: on-peak, off-peak). Hard-coded time of use periods will likely require reprogramming in the future when those periods change. Meter Data Management can easily calculate time of use values from interval data.
- Oracle does not recommend customers hard-code demand channels (such as channel used to measure kW), since these must be reset every bill cycle. Demand can be derived from kWh interval data.
- Likewise, Oracle does not recommend customers hard-code channels for Power Factor since that can be derived from kWh and kAVRh interval data.

Data Conversion

- Only convert essential data. Only convert objects that are essential to running the business.
- Pay careful attention to measurement data. Measurement data is very, very large and may take weeks to convert. Consider this: if it takes one hour to load measurements every day, how long will it take to load 5 years of measurements? Although conversion jobs are faster than regular data loading, measurement conversion still takes time. Here are a few measurement best practices:
 - Projects are encouraged to only convert the minimum amount of measurement data required.
 - If historical measurements are required, try to limit the amount of data converted. The best practice is to convert 13 months of consumption to support VEE.
 - Only convert channels absolutely required, usually billing channels, and don't convert other interval data if not needed.
 - Measurement data values should be converted directly into the Measurement table and not use the IMD and VEE processes.
 - **Do not convert Initial Measurement (IMDs).** Completed IMDs are not needed for any Meter Data Management processes.
 - Remember that billing quantities will likely also be stored in the customer information system, so confirm that the measurement data is required before conversion.

Initial Measurement Loading Recommendations

- When processing payloads using middleware implementations, keep the number of devices to 1,000 per file for optimum usage and event processing through Oracle Service Bus. A lower number of devices, per file, will take more time for processing. A higher number of devices, per file, leads to high growth in garbage collection leading to waits and results in lower throughput. Please note, the optimum number of transactions per file may vary by head-end system.
- Initial measurement payloads should have very selective criterion to get to the exact measuring component (MC). In an ideal case, it should be the MC identifier along with device serial number. If this is not provided, then the UOM/TOU/SQI configured on the MC type is used to retrieve the exact business object (BO) from the Service Provider which might have the same values for multiple channels.
- Populating the raw data section of the IMD record will reduce overall throughput. Avoid retaining “raw” data in Smart Grid Gateway payload processing whenever possible.
- Payload processing (in which usage and event data are loaded into the system) should be run separately from measurement processing (in which VEE is performed and final measurements are created). Do not run these processes simultaneously.
- Load initial measurements and perform VEE processing every 4 to 6 hours to optimize performance.
- The duration of individual initial measurements (IMDs) within a payload should be no shorter than the time elapsed between when payloads are collected and delivered (with a minimum of 4 to 6 hours per initial measurement). For example if your system is collecting and delivering measurements three times a day, the duration of individual initial measurements should be approximately eight hours.
- Avoid loading large numbers of initial measurements for a single device configuration in a single payload.
- We recommend configuring a monitor process on the Pending status of the Initial Load initial measurement business objects so that the VEE and measurement creation processes can be deferred to batch processing.
 - Deferring processing has the following additional benefits:
 1. It can ensure chronological processing for scalar reads which provides more efficient processing. Processing scalar reads out of order can result in additional work as reconciliation initial measurements will be created and processed to true up the consumption calculations.
 2. It can ensure measuring components are processed in order based on their relationships. For example, if a scalar channel is configured as the check channel for an interval channel, the scalar channel will be processed first so that its data is available for sum checks and any interval gap filling required.
 - Configuring deferred processing involves adding the “IMD Monitor – Physical Devices” Batch Control as the Monitor Process on the Pending status to the following business objects:
 - D1-InitialLoadIMDInterval
 - D1-InitialLoadIMDScalar
 - When initial measurement processing is deferred it will be necessary to schedule the “IMD Monitor – Physical Devices” Batch Control to run more frequently. It should be scheduled such that it runs with a higher thread count immediately after the Itron Scheduled Reads cycle has completed and with fewer threads throughout the rest of day to pick up any other initial measurements that might be received (such as those received via On Demand Read commands).

VEE Recommendations

- The High-Low VEE Rule is very “heavy” in terms of performance. This rule has an intensive hit on performance of the Initial Measurement loading process. Customers are encouraged to use the Usage High-Low rule, which has a less significant performance impact. If the VEE rule version is being used, the historic pre window should be set as low as possible based on business needs.

- Each VEE Rule included in VEE processing can have an impact on overall performance. The table below summarizes the relative costs in terms of performance for several commonly used VEE Rules. Using this table when designing your VEE groups and rules can help identify potential performance challenges.
- For example, using "Minimal Impact" rules will likely have little to no significant impact on performance, while using several "Moderate Impact" rules could result in performance challenges, and using the High Low Check rule is very likely to introduce noticeable impacts to VEE processing performance.

Relative Cost	VEE Rules
Minimal Impact (0% - 5%)	Interval Interpolation Interval Replacement Rule Interval Size Validation Interval Spike Check Negative Consumption Check Scalar Replacement Rule UOM Check
Moderate Impact (5% - 20%)	Final Measurement Validation Interval Adjustment From Scalar Interval Averaging Multiplier Check Scalar Calculation From Interval Scalar Proration Sum Check
Significant Impact (20%)	High/Low Check

- Consumption sync processes should only be run on devices where the difference in consumption is outside the defined tolerance as dictated by the sum check tolerance. In a production environment, running consumption sync for two percent of devices or less is advisable.
- For cloud implementations, custom rules must be written using Groovy or Oracle Utilities Application Framework scripting.
- Run performance testing on all configuration changes performed that impact portions of Oracle Utilities Meter Data Management with high transactional processing.
- Any VEE Rules, whether provided as part of base product or custom developed, should be configured to query no more than 30 cumulative days of historical data (i.e. High/Low) to help optimize the data loading process
- A good way to troubleshoot a VEE Rule is to use the Trace section of the IMD Log. When an IMD is in Pending status, the **Trace On** button can be used to trace all VEE Rules fired during IMD processing. Once processing is complete, view the Log tab of the IMD and review the results in the **IMD Trace Log** section. For any custom developed VEE Rules, the average run time should be no longer than the average run time of other base product VEE Rules. Also, the impact of different configuration can be checked through this method as well.
- Load initial measurements and perform VEE processing every 4 to 6 hours to optimize performance.

Measurement Processing Recommendations

- Payload processing (in which usage and event data are loaded into the system) should be run separately from measurement processing (in which VEE is performed and final measurements are created). Do not run these processes simultaneously.
- When performing Periodic Estimation for the first time, avoid running estimation for large numbers of devices for a long periods of time. The Smart Meter State Monitor Process (D1-SMMTR) used to initiate periodic estimation is designed to perform estimations for a small number of devices per run, not the entire meter population in the system.

Usage Transaction Recommendations

- Usage transactions should NOT be used as an extraction tool to perform the mass export of measurement data.
- Saving derived interval data and sending the data to an external system via the "Save Interval Vector" and "Extract Interval Data" options on the "Vector and Service Quantity Math" and "Get Interval Data" usage calculation rules can have a noticeable impact on usage transaction processing. Usage transaction processing can be improved by up to 45% if extraction of interval data is eliminated. Use of these options should be limited to situations in which they are absolutely required.
- Use the Usage High Low rule instead of the VEE High Low rule where possible.
- For Outbound Messages, the schema extraction for usage transactions should be converted into a RAW string operation to allow for more efficient Pre-Processing logic.

User Interface Recommendations

- For better performance, user interface zones should be initially collapsed when not required for 90% or more of business processes. The initial state of zones (collapsed or not) can be controlled via the "Portal Preferences" tab on the **User** portal.
- The number of records returned to the user interface for a zone should be limited to 50 rows when building custom zones against large transactional tables.
- UI Map schemas should be specific to the displayed data. This will make sure that application will not visit all the elements that are not required for display.
- A good way to troubleshoot a screen in the user interface is to go to the **Preferences** in the top right hand corner of the application and choose the **Portal Preferences** tab. Choose the appropriate portal and set all zones to "Initially Collapsed". Next, navigate back to the screen that has performance issues, expand the zones one by one, and measure the execution time of each zone. This should be an accurate step-by-step representation of the full screen execution. This testing is especially important for **custom** user interfaces.
- For optimal user interface performance, Oracle Utilities Meter Data Management users should ensure their computer set to **high performance mode** so all CPU resources are used. Also, check if allocating additional memory through your browser's default settings helps improve performance.

Exception Handling Recommendations

- Don't create To Do entries unless they are absolutely required
- Use the VEE Exception Handler (D1-VEERuleExceptionHandler) and Usage Exception Handler (D2-UsageRuleExceptionHandler) rules to limit the number of To Do entries created by VEE and usage rule processing.
- Do not create To Do entries for exceptions for which Service Investigative Orders are being creative.
- Purge To Do data on a regular basis (see [Partitioning and Data Removal](#))

SQL Recommendations

- Avoid making unbounded SQLs statements with no boundary condition on date columns.
- Reduce CLOB searches and use physical columns wherever possible.
- Implement caching to pre-fetch data instead of issuing multiple SQLs.

Custom Rules and Processes

- When creating custom rules and processes, don't use plug-in scripts for high volume transactions. Use Groovy or Java (on-premises implementations only).

Cloud Services

- Java is not allowed in cloud service environments, so implementations are encouraged to use Groovy when creating custom VEE and or usage calculation rules. Training regarding using Groovy with Oracle Utilities Application Framework applications can be found in the [Oracle Utilities Learning Subscription](#) available from Oracle University.

Testing Recommendations

- "Day in the Life" performance testing with production-level data volumes should be performed on a Test Environment before going live.

Java Recommendations — On-Premises Implementation Only

1. For areas where the transactional volume is high (such as Initial Measurement), use Hibernate SQL for non-CLOB fields whenever possible as opposed to reading entire Business Object. If a CLOB field must be retrieved, then either Entity or Lite BO should be used. Reading the full Business Object should be used as the last resort for high volume areas. This process should be considered for updating data as well when it provides the same functionality as updating the Business Object. These methods should only be considered if BO level validations, pre-processing, and post-processing aren't required.
2. For a simple SQL select statement needed in Java (not many joins and no complex logic), using Hibernate SQL provides a benefit over using a Business Service and a Zone since the entities are cached for Hibernate SQL.
3. "Lite" Business Objects are provided as a way to access the main fields for a BO without pulling back all of the information. Retrieving less information will speed up the process for reading the BO.

Referencing Master Data by Identifiers

Understanding Referencing Master Data by Identifiers

There are many places within admin configuration where direct references to master data can be made. Since master data relies on system generated keys this configuration often breaks once migrated to a new environment since the master data referenced does not exist in the target environment. To alleviate this issue, in each of these instances, a user defined identifier can be used instead of the system generated keys.

This has an added benefit for installations that support multiple time zones by enabling the identification of the master data to not only search by the user defined identifier but also the time zone of the instance data. This is advantageous because it allows one set of admin configuration to satisfy master data in multiple time zones since things like TOU Maps and profile measuring components will be identified at run time using the identifier and time zone.

The following types of data can be referenced by an identifier on admin configuration:

- **Device:** can be referenced by a device identifier type. An example of this can be seen on the Specification Lookup (D1-SpecificationLookup) extendable lookup.
- **Measuring Component:** can be referenced by a measuring component identifier. When multiple time zone support is enabled the measuring component's time zone will also be evaluated. There are two major patterns for this:

- *Profile Factors*: The profile factor itself will reference the measuring component by identifier and then the admin configuration will point to the profile factor. An example of this is the profile factor list on interval measuring component types.
- *Direct Measuring Component references*: An example of this is the Final Values Overlay Profile (D1-FinalValuesOverlayProfile) extendable lookup.
- **TOU Map**: can be referenced by the TOU map template code. The appropriate TOU map is then found by searching for the appropriate TOU map that references a TOU map type for the supplied TOU map template. When multiple time zone support is enabled the TOU map type time zone will also be evaluated. An example of this is the default TOU map that can be configured in the display profile of a measuring component type.

During execution the identifier supplied will be used to find the appropriate master data entry. The following validation will occur:

When multiple time zone support is off: the search must find one and exactly one master data entry for the identifier type and value.

When multiple time zone support is on: the search must find one and exactly one master data entry for the identifier type, identifier value, and time zone. Note: some installations may want to use master data across time zones, this can still be achieved by supplying one and only one master data entry for the identifier type and value:

When the search fails to find the master data for the identifier type, identifier value, and time zone and there is only one entry for the identifier type and value that master data will be used (thus allowing one master data entry to be used across time zones)

When the search fails to find the master data for the identifier type, identifier value, and time zone and there are multiple entries for the identifier type and value an error will be encountered.

Recommendations for Creating an On-Premises Production Environment

Oracle recommends that you do not clone the demonstration environment as a basis for a new production environment. The demonstration environment typically includes transactional data that will be irrelevant to your production environment and can cause unexpected issues if it is not purged correctly. The recommended process is to start a new production environment from a new installation and migrate "clean" system data (such as business objects and algorithms) and administrative data (such as sample activity types or other administrative entities) from the demonstration and/or test or development environments as applicable.

Your implementation can use bundling and/or the Content Migration Assistant to move system and administrative data. Instructions for using these tools are contained in the [Bundling](#) and [Content Migration Assistant](#) sections in the Oracle Utilities Application Framework *Administrative User Guide*.

Contact [Oracle customer support](#) if further assistance is required.

Additional Resources

How to Get Support

Oracle is deeply committed to technical support services for its products. The Oracle Support online portal provides a reliable, easy-to-use method for obtaining technical support for Oracle Utilities Meter Data Management. To register as a new user for Oracle Support, go to <https://support.oracle.com> and follow the steps shown on the screen.

Oracle policies for standard technical support services are available at <http://www.oracle.com/us/support/policies/index.html>.

Knowledge Base Articles

Once you have access to Oracle Support, finding Knowledge Base articles is an easy process.

1. Log in to <https://support.oracle.com>.
2. Select the **Knowledge** tab at the top of the Oracle Support portal.
3. Under the Knowledge Base section, type "**Oracle Utilities Meter Data Management**" as the product.
4. Enter key search topics into the **Enter search terms** box.
5. Click **Search**.

The search results will display all knowledge articles stored on Oracle Support related to Oracle Utilities Meter Data Management for your key topics.

Important Articles

While there is a vast library of important Knowledge Base articles on Oracle Support, the list below highlights a few of the key knowledge articles that should be helpful if you're looking for additional detailed information about Oracle Utilities Meter Data Management:

Article Name	Knowledge Base Article Number
Information Center: Meter Data Management and Smart Grid Gateway Version 2	1907636.2
Related Measuring Component Consumption Sync Technical Reference Paper	1672461.1
Overview and Guidelines for Managing Business Exceptions and Errors (this document was created by the CC&B team but pertains to MDM as well)	1628358.1

Support Hot Topic Emails

Oracle Support provides a way to receive daily or weekly updates on new information posted for Oracle Utilities Meter Data Management.

1. Log in to <https://support.oracle.com>.
2. Select the **Settings** tab at the top of the Oracle Support portal. (Note: this tab may be hidden for you and may require clicking a dropdown on the right side of the tabs)
3. Once on the Settings screen, choose the **Hot Topics E-mail** from the set of options on the left.
4. Under Delivery Options, choose **Send With Selected Options**.
5. Choose your delivery frequency: either Daily or Weekly.
6. Add content which interests you: there are a number of options available. To subscribe to updates for Oracle Utilities Meter Data Management, hit the **Add...** button under Selected Products. Enter "Oracle Utilities Meter Data Management" for the Product then choose the types of information for which you'd like to receive an email.
7. Make sure you click **Apply** at the bottom once you've made all of your selections.

Embedded Help

Oracle Utilities Meter Data Management, like all Oracle Utilities Application Framework applications, provides extensive internal documentation. For example, detailed descriptions of system objects are included in the objects' maintenance portals. The lifecycle of each business object is described on the Lifecycle tab and depicted in flow diagrams on the Summary tab. This information is extremely useful for implementers and system administrators.

Embedded help is provided for all non-obvious fields in most portals and zones. If a field has associated help text, a question mark icon appears next to the field when the zone is displayed.

Leveraging Demonstration Data

One of the best ways to understand Oracle Utilities Meter Data Management is through a thorough review of the demonstration data (also referred to as "demo data") provided by Oracle. The demo data for Oracle Utilities Meter Data Management provides the following:

- An overall view of how to implement the product for common needs
- Examples of the productized solutions to solve key utility scenarios
- Some examples of adding "customer modifications" on top of Oracle Utilities Meter Data Management

This demo data can be downloaded along with the Oracle Utilities Meter Data Management. It's recommended that this be installed into an isolated environment for reference purposes separate from other development or testing environments.

Once installed, the demo data scenarios can be found in two places within Oracle Utilities Meter Data Management:

- A zone named **Demo Scenarios** is shown in the right side Dashboard. This provides a quick method to link to the 360 Degree View for the specific demo meter.
- An extendable lookup named **Demo Scenarios Catalog** describes each of the scenarios in detail. This matches the scenarios displayed in the Demo Scenarios zone.

NOTE: Oracle recommends that you do not clone the demonstration environment as a basis for a new production environment. The demonstration environment typically includes transactional data that will be irrelevant to your production environment and can cause unexpected issues if it is not purged correctly. The recommended process is to start a new production environment from a new installation and migrate "clean" system data (such as business objects and algorithms) and administrative data (such as sample activity types or other administrative entities) from the demonstration and/or test or development environments as applicable. Instructions for using these tools are contained in the [Bundling](#) and [Content Migration Assistant](#) sections in the Oracle Utilities Application Framework *Administrative User Guide*.

Customer User Groups

A number of Customer User Groups have been established (one in the United States and others internationally) that are specific to sharing best practices and learnings about Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway (SGG). If you're interested in participating in a Customer User Group, contact the appropriate Product Manager.

Customer To Meter Configuration

Oracle Utilities Customer to Meter employs functionality from Oracle Utilities Customer Care and Billing, Oracle Utilities Meter Data Management, and (optionally) Oracle Utilities Operational Device Management. While much of the configuration of the application is very similar to that used with the individual applications, the merging of functions requires some configuration that is unique to Customer To Meter.

This chapter describes topics specific to configuring Customer To Meter to support a seamless integration between Customer Care and Billing, Meter Data Management, and Operational Device Management functionality.

Cross Product Configuration Master Configuration

The Cross Product Configuration master configuration provides a single point of access for configuration information related to consolidated data maintenance, data mapping, and other master configurations used with Customer To Meter.

To open the master configuration, select **Admin, General, Cross Product Configuration**. The master configuration opens in the **Cross Product Configuration** portal.

The **External System** field references the external system used for communication between Customer Care and Billing, Meter Data Management, and Operational Device Management including data synchronization requests, Service Order Management (SOM) queries, etc.

Consolidated Maintenance

The **Consolidated Maintenance** section documents objects that use some form of consolidated maintenance in Customer To Meter.

Merged Maintenance references the extendable lookup used to configure [Merged Maintenance](#). Click **Joint Maintenance Lookup** to view values for this extendable lookup.

The **Consolidated Maintenance Objects** table lists objects that use [Master Data Synchronization](#) and [Data Audit Maintenance](#) for consolidated maintenance. Click on an object's name to view its maintenance object.

Customer and Device Value Mapping

The **Customer and Device Value Mapping** section lists objects used to map data between Customer Care and Billing and Meter Data Management.

SA Type Mapping references the extendable lookup used to map Customer Care and Billing service agreement (SA) types to Meter Data Management usage subscription types. Click **C2M SA Type Mapping Values** to view values for this extendable lookup.

The table lists fields that use [Lookup Value Mapping](#) to map values between Customer Care and Billing and Meter Data Management. Click the Description link to view and/or edit mapping values for a specific field. A plus sign (+) indicates that mapping values have not been defined for that field. Click the icon to configure values for that field.

Device and Asset Value Mapping

The **Device and Asset Value Mapping** section lists objects used to map data between Meter Data Management and Operational Device Management.

The table lists fields that use [Lookup Value Mapping](#) to map values between Meter Data Management and Operational Device Management. Click the Description link to view and/or edit mapping values for a specific field. A plus sign (+) indicates that mapping values have not been defined for that field. Click the icon to configure values for that field.

Related Master Configurations

The **Related Master Configurations** section lists other master configurations used with Customer To Meter, including:

- Master Data Synchronization Configuration
- Seeder Sync Request Master Configuration
- Service Order Management Master Configuration
- Service Order Management Integration

Click the **Master Configuration** link to view a specific master configuration.

Customer to Meter Consolidated Maintenance and Data Mapping

Oracle Utilities Customer to Meter uses data from Oracle Utilities Customer Care and Billing, Oracle Utilities Meter Data Management, and (optionally) Oracle Utilities Operational Device Management. This chapter describes how data used by these applications can be maintained through a consolidated maintenance process, and how data in each application is mapped to similar data in other applications..

There are several types of consolidated maintenance and data mapping used by Customer to Meter, including:

- **Merged Maintenance:** maintenance of data in applications through use of a single portal.
- **Master Data Synchronization:** master data used by the applications is kept synchronized when data is created or updated.
- **Data Audit Maintenance:** creating specific types of Meter Data Management data triggers creation of corresponding Customer Care and Billing data via Audit algorithms
- **Lookup Value Mapping:** lookup values used by one application are mapped to corresponding values in other applications via extendable lookups
- **Transactional Data Mapping:** creating specific types of transactional data in one part of Customer to Meter triggers the creation of corresponding transactions in other parts.

Merged Maintenance

Merged maintenance allows data in multiple product—specific maintenance objects to be updated via a single maintenance portal.

Administrative Data Merged Maintenance

Merged maintenance is used with several types of administrative data in Customer Care and Billing and Meter Data Management that are used in nearly identical ways in both applications. These include:

- Service Type
- SP Type (Service Point Type)
- Service Quantity Identifier
- Time of Use
- Unit of Measure

When a user creates or updates data of these types, the maintenance portal displays a superset of data elements from product-specific business objects based on a “superset” service script (defined in the Joint Maintenance Lookup extendable lookup (see below)). When the data is saved, the corresponding maintenance objects in Customer Care and Billing, Meter Data Management, and Operational Device Management are updated. For example, when a user navigates to the **Unit of Measure** portal and selects a record to update, the portal displays a combination of data from the X1-UnitOfMeasure and D1-UnitOfMeasure business objects. When the user saves the data, the changes are saved to both the UOM Customer Care and Billing maintenance object and the D1_UOM Meter Data Management maintenance object.

NOTE: Service Point Types (asset location types) are also used by Operational Device Management.

Service Point Merged Maintenance

In addition to the above types of administrative data, Customer to Meter service points are also maintained through merged maintenance. Service point merged maintenance does NOT make use of a “superset” service script, but does use product-specific business objects. Oracle Utilities Customer to Meter service points (asset locations in the case of Operational Device Management) are maintained through these product-specific business objects and extendable lookups.

The Customer to Meter base package uses the following service point business objects:

- Meter Data Management: X1D-ServicePoint
- Customer Care and Billing: X1-ServicePoint
- Operational Device Management: W2-ServicePoint

When a Customer to Meter service point is created or updated, the “Maintain CCB Service Point” (X1-CCBSPMNT) and “Maintain ODM Service Point” (X1-ODMSPMNT) Pre-Processing algorithms on the X1D-ServicePoint business object uses the C2M Mapping Field Values (X1-CCBMDM-MDMCCB-Lookup) and ODM-MDM Mapping Field Values (X1-ODMMDM-MDMODM-Lookup) extendable lookups to map lookup values between Customer Care and Billing and Meter Data Management and between Meter Data Management and Operational Device Management, and creates or updates an instance of the X1-ServicePoint and W2-ServicePoint business objects (which are used to update the their corresponding maintenance objects).

NOTE: Customer to Meter service point types should reference the “Service Point — MDM” (X1D-ServicePoint) business object.

Joint Maintenance Extendable Lookup

The specific business objects and service scripts used by merged maintenance are defined in the Joint Maintenance Lookup (X1-JointMaintenance) extendable lookup. Records in this extendable lookup define the superset script that contains the union of the elements of the objects that exist in Customer Care and Billing and Meter Data Management, as well as the corresponding product-specific business objects.

Merged maintenance lookup values are defined by the following:

- **CCB Maintenance Object:** the unique identifier for the joint maintenance lookup value
- **Superset Script:** the superset script that contains the union of the elements of the objects that exists in Customer Care and Billing and Meter Data Management. Used for administrative data maintenance only.
- **CCB Business Object:** the business object used to update the Customer Care and Billing maintenance object
- **MDM Business Object:** the business object used to update the Meter Data Management maintenance object
- **ODM Business Object:** the business object used to update the Operational Device Management maintenance object

Customer To Meter Master Data Synchronization

This section describes the master data synchronization processes supported by Oracle Utilities Customer to Meter.

In Customer to Meter, Customer Care and Billing information is generally considered the data of record for account, customer, or service agreement-related data. Synchronizing master data between Customer Care and Billing tables and Meter Data Management tables ensures that all account, customer, and service point-related data is correct and up to date before usage transaction calculations are performed. Master data synchronization ensures that when specific types of Customer Care and Billing data are created or updated, corresponding Meter Data Management data is also created or updated.

Initial master data synchronization is performed via a data conversion and migration process. [Initial Master Data Conversion](#) for more information.

The table below summarizes the types of data ongoing master data synchronization supported in Customer to Meter:

When Customer Care and Billing data of this type is created and/or updated:	Master Data Synchronization creates and/or updates this type of Meter Data Management data:
Bill Cycle / Bill Cycle Schedule	Bill Cycle / Bill Cycle Schedule
Contract Option	Dynamic Option
Contract Option Event	Dynamic Option Event
Person	Contact

When Customer Care and Billing data of this type is created and/or updated: **Master Data Synchronization creates and/or updates this type of Meter Data Management data:**

Service Agreement	Usage Subscription
-------------------	--------------------

For example, when a Customer Care and Billing Service Agreement is created, the synchronization process creates a corresponding Meter Data Management usage subscription.

NOTE: Master data synchronization is a one-way process. When Customer Care and Billing data is created or updated, corresponding Meter Data Management data is created or updated, but changes made to Meter Data Management data are NOT synchronized to the Customer Care and Billing data. As a general rule, changes to the types of data outlined above should be made in the Customer Care and Billing entities instead of their Meter Data Management counterparts.

The Customer to Meter synchronization process is based on the [Data Synchronization](#) functionality of the Oracle Utilities Application Framework, and is supported through a set of maintenance objects, master configurations, business objects, and service scripts.

Maintenance Objects

Customer to Meter supports master data synchronization for the following maintenance objects.

Customer Care and Billing Maintenance Object	Meter Data Management Maintenance Object
BILL CYCLE (Bill Cycle)	D1-BILLCYCLE (Bill Cycle)
CONTRACT OPT (Contract Option)	D1-DOP (Dynamic Option)
CONTRACT OPT (Contract Option Event)	D1-DOPEVT(Dynamic Option Event)
PERSON (Person)	D1-CONTACT (Contact)
SA (Service Agreement)	D1-(Usage Subscription)

Master Configurations

The following master configurations are used to configure the sync process between Customer Care and Billing data and Meter Data Management data:

Master Configuration	Name / Description
Master Data Synchronization Configuration	Lists all foreign key references that need resolution. Each one should reference the view that contains the external key / production key cross-reference. If initial synchronization process are also configured for data conversion in addition to the ongoing synchronization process, two views are specified. For entities that undergo the ongoing synchronization, an external system / ID type mapping is specified to cater for entities that might be synchronizing from more than one external system.
Seeder Sync Request Master Configuration	Lists the maintenance objects (contact, usage subscription, etc.) that require synchronization. Each references the synchronization business object that needs to be instantiated when processing a synchronization request for that maintenance object. For maintenance objects that undergo both initial and the ongoing synchronization, two business objects are specified.

Outbound Data Synchronization Business Objects

When data is created for one of the above Customer Care and Billing maintenance objects, an outbound synchronization request is created to create the appropriate Meter Data Management data.

Synchronization of Customer Care and Billing data and Meter Data Management data uses the following outbound synchronization business objects:

Data Sync	Object Name	Business Object
Bill Cycle/Schedule > Bill Cycle/Schedule	MDM2 Bill Cycle Sync Request	C1-MDM2BillCycleSyncRequest
Contract Option > Dynamic Option	MDM2 Contract Option Sync Request	C1-MDM2ContractOptSyncRequest
Contract Option Event > Dynamic Option Event	MDM2 Contract Option Event Sync Request	C1-MDM2ContrOptEvtSyncRequest
Person > Contact	MDM2 Person Sync Request	C1-MDM2PersonSyncRequest
Service Agreement > Usage Subscription	MDM2 SA Sync Request	C1-MDM2SASyncRequest

Inbound Data Synchronization Service Scripts

When outbound synchronization requests enter the “Send Request” state, Enter algorithms invoke service scripts to create corresponding inbound data synchronization requests.

Synchronization of Customer Care and Billing data and Meter Data Management data uses the following inbound data synchronization service scripts:

Data Sync	Name	Service Script
Bill Cycle/Schedule > Bill Cycle/Schedule	Bill Cycle Inbound Sync Request	X1-InBCSynSS
Contract Option > Dynamic Option	Inbound Dynamic Option Sync	X1-InSyDyOp
Contract Option Event > Dynamic Option Event	Inbound Dynamic Option Event Sync	X1-InSyDyOpE
Person > Contact	Inbound Contact Sync	X1-InSyCont
Service Agreement > Usage Subscription	Inbound Usage Subscription Sync	X1-InSyUS

Inbound Data Synchronization Business Objects

When outbound synchronization requests enter the “Send Request” state, service scripts create corresponding inbound data synchronization requests. Master data synchronization uses **ongoing synchronization requests** to continuously keep Meter Data Management data synchronized with corresponding Customer Care and Billing data. Ongoing synchronization requests can be used to maintain contacts, usage subscriptions, dynamic options, and bill cycles.

Ongoing synchronization of Customer Care and Billing data and Meter Data Management data uses the following data synchronization business objects:

Data Sync	Ongoing Synchronization Object Name	Business Object
Bill Cycle/Schedule > Bill Cycle/Schedule	Inbound Bill Cycle Sync Request	D2-InboundBillCycleSyncRequest
Contract Option > Dynamic Option	Dynamic Option Ongoing Sync Request	D2- OngoingSyncRequestDynOpt
Contract Option Event > Dynamic Option Event	Dynamic Option Event Ongoing Sync Request	D2- OngoingSyncRequestDynOptEvt
Person > Contact	Contact Ongoing Sync Request	D1-OngoingSyncRequestContact
Service Agreement > Usage Subscription	Usage Subscription Ongoing Sync Request	D2-OngoingSyncRequestUS

Example Synchronization Process Steps

This section provides an overview of the processing that takes place when an ongoing synchronization request is sent. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific objects involved.

Step	Process	Objects
1	Data in Customer Care and Billing is created or changed, triggering a synchronization request. For example, a service agreement is updated, and the corresponding usage subscription must be updated.	
2	An outbound synchronization request is created.	Outbound Synchronization Request business object: C1-MDM2SASyncRequest
3	When the synchronization requests enters the "Send Request" status, an Enter algorithm invokes the inbound synchronization service script to create an inbound sync request.	Inbound Synchronization Service Script: X1-InSyUS
4	The service script creates the appropriate inbound synchronization request. In this case, it's an ongoing synchronization request.	Inbound Synchronization Request business object: D2-OngoingSyncRequestUS
5	For ongoing synchronization requests, the following steps are performed by Enter algorithms on the synchronization request business object lifecycle states: <ul style="list-style-type: none"> • Data Transformed/Basic Schema Validated • Determine Sync Request BO • Setup Transformed Data • Pre-Added • Sync Request Pre-Add Data • FKs Resolved • Resolve Keys - Ongoing Sync • Updating • Sync Request Update Data 	Setup Transformed Data Algorithm: D1- SETTRANDT Sync Request Pre-Add Data Algorithm: D1-SR-PREADD Resolve Keys - Ongoing Sync Algorithm: D1-RESKEYFAL Sync Request Update Data Algorithm: D1- SR-UPDDAT

Initial Master Data Conversion

This section describes the initial master data conversion processes supported when migrating data from Oracle Utilities Customer Care and Billing to Oracle Utilities Customer to Meter.

Initial data conversion facilitates creation of data in Meter Data Management and Operational Device Management based on corresponding data in Customer Care and Billing. After creating master data (and its corresponding administrative data) in Customer Care and Billing, batch processing can be used to create corresponding master data (and its corresponding administrative data) in Meter Data Management and Operational Device Management. The table below lists the specific types of master data that can be converted using this process.

Customer Care and Billing Data	Meter Data Management / Operational Device Management Data
Service Point	Service Point (Node)
Person	Contact
Service Agreement	Usage Subscription
Meter	Device (Asset)
Item	Device (Asset)
Service Point Item History	Install Event (Asset Disposition)
Service Point Meter History	Install Event (Asset Disposition)
Meter Reads	Measurements
Interval Profile	Measuring Component
Contract Options and Contract Option Events	Dynamic Options and Dynamic Options Events

CCB/MDM/ODM Data Migration Master Configuration

In addition to the above listed master data, the initial data conversion process also converts various administration data from Customer Care and Billing to Meter Data Management and Operational Device Management. The CCB/MDM/ODM Data Migration Master Configuration is used to identify how specific types of administration data are to be migrated, including:

- **Interval Meter Types:** a list of Customer Care and Billing interval meter types that will be converted to Meter Data Management device types
- **Interval Profile Types:** a list of Customer Care and Billing interval profile types that will be converted to Meter Data Management measuring component types
- **Tracked and Item Types:** a list of Customer Care and Billing meter types and item types that will be tracked as assets and components in Operational Device Management
- **Out of Service Location Type:** the Out of Service Location Type used in creating Out of Service Location for meter and item data migration
- **Out of Service Location:** the Out of Service Location used on assets created from retired Customer Care & Billing meters
- **Service Agreement Types Pivot to Bill Determinants:** Allows you to navigate to the Service Agreement Type portal, to review and manually update the **Special Role** flag to “Bill Determinants Required” for those service agreement types that should be pivoted to require bill determinants (in other words, those that require service quantities created by Meter Data Management usage transactions).
- **Inflight FA Configuration:** options related to field activity related administration data, including whether or not to create Service Order Management field activity data, whether or not to include a Field Activity Type Profile on service point types, and mapping of Customer Care and Billing field activity types to Service Order Management field task types.

Refer to the embedded help for each of the above for more information about each.

Interval Profile Migration

The **Interval Profile** section of the master configuration should be configured to define the specific business objects to use when creating measuring component types and measuring components based on interval profiles. Interval profile measuring components should be created as "standalone" measuring components, Options include the following (values in parentheses are recommended settings):

- **Measuring Component Type BO:** Defines the measuring component type business object to use when creating measuring component types based on interval profile types (D1-StandaloneIntrvlMCType).
- **Sub Type/Measuring Component BO Mapping:** Maps Interval Profile Sub Types to specific measuring component business objects (D1-StandaloneInterval).
- **Migrate SA Profile:** Indicates if SA Profiles should be migrated.
- **Interval Profile Relationship Type Mapping:** Maps CCB Interval Profile Relationship Types to MDM Direct Channel Relationship Types (Standalone Data Request)

Data Conversion Batch Controls

Batch controls perform processing for data conversions, including such as allocating keys to data, resolving foreign keys, and loading data.

The table below lists the batch controls used for each type of data:

Customer Care and Billing Data	Meter Data Management Data	Batch Job
Administrative Data	Administrative Data	Migrate Admin Data (X1-MIGAD)
Service Point	Service Point	Migrate Service Point (X1-MIGSP)
Person	Contact	Migrate Person (X1-MIGP)
Service Agreement	Usage Subscription	Migrate Service Agreement (X1-MIGSA)
Meter	Device	Migrate Meter (X1-MIGMT)
Item	Device	Migrate Item (X1-MIGIT)
Interval Profile	Measuring Component	Migrate Interval Profile (X1-MIGIP)
SP Item History	Install Event	Migrate SP Item History (X1-MIGSI)
SP Meter History	Install Event	Migrate SP Meter History (X1-MIGSM)
Meter Reads	Measurements	Migrate Meter Reads (X1-MIGMR)
Contract Options	Dynamic Options	Migrate Contract Options (X1-MIGCO)

Processing Modes

The data conversion batch controls listed above include parameters to control the manner in which data conversion processing is performed. These parameters include the following:

- **Low ID Override Value:** Used to specify an ID value to override the low ID in the thread ID range calculation. This, along with the High ID Override Value, can be used to limit the number of records processed by each batch run.
- **High ID Override Value:** Used to specify an ID value to override the high ID in the thread ID range calculation. This, along with the Low ID Override Value, can be used to limit the number of records processed by each batch run.
- **Mode:** Used to specify whether the batch process will Insert or Delete data.
- **Migration Option:** Used to specify the type of data migration being processed, One Time Migration or Staggered. Staggered mode inserts an ad hoc characteristic that is used to detect if the record has been changed since its initial creation (used by the “Delete” mode).

For implementations with relatively small data volumes, in which data conversion can be performed in a single set of batch processes, these jobs can be run in the “Insert” Mode using the “One Time Migration” Migration Option.

For implementations with larger data volumes, in which data conversion might require running multiple instances of each batch process, the Mode and Migration Option parameters can be used to adopt a “staggered” approach to migrating the data. This mode allows identification of data that may have been updated since its initial creation which can be deleted, and then re-inserted. Running batch processing in staggered mode involves running a series of batch process runs, as follows:

1. Mode: Insert / Migration Option: Staggered — This performs the initial data conversion/migration, and flags records with an ad hoc characteristic noting the record’s version at the time of the migration, which is used to detect if the record has been changed since its initial creation.
2. Mode: Delete — This removes records that have changed in production (by comparing the versions recorded in the ad hoc characteristic) as well as records that have been deleted in production.
3. Mode: Insert / Migration Option: Staggered — This re-inserts records deleted in the previous step, including those that have changed in production since the initial migration, and inserts new records that were added in production since the initial migration.

Batch Process Sequence

The table below lists the sequence in which these migration batch processes should be executed.

Sequence	Maintenance Object
1	Admin
2	Item
3	Meter
4	Interval Profile and Interval Profile Data (see Interval Profile Migration and Converting Interval Profile Data Sets for more information.)
5	Service Point
6	Service Point Item History
7	Service Point Meter History
8	Person
9	Contract Option
10	Service Agreement
11	Meter Read

Operational Device Management Data Synchronization

This section describes the master data synchronization processes used to synchronize data between Oracle Utilities Operational Device Management and Oracle Utilities Meter Data Management, including:

- Asset and Device Synchronization
- Install Event and Asset Disposition Synchronization
- Contact and Contact Type Synchronization
- Manufacturer Synchronization
- Field Task Type and Asset Activity Type Synchronization

Asset and Device Synchronization

When assets are created (or updated) in Operational Device Management, a related Meter Data Management device is created / updated. This synchronization is performed in a manner very similar to the process outlined in [Customer To Meter Master Data Synchronization](#). The primary difference in how asset-device synchronization works is that instead of triggering the process based on the Asset maintenance object, the synchronization is triggered via the Generic Change Data Capture (W1-GCHG-CDCP) Audit algorithm on the parent business object (W1-TrackedAsset) of the following asset business objects:

- Item (W1-Item)

- Smart Meter (W2-SmartMeter)
- Analog Meter (W2-ManualMeter)
- Communication Component (W2-CommunicationComponent)

For asset-device synchronization, the specific synchronization objects used include the following:

- **Outbound Data Synchronization Business Object:** MDM Asset Synchronization Request (W1-MDMAssetSyncRequest)
- **Inbound Data Synchronization Service Script:** Inbound Device Sync (X1-InSyDvc)
- **Inbound Data Synchronization Business Object:** Device Ongoing Sync Request (D1-OngoingSyncRequestDevice)

Install Event and Asset Disposition Synchronization

When a device is installed at a service point, the disposition of its related asset is updated to “Installed”. The update to the device’s install event triggers the update to the asset disposition, changing its **Status** and **Asset Disposition** to “Installed” and its **Location** to the service point with an effective date matching the install event’s **Installation Date/Time**. This synchronization is performed in a manner very similar to the process outlined in [Customer To Meter Master Data Synchronization](#). In this case, the synchronization is triggered via the Generic Change Data Capture (W1-GCHG-CDCP) Audit algorithm on the Install Event maintenance object (D1-INSTLEVT).

For install event / asset disposition synchronization, the specific synchronization objects used include the following:

- **Outbound Data Synchronization Business Object:** ODM Install Event Sync request (D1-InstallEventSyncRequest)
- **Inbound Data Synchronization Service Script:** Inbound Asset-Node Sync (X1-InSyAstNd)
- **Inbound Data Synchronization Business Object:** Asset-Node Ongoing Sync Request (W1-OngoingSyncRequestAssetNode)

Contact and Contact Type Synchronization

Contacts in Operational Device Management can be associated to asset locations (service points). Operational Device Management contacts are created when a Meter Data Management service point has a contact associated with it via the Maintain ODM Service Point (X1-ODMSPMNT) algorithm on the Service Point - MDM (X1D-ServicePoint) business object (see [Service Point Merged Maintenance](#) for more information about how service points are maintained).

Operational Device Management contacts and contact types are maintained via Pre-Processing algorithms on the following Meter Data Management business objects:

Meter Data Management Business Object	Pre-Processing Algorithm	Operational Device Management Business Object
Business (D1-Business)	Maintain ODM Business (X1-MNTODMBUS)	Business (W1-Business)
Person (D1-Person)	Maintain ODM Person (X1-MNTODMPER)	Person (W1-Person)
Contact Type (D1-ContactType)	Maintain ODM Contact Type (X1-MNTODMCTY)	Contact Type (W1-ContactType)

NOTE: Out of service locations reference Meter Data Management contacts.

Manufacturer Synchronization

When manufacturers are created or updated in Operational Device Management, corresponding data is created or updated in Meter Data Management.

When a manufacturer is created or updated in Operational Device Management, a corresponding Meter Data Management manufacturer is created / updated. This synchronization is performed via the Manufacturer Joint Maintenance (X1-MAINTMANF) Post-Processing algorithm on the W1-Manufacturer business object.

NOTE: Operational Device Management is considered the “system of record” for manufacturers and models in Customer To Meter.

Field Task Type and Asset Activity Type Synchronization

When Field Task Types are created in Service Order Management (as values for the Field Task Type extendable lookup), corresponding Operational Device Management Asset Activity Types are created. This synchronization is performed via the Maintain MDM/SOM field task type to a corresponding ODM activity type (X1-MNTFLDTSK) Post-Processing algorithm on the D1-FieldTaskTypeLookup business object.

Asset activity types created in this manner are based on the Service Order Management Activity Type (W1-SOMActivityType) business object. The **Activity Business Object** for these asset activity types is Service Order Management Activity (W1-SOMActivity).

Lookup Value Mapping

Oracle Utilities Customer to Meter service points and other records reference field and lookup values from Oracle Utilities Customer Care and Billing, Oracle Utilities Meter Data Management, and Oracle Utilities Operational Device Management. This section describes how field and lookup values used by Customer Care and Billing are mapped to similar field and lookup values used by Oracle Utilities Meter Data Management, and how field and lookup values used by Oracle Utilities Operational Device Management are mapped to similar field and lookup values used by Oracle Utilities Meter Data Management

Customer Care and Billing / Meter Data Management Mapping

Mapping of field and lookup values between Oracle Utilities Customer Care and Billing and Oracle Utilities Meter Data Management is supported through the use of two extendable lookups:

- **C2M Mapping Field List** (X1-CCBMDM-MDMCCB-MappingField): used to capture the fields that require translation mapping between Customer Care and Billing and Meter Data Maintenance maintenance objects in Customer to Meter. Values in this extendable lookup are identified by a field or lookup used by Customer Care and Billing, such as Disconnect Location (DISCON_LOC_CD) or Life Support / Sensitive Load (LS_SL_FLG).
- **C2M Mapping Field Values** (X1-CCBMDM-MDMCCB-Lookup): used to capture the mapping values for the fields and lookups defined in the C2M Mapping Field List extendable lookup. Values in this extendable lookup are identified by a Customer Care and Billing field or lookup defined in the C2M Mapping Field List extendable lookup. Each value also defines the specific value mappings for the field or lookup.

Examples

Value Mappings for the Disconnect Location (DISCON_LOC_CD) field include the following:

CCB Value	MDM Value
Disconnected at meter	Device
Disconnected at pole	Source

Value Mappings for the Activity Type (FA_TYPE_CD) lookup include the following:

CCB Value	MDM Value	MDM Value 2
Start Service	Enable Service	
Stop Service	Disable Service	
Re-read meter	Field Activity	Read Meter

Value Mappings for the Life Support / Sensitive Load (LS_SL_FLG) lookup include the following:

CCB Value	MDM Value
None	Not on life support
LS/SL	On life support

Operational Device Management / Meter Data Management Mapping

Mapping of field and lookup values between Oracle Utilities Operational Device Management and Oracle Utilities Meter Data Management is supported through the use of two extendable lookups:

- **ODM—MDM Mapping Field List** (X1-ODMMDM-MDMODM-MappingField): used to capture the fields that require translation mapping between Operational Device Management and Meter Data Management maintenance objects in Customer to Meter. Values in this extendable lookup are identified by a field or lookup used by Meter Data Management, such as the Life Support / Sensitive Load (LIFE_SUPPORT_SENS_LOAD_FLG) or Ok to Enter (OK_TO_ENTER_FLG).
- **ODM—MDM Mapping Field Values** (X1-ODMMDM-MDMODM-Lookup): used to capture the mapping values for the fields and lookups defined in the C2M Mapping Field List extendable lookup. Values in this extendable lookup are identified by a Operational Device Management field or lookup defined in the ODM—MDM Mapping Field List extendable lookup. Each value also defines the specific value mappings for the field or lookup.

Examples

Value Mappings for the Life Support / Sensitive Load (LIFE_SUPPORT_SENS_LOAD_FLG) lookup are as follows:

ODM Value	MDM Value
Life Support/Sensitive Load	LS/SL
None	None

Value Mappings for the Ok to Enter (OK_TO_ENTER_FLG) field are as follows:

ODM Value	MDM Value
No	False
Yes	True

Data Audit Maintenance

Different functions in Customer Care and Billing and Meter Data Management use similar types of data when calculating usage and billing charges, and it's critical that the data be consistent between the applications. For example, both Usage Rules in Meter Data Management and Calculation Rules in Customer Care and Billing make use of TOU Groups, TOU Map Templates, TOU Map Types, etc., and when calculating usage and billing charges for an account, the data used by both systems should be effectively identical. The process of maintaining similar sets of data usable by each system is called Data Audit Maintenance.

When specific types of Meter Data Management data is created or updated, Audit algorithms create or update corresponding Customer Care and Billing data. For instance, when a TOU Map Type usable by Meter Data Management Usage Rules is created, data auditing creates a similar TOU Map Type usable by Customer Care and Billing Calculation Rules.

Data audit maintenance is used with several types of Meter Data Management data in Customer to Meter, including:

- TOU Group
- TOU Map Template

- TOU Map Type
- TOU Map
- Device Type (Item Type)

The table below outlines the business objects and algorithms used by data audit maintenance:

Data Type	Business Object	Audit Algorithm
TOU Group	D2-TOUGroup	Maintain CCB TOU Group (X1-MCCBTOUGP)
TOU Map Template	D2-TOUMapTemplate	Maintain CCB TOU Map Template (X1-MCCBTOUTM)
TOU Map Type	D2-TOUMapType	Maintain CCB TOU Map Type (X1-MCCBTOUMT)
TOU Map	D2-TOUMap	Maintain CCB TOU Map (X1-MCCBTOUMP)
Device Type (Item Type)	D1-ItemType	Maintain CCB Item Type (X1-MCCBITEMT)

Refer to the Business Object and Algorithm portals to view additional details regarding these audit algorithms.

Other Data Auditing

In addition to the objects listed above, Customer To Meter uses data auditing with other objects in Customer Care and Billing to ensure that changes to data reflected in related data in Meter Data Management. These objects use Audit algorithms on their maintenance objects to capture any changes and update the corresponding data. The objects that make use of this approach include the following:

- **Account:** When service agreement-related account data is changed in Customer Care and Billing, the audit algorithm creates a Service Agreement outbound data synchronization request to captures the change and update the corresponding usage subscription in Meter Data Management.
- **Premise:** When a Customer Care and Billing premise is changed, the audit algorithm updates the address information in the service point in Meter Data Management.

The table below outlines the data types, maintenance objects, and algorithms used by these.

Data Type	Maintenance Object	Audit Algorithm
Account	ACCOUNT	C2M Account Change Data Capture (SA-Based) (X1-ACCTDCSA)
Premise	PREMISE	Update MDM SP from CCB Premise (X1-UPSPFRPR)

Refer to the Maintenance Object and Algorithm portals to view additional details regarding these audit algorithms.

Transactional Data Mapping

Certain types of transactional data created in Customer Care and Billing result in related transactional data in Meter Data Management (and vice-versa). This section describes these transactional mappings.

Usage Requests / Usage Transactions

Customer Care and Billing creates usage requests during the billing process to request usage calculations in Meter Data Management. These requests in turn create Meter Data Management usage transactions, which perform the usage calculations.

Customer Care and Billing usage requests use the following business objects:

- MDM Cyclical Usage Request (C1-UsageRequestCyclicalBilling): Used with usage requests created from the cyclical or batch billing process.

- MDM Non-Cyclical Usage Request (C1–UsageRequestNonCyclical): Used with usage requests created from non-cyclical or online bill generation.
- MDM Usage Request (C1–UsageRequest): Parent business object that defines the lifecycle for Cyclical and Non-Cyclical usage requests.

When a usage request enters the “Send Request” state, the “Send Usage Request Message to MDM” (X1–SENDUSGR) Enter algorithm invokes the “Usage Transaction Request Inbound” (X1–UsgTrRqIn) service script which uses the Usage Transaction Seeder (D1–UsgTranSeeder) business object to create a usage transaction.

When a Meter Data Management usage transaction enters a “Subsequent Correction” state, the “X1–SEND–SUBC” Enter algorithm invokes the “Call Subsequent Correction Notification” (X1–SendSubC) service script to process a corrected read notification for Customer Care and Billing by finding the account associated with the corrected read and creating an off cycle bill generator to handle associated correction processing.

Refer to [The Big Picture of Usage Requests](#) for more information about usage requests and usage transactions.

Field Activity Requests / Service Order Activities

Customer Care and Billing creates Field Activity Requests to initiate service orders to perform tasks at a service point. Most field activity requests are created:

- When a customer service representative starts or stops service at a premise. When this happens, the system automatically creates field activity requests for each service point.
- When service is cut due to lack of payment or reconnected for sufficient payment or arrangement.

When Customer Care and Billing creates a field activity request, a corresponding Service Order Activity is created to orchestrate the various activities required to fulfill the service order by continuously monitoring the status of the service point, device installation, and related measurements. This orchestration can include field activities to instruct a field crew to install, remove, or exchange a meter, as well as eligible smart meter command activities to connect or disconnect the meter, etc.

Service Order Field Activities are specific activities that typically exist only in Service Order Management and not Customer Care and Billing. However, field activity remarks notification, appointment notification (if required by the service order field activity), a missed appointment (which can create an adjustment) and create customer contact actions can be invoked in Customer Care and Billing when triggered from service order field activities.

Refer to [Understanding Service Order Management](#) for more information about service order activity processing.

Other Transactional Data

Data synchronization of interval register data, interval profiles, and field activities is performed via a data conversion and migration process. See [Transactional Data Conversion](#) for more information.

Transactional Data Conversion

This section describes transactional data conversion processes supported when migrating data from Oracle Utilities Customer Care and Billing to Oracle Utilities Customer to Meter or Oracle Utilities Customer Cloud Service, including conversion of interval register data, interval profiles, and “inflight” field activities.

Converting Interval Register Data

Interval register data from Oracle Utilities Customer Care and Billing can be converted into Measurement data for use in Customer to Meter (and Customer Cloud Service).

Note: Refer to **Maintaining Interval Data** and **Maintaining Interval Data** in the *Oracle Utilities Customer Care and Billing Administrative User Guide* for more information about interval register data in Oracle Utilities Customer Care and Billing.

Interval Registers should have been migrated to Interval Measuring Components as part of the Initial Master Data Conversion process (see [Initial Master Data Conversion](#)). Once the registers have been converted, register reads (also known as Register Data Sets) can be converted to measurement data.

A batch control (see below) is used to convert register read data from Interval Register reads to the Customer to Meter (Customer Cloud Service) Measurement table. Processing can be defined for a specified year and month range, and optionally for a range of Register IDs.

Processing Notes:

- Only Register Data Sets with a status of "Complete" will be converted. Data sets that have 'No Data' will be excluded from the conversion.
- No validation is performed on the interval data. All the interval data is assumed to be valid.
- If the **Data Set Type** is not defined for the register data set, the converted measurements will have a Condition of "Regular".
- Register data sets with a **Data Set Type** of "Estimated" will result in measurements with a Condition of "Estimated".
- If overlapping register data sets are processed, the values from the data set with the latest Set Data Time are selected for the conversion.
- The conversion process will not fill-in data for periods without interval data.

Creation of records in the Measurement table is performed via an Insert Select of the Interval Register Data, for a month's worth of data at a time, which will be immediately committed.

Conversion should only be run for a given range of Register IDs for a given date range once. Attempting to convert the Register IDs for the same date range multiple times can result in errors.

Interval Register Data Conversion Batch Control

The Migrate Register Data Set (X1-MIGRD) batch control performs processing for interval register data conversion.

The registers to be converted for each batch run can be defined using the Register ID Low and Register ID High parameters. To process data for a single register, you can set both of these parameters to the same Register ID. If neither parameter is defined, the process will convert data for all registers.

The batch process can convert up to 1 year of data at a time, the specific year is designated by the Year parameter. The Start Month and End Month parameters can be used to further limit the time range for the conversion.

This batch control uses the following parameters:

- **Register ID Low:** Optional. Used to specify an ID value to override the low ID in the thread ID range calculation. This, along with the Register ID High be used to limit the number of records processed by each batch run. If not specified, the process will convert data for all registers whose ID is lower than the Register ID High parameter (if defined).
- **Register ID High:** Optional. Used to specify an ID value to override the high ID in the thread ID range calculation. This, along with the Register ID Low, can be used to limit the number of records processed by each batch run. If not specified, the process will convert data for all registers whose ID is higher than the Register ID Low parameter (if defined)
- **Year:** The year for which data will be converted. (Required)
- **Start Month:** The start month of the time range for which data will be converted. (Required)
- **End Month:** The start month of the time range for which data will be converted. (Required)

Examples:

To convert data for all registers from the year 2020, you would set the parameters as follows:

- Year: 2020
- Start Month: 01
- End Month: 12

To convert data for all registers for the months of January through May of 2020, you would set the parameters as follows:

- Year: 2020
- Start Month: 01
- End Month: 05

To convert data for registers whose IDs range from 10001000 to 10009000 for from the year 2020, you would set the parameters as follows:

- Register ID Low: 10001000
- Register ID High: 10009000
- Year: 2020
- Start Month: 01
- End Month: 12

To convert data for registers whose IDs range from 1001000 to 1009000 for the months of January through May of 2020, you would set the parameters as follows:

- Register ID Low: 10001000
- Register ID High: 10009000
- Year: 2020
- Start Month: 01
- End Month: 05

Converting Interval Profile Data Sets

Interval profile data sets from Oracle Utilities Customer Care and Billing can be converted into measuring components and measurement data for use in Customer to Meter (and Customer Cloud Service).

Note: Refer to **Maintaining Interval Data** and **Maintaining Interval Profile Data** in the *Oracle Utilities Customer Care and Billing Administrative User Guide* for more information about interval profile data in Oracle Utilities Customer Care and Billing.

Interval Profiles should have been migrated to Interval Measuring Components as part of the Initial Master Data Conversion process (see [Initial Master Data Conversion](#)). Once the profiles have been converted, profile data can be converted to measurement data.

A batch control (see below) is used to convert interval profile data to the Customer to Meter (Customer Cloud Service) Measurement table. Processing can be defined for a specified year and month range, and optionally for a range of Register IDs.

Processing Notes:

- Only Profile Data Sets with a status of "Complete" will be converted. Data sets that have 'No Data' will be excluded from the conversion.
- No validation is performed on the interval profile data. All the interval profile data is assumed to be valid.
- If the **Data Set Type** is not defined for the profile data set, the converted measurements will have a Condition of "Regular".
- Profile data sets with a **Data Set Type** of "Estimated" will result in measurements with a Condition of "Estimated".
- If overlapping profile data sets are processed, the values from the data set with the latest Set Data Time are selected for the conversion.
- The conversion process will not fill-in data for periods without interval data.

Creation of records in the Measurement table is performed via an Insert Select of the Interval Profile Data, for a month's worth of data at a time, which will be immediately committed.

Conversion should only be run for a given range of Profile IDs for a given date range once. Attempting to convert the Profile IDs for the same date range multiple times can result in errors.

Data Conversion Batch Control

The Migrate Interval Profile Data Set (X1-MIGID) batch control performs processing for interval profile data set conversion.

The profiles to be converted for each batch run can be defined using the Interval Profile ID Low and Interval Profile ID High parameters. To process data for a single interval profile, you can set both of these parameters to the same Interval Profile ID. If neither parameter is defined, the process will convert data for all interval profiles.

The batch process can convert up to 1 year of data at a time, the specific year is designated by the Year parameter. The Start Month and End Month parameters can be used to further limit the time range for the conversion.

This batch control uses the following parameters:

- **Interval Profile ID Low:** Optional. Used to specify an ID value to override the low ID in the thread ID range calculation. This, along with the Interval Profile ID High be used to limit the number of records processed by each batch run. If not specified, the process will convert data for all interval profiles whose ID is lower than the Interval Profile ID High parameter (if defined).
- **Interval Profile ID High:** Optional. Used to specify an ID value to override the high ID in the thread ID range calculation. This, along with the Interval Profile ID Low, can be used to limit the number of records processed by each batch run. If not specified, the process will convert data for all interval profiles whose ID is higher than the Interval Profile ID Low parameter (if defined)
- **Year:** The year for which data will be converted. (Required)
- **Start Month:** The start month of the time range for which data will be converted. (Required)
- **End Month:** The start month of the time range for which data will be converted. (Required)
- **Clear Measurements:** Flag indicating whether or not to delete existing measurements within the date range

Examples:

To convert data for all interval profiles from the year 2020, you would set the parameters as follows:

- Year: 2020
- Start Month: 01
- End Month: 12

To convert data for all interval profiles for the months of January through May of 2020, you would set the parameters as follows:

- Year: 2020
- Start Month: 01
- End Month: 05

To convert data for interval profiles whose IDs range from 10001000 to 10009000 for from the year 2020, you would set the parameters as follows:

- Interval Profile ID Low: 10001000
- Interval Profile ID High: 10009000
- Year: 2020
- Start Month: 01
- End Month: 12

To convert data for interval profiles whose IDs range from 100100 to 100900 for the months of January through May of 2020, you would set the parameters as follows:

- Interval Profile ID Low: 10001000
- Interval Profile ID High: 10009000
- Year: 2020
- Start Month: 01
- End Month: 05

Converting Field Activities

Completed and inflight (activities that are in the "Pending" state) customer event orchestration events and field activities from Oracle Utilities Customer Care and Billing can be converted into corresponding field activity requests and service order activities and service order field activities for use in Customer to Meter (and Customer Cloud Service).

NOTE: Refer to **Service Orders** in the *Oracle Utilities Customer Care and Billing Administrative User Guide* for more information about field activities Oracle Utilities Customer Care and Billing. Refer to [Service Orders](#) in the *Business User Guide* for more information about service order activities and service order field activities in Customer to Meter and Customer Cloud Service.

A batch control (see below) is used to create new field activity requests and corresponding Service Order Management activities. Processing can be defined for a specified date range and optionally for activities of a specific status, and/or a range of field activity IDs.

Administration Data

Before this conversion process can be run, the Migrate Admin Data (X1-MIGAD) batch process must be run. Note that the **Inflight FA Configuration** section of the CCB/MDM/ODM Data Migration master configuration must be configured to map Customer Care and Billing field activity types to Field Task Types before the Migrate Admin Data batch process is run. See [Initial Master Data Conversion](#) for more information about the CCB/MDM/ODM Data Migration master configuration.

The Migrate Admin Data process performs the following field activity related steps:

- Creates Customer Care and Billing field activity types used as customer event orchestration in Service Order Management (such as SOM-STRT (Start Service), SOM-STOP (Stop Service), and so on).
- Creates Service Order Management service order activity types and service order field activity types (Enable Service, Disable Service, Field Activity, and so on).
- Creates a "Service Order Management Profile" (SOM) Field Activity Type Profile mapping Customer Care and Billing field activity types for customer event orchestration events, such as Enable Service, Disable Service, Back to Back, Cut for Non Payment and Reconnect for Payment to corresponding Service Order Management orchestration activity types
- Creates and/or updates the Field Activity Type Value in the C2M Mapping Field Values extendable lookup mapping Customer Care and Billing customer event orchestration field activity types to corresponding Service Order Management orchestration activity types
- Copies the CCB FA Cancel Reason to MDM FA Cancel reason extendable look-up
- Copies the CCB FA Reschedule Reason to MDM FA reschedule reason extendable look-up
- Creates outbound and inbound communication types (Field Activity Outbound Communication Type and Field Activity Inbound Communication Type).

The following administration data and configuration must be in place before the conversion process can be run:

- Customer Care and Billing field activity types for customer event orchestration events, such as Enable Service, Disable Service, Back to Back, Cut for Non Payment and Reconnect for Payment have been created and configured on the Field Activity Type Profile. This is done by the Migrate Admin Data batch process (see above).
- Meter Data Management/Service Order Management service order activity types have been created and mapped to the corresponding Customer Care and Billing customer event orchestration field activity types in the Field Activity Type value of the C2M Mapping Field Values extendable lookup (accessible from the **Customer and Device Value Mapping** section of the Cross Product Configuration master configuration). This is done by the Migrate Admin Data batch process (see above).
- Customer Care and Billing field activity types for specific tasks (such as "Reread meter") are mapped to the corresponding field task types (such as "Read Meter") in the Field Activity Type value of the C2M Mapping Field Values extendable lookup (accessible from the **Customer and Device Value Mapping** section of the Cross Product Configuration master configuration).

Processing Notes

- The Customer Care and Billing field activity will be identified as either an orchestrator or specific field activity via its relationship to the service agreement/service point or a severance event.
- Existing Customer Care and Billing field activities in the "Pending" and "Completed" states will be recreated and used linked to service order activities. This is important for inflight field activities created using Customer Care and Billing field activity templates and steps, which are retained because they provide a link to the field work application.
- When converting activities in the "Completed" state, only the service order activity or service order field activity will be created. The process does not create child activities or communications. For example, if converting a completed "Start Service" field activity, the result will be an "Enable Service" service order activity, but not its children service order field activities or outbound communications.
- The original Customer Care and Billing field activity will be captured on the corresponding service order activity and/or service order field activity to ensure a record of the original field activity that resulted in the creation of the new service order activity.
- The service order management communication business objects and algorithms have been updated to accommodate existing inflight Customer Care and Billing field activities. This includes providing for identifying outbound communications created based on the original Customer Care and Billing field activity, as well as receiving inbound communications and status updates based on the original Customer Care and Billing field activity.
- Customer Care and Billing field activities in the "Cancelled" and "Held" states will not be converted. If the batch process is submitted for Customer Care and Billing field activities in the "Held" state, the "Held" field activities will be deleted. Also, the conversion process will convert Customer Care and Billing field activities of types without a corresponding service order management activity type.

Conversion of field activities can be performed using a "staggered" approach by converting different type of field activities based on field activity status at different stage in the implementation. For instance, performing conversion of completed field activities first (though some implementations may opt not to migrate historical completed field activities at all), since these are static data, following by conversion of inflight field activities. In addition to status, field activity conversion may be staggered by field activity Id range or field activity Date range.

Data Conversion Batch Control

The Migrate Field Activity (X1-MIGFA) batch control performs processing for field activity conversion.

Field activities are converted based on their Status, and by date range. In addition, field activities to be converted for each batch run can be defined using the Low FA Id Override Value and High FA Id Override Value parameters. For instance, to convert a single activity, you can set both of these parameters to the same ID. If neither parameter is defined, the process will convert all field activities of the specified status for the specified date range.

This batch control uses the following parameters:

- **Low FA Id Override Value:** *Optional.* Used to specify an ID value to override the low ID in the thread ID range calculation. This, along with the High FA Id Override Value be used to limit the number of records processed by each batch run. If not specified, the process will convert all field activities whose ID is lower than the High FA Id Override Value parameter (if defined).
- **High FA Id Override Value:** *Optional.* Used to specify an ID value to override the high ID in the thread ID range calculation. This, along with the Low FA Id Override Value, can be used to limit the number of records processed by each batch run. If not specified, the process will convert all field activities whose ID is higher than the Low FA Id Override Value parameter (if defined)
- **FA Status (C/P/H):** The status ("Completed", "Pending", or "Held") for which field activities will be converted. (Required)
- **Start FA Date:** The start date of the time range for which field activities will be converted. (Required. If not provided defaults to earliest date)
- **End FA Date:** The start month of the time range for which field activities will be converted. (Required. If not provided defaults to the business date)

Examples:

To convert all Pending field activities for the month of July 2022, you would set the parameters as follows:

- FA Status (C/P/H): P
- Start FA Date: 2022-07-01
- End FA Date: 2022-07-31

To convert all Completed field activities for the months of April through June 2022, you would set the parameters as follows:

- FA Status (C/P/H): C
- Start FA Date: 2022-04-01
- End FA Date: 2022-06-30

To convert Pending field activities whose IDs range from 10001000 to 10009000 for the month of July 2022, you would set the parameters as follows:

- Low FA Id Override Value: 10001000
- High FA Id Override Value: 10009000
- FA Status (C/P/H): P
- Start FA Date: 2022-07-01
- End FA Date: 2022-07-31

To convert Completed field activities whose IDs range from 10001000 to 10009000 for the months of April through June 2022, you would set the parameters as follows:

- Register ID Low: 10001000
- Register ID High: 10009000
- FA Status (C/P/H): C
- Start FA Date: 2022-04-01
- End FA Date: 2022-06-30

Customer To Meter Table Setup Sequence

This section provides guidelines for setting up control tables and administrative data used with Oracle Utilities Customer To Meter.

Customer Care and Billing Control Table Setup Sequence

The topics in this section describe the order in which the control tables should be set up.

Core Control Table Setup Sequence

To implement the system, you must set up your organization's business rules in "control tables". Setting up these tables is time-consuming because we allow you to tailor many aspects of the system to meet your organization's requirements. We strongly recommend that you take the time to document how you plan to set up all of these tables before you use the following roadmap to enter the core control data. Time spent understanding the interrelationships between this data will reap the rewards of a clean system that meets your current and long term needs.

While we describe the transactions and options in more detail in other sections of this manual, use the following chart (and the remaining sections of this chapter) as your roadmap. Here we list the order in which you perform tasks and the pages you'll use to set up your system. The order is important because some information must exist before other information can be defined (i.e., many dependencies exist).

NOTE: Auto setup. The Auto Setup column in the following table contains suggestions to save you time. It also indicates if a control table contains information when the system is installed.

NOTE: You don't have to set up every control table. You need only set up those control tables that govern functions that are applicable to your organization.

Function	Menu	Auto Setup
Global Context		
Algorithm	Admin, Algorithm. You will need to set up an algorithm that populates global context values. The global context is used by various zones in the system to display relevant data. This algorithm is plugged-in on the installation record .	
Accounting Environment		
Country and State	Admin, Country	
Currency Codes	Admin, Currency Code	USD is automatically populated
Accounting Calendar	Admin, Accounting Calendar	
GL Division	Admin, General Ledger Division	
Security Environment		
Application Service	Admin, Application Service	All base package transactions are automatically populated
Security Type	Admin, Security Type	

User Group	Admin, User Group Note, you won't be able to set up users at this point	One user group, ALL_SERVICES, is automatically setup. It references all other application services and a single user called SYSUSER.
Language	Admin, Language	ENG is automatically populated
Display Profile	Admin, Display Profile	Two display profiles are automatically setup: NORTHAM displays currencies and dates in a classic American format; EURO displays information in a classic European format
Data Access Role	Admin, Data Access Role	
Access Group	Admin, Access Group	
User	Admin, User	SYSUSER is automatically set up. Note that you may import your users (and user groups) from an external source .
Return to User Group	You must return to your user groups and define all of their users	
Customer Class Environment		
Customer Class	Admin, Customer Class. At this point, you'll only be able to set up your customer class codes. You will return to these customer classes throughout the setup process to populate additional information.	
Financial Transaction Environment		
Work Calendar	Admin, Work Calendar	
CIS Division	Admin, CIS Division	
Revenue Class	Admin Revenue Class	
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs a distribution code's corresponding GL account when it is interfaced to the general ledger	
Distribution Code	Admin, Distribution Code	
Bank and Bank Accounts	Admin, Bank	
Billable Charge Template	Admin, Billable Charge Template. Note, if you want the system to default service quantities onto billable charges created using this template, you must setup the appropriate unit of measure code, time-of-use code and/or service quantity identifier.	
Billable Charge Upload Line Type	Admin, Billable Charge Line Type	
Algorithm	Admin, Algorithm. You will need to set up several algorithms. These algorithms: 1) retrieve a bill segment's consumption, 2) calculate a bill segment's bill lines, 3) construct a bill segment's financial transaction, 4) cancel previously estimated bill segments	

Bill Segment Type	Admin, Bill Segment Type
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Bill Segment information that is displayed throughout the system for a specific Bill Segment Type. This algorithm is plugged-in on the Bill Segment Type.
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs a payment segment's financial transaction
Payment Segment Type	Admin, Payment Segment Type
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs an adjustment's financial transaction
Algorithm	Admin, Algorithm. Several plug-in spots are available to perform additional logic when processing adjustments. For example, if you have the system calculate adjustments, you must set up an adjustment generation algorithm. Refer to Adjustment Type for other available plug-in spots that may be used by your implementation.
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system for a specific Adjustment Type. This algorithm is plugged-in on the Adjustment Type .
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system. This algorithm is plugged-in on the installation record .
Adjustment Type	Admin, Adjustment Type
Adjustment Type Profile	Admin, Adjustment Type Profile
Approval Profile	Admin, Approval Profile. Note, an approval profile references a To Do type and one or more To Do Roles; these must be set up before you can set up the approval profile. After the approval profile(s) are set up, they must be referenced on the adjustment types that they govern.
Cancel Reason - Bill	Admin, Bill Cancel Reason
Cancel Reason - Payment	Admin, Payment Cancel Reason
Cancel Reason - Adjustment	Admin, Adjustment Cancel Reason
Tender Type	Admin, Tender Type
Tender Source	Admin, Tender Source
A/P Request Type	Admin, A/P Request Type

Issuing Center	Admin, Issuing Center. You will need to set up issuing centers if your organization assigns document numbers to bills.
Installation	Admin, Installation Options - Framework and Admin, Installation Options. Many fields on the installation record impact the financial transaction environment. Refer to the description of the Billing and Financial Transaction tabs and the Messages tab in the Framework page for more information.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that distributes payments.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that handles overpayment situations.
Algorithm	Admin, Algorithm. You may need to set up an algorithm if specific customers can have individual bill due dates.
Algorithm	Admin, Algorithm. You may need to set up an algorithm if you want the system to delete bills that contain only information about historical payments.
Algorithm	Admin, Algorithm. You may need to set up an algorithm if you want the system to levy a non-sufficient funds charge if a payment is canceled due to non-sufficient funds.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the bill information that is displayed throughout the system. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the payment information that is displayed throughout the system. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. You will need to set up an algorithm that defaults the amount when a payment is manually added. This algorithm also calculates the amount of an automatic payment for a bill for an account with an active auto pay option. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. Refer to Customer Class for other available plug-in spots that may be used by your implementation to perform additional logic when processing payments and bills.
Return to Customer Class	Admin, Customer Class. You will need to plug-in the algorithms defined above on your customer classes.

Budget Environment

Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: How To Calculated The Recommended Budget Amount, How To Periodically True Up A Customer's Budget Amount, The Circumstances When The System Should Highlight A Customer As Having An Anomalous Budget.
-----------	--

Budget Plan	Admin, Budget Plan
-------------	--------------------

Algorithm	Admin, Algorithm. Budget eligibility is set at the SA type level. You will need to set up an override budget eligibility algorithm if some service agreements for an SA type are not eligible for budget based on certain conditions.
-----------	---

Customer Environment

Account Management Group	Admin, Account Management Group. Note, you will probably have to set up To Do Type and To Do Roles before you can setup account management groups. Refer to Assigning A To Do Role for more information on how account management groups may be used to define an entry's role.
--------------------------	---

Account Relationship	Admin, Account Relationship Type
----------------------	----------------------------------

Alert Type	Admin, Alert Type
------------	-------------------

Bill Message	Admin, Bill Message
--------------	---------------------

Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your bill image software.
-----------	---

Bill Route Type	Admin, Bill Route Type
-----------------	------------------------

Contract Quantity Type	Admin, Contract Quantity Type
------------------------	-------------------------------

Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a letter in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your letter image software.
-----------	---

Letter Template	Admin, Letter Template
-----------------	------------------------

Customer Contact Class	Admin, Customer Contact Class
------------------------	-------------------------------

Customer Contact Type	Admin, Customer Contact Type
-----------------------	------------------------------

Conservation Programs	Admin, Conservation Program. You will need to set up conservation programs if your organization provides rebates to customers based on eligibility and verification of newly
-----------------------	--

	purchased appliances and hardware that are rated to conserve the demand for energy.
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if person ID's are in a predefined format.
Person Identifier Type	Admin, Person Identifier Type
SICs	Admin, SIC Code
Tax Exempt Type	Admin, Tax Exempt Type
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if phone numbers are in a predefined format.
Phone Type	Admin, Phone Type.
Person Relationship Type	Admin, Person Relationship Type.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the person information that is displayed throughout the system. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. You will need to set up an algorithm to validate a person's name. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. You can override the system's standard account information string by setting up an algorithm that produces this string of information. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record .
Installation	Admin, Installation Options. Many fields on the installation record impact the Customer Environment. Refer to the description of the Main , Person , and Account tabs for more information.
Statements	
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your statement image software.
Statement Route Type	Admin, Statement Route Type
Statement Cycle	Admin, Statement Cycle

Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record .
<hr/>	
Automatic Payment (EFT) Environment	
Algorithm	Admin, Algorithm. You will need to set up an algorithm to create automatic payments. This algorithm is plugged-in on the installation record .
<hr/>	
Tender Source	Admin, Tender Source Note: earlier, you created tender sources for the remittance processor and your cash drawers. At this point, you'll need to add at least one tender source for automatic payments. Why? Because automatic payments get linked to a tender control (which, in turn, gets linked to a tender source) when they are interfaced out of the system.
<hr/>	
Algorithm	Admin, Algorithm. You will need to set up the appropriate automatic payment date calculation algorithm to populate the extract, GL interface and payment dates on automatic payments.
<hr/>	
Auto Pay Route Type	Admin, Auto Pay Route Type
<hr/>	
Tender Type	Admin, Tender Type Note: earlier, you created tender types for things like cash, checks, etc. At this point, you'll need to add a tender type for each type of automatic payments (e.g., direct debt, credit card, etc.).
<hr/>	
Work Calendar	Admin, Work Calendar. You need only set up additional work calendars if the auto pay sources (i.e., the financial institutions) have different working days than does your organization
<hr/>	
Algorithm	Admin, Algorithm. If you need to validate the customer's bank account or credit card number, you will need to set up the appropriate validation algorithms.
<hr/>	
Auto Pay Source Type	Admin, Auto Pay Source Type
<hr/>	
Algorithm	Admin, Algorithm. You may need to set up an algorithm if your customers can define a maximum withdrawal limit on their autopay options.
<hr/>	
Return to Customer Class	Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class.
<hr/>	

Deposit Environment

Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: The Definition Of A Good Customer, When To Refund A Deposit To A Customer, When To Recommend An Additional Deposit, How / When To Calculate Interest, How To Generate The Recommended Deposit Amount.
Deposit Class	Admin, Deposit Class
Non Cash Deposit Type	Admin, Non Cash Deposit Type
Field Work Environment	
Field Activity Type and Steps	Admin, Field Activity Type
Field Activity and Field Order Cancellation Reason	Admin, Fieldwork Cancel Reason
Field Activity Type Profiles	Admin, Field Activity Type Profile
Algorithm	Field activities for Start/Stop will only be created if the SA Type linked to the service point has a SASP field work creation algorithm. Refer to the SA Type section below.
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a field order in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record .
Credit & Collections Environment (if you collect on overdue bills (as opposed to overdue debt), you will NOT set up these tables; refer to Overdue Processing - Set Up Tasks for the list of control tables required to collect on overdue bills)	
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard collection events.
Collection Event Type	Admin, Collection Event Type
Algorithm	Admin, Algorithm. You may need to set up a collection process cancellation algorithm if your organization allows individual service agreements to be removed from a collection process if they are paid (rather than performing cancellation based on all SAs in a debt class).
Collection Process Template	Admin, Collection Process Template
Collection Class	Admin, Collection Class
Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: Collection process cancellation criteria, Severance process cancellation criteria, and Override arrears due to pay plans.

Debt Class	Admin, Debt Class
Write Off Debt Class	Admin, Write Off Debt Class
Algorithm	Admin, Algorithm. You will need to set up Collection Condition algorithms.
Collection Class Control	Admin, Collection Class Control
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard severance events.
Severance Event Type	Admin, Severance Event Type
Algorithm	Admin, Algorithm. You may need to set up a severance process cancellation algorithm if your organization allows a severance process to be canceled when the related service agreement is paid (rather than performing cancellation based on all SAs in a debt class).
Severance Process Template	Admin, Severance Process Template
Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: How to refer debt to a collection agency, How to transfer debt to another active service agreement, How to write down small amounts of debt, and How to refund credit balances to a customer.
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard write-off events.
Write Off Event Type	Admin, Write Off Event Type (Note, you'll have to wait until you have defined your SA Types before you can set up the Write Off Events because SA Type is a necessary parameter to write off debt).
Write Off Process Template	Admin, Write Off Process Template
Write Off Control	Admin, Write Off Control
Collection Agency	Admin, Collection Agency. Note, each collection agency references a person therefore you must set up a person for each agency before you can enter collection agency information.
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have special logic that should be executed when a pay plan is canceled.
Pay Plan Type	Admin, Pay Plan Type
Payment Method	Admin, Payment Method
Third Party Payor	Admin, Third Party Payor. Note, you must create an account before you can create a third party payor.

Installation	Admin, Installation. Several fields on the installation record impact the Credit & Collections Environment.	
Algorithm	Admin, Algorithm. You will need to setup an algorithm that's called when a user write-off debt real time.	
Return to Customer Class	Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class.	
Services and Characteristics		
Service Type	Admin, Service Type	
Algorithm	Admin, Algorithm. If you have ad hoc characteristic types, you may need to set up the algorithms that control how they are validated	
Foreign Key Reference	Admin, FK Reference. If you have foreign key characteristic types, you may need to set up foreign key references to control how the user selects the characteristic values (and how the foreign key values are validated).	All base package FK references are automatically populated
Characteristic Type and Values	Admin, Characteristic Type	
Meter and Item Environment	Refer to the Meter Data Management Configuration Setup Sequence for control tables used with Meter Data Management, and configure the control tables as specified in this section.	
Premise and Service Point Environment		
Premise Type	Admin, Premise Type	
Algorithm	Admin, Algorithm. You will need to set up an algorithm to format the standard premise info that appears throughout the system. This algorithm is plugged-in on the installation record .	
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the service point information that is displayed throughout the system. This algorithm is plugged-in on the installation record .	
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if geographic ID's are in a predefined format.	
Geographic Type	Admin, Geographic Type	
Service Point Type	Admin, SP Type. [Note - you won't be able to define the SP Type's SA Types until after you define the SA Types or the FA Type Profiles until after you define the Field Activity Type Profiles.]	
Bill and Service Cycle Environment		
Bill Cycle, Bill Cycle Schedule	Admin, Bill Cycle	
Bill Period, Bill Period Schedule	Admin, Bill Period	

Rate Environment

Frequency	Admin, Frequency	
Service Quantity Identifier	Admin, Service Quantity Identifier	
Algorithm Type	Admin, Algorithm Type. If you create new pre-processing calculation rules, you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the calculation rule).	All base package algorithm types are automatically populated
Bill Factor	Main, Rates, Bill Factor	
Algorithm Type	Admin, Algorithm Type. If you create new Register Rules you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the register rule).	All base package algorithm types are automatically populated
Rate	Main, Rates, Rate Schedule	
Calculation Group	Main, Rates, Calculation Group	
Algorithm	Admin, Algorithm. If you use algorithms to dynamically change step boundaries, calculate prices, or implement calculation rule eligibility rules, you must set up these algorithms.	
Calculation Rule	Main, Rates, Calculation Rule	
Bill Factor Value	Main, Rates, Bill Factor Values	
Bill Factor Interval Values	Main, Rates, BF Interval Values	
Item Type SQ Estimate	Admin, Item Type SQ Estimate	
Degree Day	Admin, Degree Days	
Late Payment Environment		
Algorithm	Admin, Algorithm. You will need to set up the algorithm that determine if customers in a customer class are eligible for late payment charges	
Algorithm	Admin, Algorithm. You will need to set up the algorithm that levies late payment charges for customers in a customer class	
Return to Customer Class	Admin, Customer Class. You will need to plug-in the late payment charge algorithms set up above.	
SA Configuration		
Algorithm	Admin, Algorithm. You will need to set up the algorithms that determine: <ul style="list-style-type: none">• How to calculate the late payment charge amount for service agreements of a given type• Special criteria to be tested before a service agreement is severed.	

- How to create field activities for service agreements of a given type.
- Special processing that should take place prior to the completion of a bill that references service agreements of a given type.
- Special processing that should take place during completion of a bill that references service agreements of a given type.
- Special processing that should take place when service agreements of a given type are created.
- Special processing that should take place when a financial transaction is frozen for service agreements of a given type.

Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system. This algorithm is plugged-in on the installation record .
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system for a specific SA Type. This algorithm is plugged-in on the SA Type .
Algorithm	Admin, Algorithm. If you want a Control Central alert to highlight when the current account has any stopped service agreement(s), you will need to set up the algorithm that does this. This algorithm is plugged-in on the installation record .
Service Agreement Type	Admin, SA Type
Terms and Conditions	Admin, Terms and Conditions
SA Type Start Options	Admin, SA Type Start Option
Update SP Types with initial SA types and with FA Type Profiles	Admin, SP Type
SA Relationships	
SA Relationship Type	Admin, SA Relationship Type
Service Provider	Admin, Service Provider. Note, you must create a person before you can create a service provider. If you have financial relationships (you bill for them or they bill for you), you must also create an account and a financial settlement service agreement before you can create the service provider.
SA Type / SA Relationship	Admin, SA Type SA Relationship Type
Service Provider.	Admin, Service Provider. Note, you must create a person before you can create a service provider.

Sales and Marketing

Order Hold Reason	Admin, Order Hold Reason
Order Cancel Reason	Admin, Order Cancel Reason
And more...	Refer to Campaign and Package Setup Sequence for additional setup requirements
Service Credit Membership	
Algorithm	Admin, Algorithm. You may need to set up algorithms for the service credit membership type and service credit event type to control behavior for the service credit membership and its events.
Credit Unit	Admin, Credit Unit. If your service credits record non-monetary units.
Service Credit Membership Type	Admin, Service Credit Membership Type
Service Credit Event Type	Admin, Service Credit Event Type
Membership Inactive Reasons	Admin, SC Membership Inactive Reason
Wrap Up	
Algorithm	Admin, Algorithm. You will need to set up the algorithms that determine: #x2022; Special alerts on Control Central (assuming you have special alerts)
Installation Options	Admin, Installation Options - Framework and Admin, Installation Options. At this point, it's a good idea to double-check everything on the installation record.
Postal Default	Admin, Postal Code Default

If you have cash drawers you will also need to set up the following information:

- Create a person / account to which you will link your over / under service agreement. Refer [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#) for more information.
- Create a service agreement to which your over/under payments will be linked. This service agreement will reference your over / under SA type. Refer to [Over / Under Cash Drawer Segmentation](#) for more information.

If you upload payments from an external source (e.g., a remittance processor or lock box), you must set up the following information:

- Create a person and account to which the system will link payments with invalid account. Refer to [Phase 3 - Create Payment Events, Tenders, Payments and Payment Segments](#) for information about the process that books invalid payments to this account. Refer to [How To Transfer A Payment From One Account To Another](#) for how a user transfers the payment from the invalid account to the correct account (once known).
- Create a service agreement for this account. This service agreement will reference your payment suspense SA type. The system needs this service agreement so that it can distribute the invalid account's payment (and this is necessary so that cash will reflect the payment). Refer to [Payment Upload Error Segmentation](#) for more information.
- Update the tender source associated with the respective source of payments to indicate the service agreement created in the previous step should be used for payments with invalid accounts. Refer to [Setting Up Tender Sources](#) for more information.

- Because the payment upload process simply books payments that reference invalid accounts to the account associated with the suspense service agreement on the payment's tender source, this account should belong to a customer class with the appropriate payment distribution algorithms. This may entail creating a new customer class that will only be used on suspense accounts. This customer class would need the following algorithms:
- We'd recommend using a simple payment distribution algorithm like PYDIST-PPRTY (distribute payment based on SA type's payment priority).
- We'd recommend using an overpayment distribution algorithm like OVRPY-PPRTY (distribute overpayment to highest priority SA type).

The remaining sections describe additional control tables that must be set up for specific functional areas.

Cross-Reference To The Remaining Chapters

The table in the previous section describes the order in which you should enter your control tables. These tables are described at length in the following chapters.

- Refer to [Defining General Options Addendum](#) and [Defining General Framework Options](#) for a discussion of the control tables associated with general functionality (e.g., country codes, state codes, etc.).
- Refer to [Defining Financial Transaction Options](#) for a discussion of the tables affecting your financial transactions (e.g., bill segment types, payment segment types, etc.)
- Refer to [Defining Customer Options](#) for a discussion of the control tables affecting persons, accounts and service agreements.
- Refer to [Defining Service Order Options](#) for a discussion of the control tables affecting fieldwork.
- Refer to [Defining Credit and Collections Options](#) for a discussion of the control tables affecting your collection activities.
- Refer to [Defining Device Options](#) for a discussion of the control tables affecting your meters and items.
- Refer to [Defining Device Installation Options](#) for a discussion of the control tables affecting your premises and service points.
- Refer to [Defining Cycles and Schedules](#) for a discussion of the control tables affecting your cyclical processes.
- Refer to [Rates](#) for a discussion of the control tables affecting your rates.
- Refer to [Defining SA Type Options](#) for a discussion of the control tables affecting your service agreement types.
- Refer to [Defining Background Process](#) for a discussion of the control tables affecting your background processes.
- Refer to [Defining Algorithms](#) for a discussion of the control tables affecting the algorithms referenced on many control tables.
- Refer to [Defining SA Relationships](#) for a discussion of the control tables affecting the relationships between service providers.
- Refer to [Statements](#) for a discussion of the tables affecting the statement setup options for your customers.
- Refer to [Defining Service Credit Options](#) for a discussion of the tables affecting the service credit membership setup options for your customers.

Open-Item Accounting Table Setup Sequence

Open-item accounting tables need only be set up if your organization practices [Open Item Accounting](#). Refer to [Setting Up The System To Enable Open Item Accounting](#) for a description of the tables that must be set up to enable this functionality.

Fund Accounting Table Setup Sequence

Fund accounting tables need only be set up if your organization practices [Fund Accounting](#). Refer to [Setting Up The System To Enable Fund Accounting](#) for a description of the tables that must be set up to enable this functionality.

Payment Event Distribution Table Setup Sequence

Payment event distribution tables need only be set up if your organization opted to use the distribution rules method to create payment events. Refer to [Setting Up The System To Use Distribution Rules](#) for a description of the tables that must be set up to enable this functionality.

Loans Table Setup Sequence

Loans need only be set up if your organization offers [loans](#) to your customers. Refer to [Setting Up The System To Enable Loans](#) for a description of the tables that must be set up to enable this functionality.

Quotes Table Setup Sequence

Quotes need only be set up if your organization sends quotes to customers or prospects. Refer to [Defining Quotation Options](#) for a description of the tables that must be set up to enable this functionality.

Non-Billed Budget Table Setup Sequence

[Non-Billed Budgets](#) need only be set up if your organization allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Refer to [Setting Up The System To Enable Non-Billed Budgets](#) for a description of the tables that must be set up to enable this functionality.

Scripting Table Setup Sequence

Scripts need only be set up if your organization opts to create [scripts](#) to step your users through business processes. Refer to [Defining Script Options](#) for information about scripting and the tables that must be set up to enable this functionality.

Reports Setup Sequence

In order to use the reporting tool, you will need to set up reporting options. Refer to [Configuring The System To Enable Reports](#) for more information.

External Messages Setup

To configure the system to communicate with an external system, refer to [External Messages](#).

Case Management Setup Sequence

Case management options need only be set up if your organization uses cases to manage issues. Refer to [Setting Up Case Types](#) for more information.

Umbrella Agreement Management Setup Sequence

Umbrella agreement management options need only be set up if your organization uses umbrella agreements to manage contracts. Refer to the integration documentation for more information.

Outage Management Setup Sequence

Outage management options need only be set up if your organization interfaces with Oracle Utilities Network Management System. Refer to the integration documentation for more information.

Prepaid Metering Setup Sequence

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to [Defining Prepaid Metering Options](#) for more information.

Zone Set Up

Most zones are delivered with the base-package and do not require any configuration. However, some zones are only available if configured by your implementation. Refer to [Configuring Zones](#) for more information.

To Do Options Setup

Refer to [Setting Up To Do Options](#) for more information on how to configure the system to match your organization's To Do management needs.

Meter Data Management Configuration Setup Sequence

This section provides the suggested order for the setup of Meter Data Management and Smart Grid Gateway administrative data.

	Entity	Description
1	Feature Configuration	These are options that can be set to impact system processing. Typically these have wide ranging impact across several modules (e.g., multi-time zone support)
1	Country	Your organization's country.
1	Currency	Your organization's native currency.
1	Display Profile	Controls how dates, times, and numbers displayed.

1	Language	The language to use for this implementation.
1	Time Zone	Your organization's base time zone.
1	Work Calendar	The work calendar for your organization, which identifies your public holidays.
2	Installation Options	Control various global aspects of the system.
2	To Do Role	Used to associate users with To Do entries.
2	To Do Type	Used to define types of To Do Entries.
3	User	Defines a user's user groups, data access roles, portal preferences, default values, and To Do roles.
3	User Group	A group of users who have the same degree of security access.
3	Service Type	Defines specific types of service for which usage can be recorded and captured (electric, gas, steam, etc.).
4	Division	Delineates between different operating companies within a large conglomerate of utilities.
4	Unit of Measure	Quantities measured and recorded by the system (CCF, KWH, KW, etc.).
4	Service Quantity Identifier	Used to further distinguish between measured quantities that have identical UOM/TOU combinations.
4	Time of Use	Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used (On- Peak, Off-Peak, etc.).
4	Factor	Centrally stored sets of values for use in validation rules, bill determinants calculations, and other processes.
4	Market	Defines jurisdictions or regulatory environments in which a Service Point participates.
4	Measurement Cycle	Defines the schedule for manual meter reading of devices at Service Points in that cycle
4	Measurement Cycle Schedule	Define the dates on which devices are scheduled to be read for a given measurement cycle.
4	Outbound Message	Defines messages sent to external systems.
4	Processing Timetable Type	Defines types of schedules that can be referenced by different processes and objects.
5	External System	Defines External Systems with which Oracle Utilities Meter Data Management should be able to communicate.
6	Head End Systems External Applications Market Participants	External entities that serve various roles relative to the application (head-end systems, billing systems, market participants, outage management systems, etc.).
6	Contact Type	Defines properties of a class of entities (businesses, persons).
7	Activity Type	Defines properties common to a specific type of activity.
7	Communication Type	Define properties common to a specific type of communication.
7	Service Task Type	Defines specific types of tasks performed by external users (self-service meter reads, self-service outage notifications, etc.)

7	Dynamic Option Type	Defines information common to dynamic options of a specific type.
7	Manufacturer	Individual companies that makes devices. Manufacturers also reference models.
7	Exception Type	Defines properties common to VEE Exceptions of a specific type.
8	VEE Group	Collections of VEE Rules that are applied to initial measurement data.
9	VEE Rule	Standard and custom VEE Rules that perform checking and/or manipulation of initial measurement data.
10	VEE Eligibility Criteria	Dictates whether a VEE Rule can execute based on a set of defined criteria.
11	Measuring Component Type	Defines the most important properties of a measuring component.
11	Measuring Component Comparison Type	Defines details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated.
12	Device Configuration Type	Defines properties of Device Configurations of a given type.
13	Device Type	Defines information about a class of devices.
14	Service Point Type	Defines specific types of points at which service is delivered.
14	Service Point Quantity Type	Defines types of quantities that can be stored for a service point.
14	Usage Subscription Quantity Type	Defines types of quantities that can be stored for a usage subscription.
15	TOU Group	Used to limit the set of Time Of Uses that are usable in a TOU schedule.
16	TOU Map Template	Schedules used for TOU map data generation.
17	TOU Map Type	Define important properties of TOU maps of a given type.
18	Usage Transaction Exception Type	Defines properties common to Usage Transaction Exceptions of a specific type.
18	Usage Calculation Group	Collections of usage calculation rules that are applied to measurement data to calculate bill determinants for Usage Subscriptions.
19	Usage Calculation Rule	Defines rules that perform calculations on measurement data to generate bill determinants and other values used by external systems.
20	Usage Calculation Rule Eligibility Criteria	Dictates whether a usage calculation rule can execute based on a set of defined criteria.
21	Usage Subscription Type	Defines collections of properties common to a set of Usage Subscriptions.
22	Data Source	Defines the source of data for dynamic aggregation, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or measuring component sets
22	Dynamic Aggregation Measuring Component Type	Define the most important properties of a measuring component used with dynamic aggregation.
22	Measuring Component Set	Define the dimensions and criteria by which dynamic aggregation will be performed.
22	Aggregation Group	Define the ordering of a series of related aggregations based on a set of configured measuring component Sets.

23	Settlement Subscription Type	Defines collections of properties defining a class of settlement subscriptions.
23	Settlement Unit	Defines the “lowest common denominator set” of dynamic aggregation dimensions.
23	Settlement Calculation Group	Defines collections of settlement calculation rules that are used to perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE).
23	Settlement Calculation Rule	Defines rules that perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE).
23	Settlement Item Type	Defines specific types of end-customer settlement accounts.
23	Market Contract Type	Defines specific types of market contracts used in settlement processing.
23	Market Product Set	Defines the highest level grouping for a set of market products that will be processed together.
23	Market Product Type	Define types of products used in settlement processing.
23	Attribute Data Snapshot	Define types of attribute data snapshots used in settlement processing.
23	Measurement Data Snapshot	Define types of measurement data snapshots used in settlement processing.
24	Processing Methods	Control various behaviors for external applications, head end systems, and market participants within the system such as which message is sent, how an external value is translated, among others.
24	Master Configuration	Configuration that applies to series of modules that acts as a central point of configuration rather than embedding repetitive configuration throughout a set of algorithms.
24	Information Lifecycle Management	Information Lifecycle Management (ILM) is designed to address data management issues, with a combination of processes and policies so that the appropriate solution can be applied to each phase of the data’s lifecycle.
24	Analytics	Defines the extract parameters, the bucket configurations and configuration snapshots used for extracting data for Oracle Utilities Analytics

Operational Device Management Table Setup Sequence

This section provides the suggested order for the setup of Operational Device Management administrative data.

Sequence	Entity	Description
1	Configuration Type	Defines the information required for various asset configurations with other assets, components, firmware, and other data.
1	Service History Questions	Used to guide workers through corrective and preventive inspection processes as part of an asset’s service history.

1	Service History Type	Defines the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.
2	Asset Location Type	Defines the details of asset or component locations of a certain type. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.
2	Out of Service Location Type	Defines attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.
2	Organization	Used for categorization and reporting for locations.
2	Configuration	Documents and manages valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.
3	Out of Service Location	Defines physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as "In Repair" or "Pending Disposition" the asset location is typically moved to an out of service location.
3	Configuration Reports	Provides a summary of currently installed configurations.
4	Asset Type	<p>Defines the attributes for assets and components of a certain type, including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.</p> <p>When setting up Asset Types, asset type codes should match corresponding device type codes in Meter Data Management (see Meter Data Management Table Setup Sequence).</p>
5	Asset Activity Type	<p>Defines the attributes for asset activities of a certain type, including scheduling information, exception handling, attachments, and related completion event types.</p> <p>NOTE: Asset activity types are automatically created when Service Order Management Field Task Types are created (values for the Field Task Type extendable lookup).</p>
5	Asset Completion Event Type	Define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.
5	Asset Inbound Communication Type	Defines the information required for the system to receive messages from external systems.

Understanding Online / Batch Loaders

Online / Batch Loaders enable the quick loading of data into the system. Data can be loaded for any business object as it uses the business object's schema to load data into the application.

Note: We recommend that this process not be used to load data for objects maintained through merged maintenance, such as Service Type, Unit of Measure, Service Quantity Identifier, Time of Use, Service Point Type, or Service Point as this process may not properly populate data for all maintenance objects supported by merged maintenance.

Two types of loaders are supported:

- **Online Loaders** easily upload smaller amounts of data. Use this type of upload process when uploading small numbers of records or data for business objects without complex lifecycles and business object rules such as Organizations. The data is loaded through the user interface to create the target objects.
- **Batch Loaders** should be used for larger volumes of data and for complex business objects such as Assets. Batch loaders load data from files on the server or attachments. Batch loaders use a two-step process that first creates the inbound sync request and uploads the file to a staging table and secondly, uploads the sync request from the staging table to either create the target objects or create another dedicated inbound sync request that handles the complexity of a particular object.

Processing uses the creation of a request type to facilitate the upload process:

- For online request types, the actual data is stored within and processed by the request.
- For batch request types, two options for batch load are supported; from a file located on the server or from an attachment in the application. Either the file name (file on server) or the attachment id (attachments) is stored on the request, the data is loaded into the generic inbound sync requests, and the request acts as a header record for all the generic inbound sync requests.

A csv file is the format used for loading data (see **Creating CSV Files**, below). The loader has very strict requirements as to the format of the file. Please see the embedded help in the **Data** section on the Online Loader Request business object for details and additional tips.

Creating CSV Files

While data can be manually entered into the system, the most efficient method for uploading the data is to use one of the CSV data templates already available for all appropriate business objects.

The first step is to create a .csv file (comma delimited) from the business object of the portal being loaded.

The following is an example using Organization (W1-Organization):

1. Navigate to **Admin**, select **Location**, select **Organization**, and then select **Search**.
2. Search for and select a record.
3. Expand the **Record Information** section and click the "Organization" **Business Object** link to navigate to the **Business Object** portal.
4. Click the **View Schema** link on the **Main** tab and then copy the elements from the business object to a CSV file to create your data.

1	Sequence	Primary Key	Field 01	Field 02	Field 03
2	1	Organization	Organization Type	Disposition	description
3	2	nodeId	nodeType	nodeDisposition	description
4	3		Group	W1AC	Group 1
5	4		Group	W1AC	Group 2

Notes:

- Columns in the top row match the elements in the list of the request business object (header).
- The row with the lowest sequence number (1) is the description of xpaths to help users read the file and is ignored by the processing.
- The business object processing treats the row with the second lowest sequence number (2) not as data, but as the xpath to move data to the target business object, in this case, W1-Organization.
 - Note that the configuration of some business object mean that this cell may start with a “+” sign. Also note that the file always treats this cell as a formula and adds an “=” sign to the front of the data string, as indicated by “#NAME?” (For example: =+nodeId/nodeType). You must reformat the cell to “Text” and remove the “=” sign.
- Rows with sequence number three (3) and up are treated as data.
- For objects where the primary key is a system generated ID (such as the case with Organization), the Primary Key column cells blank.

Note: When adding records that reference look up values use the lookup field value, not the description. For instance, the Disposition field references the NODE_DPOS_FLG lookup, for which the "Active" field value is "WIAC". For fields that reference other objects, use the code, not the description.

Other Formatting Issues

The following information addresses known formatting issues in working with the CSV data template:

- Dates need to be formatted as yyyy-mm-dd (2020-10-27).
- Date and Time should be formatted as yyyy-mm-dd-hh.mm.ss.
- Columns based on lookup values that have leading zeroes will need to match the values in the CSV file.
- A link needs to be created when you want to include the “parent”, which has a system generated ID, in the same file with the “child”. For example, if you want to populate the Parent Organization’s ID in the same file, you would need to insert a link (for example, @3, which is the @ symbol plus the Sequence #) in the row where the system generated ID would reside.
- If multiple rows contain the same Primary Key, only the last row is loaded. All values for the Primary Key need to be on the same row.

Initiating Requests

There are two steps involved in loading data using this process: creating the request type and the request.

Creating Request Types

1. Navigate to **Admin**, select **General**, select **Request Type**, and then select **Add**. The **Select Business Object** screen opens.
2. Select the request type business object that corresponds to your request type (“Online Loader Request Type” or “Batch Loader Request Type”) from the **Request Type Business Object** drop-down list and click **OK**. The **Online Request Type** or **Batch Request Type** screen opens (based on the business object selected).
3. Enter a code and meaningful description for the request type in the **Request Type** and **Description** fields. For example, "Online Loader Request Type" or "Batch Loader Request Type".
4. Enter a **Detailed Description** (optional).
5. For request types based on the Batch Loader Request Type business object, specify whether or not the contents from the attachment record will be deleted once the upload is finished (Yes or No) in the **Deleted Attachment Upon Finish** drop-down list.
6. Click **Save**.

Creating Requests

Online Requests

1. Navigate to **Menu**, select **Tools**, select **Request**, and then select **Add**. The **Select Type** screen opens.
2. Select your online loader request type and then click **OK**. The **Online Loader Request** screen opens.
3. Select the business object for your loader in the **Business Object** field.
4. Select your CSV file to upload or enter the data directly into the **Data** section and then click **Save**. Note: If examples of online requests are already available in your system, search for the appropriate request, click **Edit**, and either use the existing data if it applies, or click **CSV File To Upload** to upload your already formatted and populated CSV file. You can also click **Download To CSV File** and manually populate the data into the file and then click **CSV File To Upload** to upload the file. Your request will open in the **Request** zone in the "Created" state.
5. Click **Load Data** in the **Record Actions** section to submit the request. If successful, the status of the request will be "Loaded". Check the **Request Log** for requests that do not transition to a "Loaded" status. You will need to click **Back to Created** to reset the request back to the "Created" status and click **Edit** to fix the issue before resubmitting the request.

Batch Requests

1. Navigate to **Menu**, select **Tools**, select **Request**, and then select **Add**. The **Select Type** screen opens.
 2. Select your batch loader request type and then click **OK**. The **Batch Loader Request** screen opens.
 3. Select an external system from the **External System** drop-down list.
 4. Select the business object for your loader in the **Business Object** field.
 5. Enter a commit frequency in the **Commit Frequency** field.
 6. Enter the **File Name** or search for and select the **Attachment** that should be in the request and click **Save**.
- For **Batch File Upload** — The Filename is specified in the request. Comma delimited files should be uploaded to or available on the server. Run the W1-GBUPL batch job to create the sync request. Parameter File Name and File Path should match the file name and path of the file. Once the job has ended and the request is loaded, run the F1-SYSRQ batch job to process the created sync request.
 - For **Batch Attachment Upload** — The Attachment ID is specified in the request. Comma delimited file is uploaded as an attachment. Run the W1-GAUPPL batch job to create the sync request. Parameter Request ID should match the created request. Once the job has ended and the request is loaded, run the F1-SYSRQ batch job to process the created sync request.
 - Use the following parameters when running the F1-SYSRQ batch job:
 - Maintenance Object: F1-SYNCREQIN
 - Restrict by Batch Code: True
 - Restrict by Business Object: W1-GenericDataLoaderSync
 - Restrict by Status Code: PENDING

Customer To Meter Batch Processing

This section provides guidelines for configuring batch processing with Oracle Utilities Customer To Meter.

Batch Process Dependencies

The contents of this section illustrate the periodicity and dependencies between the various background processes described above.

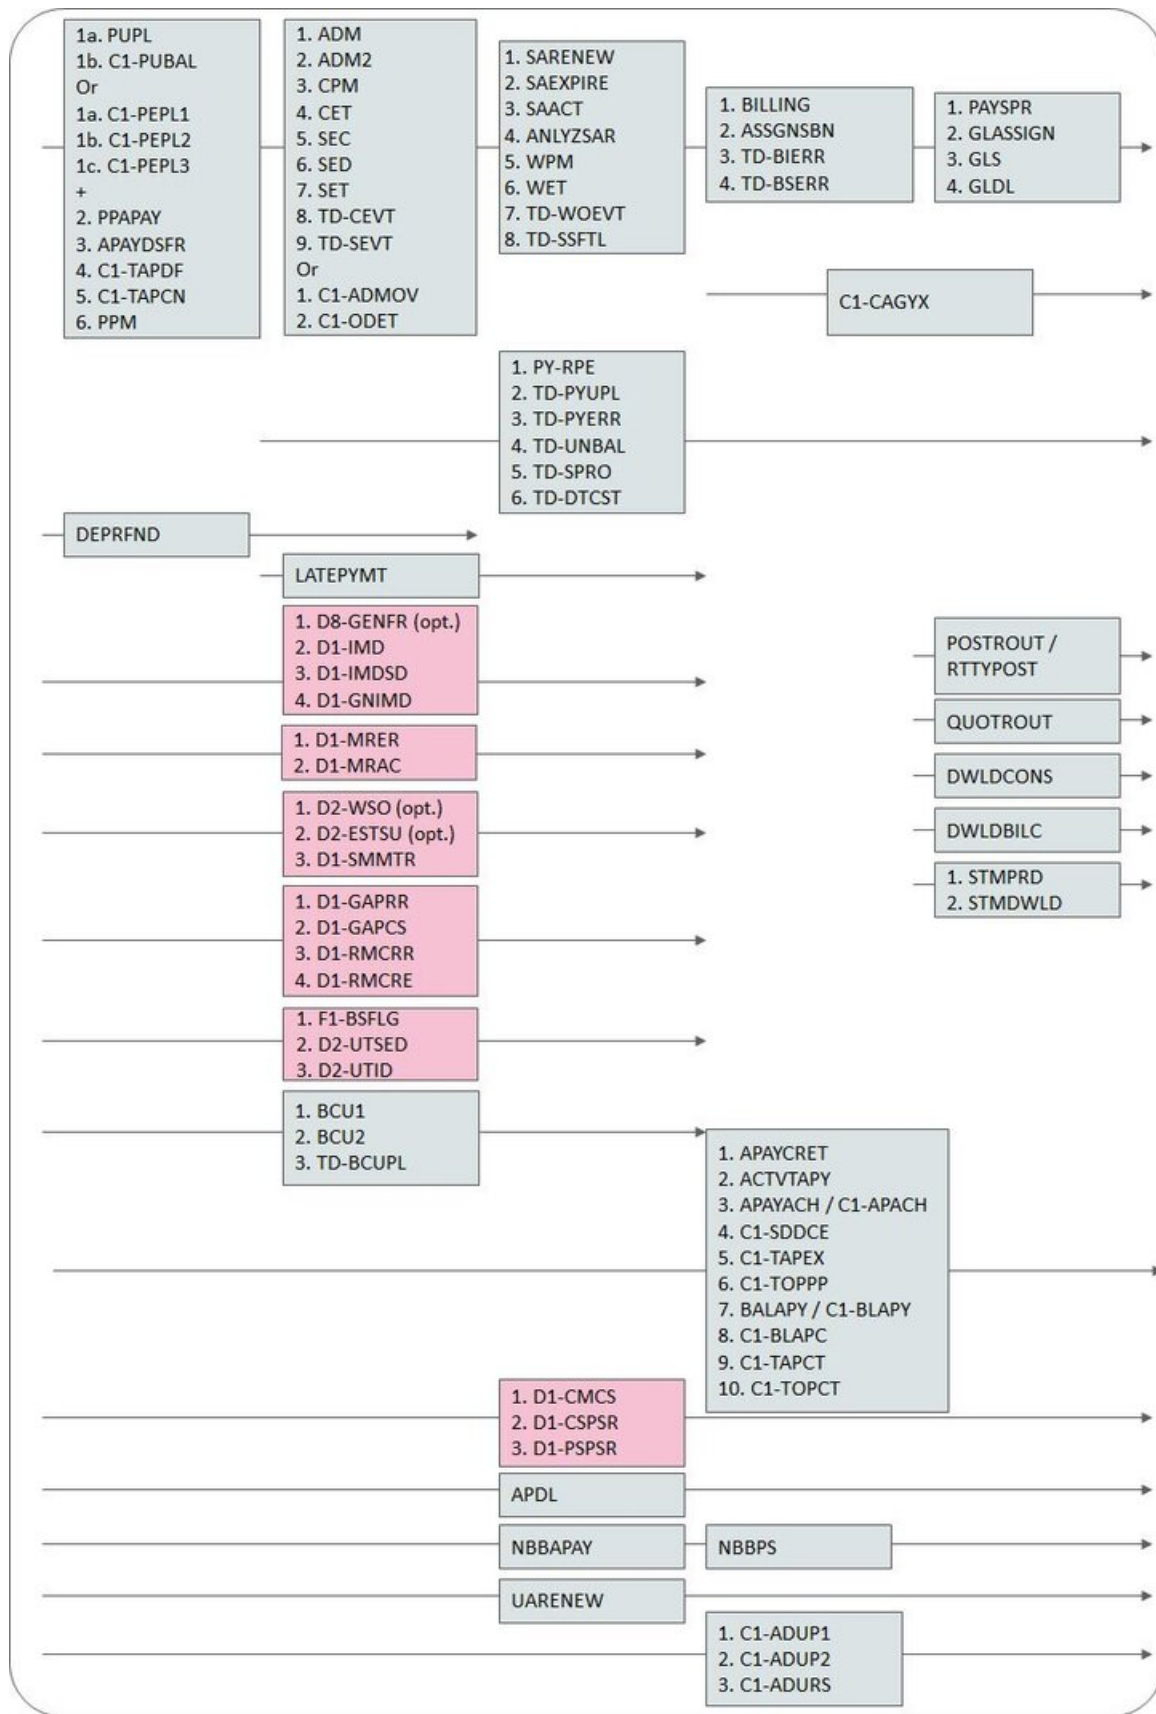

Batch Schedulers and Return Codes

If you use a batch scheduler (e.g., Control-M, Tivoli) to control the execution of your batch processes, it will be interested in the possible values of each process's return code. The return code is a number that indicates if the process ended successfully. All product processes will return one of the following return code values:

- 0 (zero). A value of zero means the batch process ended normally.
- 2. A value of 2 means the batch process detected a fatal error and aborted.

The Nightly Processes

The following diagram illustrates the dependencies between the batch processes.

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially. When multiple boxes exist on a timeline, all processes in an earlier box must execute before the subsequent box is executed. Those timelines that appear beneath the Main Job Stream's timeline indicate when the timeline's respective processes can be executed in respect of the Main Job Stream.

The following diagram illustrates the daily batch processes for which there are no dependencies.

The mnemonics in the boxes refer to the individual batch processes described above.

NOTE:

No dependencies exist. As you can see, there are no dependencies between the boxes (meaning they may be run in parallel).

The Ongoing or Hourly Processes

The following diagram illustrates the dependencies between the ongoing or hourly batch processes.

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially.

NOTE:

No dependencies exist. As you can see, there are no dependencies between the boxes (meaning they may be run in parallel).

Throughout the course of the day, you will likely want to run jobs to bring measurement and event data in from the various metering / head-end systems and other external systems. To accompany this, you should consider running the following batch processes:

- **Ongoing Master Data Sync Processing**

With the Oracle Utilities Customer to Meter deployment, data synchronization is used to keep certain objects synchronized. Refer to the C2MIntegration section for further details. Cleaning out synch staging records in error by running D1-SIOER may be necessary.

- **Command Processing**

If using Oracle Utilities Smart Grid Gateway to process device commands, it's important to keep communications flowing to and from smart meters to provide the most accurate picture of the state of a given meter. This would include:

- Retrying inbound communications in error (D1-ICERR)
- Retrying outbound communications in error (D1-OCERR)
- Processing outbound communications waiting for a response (D1-OCWT) to see if they should be timed out.
- Processing command request activities in error (D1-CRERR) and those that are waiting (D1-CRWT)

NOTE: Base package business objects for communications and command activities are designed to trap any processing errors encountered and transition the object into an Error state. To deal with unexpected errors that can't be trapped, which could leave communications / command activities in unmonitored states, implementations can choose to configure their own batch controls based on the delivered D1-ACTVY and D1-COMM batch controls, restricting records processed by business object or maintenance object as needed

- **Initial Measurement Processing**

For initial measurement processing, the following batch processes should be scheduled on an ongoing basis per business requirements:

- Processing initial measurements in the pending state (D1-IMD).
- Processing initial measurements seeders in error (D1-IMDSD).
- Processing initial measurements in the exception state (D1-GNIMD).

These processes are also highlighted in the Nightly Processes stream to reflect the need to bring in as much measurement data as possible prior to running billing, both up-to-date data from late-reporting meters and corrected readings from the head-end system.

- **Event Processing**

The base package is configured such that device events are processed immediately upon receipt, since they might need to be sent to some other application such as an outage system. This can be changed by configuring a monitor process on the device event business object to stop records in a specified state, and then use a batch process to process the events all at once. Beyond this type of batch-oriented processing for events, other event processing could include:

- Re-processing device event "seeders" in error (D1-DVEVS)
- Processing all device events that can come in as pairs (D1-DEVPR)
- Picking up device events for processing if they've stopped in any state (D1-DVEVT)

If device events are configured to be held from being sent onto downstream applications, such as to prevent "flicker" outage events (an outage event and a restore event received in rapid succession) from being sent, device event monitoring (D1-DEVPR and D1-DVEVT) should be set up to be run periodically to ensure timely transmission of events.

The Letter Processes

To extract information for your various letters, only one background process, LTRPRT, is required regardless of the different types of letters you have. This process simply calls an algorithm plugged-in on the respective letter template to construct its flat-file content.

The following diagram illustrates the dependencies for the letter background process. While this process should be run at least on a daily basis, you may want to consider running it more frequently (depending on how frequently you produce letters).

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially. When multiple boxes exist on a timeline, all processes in an earlier box must execute before the subsequent box is executed.

The Periodic Processes

The following diagrams illustrate the dependencies between the periodic background processes. You may want to consider running these processes more or less frequently than suggested (depending on business requirements).

Periodic Processes: Weekly

The following processes should be run roughly once a week, or as per business requirements.

Periodic Processes: Monthly

The following processes should be run at least once a month, or as per business requirements.

Periodic Processes: Annually

The following processes should typically be run once a year, or as per business requirements.

Periodic Processes: Per Business Requirements

The following processes should be run as frequently as dictated by business requirements.

The mnemonics in the boxes refer to the individual batch processes described above.

NOTE:

Few dependencies exist. As you can see, there are few dependencies between the boxes (meaning they may be run in parallel).

TOU Map Data Generation

TOU map data must be in place for all TOU maps used in usage calculations. Generation of this data is performed using the “Time of Use Map Data Generation Monitor” batch control (D1-TOUTr). This process can be performed for long time periods, such as a year, generating data for all time-of-use maps for the entire following year, or it could be done more frequently, such as whenever schedules are updated via the TOU map templates

Defining General Options

This section describes control tables that are used throughout Oracle Utilities Customer Care and Billing.

Defining Installation Options

The topics in this section describe the various installation options that control various aspects of the system that are specific to the Oracle Utilities Customer Care and Billing product.

FASTPATH:

Refer to [Installation Options - Framework](#) for options that are common to products on the same framework.

Installation Options - Main

Select **Admin > General > Installation Options** and use the **Main** page to define system-wide installation options.

Description of Page

Use **Quick Add Tender Type** to define the tender type [defaulted on payments added using the Payment Quick Add transaction](#).

Use **Starting Balance Tender Type** to define the tender type of the starting balance recorded on your tender controls (this will almost always be the tender type associated with "cash"). This value is used during tender control balancing as a separate balance is required for each tender type in order to balance a tender control. Refer to [The Lifecycle Of A Tender Control](#) for more information.

FASTPATH:

For more information, refer to [Setting Up Tender Types](#).

Turn on the **Create Field Activity Start Stop** if field activities should be created when a start or stop is recorded (as opposed to shortly before the start/stop date). You might want to turn this switch off if it's possible for the state of the service point (or its meter / item) to change between the time service is requested and the actual service date. Why? Because the state of the service point and the state of its meter / item affects the type of field activity that is created. For example, if a customer wants to start service and there is no meter at the metered service point, an "install meter" field activity is created. However, if by the time the install date comes around, a meter has been installed by some other means; this field activity is inappropriate. This is why you might want to setup the system to wait until shortly before the service date to create the field activity (i.e., it reduces the likelihood that an inappropriate field activity is created). Refer to [Starting Service and Field Activities](#) for more information.

If you use orders to create new customers, define the **Campaign** that should be defaulted on orders created when the order transaction is opened for a new customer. Refer to [Real time Marketing of Services to a New Customer](#) for more information.

Use the **Premise Geo Type** to indicate whether at least one geographic identifier (e.g., GPS coordinate) is Required or Optional on a premise. Refer to [Defining Geographic Types](#) for more information.

The **Alternate Representation** flag should be set to None unless your organization uses multiple character sets for a person's main name and / or a premise's address. Alternate representations are typically only used in countries where multiple character sets are used. For example,

- In Hong Kong, a person's name may be written in both Chinese characters and in English.
- In Japan, a person's name may be written in both Kanji and Katakana.

In both of the above situations, users need to be able to use both representations to find a customer or a premise.

NOTE:

Spouses. If your organization doesn't use multiple character sets, you might want to consider using this functionality for spousal relationships. For example, rather than setup a person for each party in a spousal relationship, you could simply define one party using the person's main name and the spouse using the alternate name. While this is a bit of a "hack", it might be sufficient for your implementation as it will be much easier for an end user to use.

Alerts that should appear adjacent to a person's name or address. If your organization doesn't use multiple character sets, you might want to consider using this functionality to implement critical person or premise alerts. For example, if you have a customer who's supported by a specific account representative, you could enter the account rep's name as the person's alternate name. If you do this, the account rep's name would appear in parenthesis following the customer's name. In addition, you can search for the customers supported by the account rep on Control Central by entering the account rep's name. This is a bit of a "hack", but it might prove useful for a variety of functions.

If your organization uses alternate representations of person name or address, set this flag to one of the following values:

- Use a value of Address if you only use alternate representations for premise addresses.
- Use a value of Name if you only use alternate representations for a person's primary names.
- Use a value of Name & Address if you use alternate representations for both premise addresses and person names.

The following points describe the ramifications of this flag in the system:

- If you support alternate representations of a person's primary name,
- The name grid on [Person - Main](#) allows you to specify an Alternate name for the person.
- If you use the base package name formatting algorithm, a person's name will be shown throughout most of the system in the format AAA (BBB), where AAA is the person's primary name and BBB is the person's alternate name. Note, this format does not apply to names that appear in search results (i.e., the alternate name is not concatenated to the main name in search results; however you can search for information using the alternate name).
- Most of the system's person name-oriented searches will allow users to use both a person's primary and alternate names to search for information.
- If you support alternate representations of a premise's address,
- A new tab is available on the [Premise](#) page that allows a user to define an alternate address for a premise.
- If you use the base package address formatting algorithm, a premise's address will be shown throughout most of the system in the format AAA (BBB), where AAA is the premise's primary address and BBB is the premise's alternate address.
- Most of the system's premise-oriented searches will allow users to use both a premise's primary and alternate addresses to search for information.

If the CTI Integration flag has been enabled, set the **CTI Integration** flag to Yes if your organization integrates with an external computer telephony integration (CTI) system that supports a "get next caller in the queue" function.

The **Control By CIS Division** flag affects system behavior in many areas. This flag should be set if your business operates in different jurisdictions and CIS Division is used to delineate accounts and premises that users can access. When this flag is set, all users must be associated with at least one CIS division. See [Users and CIS Division](#) for more information.

The following system behaviors are affected by this flag:

- On Person, CIS Division is presented and is required when adding an account. Customer class is defaulted after CIS Division is set.

- On Order, CIS Division is presented when a new account is being added and is required. Customer class is defaulted after CIS Division is set..
- On Person, Order, Account and Premise, the list of CIS Divisions that can be chosen is restricted to the CIS Divisions associated with the user. The user's primary CIS Division is defaulted.
- On Account, CIS Division is presented before customer class. Customer class is defaulted after CIS Division is set.

The **Premise/SP Search** flag is used to provide access security to premises and service points that are not linked to an account.

- When the flag is set to Not Restricted, access to premises and service points that are not linked to an account is not secured.
- When the flag is set to Restricted by CIS Division, access to premises and service points that are not linked to an account is secured by the user's CIS Divisions. If the premise has a CIS Division, then only users that have access to that CIS division can access that premise or its service points. See Users and CIS Division for more information. Premise and service points belonging to premises without a CIS Division are not secured. A Premise Type setting can control whether premises of that type require a CIS Division.

NOTE: Premises and service points that are linked to an account are secured by the account access group

WARNING:

In order to improve response times, installation options are cached the first time they are used after a web server is started. If you change this field's option and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. Refer to [Caching Overview for information](#) on how to clear the system login cache (this is the cache in which installation options are stored).

Installation Options - Person

Select **Admin > General > Installation Options** and use the **Person** page to define person-specific installation options.

Description of Page

Use the **Person ID Usage** to indicate whether or not at least one form of identification is Required or Optional when a new person is added. If required, indicate when the identifier is required based on the person's association with account(s).

Each form of identification has an identifier type. For persons that are humans (as defined by the person type), the system defaults the identifier type defined in **Identifier Type (Person)**. For persons that are businesses (as defined by the person type), the system defaults the identifier type defined in **Identifier Type (Business)**.

The **Use Name Separator** and **Person Name Separator Character** are used when formatting person names for persons (not businesses). The person name format algorithm type (NMFMT-VALFMT) that is provided with the system uses these settings.

Installation Options - Account

Select **Admin > General > Installation Options** and use the **Account** page to define account-specific installation options.

Description of Page

When a new account is added, the system requires it have a customer class. If the main customer linked to the account is a human (as defined by the customer's person type), the system defaults the customer class defined in **Customer Class (Person)**. For persons that are businesses (as defined by the person type), the system defaults the customer class defined in **Customer Class (Business)**. For more information, refer to [Setting Up Customer Classes](#).

In addition to requiring a customer class when a new customer is added, the system also requires a "main customer" (i.e., a reference to a person who is identified as the main customer for the account). Enter the default **Account Relationship Type Code** to be used to define the main customer relationship. For more information, refer to [Setting Up Account Relationship Codes](#).

Enter the default **Bill Route Type** to be used to define how bills should be routed to a customer. For more information, refer to [Setting Up Bill Route Types](#).

Enter the default **Quote Route Type** to be used to define how quotes should be routed to a customer. For more information, refer to [Setting Up Quote Route Types](#).

If the number of pending start and pending stop service agreements exceeds the **Start Stop Detail Threshold** for an account, it is considered a large account for start stop purposes. Refer to [Start/Stop Maintenance](#) for more information.

Installation Options - Billing

Select **Admin > General > Installation Options** and use the **Billing** page to define billing-specific installation options.

Description of Page

The **Bill Segment Freeze Option** controls when a service agreement's balance and the general ledger is affected by bill segments and certain types of adjustments. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) to understand the significance of this option.

The **Accounting Date Freeze Option** controls how the accounting date defined on financial transactions is populated. Refer to [Forcing The Freeze Date To Be Used As The Accounting Date](#) to understand the significance of this option.

Define the **Rollover Threshold Factor** used by billing to determine if a register's consumption is sensible. This value is used as follows:

- Whenever billing calculates a meter's register's consumption, it compares it to a value equal to X times the register's maximum capacity (where X is the Rollover Threshold Factor).
- If consumption exceeds this value, a bill segment error is generated. If this consumptive value is correct, a user will need to override the consumption value billed on the bill segment (billing will never use such a read).

Define the **Minimum Amount for Final Bill**. If a final bill is less than this amount, the bill is still produced; it's just not printed.

Typically, the system sets a bill's Bill Date equal to the date on which it is completed. If you want to be able to specify a bill's Bill Date when you complete a bill, turn on **User Can Override Bill Date**. You would only want to override the bill date if you are setting up sample bills from historical period whose bill date needs to reflect the respective historical period.

Turn on **Use High Low Failures on Bill** if the system should mark meter reads that fail high / low checks as billable. Turn off this switch if such reads should not be used by billing. Users may override this default value on a specific read. Refer to [Validations](#) for more information.

Base Time is used by billing algorithms to determine the effective start and end times for a given period. The **Start Day Option** further defines how to use the base time, indicating whether the base time is for the Current Day or for the Previous Day.

Turn on **Use Alternative Bill ID** if your implementation uses assigned document numbers or sequential bill numbers. In the **Alternative Bill ID Option** list:

- Select **Document Numbers** if you require a system-assigned document number for each bill in addition to the Bill Id, which is a system-assigned random number used as the bill's primary identifier. Refer to [Document Numbers](#) for more information.
- Select **Sequential Bill Numbers** if you require a system-assigned unique sequential number for each bill in addition to the Bill Id, which is a system-assigned random number used as the bill's primary identifier. Refer to [Sequential Bill Numbers](#) for more information

NOTE:

Document Number Algorithms. In addition to turning on **Use Alternative Bill ID** and specifying the **Alternative Bill ID Option**, the Document Number and Document Number Details algorithms must be enabled on the [Installation](#) record. These algorithms contain the logic used by the system to assign a document number to a bill.

The **Bill Correction** option lets you control whether your implementation uses Credit Notes or Correction Notes. Select the **Credit Note** option if you require bill segment cancellation details to be presented to the customer on a separate bill (referred to as a credit note). Refer to [Credit Notes](#) for more information. Select the **Correction Note** option if you require bill segment cancellation details and bill segment rebill details to be presented to the customer on a separate bill (referred to as a correction note). Refer to [Correction Notes](#) for more information.

NOTE:

Credit Notes or Correction Notes. The Bill Correction option on the Installation record controls whether Credit Notes or Correction Notes are allowed. If your implementation uses Correction Notes, the override label on the following should be customized accordingly:

Lookup value CRNT on the customizable lookup field TXN_FLTR_TYPE_FLG (this lookup value is used on the Match Event Page and Account Bill History transactions)

Lookup value CR on the customizable lookup field PYCAN_SYS_DFLT_FLG (this lookup value is used on the Pay Cancel Reason transaction)

Metadata field CR_NOTE_FR_BILL_ID (this field is used on the Bill Search Page)

The **Autopay Creation Option** controls when automatic payments are created, distributed, and frozen. This option allows you to control when automatic payments will affect customer's balances and when their financial impact affects the general ledger. Refer to [How And When Are Automatic Payments Created](#) to understand the significance of this option.

Installation Options - C&C

Select **Admin > General > Installation Options** and use the **C&C** page to define credit and collections-specific installation options.

Description of Page

When you look at an account or service agreement's debt, the system shows the respective age of each piece of outstanding debt. The **Oldest Bucket Age (Days)** defines the debt age after which the system groups all outstanding debt together. For example, if this field is 180:

- The exact age of each element of debt that is less than 180 days old would be shown as a separate line item in the aged debt information.
- All debt older than 180 days would be amalgamated into a single "bucket".

Oldest Bucket Age (Days) also has another use - it defines the age of financial transactions that are considered by the background process that marks old debt as "redundant". This batch process is referred to by the batch code of REDSAAMT.

WARNING:

If you change the value of **Oldest Bucket Age (Days)** after debt has been marked as "redundant" by REDSAAMT, the system will NOT re-age the old debt (i.e., once a financial transaction has been marked as "redundant", it is "redundant" forever).

Enter what you consider to be an excellent credit rating in **Beginning Credit Rating**. Collection events can cause an account's credit rating to decrease. When an account's credit rating falls below a certain level, different collection processes may ensue.

Use **Beginning Cash-Only Score** to define the cash-only score for accounts with a perfect payment history (i.e., one without non-sufficient funds). When you cancel a payment tender and use a cancellation reason marked as NSF, the system will cause the account's cash-only score to increase by the value on the payment cancellation reason.

Use **Credit Rating Threshold** to define when an account's credit rating becomes risky. When an account's credit rating falls beneath the Credit Rating Threshold, the system will:

- Assuming you've enabled the Control Central alert algorithm, C1-CRRT-ACCT, an alert displays when an account's credit rating falls below the credit rating threshold on the installation record. This algorithm is plugged-in on the [installation record](#).
- Subject the account's debt to different collection criteria. For more information, refer to [Designing Your Collection Class Control Overrides](#).

Use **Cash-Only Threshold** to define the number of cash-only points a customer must have before the system warns the CSR accepting payments that the account is cash-only.

Installation Options - Financial Transaction

Select **Admin > General > Installation Options** and use the **Financial Transaction** page to define financial transaction installation options.

Description of Page

Use **GL Batch** to define the batch process that is used to interface your financial transactions to your general ledger. The process is snapped on FT download records by the GLS background process.

Use **A/P Batch** to define the batch process that is used to interface your check requests (initiated with adjustments with an adjustment type that reference an A/P request type) to you accounts payable system.

Use **Fund Accounting** to indicate if [fund accounting](#) is Practiced or Not Practiced at your organization.

Use **Alternate Currency** to indicate if your organization accepts customer payments in currencies other than the account's currency.

FASTPATH:

Refer to [Alternate Currency Payments](#) to understand the significance of this option.

Installation Options Framework - Algorithms

Select **Admin > General > Installation Options - Framework** and use the **Algorithms** page to define specific system events.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Account Information	Optional	We use the term "Account information" to describe the basic information that appears throughout the system to describe an account. The data that appears in "account information" is constructed using this algorithm. Plug an algorithm into this spot to override the system default "Account information".
Adjustment Information	Optional	We use the term "Adjustment information" to describe the basic information that

appears throughout the system to describe an adjustment. The data that appears in "Adjustment information" is constructed using this algorithm.

Plug an algorithm into this spot to override the system default "Adjustment information".

Note: This algorithm may be further overridden by an "Adjustment information" plug-in on the Adjustment Type. Refer to [Adjustment Type](#) for how algorithms of this type are used.

Appointment Information	Required	We use the term "Appointment information" to describe the basic information that appears throughout the system to describe an appointment. The data that appears in "appointment information" is constructed using this algorithm.
Auto Pay Creation	Required if you allow customers to pay automatically	This algorithm is executed to create automatic payments whenever the system creates automatic payments. Refer to How And When Are Automatic Payments Created for the details.
Bill Cycle Selection	Optional	This algorithm is only used if your organization has specific rule for assign a bill cycle to an account. This plug-in spot is invoked by the SA Activate/Stop common routine. The spot is called right after the system has updated the account.
Bill Information	Required	We use the term "Bill information" to describe the basic information that appears throughout the system to describe a bill. The data that appears in "bill information" is constructed using this algorithm.
Bill Segment Information	Optional	We use the term "Bill segment information" to describe the basic information that appears throughout the system to describe a bill segment. The data that appears in "bill segment information" is constructed using this algorithm.
Case Information	Optional	We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm. Plug an algorithm into this spot to override the system default "Case information". Note: This algorithm may be further overridden by a "Case information" plug-in on the Case Type. Refer to Case Type for how algorithms of this type are used.

Collection Agency Referral Information	Optional	<p>We use the term "Collection Agency Referral information" to describe the basic information that appears throughout the system to describe a collection agency referral.</p> <p>Plug an algorithm into this spot to override the system default "collection agency referral information".</p>
Collection Process Information	Optional	<p>This algorithm displays additional information related to a collection process in a special field on the collection process main page.</p>
Control Central Alert	Optional	<p>These algorithms produce the alerts shown on the Alert Zone. Additionally, system-generated alerts can be show on the alert zone if enabled. (See the Alert Zone for more information and the list of system-generated alerts.)</p>
Credit Rating 'Created By' Information	Required	<p>The data that appears in the credit rating "created by" information is constructed using this algorithm.</p> <p>Refer to Account - C&C for more information about the credit rating.</p>
Credit Rating History Information	Optional	<p>We use the term Credit Rating History information to describe the basic information that appears throughout the system to describe a credit rating history entry.</p> <p>Plug an algorithm into this spot to override the system default "credit rating history information".</p>
Digital Signature	Optional	<p>This algorithm is only used if your organization generate and store digital signatures for each bill.</p> <p>Refer to Digital Signatures for the details.</p>
Document Number	Optional	<p>If document numbers have been enabled on the installation record, this algorithm type assigns a document number to a bill or payment event.</p>
Document Number Details	Optional	<p>If document numbers have been enabled on the installation record, this algorithm type is responsible for returning the details used to construct the document number.</p>
Determine Open Item Bill Amounts	Required if you use overdue functionality to collect on bills	<p>This algorithm is responsible for determining the unpaid amount of an open-item bill. It can also be used to return the unpaid amount for a specific SA on a bill.</p>
Document Sequence Number	Optional	<p>If document numbers have been enabled on the installation record, this algorithm type is responsible for generating document sequence number only.</p>

FA Additional Information	Optional	<p>This algorithm displays additional information related to a field activity in a special field called Additional Info on the field activity main page.</p> <p>For example, contact information linked to the field activity's field order may be displayed.</p>
FA Information	Required	<p>We use the term FA information to describe the basic information that appears throughout the system to describe a field activity. The data that appears in "FA information" is constructed using this algorithm.</p>
Item Information	Required if you have items	<p>We use the term "Item info" to describe the basic information that appears throughout the system to describe an item. The data that appears in "Item info" is constructed using this algorithm.</p>
Meter Information	Required if you have meters	<p>We use the term "Meter info" to describe the basic information that appears throughout the system to describe a meter. The data that appears in "Meter info" is constructed using this algorithm.</p>
Meter Read High Low Limits	Not used with Customer To Meter	
Online Bill Display	Optional	<p>This algorithm constructs or retrieves a PDF that contains the image of a bill. This algorithm is executed when the Display Bill button is clicked on the Bill page. Refer to Technical Implementation of Online Bill Display for more information.</p>
Online Field Order Display	Optional	<p>This algorithm constructs a PDF that contains the image of a field order.</p>
Online Letter Display	Optional	<p>This algorithm constructs or retrieves a PDF that contains the image of a letter. This algorithm is executed when the Display Letter button is pressed on the Customer Contact portal. Refer to Technical Implementation of Online Letter Display for more information.</p>
Online Quote Display	Optional	<p>This algorithm constructs a PDF that contains the image of a quote. This algorithm is executed when the Display Quote button is pressed on Quote - Main. Refer to Technical Implementation of Online Quote Display for more information.</p>
Online Statement Display	Optional	<p>This algorithm constructs a PDF that contains the image of a statement. This algorithm is executed when the Display Statement button is pressed on Statement - Main. Refer to Technical Implementation of Online Statement Display for more information.</p>

Override Proration Factors	Optional	This algorithm is only used if your organization has unusual rate proration requirements that necessitate the overriding of the base package proration logic. For example, you may have certain calculation rules whose charges should never be prorated. Refer to Overriding Proration Factors for more information.
Override Seasonal Proration	Optional	This algorithm is only used if your organization has unusual method of determining the seasons for your calculation rules. For example, you may determine the seasonal boundaries for a calculation rule based on the scheduled meter read date associated with the bill cycle.
Payment Amount Calculation	Required	This algorithm is executed to calculate the amount of an automatic payment for a bill for an account with an active auto pay option. Refer to How And When Are Automatic Payments Created for more information on automatic payments. This algorithm is also executed to default the amount of a manually added payment. Refer to How To Add A New Payment Event for more information on adding a payment manually.
Payment Event Information	Optional	We use the term "payment event information" to describe the basic information that appears throughout the system to describe a payment. The data that appears in "payment information" is constructed using this algorithm.
Payment Information	Required	We use the term "payment information" to describe the basic information that appears throughout the system to describe a payment. The data that appears in "payment information" is constructed using this algorithm.
Person Information	Required	In most parts of the system, a person's Main name is displayed to describe a person. However, several transactions do not use this method. Rather, these transactions call the algorithm that's plugged into this spot to construct the person's name. Refer to the description of the Alternate Representation flag on the Main tab for a list of these transactions and for the rationale behind this algorithm.
Person Name Format	Required	The format of names entered on Person - Main and Order - Main is validated using this algorithm.

Premise Information	Required	We use the term "premise info" to describe the basic information that appears throughout the system to describe a premise. The data that appears in "premise info" is constructed using this algorithm.
SA Information	Optional	We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm. Plug an algorithm into this spot to override the system default "SA information". Note: This algorithm may be further overridden by an "SA information" plug-in on the SA Type. Refer to SA Type - Algorithms for how algorithms of this type are used.
Severance Process Cancellation	Optional	This algorithm is executed to perform additional processing when the system cancels a severance process. Note: This algorithm is executed before the Severance Process Template - Post Cancel Algorithm is executed. Canceling a severance process on-line manually does not execute this algorithm.
SP Information	Required	We use the term "SP info" to describe the basic information that appears throughout the system to describe a service point. The data that appears in "SP info" is constructed using this algorithm.

Defining Customer Languages

As described under [Defining Languages](#), you define the language in which each user see the system. In addition to defining each user's language, the system allows you to define each customer's preferred language. For example, one customer can receive bills in English whereas another customer could receive their bills in Chinese.

Each customer's language is defined by the [language code](#) on their [person record](#). Bills, adjustments and other system-generated records will then be done in the language of the main customer of the account. In addition, the language code is passed on to all customer-facing interfaces, such as letter requests and bill print.

NOTE:

You can define Rates in multiple languages - when a bill is generated, the line-item descriptions are generated and stored in the account's main customer's language of choice. Anyone who subsequently views these bills can only see the descriptions in that language.

To support bills and other correspondence, you must also provide translations of standard bill stock and letters. This must be handled by your printing software vendor.

Defining Accounting Calendars

Accounting calendars determine the accounting period to which a financial transaction will be booked. The following points describe how the system determines a financial transaction's account period:

- Every financial transaction references an accounting date and its service agreement
- Every service agreement references a service agreement type
- Every service agreement type references a GL division
- Every GL division references an accounting calendar
- The accounting calendar contains the cross-reference between the accounting date specified on the financial transaction and related accounting period in your general ledger

WARNING:

This information must be the same as the information in your financial database.

To add or review an accounting calendar, choose **Admin > General > Accounting Calendar > Search**.

Description of Page

Enter a unique **Calendar ID** and **Description** for the calendar.

Enter the **Number Of Periods** for the calendar. Don't count the adjustment period, if you use one, or any special "system" periods.

Specify the **Fiscal Year**, each **AccountingPeriod** in that year, a **Period Description**, the **Begin Date** and the **End Date**.

When you enter begin and end dates, you can define monthly calendar periods or any fiscal period that matches your accounting calendar (weekly, bimonthly) as long as the begin and end dates of successive periods do not overlap. Every day of the year must be included in a period; do not leave gaps between period dates.

For each fiscal period, enter the **Open From Date** and **Open To Date**. These dates define when that particular business dates are open for posting financial transactions to that fiscal period. For example, you might calculate a bill on Sept 1 for usage recorded on 31 August. To post this financial transaction in the August period, you must keep it open through Sept 1.

As time passes, you will need to return to this transaction to manually enter ensuing years. You can enter several years at a time or incorporate the task into end-of-year system maintenance.

Defining General Ledger Divisions

There are two types of Divisions referenced in the system: a CIS Division and a GL Division. This is a rather powerful structure, but it can be confusing.

- General Ledger divisions typically comprise individual entities (e.g., companies) in your general ledger. You must set up a GL division for each such entity. The GL division's sole purpose in the system is to define the accounting period associated with financial transactions linked to service agreements associated with the GL division (service agreements are associated with GL divisions via their SA type). The system cares about accounting periods in order to prevent a user from booking moneys to closed periods. It also uses accounting periods when it produces the flat file that contains the consolidated journal entry that is interfaced to your general ledger (refer to [The GL Interface](#) for more information).

NOTE:

When determining how many GL Divisions you need, be sure to consider your general ledger and how your chart-of-accounts is structured. You will typically have one GL division for each "company" in your general ledger.

- A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.
-

FASTPATH:

Refer to [Setting Up CIS Divisions](#) for information about CIS Divisions.

To define a general ledger division, select **Admin > General > General Ledger Division**.

Description of Page

Enter a unique **GL Division** for the general ledger division.

Enter a **Description** of this general ledger division.

Define the accounting **Calendar ID** that controls how to convert an FT's accounting date into an accounting period. Refer to [Defining Accounting Calendars](#) for more information.

You may define a **Currency Code** for the GL division. Note that the system does not use this currency code.

Defining Banks & Bank Accounts

The topics in this section describe how to maintain your implementation's bank accounts.

Bank - Main

To review Banks choose **Admin > Financial > Bank > Search**.

Description of Page

Enter a unique **Bank** and **Description** for the bank.

The **Bank Accounts** collection displays the bank accounts currently linked to this bank code. Use the drill down button to view more details or to modify the bank account details. Alternatively, you may navigate to the Bank Account tab and scroll to the desired bank account.

Bank - Bank Account

To review Bank Accounts for a Bank, choose **Admin > Financial > Bank > Search** and then navigate to the **Bank Account** page.

Description of Page

Use the **Bank Accounts** tab to define the attributes of each bank account. For each account, enter the following information:

- Enter a **Bank AccountKey** to identify an Account at a Bank. You may have more than one account at a given bank, and you may have accounts at more than one bank. This code will allow the system to easily identify a specific account.
- Enter a **Description** to appear on prompt lists, inquiries, and reports.
- Enter the **Account Number**, **Check Digit** and if needed, the **Branch ID** of the bank where the account is held.

- Enter the **CurrencyCode** for the currency in which the account is denominated.
- Use **DFI ID** to define the Depository Financial Institution ID that is interfaced to the automatic payment-processing agent as part of the automatic payment interface.
- Enter the **Distribution Code** to be used for cash GL distributions when a payment is frozen or canceled.

Defining Issuing Centers

This section provides information about defining issuing centers that are used to assign document numbers to bills and payment events. An issuing center should be configured for each location that issues bills. The installation record Document Number and Document Number Details algorithms contain the logic used by the system to assign a document number to a bill. To set up an issuing center, open **Admin > General > Issuing Center > Add**.

FASTPATH:

Refer to [Document Numbers](#) for information about document number assignment.

NOTE:

This section is only relevant for some organizations. The information in this section is only relevant if your organization indicated on the installation record that it uses document numbers as an alternative bill id. If your organization does not use document numbers as an alternative bill id, then no other setup is required.

The topics in this section describe the base-package zones that appear on the Issuing Center portal.

Actions

This is a standard [actions zone](#).

If the issuing center is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Issuing Center List

The Issuing Center [List zone](#) lists every issuing center. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent issuing center.
- Click the Add link in the zone's title bar to add a new issuing center.

Issuing Center

The Issuing Center zone contains display-only information about an issuing center, including its current and historic branches. This zone appears when an issuing center has been broadcast from Issuing Center List zone or if this portal is opened via a drill down from another page.

Please see the zone's help text for information about this zone's fields.

Issuing Center Log

This is a standard [log zone](#).

Defining Service Tasks Options

This section describes concepts and procedures related to service tasks.

About Service Tasks

Service tasks are records that can be used to perform a variety of tasks. Examples include:

- Task-related records performed by users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service.
- Task-related records performed by Oracle Utilities Customer Care and Billing to manage specific processing, such as net energy metering true-ups, or prepaid billing to create bill segments for smart meter prepaid service agreements.

The main attribute used to define a service task is service task type. The service task type defines properties common to specific types of service tasks.

For more information, see [Searching and Viewing Service Tasks](#).

About Service Task Types

Service task types define properties common to specific types of service tasks. Service task types represent different types of tasks that can be performed by:

- Users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service. An example of a service task includes self service meter reads, in which users enter their own meter reads via the Customer Self Service application.
- Oracle Utilities Customer Care and Billing to manage specific processing. Examples include net energy metering true-ups, or prepaid billing to create bill segments for smart meter prepaid service agreement.

Service task types can be defined by the following attributes:

- **Service Task Type:** the name of the task type.
- **Service Task Type Business Object:** the business object that defines the behavior of the service task type.
- **Service Task Business Object:** the business object instantiated when service tasks of this type are created.
- **Service Task Class:** the category used to define service task types for reporting purposes (self-service, miscellaneous, etc).
- Other data based on the specific type of service task (such as minimum days in true-up period, billing frequency, or default payment method.)

For more information about defining service task types, see [Defining Service Task Types](#).

For more information about the service task types delivered with the application, see [Base Package Service Task Types](#).

Defining Service Task Types

To maintain existing service task event types, select **Admin > Customer > Service Task Type**, then use standard actions to edit, duplicate, or delete a service task type.

To define a new service task type, follow these steps:

1. Select **Admin > Customer > Service Task Type**.
2. Enter a name and a meaningful description for the service task type.
3. If needed, select the business object to use when creating service tasks of this type.
4. Select the service task class applicable to service tasks of this type, if applicable.
Some service tasks types used solely by Oracle Utilities Customer Care and Billing have a default class of **Miscellaneous**.
5. Enter a detailed description for the service task type.
6. Complete the remaining fields and sections, as needed.
7. If applicable, select a To Do type and corresponding To Do role to use when creating To Do entries related to service tasks of this type.
8. Click **Save**.

This service task type can now be used when service tasks are received from other Oracle Utilities applications, such as Oracle Utilities Customer Self Service, or service tasks created specifically by Oracle Utilities Customer Care and Billing. For more information about service task types, see [About Service Task Types](#).

For more information about the service task types delivered with the application, see [Base Package Service Task Types](#).

Base Package Service Task Types

This section provides descriptions of the service task types provided with the base package.

Service Task Type	Business Object	Detailed Description	Related Transaction Business Object
Appointment Notification Task Type	C1-NotifyAppointmentTaskType	This business object is used to capture the information to use in appointment notification processing.	Appointment Notification Task
Create Customer Contact Task Type	C1-CreateCustContactTaskType	This business object is used to capture the information to use in create customer contact task processing.	Customer Contact Request Task
Direct Debit Task Type	C1-DirectDebitMandateTaskType	This business object defines configuration information that is used for processing Single Euro Payments Area (SEPA) direct debit transactions.	Direct Debit Mandate Task
FA Completion Task Type	C1-FACompletionTaskType	This business object captures the attributes used in field activity completion task processing.	FA Completion Task
Field Activity Remark Task Type	C1-FieldActivityRemarkTaskType	This business object is used to capture the information to use in create field activity remark task processing.	Field Activity Remark Task
Form Task Type	C1-FormTaskType	This business object captures attributes relevant for a particular	Form Task

form type to be used when a self-service customer creates a form.

Missed Appointment Notification Task Type	C1-NotifyMissedApptTaskType	This business object is used to capture the information to use in missed appointment processing.	Missed Appointment Notification Task
Notification Task Type	C1-NotifyTaskType	This business object captures information about a notification that is made available for sign-up by self-service users.	Notification Preferences
Net Energy Metering Task Type	C1-NEMTrueUpTaskType	This business object is used to maintain the various configuration options that are used by the true up monitor (TUM) business object's algorithms. It defines the length of the true up period as well as the adjustments types used during the true up process. For true up reversals, the adjustment cancel reason to use is also captured here.	True Up Monitor Task
Outage Call Type	C1-OutageCallType	This business object defines the behavior of an outage call type used to support trouble calls captured in CCB and integrated to NMS.	Outage Call
Payment Arrangement Task Type	C1-PATaskType	This business object defines the expected behavior for when a self-service user requests a payment arrangement.	Payment Arrangement Task
PPB Payment Notification Task Type	C1-PPBPaymentNotifyTaskType	This business object captures information about the Prepaid Billing Payment Request notification that is made available for sign-up by self-service users.	Notification Preferences
Prepay Biller Task Type	C1-PrepayBillerTaskType	This business object defines the behavior of a prepay biller task type used in smart meter prepay billing.	Prepay Biller Task
Product Offer Publish	C1-ProductOffer	This business object contains the product offer elements that are relevant when publishing product offers to Siebel Energy. It is used to read product offer information when building the initial and final snapshots for the sync request.	Not defined
Product Offer Task Type	C1-ProductOfferTaskType	This business object is used to define the behavior of a product offer. Product offers are configured in CCB and published to Siebel Energy.	Not defined

SA Creation Rule Publish	C1-SACreationRule	This business object contains the SA creation rule elements that are relevant when publishing product offers to Siebel Energy. It is used to read SA creation rule information when building the initial and final snapshots for the sync request.	Not defined
SA Creation Rule Task Type	C1-SACreationRuleTaskType	This business object defines the behavior of the SA creation rules for a product offer. Each SA creation rule indicates the type of service agreement to create for the product offer.	Not defined
Service Request Task Type	C1-ServiceRequestTaskType	This business object is used as a parent service task type business object for service request related task types such as appointment notification, missed appointment and customer contact creation requests.	Not defined
Siebel Customer Maintenance Task Type	C1-CustomerMaintenanceTaskType	This business object is used in the Siebel integration. When a customer maintenance request is received from Siebel, an inbound service determines the service task type to use for the event.	Siebel Customer Maintenance Task
Start/Stop Task Type	C1-StartStopTaskType	This business object defines the expected behavior for when a self-service user requests to start, stop or transfer service.	Start/Stop Request Task

Defining Customer Questions

A customer question is used to capture specific information related to a request. For example:

- A customer can be asked questions about a service call being reported.
- A customer can be asked one or more questions during a start, stop or transfer service request.

The responses to customer questions are captured on the Response object that is linked to either a customer service request or a service task.

You can access the portal from **Admin > General > Customer Question**. You are brought to a query portal with options for searching for a specific question. Once a question is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones appear as part of the portal's **Main** tab page:

- **Customer Question:** This zone provides information on question and answers. Refer to the zone's embedded help for more details.
- **Service Code List:** This zone displays a list of associated service codes. It is hidden if no service code is associated to the current question.

System-Wide Options

Installation Options - Framework

Configuring Installation Options - Framework

Installation options define the individual applications installed on your system and identify algorithms used to implement core system functions. These options also define global parameters such as the administrative menu style (alphabetical or functional), the country, language, currency code, as well as the base time zone to use for this implementation.

Installation options are stored in the installation record for your system. Use the Installation Options - Framework portal to configure these options. This portal is part of the OUAF and is described in detail in the Framework documentation.

Base Time Zone

The time zone setting of the Installation Options - Framework determines the time zone for all date/times stored within the system. Each date/time, based on the configuration of that field, is stored in either standard or legal time within this base time zone.

Refer to the [Glossary of Terms](#) in the *Oracle Utilities Meter Solution Business User Guide* for definitions Standard Time and Legal Time

Note: The installation record does not dictate the server time zone, but rather must match it.

Installation Algorithms

Installation algorithms implement global system functions and can be customized for each implementation. The base package supports the following installation options for Meter Data Management-related system events:

- **Geocoding Service:** Responsible for geocoding an address (converting an address to a geocode latitude/longitude pair).
- **Global Context:** Sets global contexts (displayed in the Global Context dashboard zone) based on the value of existing global contexts. For example, if the Service Point is specified, this algorithm sets the Device by finding the most recently installed Device on the service point. It then sets the Measuring Component by finding the most effective Device Configuration and retrieving any measuring component linked to it. It then sets the Usage Subscription by finding the most recent active usage subscription linked to the service point. The contact is set by finding the main contact for the usage subscription.

Additional detail on how global context is populated can be found in the detailed description of the D1-GBCTX-DF Algorithm Type.

- **To Do Pre-creation:**
 - In Meter Data Management, the D1-TDPRCRE (To Do Precreation) algorithm associates a To Do entry via characteristics to the related the related Device, Measuring Component, Service Point, Contact, Usage Subscription, Activity Type and Activity based on the drill keys of the To Do entry.
 - In Customer to Meter, the following algorithms are used to associate a To Do Entry via characteristics with related objects:
 - C1-TDCR-CHAR (Link Account/Premise/Person/SA/SP to To Do)
 - C1-TDCR-DFRL (Default To Do Role via Account/Premise)
 - D1-TDPRCRE (To Do Precreation)
 - X1-TDPRCRE (Customer to Meter To Do Pre-Creation)

NOTE:

Additional detail on how the To Dos are associated to related data can be found in the detailed descriptions of these algorithms type.

See [Installation Options](#) in the Oracle Utilities Application Framework *Administrative User Guide* for related information on the installation portal.

Feature Configurations

Configuring Feature Configurations

Some of the features in Oracle Utilities Application Framework based applications are configured by populating options on a "feature configuration". For example, if your implementation uses Oracle Utilities Customer Care and Billing's batch scheduler, you must populate a variety of options on the batch scheduler's feature configuration.

NOTE: Refer to [Defining Feature Configurations](#) in the Oracle Utilities Application Framework *Administrative User Guide* for additional information.

Oracle Utilities Meter Data Management uses the following types of feature configurations (please note that more information can be found on each of these options by viewing their detailed description in the Feature Configuration portal):

Measurement Data Options

Measurement Data Options are used to define behavior related to periodic estimation of initial measurement data, including:

- **No of Hours in Past to Retrieve Last Usable Measurement:** This option is leveraged by scalar periodic estimation to restrict how far into the past it will search for existing measurements when the last contiguous measurement is being initialized on the measuring component. This is to ensure that the first time scalar period estimation is executed on a large number of measuring components that have not been initialized for periodic estimation the system does not execute a large number of unbounded queries into the past which would result in poor performance.

Business Intelligence Configuration

Business intelligence configuration is used to define external data source indicators used when Oracle Utilities Meter Data Management is integrated with Oracle Utilities Business Intelligence. External data source indicators allow business intelligence extracts to properly link the external identifiers to the source external system. The Value of the Data Source Indicator option should match the Environment ID on the Installation Option of the external system.

General System Configuration

This feature configuration is owned by Oracle Utilities Application Framework but there are several important option types that have been created specific to Oracle Utilities Meter Data Management:

- **Multi Time Zone Support:** By default the system assumes an installation operates within a single time zone. In order to enable multiple time zone functionality this option must be defined and set to "DIYS".
- **CCB Link URL:** this option is used to provide the destination URL for hyperlinking into Oracle Utilities Customer Care and Billing.
- **Trace On Flag:** can be set to automatically trace any initial measurement being processed. Note: if the initial measurement has had trace explicitly turned off then no tracing will occur. This is useful for tracing initial measurements created through automated processes where you are unable to set the trace flag directly.

- **System Override Date:** this option type is provided by OUAF but it is highly useful in testing prior to production. When set it will override the system date/time for all users. The format must be entered as: YYYY-MM-DD. For example January 1st 2010 would be 2010-01-01.

NOTE:

Refer to [Configuring Multi-Time Zone Support](#) for additional information on setting up multi-time zone support.

Time Zones

Configuring Time Zones

To support businesses spanning across multiple time zones, the system stores all date and time information in a single common time zone known as the base time zone or the server time zone. Furthermore, date and time information is stored in either standard time (i.e. independent of any Daylight Savings Time adjustments, if applicable, in that time zone) or legal time (i.e. shifted according to Daylight Savings Time).

The system also allows data to be entered and displayed in a different time zone in legal time (i.e. adjusted for Daylight Savings Time, managing the conversion back and forth between the data entry time zone and the storage time zone).

Entities associated with a physical location such as measurements (initial and final), measuring components, device configurations, devices, installation events, service points, and usage subscriptions are entered and displayed in the specific time zone where they occur, the entity time zone. The rest of the application uses the base time zone to display date and time information.

When configuring time zones the following fields are of high importance:

- **Time Zone Name:** identifies the Olson time zone and as such defines the appropriate offset from Greenwich Mean Time as well as the schedule for shifting into and out of Daylight Savings Time.
- **Default Time Zone Label:** will be appended to date times that do not fall within Daylight Savings Time
- **Shifted Time Zone Label:** will be appended to date times that do fall within Daylight Savings Time

NOTE: The server time zone must be correctly specified on the installation options record for the system to work properly.

For additional information see [Defining Time Zones](#) in the *Oracle Utilities Application Framework Administrative User Guide*.

Configuring Multi-time Zone Support

As a default the system assumes operations are in a single time zone. This has a few high level impacts:

- All master data must have a time zone that is equal to the base time zone. As such all master data will have the same time zone and that time zone will be the base time zone
- Certain logical complexities are avoided during high volume processing given the knowledge that all master data time zones are equal to the base time zone.

If your implementation resides within multiple time zones then the Multi Time Zone Support feature configuration must be enabled. Doing so will allow master data to be defined with any time zone configured in the system. It will also enable logic to convert time zones between the master data time zones and the base time zones.

You can access the feature configuration portal from the **Admin > General > Feature Configuration**.

From the list of results returned select the feature name for the feature type General System Configuration. For the option type Multi Time Zone Support supply "D1YS" as the value to turn multiple time zones on.

Refer to [Multiple Time Zone Support](#) for information about how functional processing is impacted by multiple time zone support.

Defining Financial Transaction Options

Bills, payments and adjustments share one very important trait - they affect how much your customers owe. This section explains the financial design of the system and describes how to set up the tables that control the financial impact of these transactions.

NOTE:

The tables in this section are the first of many that must be set up before you can create bills and apply payments. In this section, we limit the discussion to those tables that control the financial impact of bills, payments and adjustments. In later sections, we describe the tables that control other billing-related functions like meter reading and rates. It is only after all of these tables are set up that you will be able to generate the various financial transactions.

The Financial Big Picture

This section provides an overview of the relationship between an account and the various financial transactions that influence how much a customer owes.

WARNING:

If your organization practices cash accounting for payables (i.e., you only pay the taxing authority when you get paid), refer to [Payables Cash Accounting](#). If your organization practices open-item accounting (i.e., payments must be matched to bills), refer to [Open Item Accounting](#).

Bills, Payments & Adjustments

The following diagram illustrates the relationship between an account and its financial transactions:

The following concepts are illustrated above:

Bills are produced for accounts Over time, many bills may be produced for an account. For more information about a bill, see [Bill Details](#).

Payments are made for accounts Over time, many payments may be applied to an account's debt. For more information about a payment, see [Payment Details](#).

Service agreements have debt The system maintains debt on each individual service agreement. An account's debt is the sum of its service agreements' debt.

Service agreements are adjusted Over time, the debt that is stored on an account's service agreement(s) may be adjusted. For more information about an adjustment, see [Adjustment Details](#).

Bill Details

The following diagram illustrates the relationship between an account and its bills:

The following concepts are illustrated above:

A bill is produced for an account Over time, many bills are produced for an account. Bills charge for the services supplied to a customer. The above illustration shows a single bill.

Bills contain bill segments A bill typically contains one bill segment for every active service agreement linked to its account. The only time this is not true is when service agreements for different frequencies exist. For example, an account with a monthly and a quarterly service agreement will only have 4 bills a year that contain both bill segments; the other months' bills will contain a single bill segment for the monthly service agreement.

Bill segments contain calculation details A bill segment contains information showing how the segment was calculated and how it should be printed on the customer's bill.

A bill segment has a financial transaction A bill segment has a related financial transaction. A financial transaction contains the financial effects of the bill segment on the service agreement's current and payoff balances and on the general ledger.

Canceling a bill cancels the financial tran. If the bill segment is eventually cancelled, another financial transaction will be linked to the bill segment to reverse its original financial transaction. The cancellation financial transaction appears on the next bill produced for the account as a bill correction.

Payment Details

The following diagram illustrates the relationship between an account and its payments:

The following concepts are illustrated above:

Payments are made for accounts Over time, many payments may be applied to an account's debt. The above illustration shows a single payment.

Payments contain payment segments A payment contains one payment segment for every service agreement to which the payment is distributed. For a customer who pays in full, the number of payment segments will coincide with the number of bill segments on the bill being paid.

A pay. segment has a financial transaction A payment segment has a related financial transaction. A financial transaction contains the financial effects of the segment on the service agreement's current and payoff balances and on the general ledger.

Canceling a payment cancels the fin. tran. If the payment is eventually cancelled, another financial transaction will be linked to the related payment segment(s) to reverse their financial effect. The cancellation financial transaction appears on the next bill produced for the account as a negative payment.

FASTPATH:

A payment cannot be applied to an account's debt without an associated payment event. Refer to [The Big Picture of Payments](#) for more information.

Adjustment Details

The following diagram illustrates the relationship between an account and its adjustments:

The following concepts are illustrated above:

Service agreements have adjustments Over time, a service agreement may have many adjustments. The above illustration shows a single adjustment to one of the account's service agreements.

An adjustment has a financial transaction An adjustment has a related financial transaction. The financial transaction contains the financial effects of the adjustment on the service agreement's debt and on the general ledger.

Canceling an adjust. cancels the fin. tran. If the adjustment is eventually canceled, another financial transaction will be linked to the adjustment to reverse its financial effect. The cancellation financial transaction appears on the next bill produced for the account as an adjustment.

Current Amount versus Payoff Amount

A financial transaction contains two very important attributes: payoff amount and current amount. These attributes contain the grand total of how much the customer owes.

- Current amount contains how much the customer THINKS THEY OWE.
- Payoff amount contains how much the customer REALLY OWES.

You may be wondering when these two values can be different? Well, for most financial transactions, these values are the same. These values differ under the following situations:

- When a bill segment charges a customer for a charitable contribution, payoff amount will be zero because the customer doesn't really owe anything (they don't have to contribute if they don't want to). Current amount will be equal to the agreed charitable contribution amount (the customer thinks they owe the contribution).
- When a bill segment charges a customer for a deposit, payoff amount will be zero because the customer doesn't really owe anything (billed deposits are typically not viewed as being a receivable). Current amount will be equal to the amount billed (the customer thinks they owe the deposit amount).
- When a bill segment charges a customer who participates in a levelized payment program (e.g., budget billing or non-billed budgets) the two "amounts due" will contain different values. Payoff amount is equal to how much the customer really owes for the service they consumed; current amount is equal to how much they think they owe in accordance with their monthly budget.

A perhaps easier way to view these two attributes is to consider payoff amount as the "cash out amount", i.e., the amount the customer would owe the utility if they wanted to clear up all debt. The current amount contains the amount the customer

thinks they owe. If you're still struggling with the difference, think about your monthly Visa bill: it contains a monthly minimum payment and the total amount owed. The minimum payment is the current amount; the total amount owed is the payoff amount.

The topics in this section provide more information about these two fields.

What Controls What Gets Booked To Current And Payoff Amount?

As described in [Bill Details](#), every bill segment has a sibling financial transaction. The financial transaction defines the bill segment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the bill segment's bill segment type.

FASTPATH:

For more information, refer to [Billing - Current Balance versus Payoff Balance](#) and [Designing and Defining Bill Segment Types](#).

As described in [Payment Details](#), every payment segment has a sibling financial transaction. The financial transaction defines the payment segment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the payment segment's payment segment type.

FASTPATH:

For more information, refer to [Payment - Current Balance versus Payoff Balance](#) and [Setting Up Payment Segment Types](#).

As described in [Adjustment Details](#), every adjustment has a sibling financial transaction. The financial transaction defines the adjustment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the adjustment's adjustment type.

FASTPATH:

For more information, refer to [Adjustments - Current Balance versus Payoff Balance](#) and [Setting Up Adjustment Types](#).

Arrears

The system keeps track of the age of each customer's debt to the day. For example, if a customer hasn't paid their last two bills, the customer's aged debt might look as follows:

- \$124.50: 22 days old
- \$213.41: 51 days old

Please be aware that it is the current balance (i.e., what the customer thinks they owe) that is aged. Also keep in mind that the moment an FT is frozen, it impacts a customer's current balance.

The system represents aged debt in a variety of ways of the various transactions in the system. On the [Current Customer Zone](#) and the [Financial Information Zone](#) arrears are shown in a colorful bar (where each color corresponds to different aged buckets):

Whereas on [Service Agreement - Main](#), aged debt is shown in a grid:

Debt Class Arrears

Days Old	Arrears Amount
4	\$99.45
32	\$76.36

The grid method is used on many pages throughout the system. The following rows *may* appear in the grid:

- A row labeled New Charge highlights all debt that hasn't started aging yet. For example, if you've created a late payment charge and it hasn't appeared on one of the customer's bills, it will be classified as a New charge until the next bill is completed for the customer (unless a user overrides the late payment charge's arrears date by drilling into the financial transaction).
- A row with a label containing n Future (where n is the number of days) appears if there is "future debt". Future debt is very rare and can only exist if a debit financial transaction has a future arrears date. Financial transactions can receive a future arrears date if a bill is completed with a future date or if a user overrides a financial transaction's arrears date with a future date).
- A row that contains a number (and nothing else) represents debt that has started aging. The number is the age of the respective debt. In the above example, the customer has 1 day old debt, and debt that is more than 150 days old. Notice that the 150 day old debt is prefixed with a +. This means that the related debt is more than 150 days old. This age limit is controlled by a field on [Installation Options - CC](#) called "Oldest Bucket Age". This field limits the number of days the system will age debt. For example, if you set this field to 150, the system will never age an FT more than 150 days (and all debt that's older than 150 days will be classified as 150 day old debt). Also note, the aged debt bar that appears on [Current Customer Zone](#) only ages debt a maximum of 60 days.
- A row with a label of Disputed appears if the account is an [open-item](#) customer and this customer has [disputed](#) financial transactions.

FASTPATH:

Refer to [Financial Transactions And Aged Debt](#) for more information.

GL Accounting Information

Be aware that if payoff amount is non-zero, the financial transaction has general ledger detail lines.

There are unusual financial transactions whose payoff amount is zero, but still affect the general ledger:

- Bill segments for company usage do not impact payoff amount (because your organization doesn't really owe itself anything). However, the GL is affected.
- Payment segments for charitable contributions (created when your customers contribute extra money to a charity) do not impact payoff amount. Why? Because payoff amount is never debited when a charitable contribution is billed (the customer doesn't truly owe you for this receivable). It's only when the customer pays the contribution that the GL is impacted (debit cash, credit charitable contribution payable).
- If the SA has a special role of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. This allows the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Refer to [Payoff Balance and Current Balance for Loans](#) for more information.

The effect on your GL is controlled by the financial transaction algorithm defined on your bill segment and payment segment types.

FASTPATH:

Refer to [The GL Interface](#) for how GL account information is interfaced to the general ledger.

A Complicated Example

The financial ramifications of a revolving charge account are predictable (if you're an accountant). The following table outlines the different financial events and their impact on the general ledger, arrearage history, and the amounts due (both current and payoff).

Event	GL Accounting	Arrearage Rule	Effect On Payoff Amt	Effect On Current Amt	Payoff Balance	Current Balance
Merchandise purchased	A/R 1000 Revenue <1000>	n/a (current amount is zero)	+1000	0	1000	0
Monthly bill	A/R 10 Int. Rev <10>	\$120 aged accordingly	+10	+120	1010	120
Payment received	Cash 120 A/R <120>	\$120 relieved accordingly	-120	-120	890	0

The following points describe the events in the above table:

- **Merchandise purchased.** When a customer purchases an air conditioner:
 - The system generates an adjustment to book the purchase.
 - The customer doesn't really think they owe the entire \$1,000 (because they've purchased it on credit), therefore no moneys are booked to current amount. However, if the customer wanted to cash out, they would owe your organization \$1,000, therefore the entire amount of the purchase is booked to payoff amount.
 - Because no money was booked to current amount, this event has no impact on the arrearage history.
- **Customer billed.** Monthly, the system calculates how much the client owes. In this example, interest is calculated to be \$10 and the minimum monthly payment is set at \$120.
 - The interest is posted to the GL, but principal isn't since it was booked when the merchandise was purchased.
 - The customer really thinks they owe the minimum payment amount, \$120. Therefore, current amount is affected. However, if the customer were to cash out, they would owe your organization \$1,000 + \$10 (the interest); therefore payoff amount is affected by only \$10.
 - Because current amount changed by \$120, arrearage history is affected accordingly.
- **Payment received.** With any luck, the client will pay the \$120 that was billed (note, they could obviously pay more).
 - The payment has a normal affect on the GL (debit cash, credit A/R).
 - The amount the customer thinks they owe decreases by \$120, therefore current amount is affected by the payment amount. And, if the customer was to cash out, they would owe the utility \$120 less, therefore payoff amount is affected by the payment amount.
 - Because current amount changed by \$120, arrearage history is affected accordingly.

Financial Transactions Created Between Bills

The following diagram illustrates how frozen financial transactions (FT's) accumulate between bills and are swept onto the next bill produced for the account (when the bill is completed). This example assumes

After the last bill is completed, the account's service will have no unbilled financial transactions

SA Type: Elec, Resid, Gen No unbilled financial transactions	SA Type: Gas, Resid, Gen No unbilled financial transactions
---	--

When an account is levied a late payment charge, FT's are created and linked to the account's service

SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00	SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00
--	--

When a payment is applied to the account's debt, two FT's are created and linked to the account's service

SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00	SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00
PAY Electric Service Cur Amt: \$32.00- Payoff Amt: \$32.00-	PAY Gas Service Cur Amt: \$68.00- Payoff Amt: \$68.00-

When a bill is generated for an account, two bill FT's are created and added to the account's service

SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00	SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00
PAY Electric Service Cur Amt: \$32.00- Payoff Amt: \$32.00-	PAY Gas Service Cur Amt: \$68.00- Payoff Amt: \$68.00-
BILL Electric Service Cur Amt: \$42.00 Payoff Amt: \$42.00	BILL Gas Service Cur Amt: \$73.50 Payoff Amt: \$73.50

When a bill is generated for account, it sweeps all unbilled FT's onto itself

Prior Balance	\$100.00
Bill Corrections	\$0.00
Payments	\$100.00
Adjustments	\$15.00
New Charges	\$115.50
Current Balance	\$130.50
...	

When any type of financial transaction is frozen, it impacts the related service agreement's **current and payoff balances**. If you do not want adjustments and bill segments to affect the customer's balance until they appear on the customer's next bill, refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#).

Notice the balances in the financial summary of the above bill:

- The **Prior Balance** is the ending balance from the customer's prior bill.
- The **Bill Corrections** portion is blank. It contains a value if you cancel / rebill a bill segment that appeared on an earlier bill.
- The **Payments** portion shows payment financial transactions (both new payments and cancellations) that have been created since the last bill.
- The **Adjustments** portion shows adjustment financial transactions (both new adjustments and cancellations) that have been created since the last bill.
- The **New Charges** portion shows bill financial transactions that were created when the bill was created.
- The **Current Balance** is the total amount owed.

FASTPATH:

If you practice [Open Item Accounting](#), refer to [Open Item Versus Balance Forward Accounting](#) for more information about financial transactions and bills.

Financial Transactions And Aged Debt

The system keeps track of how old a service agreement's current balance is in order to determine if the customer is in arrears (and therefore credit and collections processing should start).

A financial transaction (FT) impacts the related service agreement's current and payoff balances the moment it is frozen. However, some types of frozen FTs have no impact on a customer's aged debt until the next bill is completed for the account associated with the service agreement.

As described in the previous section, a frozen financial transaction (FT) waits in limbo until the customer's next bill is produced. This limbo period could be several weeks if the customer is billed infrequently. When the customer's next bill is completed, all such frozen FT's are linked to the bill. It is important to stress the following in respect of these FT's:

- If the FT decreases the amount of debt, the customer's aged debt is affected immediately regardless of whether the FT appears on a bill.
- If the FT increases the amount of debt, the amount the customer owes from an aged debt perspective may or may not be affected by the FT. There is a switch on an FT called New Charge that controls the arrears behavior.
 - If this switch is on, the amount of debt will be reflected as a "new charge" when you look at the customer's aged debt. This amount will remain classified as a "new charge" until the FT is swept onto a bill. The moment the FT is swept onto the customer's bill, the debt starts aging. This logic exists because you probably don't want to start aging an FT until the customer has actually seen it.
 - If this switch is off, the date on which the FT starts aging must be defined in the Arrears Date field. The Arrears Date is used to compute how many days old the debt is.

NOTE:

Aged debt limitations. It's important to be aware that there's a field on [Installation Options - CC](#) called "Oldest Bucket Age" that limits the number of days old the system will age debt. For example, if you set this field to 360, the system will never age an FT more than 360 days (and all debt that's older than 360 days will be classified as 360 day old debt). Also note, the aged debt bar that appears on [Control Central - Account Information](#) only ages debt a maximum of 60 days.

FASTPATH:

If you practice [Open Item Accounting](#), refer to [Open Item Versus Balance Forward Accounting](#) for information about how open-item FT's affect aged debt.

Preventing SA Balances And The GL From Being Impacted Until Bill Completion

It's important to understand that when any type of financial transaction is frozen, the related service agreement's balance is affected. For example:

- When a payment is frozen, the customer's balance is reduced.
- When an adjustment is frozen, the customer's balance is impacted.
- When a bill segment is frozen, the customer's balance is increased (typically).

For payments, there is no issue. However, for bill segments and certain types of adjustments, you may NOT want the customer's balance to be impacted until the next bill is completed. Consider the following scenarios:

- Late payment charges:
 - You can setup the system to create a late payment charge (i.e., an adjustment) say 5 days after an unpaid bill is due.
 - If the related adjustment is frozen, the customer's balance will be impacted. However, its impact will not affect [aged debt](#) until the next bill is completed. In other words, the amount of the frozen adjustment segment will appear as a "New Charge" until the bill is completed.
- Batch billing:
 - If a customer has multiple service agreements, it's possible for one of the service agreements to have a bill segment that's in error and the other service agreement's bill segment to be error-free.
 - If this happens and you have setup the bill cycle schedule to freeze bill segments if they're error-free, then you could have one bill segment frozen and another in error.
 - The frozen bill segment will impact the customer's balance. However, its impact will not affect [aged debt](#) until the bill is completed (and a bill cannot be completed until all of its bill segments are error-free). In other words, the amount of the frozen bill segment will appear as a "New Charge" until the bill is completed.

WARNING:

We'd like to stress that while a frozen financial transaction impacts a customer's balance the moment it is frozen, the amount of the financial transaction appears as a "New Charge" when viewing a customer's [aged-debt](#). This amount will remain classified as a "New Charge" until the next bill is completed (i.e., the customer's debt doesn't start aging until the next bill is sent to the customer).

While [aged-debt](#) isn't impacted by frozen FT's, the general ledger is. This is because a financial transaction is marked for [interface](#) to the general ledger when it is frozen. This can be problematic if you have a long period between FT freeze and bill completion (you could impact the general ledger but not impact the customer's balance). If this is unacceptable, you can setup the system to not allow certain types of FT's to be frozen until the next bill is completed. This means that neither the customer's balance nor the general ledger will be impacted until bill completion time. To do this:

- Choose the Freeze At Bill Completion option on [Installation Options - Billing](#).
- Examine each of your [adjustment types](#). Select Freeze At Bill Completion for those that should not impact the customer's balance or the general ledger until the next bill is completed. Select Freeze At Will for those that should impact the customer's balance and the GL when they are frozen. Typically, the only adjustment types for which you'd choose Freeze At Will option are those that cause a customer's balance to be reduced, those that are used to refund money to a customer, and those that are created at bill completion. Adjustment types for adjustments created during bill completion (e.g., by a bill completion algorithm) must have their adjustment freeze option set to Freeze At Will. Otherwise (i.e., if the option is Freeze At Bill Completion) they will not be frozen until a subsequent bill is completed.

Please be aware of the following in respect of the Freeze At Bill Completion options:

- If you turn on Freeze At Bill Completion on [Installation Options - Billing](#):
 - Users will not be allowed to freeze bill segments online. This means that the freeze button will be disabled on [Bill - Main](#), [Bill - Bill Segments](#) and [Bill Segment - Main](#).
 - The Billing background process will not freeze bill segments until all segments on a bill are error free (and permission has been granted on the bill cycle schedule to complete bills).
 - Bill segments will exist in the freezable state until the bill is completed.
- If you turn on Freeze At Bill Completion on [Adjustment Type - Main](#):
 - Users will not be allowed to freeze adjustments of this type online. This means that the freeze button will be disabled on [Adjustment - Main](#).

- Background processes that create adjustments will not freeze this type of adjustment. Rather, the adjustments will be frozen when the next bill is completed.
- Adjustments of this type will therefore exist in the freezable state until the next bill is completed.

NOTE:

Alerts highlight freezable FT's. Please be aware that messages appear in the [Account Information - Financial Information Zone](#) and in the [Dashboard - Financial Information Zone](#) to highlight the existence of freezable financial transactions.

Please be aware of the following in respect of the Freeze At Will options:

- If you turn on Freeze At Will on [Installation Options - Billing](#):
 - Users will be allowed to freeze bill segments online. This means that the freeze button will be enabled on [Bill - Main](#), [Bill - Bill Segments](#) and [Bill Segment - Main](#).
 - The Billing background process will freeze bill segments when the individual segment is error-free (and permission has been granted on the bill cycle schedule to freeze bill segments).
 - Bill segments will exist in the frozen state regardless of whether the bill is completed.
 - The frozen bill segment's FT will be interfaced to the GL when the interface next runs.
 - All adjustment types must be also be set to Freeze At Will (otherwise they wouldn't get frozen).
- If you turn on Freeze At Will on [Adjustment Type - Main](#):
 - Users will be allowed to freeze adjustments of this type online. This means that the freeze button will be enabled on [Adjustment - Main](#).
 - Background processes that create adjustments will freeze this type of adjustment.
 - Adjustments of this type will exist in the frozen state prior to bill completion.
 - The frozen adjustment's FT will be interfaced to the GL when the interface next runs.

Forcing The Freeze Date To Be Used As The Accounting Date

Every financial transaction references an accounting date. The accounting date controls the accounting period to which the financial transaction is booked as described below:

- Every financial transaction references an accounting date and a service agreement
- Every service agreement references a service agreement type
- Every service agreement type references a GL division
- Every GL division references an [accounting calendar](#)
- The accounting calendar contains the cross-reference between the accounting date specified on the financial transaction and the related accounting period in your general ledger

The accounting date is populated on financial transactions when they are initially generated. The following points describe the source of the accounting date:

- The user who creates or cancels a bill segment online defines the accounting date as part of the generation/cancel dialog (note, the current date defaults).
- Bill segments that are produced by the [BILLING](#) background process have their accounting date defined on the [bill cycle schedule](#) that caused the bill to be created.

- The user who creates or cancels an adjustment online defines the accounting date as part of the generation / cancel dialog (note, the current date defaults).
- Payments are unusual in that their financial transaction is only created when they are frozen (rather than when the payment is first distributed amongst the account's service agreements). At payment freeze time, the accounting date is set to the current date.

For payments, there is no issue because the accounting date is only populated on the financial transaction when a payment is frozen. However, for bill segments and adjustments, your business practice may dictate that the freeze date should be used as the accounting date rather than the original accounting date. Alternatively, your business practice may dictate that the accounting date that's originally stamped on bill segments / adjustments should be used (unless this associated period is closed at freeze time). It's really a question of the interpretation of the local accounting rules. After you've decided on your approach, populate the **Accounting Date Freeze Option** on [Installation Options - Billing](#) with one of the following values:

- Choose Always change if the accounting date on your financial transactions should be populated with the freeze date (i.e., the current date when the financial transaction is frozen).
- Choose Change if period is closed if the accounting date defined when the financial transaction is generated should be used (unless the associated accounting period is closed).

Please be aware of the following in respect of your choice:

- If you choose Always change:
 - When a user freezes a bill segment online, they will be prompted to supply an accounting date. The current date will default, but the user can override this value.
 - When a user freezes an adjustment online, they will be prompted to supply an accounting date. The current date will default, but the user can override this value.
 - The **BILLING** background process will use the current business date as the accounting date on bill segments that it freezes.
 - Also note, if you have chosen the Freeze At Bill Completion **Bill Segment Freeze Option** on the [installation record](#), bill segments and certain types of adjustments are frozen when a bill is completed. This means that the accounting date on the related financial transactions will be set to the completion date (because the completion date is the freeze date with this setting). Refer to [Preventing SA Balances And The GL From Being Impacted Until Completion](#) for more information.
- If you choose Change if period is closed:
 - When a user freezes a bill segment online, they will only be prompted to supply an accounting date if the related accounting period is closed (because the accounting period closes after the bill segment is generated but before it's frozen). The current date will default, but the user can override this date.
 - When a user freezes an adjustment online, they will only be prompted to supply an accounting date if the related accounting period is closed (because the accounting period closes after the adjustment is generated but before it's frozen). The current date will default, but the user can override this date.
 - The **BILLING** background process will use the accounting date defined on the related bill cycle schedule as the accounting date on the bill segments that it creates and freezes.

NOTE:

The above installation option only controls the final accounting date for GL recording purposes. Rate and bill factor value selection based on accounting date uses the date as initially determined.

How Late Payment Charges Get Calculated

Late payment charges are system-generated adjustments used to penalize a customer for late (or no) payments. This section describes how to set up the tables that control how and when late payment charges are generated. The following points describe how and when late payment charges are calculated.

- When a bill is completed, the system marks it with the date on which late payment charges will be calculated if the bill is not paid.
 - This date is calculated by adding grace days to the bill's due date. Grace days are defined on the account's [Customer Class / Division](#).
 - This date will be zero if the account's [Customer Class / Division](#) indicates the account is not eligible for late payment charge processing.
- The late payment charge background process (referred to by the batch ID of [LATEPYMT](#)) selects all bills on or after their late payment charge date.
 - For each such bill, the system determines if its account satisfies the late payment charge eligibility criteria defined on the account's [Customer Class / Division](#). The eligibility criteria are defined in an algorithm and can therefore be as flexible as required.
 - If an account is eligible for late payment charges, the system checks each of the account's service agreements to determine if it is eligible for late payment charges (as defined on the service agreement's [SA Type](#)).
 - If a service agreement is eligible for late payment charges, the system calls the SA type's late payment charge calculation algorithm. This algorithm should calculate the late payment charge amount, if applicable and return the calculated amount and an appropriate adjustment type to use. If this algorithm returns this information, an adjustment is generated to levy the late payment charge.

FASTPATH:

Refer to [Setting Up Customer Classes](#) for more information about how to set up an account's due days and grace period. Refer to [SA Type - Main Information](#) for more information about enabling late payment charges calculations for your service agreements.

You can update the **Late Payment Charge Details** section on the Bill - Main Information page to indicate if and when late payment charges may be levied. For more information, see [Bill - Main Information](#).

Service Agreement Type Controls Everything

The previous section illustrated three important concepts:

The true financial impact of the three financial events - bills, payments, adjustments - is at the service agreement level, not at the account level. This means that bills and payments are meaningless on their own. It's the service agreements' bill segments, payment segments and adjustments that affect how much a customer owes.

- Every bill segment, payment segment, and adjustment has a related financial transaction. These financial transactions contain the double-sided journal entries that will be interfaced to your general ledger. They also contain the information defining how the customer's debt is affected by the financial event (i.e., current amount and payoff amount).
- A single bill can contain many bill segments, each of which may have a different frequency. For example, a bill could contain future charges, monthly retroactive charges based on measurement cycle, quarterly charges that must end on a quarter-end boundary.

You control the financial effects of the various financial events using a single field on the service agreement. This field is called the service agreement (SA) Type. In this section, we describe many of the tables that must be set up before you can create a SA type.

NOTE:

Foreshadowing. You will notice that we don't explain how to set up SA types in this section. This is because SA type controls numerous aspects of a service agreement's behavior in addition to its financial behavior. The non-financial

aspects are discussed in later chapters. It's only after you have set up all of the control tables in this manual that you'll be able to finally define your SA types. Refer to [Setting Up SA Types](#) for more information.

WARNING:

Take the time to define how you will record the various financial events in your general ledger before you attempt to set up these control tables. If you have simple accounting needs, this setup process will be straightforward. However, if you sell many services and use sophisticated accounting, this setup process will require careful analysis.

Understanding CIS Divisions

There are two types of Divisions referenced on a SA type: a CIS Division and a GL Division. This is a rather powerful structure, but it can be confusing.

- General Ledger divisions typically comprise individual entities (e.g., companies) in your general ledger. You must set up a GL division for each such entity. The GL division's sole purpose in the system is to define the accounting period associated with financial transactions linked to service agreements associated with the GL division (service agreements are associated with GL divisions via their SA type). The system cares about accounting periods in order to prevent a user from booking moneys to closed periods. It also uses accounting periods when it produces the flat file that contains the consolidated journal entry that is interfaced to your general ledger (refer to [The GL Interface](#) for more information).
- A CIS division is associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.
- CIS division is also referenced on service agreement, premise and account.
 - The CIS division on SA is actually part of the SA's SA type. Because SA type controls many business rules, all business rules that are on the SA type can be thought of as being defined for a given jurisdiction and SA type combination. For example, you could define your valid rates for electric residential service in California which differ from the valid rates for electric residential service in Nevada. Refer to [Defining Service Agreement Types](#) for more information. In addition to controlling the business rules defined on the SA's SA type, the SA's CIS division also controls the type of collection criteria used to determine if and how to collect overdue debt. Refer to [Setting Up Collection Class Control](#) for more information.
 - The CIS division on premise defines the jurisdiction in which the premise is located. This jurisdiction controls the types of service agreements that can be associated with the premise's service points (e.g., you can only link California-oriented service agreements to premises governed by the California jurisdiction). You can also set up your field activity types to execute special algorithms when a field activity is completed at a service point located in specific jurisdiction.
 - The CIS division on account when combined with the account's customer class defines the jurisdiction that governs financial business rules (e.g., the bill's due date, when and how late payment charges are calculated, etc.). Refer to [Setting Up Customer Classes](#) for more information about these rules. The CIS division on account can also play a part in the addressee of To Do entries associated with the account. To assign To Do entries to a role based on the division, simply link the To Do type to the division. Refer to [To Do Entries Reference A Role](#) for more information.

CIS Division Overrides

Some configuration values in the system, such as those defined on the installation record, are global and applied to the entire system. CIS Division allows some of these values to be specified by CIS division, overriding the system-wide default configuration. The system processes check the CIS Division for the override before checking the default configuration. CIS Division allows for overrides to be specified for **customer class** (by person and business), and **credit rating** and **cash-only** beginning and threshold values.

The bill route type and quote route type are used to define the background process and extract algorithm for each route type. CIS Division allows overrides to be specified for the extract batch control and/or extract algorithms. These can be defined for any or all each bill route types and quote route types. While bill route type and quote route type allow many of each type to be configured, one of each type is defaulted from the installation record. This override allows CIS Division specific value for a common route type.

Users and CIS Division

When the installation option Control By CIS Division flag is set, it is necessary to associate the system users with CIS Division. This feature is applicable if your organization expects users to work on designated CIS Divisions only (as opposed to allowing users to serve customers across all CIS Divisions). Users can be associated with CIS Division(s) even if the above flag is not set. Some system functions take advantage of this such as defaulting CIS Division on control central searches. User - CIS Division is maintained in the user portal.

To navigate there, select **Admin > User > Search** and navigate to the **Miscellaneous** page.

How Does the System Use User CIS Division

Refer to [Installation Options – Main](#) for information on how this is used in conjunction with the Control By CIS Division and Premise/SP Search flags

The user's CIS Divisions are used in some circumstances to restrict case type and customer contact type by CIS Division.

The user's Primary CIS Division is used to default the CIS Division on the Control Central search that is provided with the system.

Restricting CIS Division

CIS Division appears through much of the system. The primary objects that reference a CIS Division are account, service agreement, and premise. It is also referenced on secondary objects such as orders and on pages that interact with the primary objects such as start/stop and payment arrangement.

A flag on CIS Division, Restrict to Account CIS Division, can be used to restrict service agreements and premise to the account's CIS Division. It is important to note that it is the account's CIS Division that matters. When this flag is set, many of the system pages default CIS Division and restrict the user for changing the value. The following rules are enforced in addition to the visible changes:

- Service agreement's CIS Division must match its account's CIS Division.
- Account CIS Division cannot be changed if the account has non-canceled service agreements.
- Account Protect CIS Division switch is turned on and is protected. This is done because the switch becomes irrelevant since all service agreements match the account's CIS Division and the account CIS Division would not change.
- When starting service, only premises that match the account CIS Division or do not have a CIS Division maybe chosen. This rule is applied when choosing a premise via start/stop or order.
- While most SA/SPs are created by the system when service is started, it is possible to manually maintain SA/SPs. When searching for a service point from Service Agreement - SA/SP, the search is limited to SPs whose premise matches the account CIS Division or does not have a CIS Division.
- As mentioned, this setting applies to the account CIS Division. When changing a premise's CIS Division, the system checks all accounts ever linked to the premise, to see if any of the accounts' CIS Division has set the Restrict to Account CIS Division option to **Restricted**.

NOTE: The Premise to Account association is checked through the relationship from Premise to Service Point to SA/SP to Service Agreement to Account.

- If the Account's CIS Division is set to restrict the CIS Division, then the Premise's CIS Division is restricted to remain the same as the Account's CIS Division. It can also be set to blank unless the premise type requires it.
- The characteristic premise on a service agreement is restricted to premises linked to the account if the service agreement requires an SP. For other service agreements the premise search is restricted to the account CIS Division.

WARNING: Do not turn on this flag without reviewing your existing data to ensure that it adheres to the rules enforced when the flag is set. The above rules are enforced on not just current data, but historic data as well such as closed service agreements. It is intended to ensure a consistency over the life of the objects associated with the CIS Division. This flag is configurable for each CIS Division, but consider the implications of setting it on some, but not all CIS Divisions.

Using CIS Division for Operational Segmentation

CIS Division is found throughout many of the entities in the system and there are many configuration settings related to CIS Division. When these configuration settings are used in conjunction with each other, it is possible to operate distinct business entities or jurisdictions that are segmented by CIS division. The following summary describes the different settings and uses of CIS Division that you can configure if your organization operates in multiple jurisdictions and needs to segment data and business processes by CIS Division. Details about each of these can be found in the section of the document where the functionality is configured.

Associate CIS Divisions with Users

CIS Divisions can be associated with users and one can be denoted as the primary.

Control By CIS Division

Setting the Control By CIS Division flag on the installation record drives many system changes. On the account it makes CIS Division required. The flag drives functionality changes on other pages such as person, premise, and order.

Premise/SP Access

Setting the Premise/SP Search flag on the installation record restricts access to premise and SPs not link to an account. The access is restricted to the user's CIS Division(s).

CIS Division

CIS Division provides the configuration of a work calendar, default customer classes for persons and businesses, credit rating and cash only beginning and threshold values, and To Do role assignment for each CIS Division. Additionally, bill route type, quote route type, and auto pay route type configuration can be overridden.

Restrict CIS Division

The Restrict to Account CIS Division flag is a setting on CIS Division. It is used to ensure that service agreements and premises match the account CIS Division and is a main component of segmenting data by CIS Division.

Customer Class

Customer class is used to default collection class on accounts.

Customer Class Control

Customer Class Control defines many business rules directly or through algorithms. These rules are specified per CIS Division. As noted above, Customer Class can be defaulted from CIS Division so there is a lot of flexibility in the configuration of these two entities. Some of the business rules are defaults such as access group and budget plan. Others such as payment distribution and billing days until due define the rule that apply to the account Customer Class/CIS Division combination.

SA Type

CIS Division is part of the SA Type key. SA Type defines the valid values for SAs of that type and also defines attributes such as debt class and write off debt class for of SAs of that type.

Collections

As noted above, Collection Class is defaulted on the account from customer class and SAs inherit their debt class from their SA Type. Collection Class Controls are defined for the unique combination of collection class and debt class. Collection class controls define the business rule and collection processes. Through configuration, collection rules can be defined for specific CIS Divisions.

Write Off

As noted above, collection class is defaulted on the account from customer class and SAs inherit their write off debt class from their SA Type. Write off controls are defined for the unique combination of collection class and write off debt class. Write off control define the business rule and write off processes. Through configuration, write off rules can be defined for specific CIS Divisions.

Premise Type

Premise Types can control if CIS Divisions are required, optional or not allowed for premise of that type. When starting service, if the premise has a premise type, only SA Types with the same CIS Division as the premise that are identified to start for SP Types for SPs at the premise will start. This allows more generic SP Types that start SA Types specific for the premise CIS Division.

Restricting Types by CIS Division

Adjustment type, budget plan, bill cycle, case type, and customer contact type allow a CIS Division to be specified if the type is used for a specific CIS Division. Types without a CIS Division are not restricted.

Background Processing By CIS Division

Batch billing and the collection, severance, and write off background processes can all be configured to select records by CIS Division. See [Choosing Which Records Are Selected](#) for more information

Setting Up CIS Divisions

This portal is used to display and maintain CIS Divisions.

Refer to [Understanding CIS Divisions](#) for more information.

You can access the portal from **Admin > General > CIS Division**.

The following zones may appear as part of the portal's **Main** page:

- **CIS Division List:** This zone lists all CIS division records. Broadcast a record to display the details of the selected record.
- **CIS Division:** This zone provides information about the selected CIS Division.

Setting Up Revenue Classes

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type defines a service agreement's revenue class. The revenue class is used when the service agreement's rate books revenue to different GL distribution codes based on the service agreement's revenue class.

FASTPATH:

See [Designing Calculation Groups and Rules](#) for more information about how revenue class is used to determine the GL revenue accounts referenced on a bill. See [Revenue Segmentation](#) for more information about how revenue class affects the number of SA types you will need.

To set up revenue classes, choose **Admin > Financial > Revenue Class**.

Description of Page

Enter an easily recognizable **Revenue ClassID** and **Description** for every revenue class.

Setting Up Distribution Codes

Distribution codes simplify the process of generating accounting entries by defining valid combinations of chart of account field values.

FASTPATH:

Refer to [The Source Of GL Accounts On Financial Transactions](#) for more information about the accounting entries associated with bills, payments and adjustments.

To set up distribution codes, open **Admin > Financial > Distribution Code > Add**.

Description of Page

Enter a unique **Distribution Code** and **Description** for the distribution code.

If this distribution code is a holding account used for payables cash accounting, check the **Use For Non-Accrual Accounting** switch and select the accounting method from the **Accounting Method** list. Select the priority level for the distribution code from the **Accounting Priority** list and enter the actual payable **Accounting Code**. The system will transfer monies from the holding account to the distribution code when the cash event occurs. Transfers will occur based on priority and debt age. For more information, refer to [Payables Cash Accounting](#) and [Deferred Accrual Accounting](#).

Define the **GL Account Algorithm** used by the system when it interfaces financial transactions that reference this distribution code to your general ledger (refer to [GLDL - Create General Ledger Download](#) for more information about the download process). The logic embedded in this algorithm constructs the actual GL account number. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that constructs your general ledger account number.

The **Write Off Controls** control how the system writes off debt associated with the distribution code. Refer to [The Ramifications of Write Offs in the General Ledger](#) for an explanation of how these fields are used at write-off time.

- Define the **Division** and **SA Type** of the service agreement to which bad debt associated with this distribution code should be transferred at write-off time. Note: only SA Types with a special role of Write Off may be selected.
- When the system transfers debt to the write-off service agreement defined above, the distribution code defined on this **Division / SA Type** will be debited unless you turn on the **Override Switch**. When this switch is turned on, the system overrides the distribution code of the transfer to side of the adjustment with the distribution code associated with the debt being written off. You'd typically turn this switch on for liability distribution codes because you want to debit the original liability account when the debt is written off. Note: if this switch is on the system also overrides the characteristic type / value with the respective value associated with the debt that is being written off.

Use the **GL Account Details** scroll to define how the system constructs the GL account associated with the distribution code when it interfaces the financial transaction to your general ledger. For each distribution code, enter the following information:

- Enter the **Effective Date** of the following information.

- Define whether, on the **Effective Date**, the following information is Active or Inactive. The system will only use effective-dated information that is Active.
- Enter the **GL Account** that the general ledger uses to process financial transactions tagged with this distribution code.
- Enter the **Statistics** that should be passed to the general ledger during the GL interface for this **GL Account**. For example, if this **Distribution Code** is used to record electric, residential revenue, the **Statistics** would be kWh if you record the number of kWh in your general ledger along with the dollar value of the revenue.
- If you have configured your installation options to indicate that **fund accounting** is practiced, define the **Fund** associated with this distribution code. If your installation options indicate that fund accounting is not practiced, the field is not visible.
- Use the characteristics grid to define characteristic values for the **Distribution Code**. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the **Distribution Code GL Account Characteristics** table. To modify a characteristic, simply move to a field and change its value. The following fields display:
 - **Characteristic Type**. Indicate the type of characteristic.
 - **Characteristic Value**. Indicate the value of the characteristic.

NOTE:

You can only choose characteristic types defined as permissible on the distribution code record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Setting Up Billable Charge Templates

A user creates a billable charge whenever a customer should be levied an ad hoc charge. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line.

NOTE:

Interfacing billable charges from an external system. In addition to being entered manually, billable charges can also be interfaced from an external system. You would interface billable charges if your organization provides "pass through" billing services for a service provider. Refer to [Uploading Billable Charges](#) for more information.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each unbilled billable charge.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

NOTE:

Rates can be applied to billable charges. Billable charges can be connected to a service agreement that also specifies a rate. The rate will be applied and lines added to the bill segment after the billable charge lines are added. For example, a rate can insert flat charges or be applied to service quantities associated with the billable charge.

Taxes on top of billable charges. Rates cannot be applied to billable charge lines. If you need to perform a calculation such as applying taxes on top of the existing lines, add a service quantity (SQ) that contains the taxable amount with an SQ identifier that describes it as a taxable amount. A calculation rule can apply the tax to this SQ.

FASTPATH:

Refer to [How To Create A One-Time Invoice](#) for instructions describing how to create a bill for a billable charge outside of the normal bill creation process.

Billable charge templates exist to minimize the effort required to create a billable charge for a customer. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge.

The information on the template may be overridden by a user when the billable charge is created. For example, you can create a billable charge template to levy tree-trimming charges. This template would contain the bill lines, amounts and distribution codes associated with a tree trimming activities. Then, when you trim a tree for a customer, a user can create a billable charge using the template and override the amount to reflect the actual amount (if it differs from the norm).

NOTE:

Templates aren't required. A billable charge can be created without a template for a truly unexpected charge.

After setting up the billable charge templates, you must indicate the SA types that can use each template. Obviously, only billable charge SA types (as defined on the SA type's special role) will reference billable charge templates.

Billable Charge Template - Main

Open **Admin > Billing > Billable Charge Template > Add** to define your billable charge templates.

Description of Page

Enter a unique **Billable Charge Template ID** and **Description** for the billable charge template.

Use **Description on Bill** to define the verbiage that should print on the customer's bill above the billable charge's line item details.

Use **Currency Code** to define the currency in which the billable charge's amounts are expressed.

Use the grid to define the line item details associated with the billable charge (note, the **Total Line Amount** field is automatically calculated. It is the sum of the **Charge Amount** on each of the Line Sequence items). The following fields are required for each entry in the grid.

Sequence Line sequence controls the order in which the line items appear on the bill segment.

Description on Bill Specify the verbiage to print on the bill for the line item.

Charge Amount Specify the default amount to charge for the line item.

Show on Bill Turn this switch on if the line item should appear on the customer's printed bill. It would be very unusual for this switch to be off.

Appears in Summary Turn this switch on when the amount associated with this line also appears in a summary line.

Memo Only, No GL Turn this switch on when the amount associated with this line does not affect the GL (or the total amount owed by the customer).

Distribution Code Specify the default distribution code associated with this line item.

If you use the drill down button on the left most column in the grid, you will be taken to the Line Characteristics tab with the selected line displayed.

FASTPATH:

For more information about creating a billable charge, refer to [Maintaining Billable Charges](#). For more information about billing billable charges, refer to [How To Create A One-Time Invoice](#).

Billable Charge Template - Line Characteristics

Open **Admin > Billing > Billable Charge Template > Search** and navigate to the **Line Characteristics** page to define your billable charge templates line characteristics.

Description of Page

The **Line Sequence** scroll defines the billable charge template line to which you wish to assign characteristic values.

The characteristics grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Billable Charge Template Line Characteristics table.

To modify billable charge template line characteristics, simply move to a field and change its value. To add characteristics, press + to insert a row and then fill in the information for each field. The following fields display:

Characteristic Type The type of characteristic.

Characteristic Value The value of the characteristic.

Billable Charge Template - SQ Details

Open **Admin > Billing > Billable Charge Template > Search** and navigate to the **SQ Details** page to define your billable charge templates service quantities.

Description of Page

To modify a template's service quantity, simply move to a field and change its value. To add a new service quantity to the billable charge template, press the + button to insert a row and fill in the information for each field. The following fields display:

Sequence Specify the sequence number of the SQ.

UOM Select the unit of measure of this SQ. One or more of UOM, TOU, or SQ identifier must be selected.

TOU Select the time of use period.

SQ Identifier Select the SQ identifier.

Service Quantity Specify the number of units of this service quantity.

Designing and Defining Bill Segment Types

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type references a bill segment type. The bill segment type controls how bill segments and their related financial transactions are created.

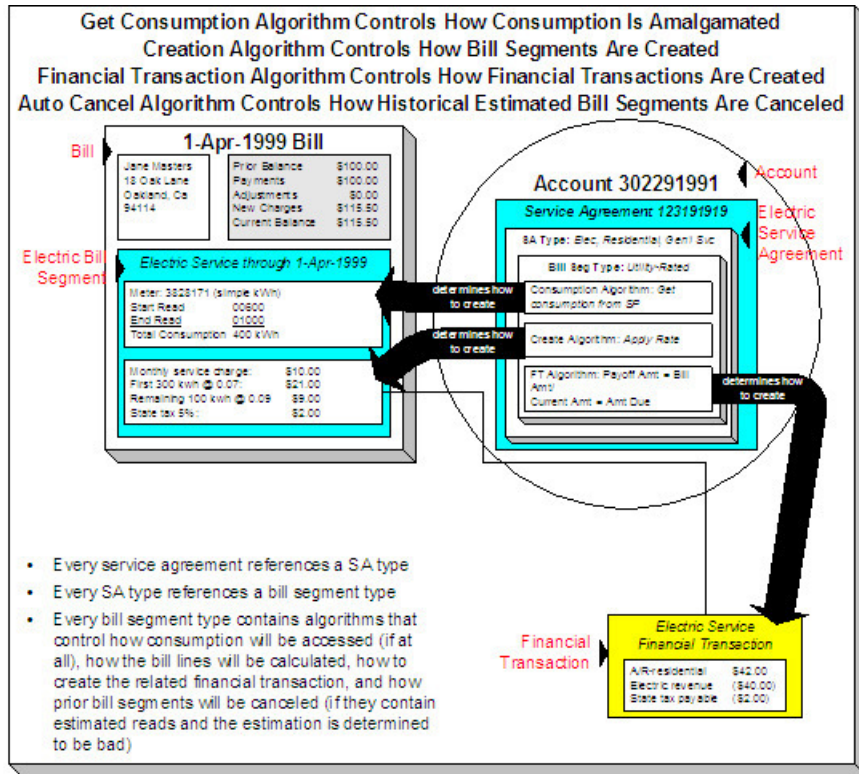

WARNING:

We strongly recommend understanding the concepts described in [The Big Picture of Billing](#) before setting up your bill segment types.

The topics in this section describe how to design and set up bill segment types.

What Do Bill Segment Types Do?

Bill segment types control how bill segments and their related financial transactions are created. The following illustration will help you understand how the system uses bill segment types during the bill segment creation process:

Designing Your Bill Segment Types

The following table contains a subset of the SA types listed under [Defining Service Agreement Types](#) and [Designing Your SA Types And Start Options For Sub SAs](#) and [Designing SA Types For Service Provider Financial Settlements](#). However, if you are reading this document from top to bottom, you probably don't know what your SA types are (they are only designed much later) and will have to forestall this task until that time.

We're going to cheat and assume you know what your SA types are and fill in the algorithms necessary to create bill segments for each SA type. After this table is complete, we will look for unique combinations of the 4 algorithms and create a bill segment type for each one.

NOTE:

Before you can fill in the columns for your own SA types, you should be comfortable with the descriptions of the algorithms described under [Setting Up Bill Segment Types](#).

Div.	Calculation	FT	Consumption	Auto Cancel
SA Type	Algorithm	Algorithm	Algorithm	Algorithm
CA/G-RES	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/G-COM	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/G-IND	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.

CA/CABLE	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/E-COY	Apply Rate To Usage Request	Payoff = 0 / Current = 0	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/E-RESU	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/E-COMU	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
CA/WO-STD	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable
CA/WO-LIA	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable
CA/CHARITY	Recurring Charge	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
CA/PA-REGU	Recurring Charge With Auto Stop	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
CA/MERCH-I	Recurring Charge For Amount To Bill	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
CA/DEP-I	Recurring Charge For Amount To Bill	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
CA/ONETIME	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed
CA/OVR UNDR	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable
CA/E-SUB ENR	Apply Rate	Payoff = Bill Amount / Current = Amount Due		
CA/E-SUB BC	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed
CA/E-FIN SETTL	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable

Now, we'll extract unique combinations of the four algorithms and create a bill segment type for each.

Bill Segment Type	Calculation Algorithm	FT Algorithm	Consumption Algorithm	Auto Cancel Algorithm
BD RATED	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.
BILLCHRG	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed
COMPUSAG	Apply Rate To Usage Request	Payoff = 0 / Current = Bill Amount	Get Consumption Using Usage Request	N/A - no consumption is needed
RECUR	Recurring Charge	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
RECUR AS	Recurring Charge With Auto Stop	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
RECURATB	Recurring Charge For Amount To Bill	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed
SUB RATE	Apply Rate	Payoff = Bill Amount / Current = Amount Due	Get Consumption From Master Bill Segment	N/A - rated sub service agreements are cancelled

when their master is canceled.

SUB BC	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed
--------	-----------------	---	--------------------------------	--------------------------------

Just to make sure everything has been designed appropriately, we will return to our SA type samples and specify their respective bill segment types:

Div.	Calculation	FT	Consumption	Auto Cancel	Bill Segment Type
SA Type	Algorithm	Algorithm	Algorithm	Algorithm	
CA/G-RES	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/G-COM	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/E-RES	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/E-COM	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/G-IND	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/CABLE	Apply Rate To Usage Request	Payoff = Bill Amount / Current = Amount Due	Get Consumption Using Usage Request	NA - can't estimate consumption.	BD RATED
CA/E-COY	Apply Rate To Usage Request	Payoff = 0 / Current = Bill Amount	Get Consumption Using Usage Request	N/A - no consumption is needed.	COMPUSAG
CA/WO-STD	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable	
CA/WO-LIA	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable	
CA/CHARITY	Recurring Charge	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed	RECUR
CA/PA-REGU	Recurring Charge With Auto Stop	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed	RECUR-AS
CA/MERCH-I	Recurring Charge For Amount To Bill	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed	RECUR-AS
CA/DEP-I	Recurring Charge For Amount To Bill	Payoff = 0 / Current = Bill Amount	N/A - no consumption is needed	N/A - no consumption is needed	RECURATB
CA/ONETIME	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed	BILLCHRG

CA/OVR UNDR	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable	
CA/E-SUB ENR	Apply Rate	Payoff = Bill Amount / Current = Amount Due	Get Consumption From Master Bill Segment	N/A - rated sub service agreements are cancelled when their master is canceled.	SUB RATE
CA/E-SUB BC	Billable Charge	Payoff = Bill Amount / Current = Amount Due	N/A - no consumption is needed	N/A - no consumption is needed	SUB BC
CA/E-FIN SETTL	N/A - non billable	N/A - non billable	N/A - non billable	N/A - non billable	

And now you're ready to set up your bill segment types.

Setting Up Bill Segment Types

To set up bill segment types, open **Admin > Billing > Bill Segment Type > Add.**

Description of Page

Enter an easily recognizable **Bill Segment Type** and **Description** for every type of bill segment.

For each bill segment type, define the **Create Algorithm**. The logic embedded in this algorithm creates the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that creates a bill segment in the appropriate manner.

WARNING:

The **BS Create Algorithm** is a very important field as it controls how the system creates bill segments. There are some restrictions in respect of the values of certain fields on the SA type and the bill segment algorithm used on a SA type. Refer to [Require Total Amount Switch versus Bill Segment Creation Algorithm](#), [Allow Recurring Charge Switch versus Bill Segment Creation Algorithm](#), and [Rate Required Switch versus Bill Segment Creation Algorithm](#) for more information.

For each bill segment type, define the **Financial Algorithm**. The logic embedded in this algorithm constructs the financial transaction associated with the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that constructs the bill segment financial transaction in the appropriate manner.

FASTPATH:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

If the bill segment requires consumption (e.g., meter reads) to be retrieved, define the **Get Consumption Algorithm**. The logic embedded in this algorithm retrieves the consumption that is billed on the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that retrieves consumption in the appropriate manner.

The **Auto Cancel Algorithm** is used by the system when it detects that a prior bill segment contains an estimated read that meets certain conditions when a non-estimated read is used on the current bill.

Examples include:

- The prior bill segment contains a bad estimated read (by "bad" we mean that the current bill has a non-estimated reading that is less than the estimated end read on the prior bill segment).
- The prior bill segment contains an estimated read (there may be situations where you want to cancel an estimated bill segment when a non-estimated read is also higher than the end read on the prior bill segment. For example, when tiered rates may cause a customer to be penalized by consumption being charged at a higher rate).

For detecting a bad estimated read on the prior bill segment, if you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that cancels bill segments that contain poorly estimated consumption.

For detecting an estimated read on the prior bill segment, if you haven't done so already, you must set up this algorithm in the system and configure a feature configuration option. To do this:

- Create a new algorithm for the Auto Cancel Algorithm.
- On this algorithm, reference an Algorithm Type that cancels bill segments that contain estimated consumption (refer to [Setting Up Algorithms](#)).
- Configure the **Always Call Auto Cancel** option type on the Financial Transactions Option feature configuration and set the option type value to 'Y'. For more information about Feature Configurations, see [Defining Feature Configurations](#).

Note that the **Auto Cancel Algorithm** is not used in Oracle Utilities Customer To Meter. The following features replace the algorithm:

- Usage Transaction Correction Processor
 - This is created during IMD processing when an anomaly is detected in the reads used in usage calculation. It sets the stage for sending the corrected read notification
 - The Usage Transaction Correction Processor monitor job (D1-UTCRN) must be scheduled after all IMD processing batch jobs.
- Corrected Reads Notification
 - The application may be configured to automatically process all corrected read notifications by submitting the Corrected Reads Notification monitor job (C1-TCRNB). Refer to the configuration guideline below for automating this process.
 - If manual rebill is preferred, billing user may navigate to the off cycle generator portal to search for a customer's corrected read notification, review and rebill them one at a time starting from the oldest bill segment.
- Final Measurement Replacement — It is recommended that this VEE rule be configured for IMD processing. It is used to reject small changes in reads, which in turn prevents the creation and sending corrected reads notification and subsequent re-bill that would have resulted to small net differences in charges.

The **Bill Segment Information Algorithm** is used by the system to format the bill segment information that appears throughout the system. If the information you'd like displayed differs for bill segment types, you must set up this algorithm in the system. To do this:

Designing and Defining Deposit Classes

If you bill for deposits, you must set up one or more deposit classes. If your company does not bill for deposits, you can skip this section.

FASTPATH:

We strongly recommend familiarizing yourself with the concepts described in [The Big Picture Of Deposits](#) before tackling the information in this section.

The topics in this section describe how to design and set up deposit classes.

What Do Deposit Classes Do?

A deposit class contains the business rules that govern:

- How and when deposit interest is calculated.
- How the recommended deposit amount is calculated.
- When a deposit will be automatically refunded to a customer.
- When the system will recommend a new or additional deposit.

When you link a deposit class to a SA type, you are indicating that the SA type's service agreements are governed by the deposit class' business rules.

In addition to linking a deposit class to the SA types used to bill for a deposit, you must also define a deposit class on SA types whose debt is covered by a deposit. Consider the following examples:

- Assume your company sells electricity, gas, and water; but deposits are only held only for electric service. In this situation, you'd need one deposit class - Electric - and you'd associate it with both the electric deposit SA type and the electric usage SA type(s) (the gas and water SA types would NOT reference a deposit class).
- If your company can apply a deposit to any type of debt, then you'd have just one deposit class - General Deposit. You'd link this deposit class to the deposit SA type, and to the other SA types whose debt is covered by the deposit.

NOTE:

Non-cash deposits. You can also use the system to manage non-cash deposits (e.g., letters of credit, surety bonds, 3rd party deposits). Non-cash deposits are held in respect of an account (and an account may have an unlimited number of non-cash deposits). Each non-cash deposit must reference a deposit class. Why? Because the system amalgamates cash and non-cash deposits when it determines if an account is holding an adequate deposit. Refer to [3rd Party Deposits](#) for more information.

Designing Your Deposit Classes

A deposit class contains the business rules that govern:

- How and when deposit interest is calculated.
- How the recommended deposit amount is calculated.
- When a deposit will be automatically refunded to a customer.
- When the system will recommend a new or additional deposit.

You will need multiple deposit classes if any of the above rules / conditions differ for different types of customers. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one deposit class for residential and another for commercial.

You will need additional deposit classes if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one deposit class for regulated debt and another for unregulated debt.

We'll design deposit classes to satisfy the needs of a theoretical company to help you understand how to design your deposit classes. The following points describe the deposit requirements of our theoretical company:

- The recommended deposit amount is 2 times the average bill (averaged over the last 12 months). This is true regardless of the type of customer or debt.
- The system should automatically refund a deposit to a customer after:
 - The deposit has been held for at least 6 months; and
 - The account's credit rating is greater than the credit rating threshold defined on the installation record or the account's CIS Division (i.e., the credit rating is no longer considered bad)
- This is true regardless of the type of customer or debt.
- Interest is calculated every 6 months. The interest rate is defined using a bill factor (refer to [Setting Up Bill Factors](#) for more information). This is true regardless of the type of customer or debt.
- When it's time to refund a deposit, all outstanding debt will be paid off first. If any moneys remain, a check should be sent to the customer for the remainder. This is true regardless of the type of customer or debt.
- A customer could have both regulated and unregulated debt under a single account. When this happens, separate deposits will be held for each type of debt (where the regulated deposit can only be used to satisfy regulated debt and the unregulated deposit can only be used to satisfy unregulated debt).

You'd need the following deposit classes to satisfy the above requirement:

Deposit Class	Recommended Amount Rule	Auto Refund Condition	Interest Rules	Deposit Refund Method
Regulated	2 x Average Bill	Held for 6 months and credit rating is good	Simple interest every 6 months	Apply to outstanding debt first, refund remainder with a check
Unregulated	2 x Average Bill	Held for 6 months and credit rating is good	Simple interest every 6 months	Apply to outstanding debt first, refund remainder with a check

You may wonder why two deposit classes are needed when the rules are the same for both? Well, besides defining the applicable business rules for a deposit service agreement, a deposit class is defined on the SA types whose debt is covered by the deposit class' deposit. So, if you have two different types of debt where each type of debt can have its own deposit, you'd need at two deposit classes. Each deposit class would be associated with the service agreements that are being secured by the deposit.

Refer to [Setting Up Deposit Classes](#) for a description of the various algorithms defined in respect of a deposit class.

Setting Up Deposit Classes

In the previous section, *Designing Your Deposit Classes*, we presented a case study that illustrated a mythical organization's deposit classes. In this section, we explain how to maintain your Deposit Classes.

Deposit Class - Main

To set up deposit classes, select **Admin > Credit & Collection > Deposit Class > Add**.

Description of Page

Enter an easily recognizable **Deposit Class** and **Description**.

Use **Refund Description on Bill** to define the information that appears on the bill segment produced when it's time to refund the customer's deposit.

The remaining information on this page is used by the various deposit-oriented processes.

Refer to [Deposit Class - Good Customer](#) for information about the **Good Customer Algorithm**.

Refer to [Deposit Class - Recommendation](#) for information about the **Recommendation Algorithm** and **Review Tolerance Percentage**.

Refer to [Deposit Class - Refund Method](#) for information about the **Refund Method Algorithm**.

Refer to [Deposit Class - Refund Criteria](#) for information about the **Refund Criteria Algorithm**.

Refer to [Deposit Class - Refund Interest](#) for information about the **Interest Refund Algorithm** and **Months Between Interest Refund**.

Refer to [Deposit Class - Review Method](#) for information about the **Review Method Algorithm**.

Deposit Class - Good Customer

On [Deposit Class - Main](#) you must define the **Good Customer Algorithm** used by the system when it determines if a customer is considered good (the system recommends new / additional deposits for bad customers). Refer to [Deposit Review](#) for a description of the background process that reviews customers for adequate deposits.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer is considered good.

Deposit Class - Recommendation

On [Deposit Class - Main](#) you must define the **Recommendation Algorithm** used by the system when it calculates a customer's recommended deposit amount.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that recommends deposits.

The system uses the **Review Tolerance Percentage** to prevent the recommendation of small deposits by the Deposit Review background process. For example, if this field contains 10(%), the system would only recommend an additional deposit if the recommended amount was more than 10% of the existing deposit.

Deposit Class - Refund Method

On [Deposit Class - Main](#) you must define the **Refund Method Algorithm** used by the system when it refunds a deposit to the customer.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).

- On this algorithm, reference an Algorithm Type that refunds a deposit to a customer.

Deposit Class - Refund Criteria

On [Deposit Class - Main](#) you must define the **Refund Criteria Algorithm** used by the system when it determines if it should automatically refund a deposit to a customer. Refer to [Deposit Review](#) for a description of the background process that reviews deposits for refunds.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer qualifies for a deposit refund.

Deposit Class - Refund Interest

On [Deposit Class - Main](#) you must define the **Interest Refund Algorithm** to define how the system calculates interest and how it refunds the interest to the customer.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates interest on a deposit.

Interest will be automatically calculated every X months where X is defined in **Months Between Interest Refund**. Refer to [Deposit Interest](#) for a description of the background process that calculates interest on deposits. Also note that interest is calculated when a [deposit service agreement is stopped](#).

Deposit Class - Review Method

On [Deposit Class - Main](#) you must define the **Review Method Algorithm** used by the system to determine what action to take if the system recommends a deposit (or additional deposit) amount for an account. Refer to [Review Deposits](#) for a description of the background process that reviews deposits for refunds. The algorithm supplied with the base product highlights new deposits and deposit amounts on the [Deposit Review](#) page.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the review method the system uses if it recommends a deposit or additional deposit be applied to an account.

Setting Up Non-Cash Deposit Types

Non-cash deposit types are used to indicate the type of monetary instrument used for non-cash deposits. Refer to [Non-Cash Deposits](#) for more information.

To define your non-cash deposit types, select **Admin > Credit & Collection > Non-Cash Deposit Type**.

Description of Page

To modify a non-cash deposit type, move to a field and change its value.

To add a new non-cash deposit type, insert a row, then fill in the information for each field. The following fields display:

Non-Cash Deposit Type The unique identifier of the non-cash deposit type.

Description The description of the non-cash deposit type.

Review Before Expiration This switch indicates if the system will create a To Do entry when non-cash deposits of this type are close to expiration.

Third Party Deposit This switch indicates if the system requires a reference to a 3rd party's deposit service agreement for this type of non-cash deposit. Refer to [3rd Party Deposits](#) for more information.

Setting Up Payment Segment Types

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type references a payment segment type. The payment segment type controls how payment segments and their related financial transactions are created. To set up payment segment types, open **Admin > Payment Segment Type**.

Description of Page

Enter an easily recognizable **Payment Segment Type** and **Description** for every type of payment segment.

FASTPATH:

For more information about the source of the distribution codes on financial transactions, see [The Source Of GL Accounts On Financial Transactions](#).

For each payment segment type, define the **Payment Segment Fin Algorithm**. The logic embedded in this algorithm constructs the actual financial transaction associated with the payment segment. Refer to [Examples of Common Payment Segment Types](#) for examples of how algorithms are used on common payment segment types.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that constructs the payment segment financial transaction in the appropriate manner.

FASTPATH:

For more information about current and payoff amount, see [Current Amount versus Payoff Amount](#).

Examples of Common Payment Segment Types

The following table shows several classic payment segment types used by many organizations:

Payment Segment Type	Payment Segment Financial Transaction Algorithm
Normal payment (if you practice accrual accounting). Refer to Accrual versus Cash Accounting for more information.	Payoff = Pay Amount / Current = Pay Amount (no cash accounting)
Normal payment (if you practice cash accounting). Refer to Accrual versus Cash Accounting for more information.	Payoff = Pay Amount / Current = Pay Amount (plus Cash Accounting)
Charity payment	Payoff = 0 / Current = Pay Amount (the GL is affected)

Designing And Defining Adjustment Types

A service agreement's debt may be changed with an adjustment. Every adjustment must reference an adjustment type. The adjustment type contains a great deal of information that is defaulted onto the adjustment, including whether the adjustment amount is calculated. It also controls many business processes associated with the adjustment. The topics in this section describe how to design and set up adjustment types.

What Do Adjustment Types Do?

An adjustment type contains the business rules that govern how its adjustments are managed by the system. Please refer to [The Big Picture Of Adjustments](#) for a complete description of how adjustment types impact the lifecycle of adjustments.

Setting Up Adjustment Types

The topics in this section describe how to set up adjustment types.

NOTE:

When a new adjustment type is added. When you introduce a new adjustment type, you must update one or more adjustment profiles with the new adjustment type. Why? Because adjustment profiles define the adjustment types that may be levied on service agreements (adjustment profiles are defined on SA types). If you don't put the adjustment type on an adjustment profile, the adjustment type can't be used on any adjustment.

Adjustment Type - Main

To set up adjustment types, open **Admin > Financial > Adjustment Type > Add.**

Description of Page

Enter a unique **Adjustment Type ID** and **Description** for the adjustment type.

If your implementation requires restricting the list of adjustments types that users are able to select by CIS Division, specify a **CIS Division** on the adjustment type.

The **AdjustmentAmount Type** indicates whether the adjustment amount is calculated or not. Select **Calculated Amount** when you want to use a rate to perform calculations to generate the adjustment amount otherwise select **Non-Calculated Amount**. Refer to [Setting Up Calculated Adjustment Types](#) for more information about calculated adjustments.

Enter the **Distribution Code** that references the GL account associated with the adjustment. For example, if this adjustment type is used to levy a charge for a bad check, the distribution code would reference the revenue account to which you associate such revenue. Note, the offsetting distribution code is kept on the SA type.

NOTE:

Distribution Code for Calculated Adjustments. Depending on the algorithm used for the [calculated adjustment](#), the distribution code may come from the adjustment type or the calculation lines of the algorithm. If the adjustment's

calculation algorithm gets the distribution code from the calculation lines, you do not need to specify a distribution code on the adjustment type.

FASTPATH:

For more information about the source of the distribution codes on financial transactions, see [The Source Of GL Accounts On Financial Transactions](#).

Enter the **Currency Code** for adjustments of this type.

Turn on **Sync. Current Amount** if adjustments of this type exist to force a service agreement's current balance to equal its payoff balance. These types of adjustments are issued before a service agreement's funds are transferred to a write-off service agreement. If this switch is on, choose an **Adjustment Fin Algorithm** that does not impact payoff balance or the GL, but does affect the SA's current balance (refer to ADJT-CA for an example of such an algorithm).

Enter a **Default Amount** if an amount should be **defaulted** onto adjustments of this type.

FASTPATH:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

If the AP Adjustment should be recorded in respect of the customer's 1099 amounts, indicate the **A/P 1099 Flag**. This would typically be used on the adjustment used to credit the deposit service agreement with accrued interest. The values of this field are Interest and Miscellaneous. This type of adjustment would also have an **A/P Request Type Code** selected, as 1099 reporting is handled in A/P.

Turn on **Print By Default** if information about adjustments of this type should print on the account's next bill.

Choose an **A/P Request Type Code** if this adjustment is interfaced to accounts payable (i.e., it's used to send a refund check to a customer). Refer to [A/P Check Request](#) for more information.

The **Adjustment Freeze Option** defines when adjustments can be frozen and therefore when a service agreement's balance and the general ledger are affected by an adjustment. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) to understand the significance of this option. Also note, if the **installation option's** Bill Segment Freeze Option is Freeze At Will, this field is defaulted to Freeze At Will and cannot be changed.

WARNING:

Adjustment types for adjustments created during bill completion (e.g., by a bill completion algorithm) must have their adjustment freeze option set to Freeze At Will. Otherwise (i.e., if the option is Freeze At Bill Completion) they will not be frozen until a subsequent bill is completed.

If adjustments of this type require approval, define an **Approval Profile**. For more information, refer to [The Big Picture of Adjustment Approvals](#).

Enter the verbiage to appear on the printed bill in **Description on Bill**.

Use the characteristics collection to define a **Characteristic Type** and **Characteristic Value** common to all adjustments of this type. These can be used for reporting purposes or in your algorithms.

Adjustment Type - Adjustment Characteristics

To define characteristics that can be defined for adjustments of a given type, open **Admin > Financial > Adjustment Type > Search** and navigate to the **Adjustment Characteristics** page.

Description of Page

Use the **Adjustment Characteristics** collection to define characteristics that can be defined for adjustments of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on adjustments of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Adjustment Type - Algorithms

To define algorithms for adjustments, open **Admin > Financial > Adjustment Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important adjustment functions. If you haven't already done so, you must [set up the appropriate algorithms](#) in your system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Adjustment Cancellation	Optional	When an adjustment is canceled an algorithm of this type may be called to do additional work. Refer to The Lifecycle Of An Adjustment for more information about canceling an adjustment.
Adjustment Freeze	Optional	When an adjustment is frozen an algorithm of this type may be called to do additional work. Refer to The Lifecycle Of An Adjustment for more information about freezing an adjustment.
Adjustment Information	Optional	We use the term "Adjustment information" to describe the basic information that appears throughout the system to describe an adjustment. The data that appears in "Adjustment information" is constructed using this algorithm. Plug an algorithm into this spot to override the "Adjustment information" algorithm on installation options or the system default "Adjustment information" if no such algorithm is defined on installation options.
Adjustment FT Creation	Required	Algorithms of this type are used to construct the actual financial transaction associated with the adjustment. The financial transaction controls the adjustment's affect on the service agreement's payoff and current balances. It also constructs the information that is

eventually interfaced to your general ledger. Refer to [Examples of Common Adjustment Types](#) for examples of how algorithms are used on common adjustment types.

Default Adjustment Amount	Optional	Algorithms of this type are used to default the adjustment amount. Refer to Default the Adjustment Amount for more information.
Determine SA	Optional	Algorithms of this type are used to find a service agreement for which the adjustment can be posted. This plug-in is used particularly during adjustment upload when a staging record does not identify the SA ID. Refer to Interfacing Adjustments From External Sources for more information.
Resolve Suspense	Optional	Algorithms of this type are used to automatically resolve adjustments that are in suspense. Refer to Suspense Adjustments for more information.
Generate Adjustment	Optional	Algorithms of this type are used to calculate the adjustment amount if an adjustment type indicates that the adjustment amount is calculated. Refer to Setting Up Calculated Adjustment Types for more information.
Validate Adjustment	Optional	Algorithms of this type are used to validate information for the adjustment after it is generated.

Setting Up Calculated Adjustment Types

You can use an algorithm to calculate an adjustment amount for example if you need to calculate tax on a base amount or calculate a non-sufficient funds charge based on the customer's credit rating. Because the base package algorithm calculates adjustment amounts by calling the rate application, calculated adjustments are sometimes referred to as ratable adjustments.

NOTE:

Ratable Adjustments Appear Deceptively Simple. But, they are not. Calculated adjustments that use the base package algorithm have all the power and flexibility (and complexity) of the rate application. Anything that you can do with a rate can be applied to a calculated adjustment. For examples that illustrate the flexibility of the rate application (and therefore calculated adjustments), refer to [Rate Examples](#).

Adjustment types that indicate they are calculated have a generate adjustment algorithm. The base package algorithm defines the rate schedule used to calculate the adjustment as well as any UOM, TOU or SQI parameters.

To set up calculated adjustment types using the base package generate adjustment algorithm type:

- Define the rate that performs the calculations, including the rate schedule, calculation groups, and calculation rules. Refer to [Rates](#) for information.

NOTE:

If you create your own Generate Adjustment algorithm type, you may not need to set up a rate that performs the calculations. It depends on the needs of your algorithm type.

- Create a Generate Adjustment algorithm (refer to [Setting Up Algorithms](#)) that references the base package algorithm type that generates calculated adjustments (see the table above).
- If you want the generation algorithm's calculation lines to provide the distribution codes when the adjustment is posted to the GL, create an Adjustment Financial Transaction algorithm (refer to [Setting Up Algorithms](#)) that references an algorithm type that creates the adjustment's financial transactions using the calculation lines. A parameter of the adjustment financial transaction algorithm determines whether the distribution codes are taken from the adjustment type (AT) or calculation lines (CL). The system comes supplied with several sample algorithm types that create adjustment financial transactions.
- Create an adjustment type where the **Adjustment Amount Type** is Calculated Amount, the Generate Adjustment event references the generation algorithm created above, and the Adj. Financial Transaction event references the adjustment financial transaction algorithm created above.

Examples of Common Adjustment Types

The following table shows several classic adjustment types used by many organizations:

Adjustment Type	Typical Distribution Code	Default Amount	Financial Transaction Algorithm	Print On Bill	A/P Adjust-ment	1099
NSF	NSF revenue	Your NSF fee	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	No	No
LPC	Late payment charge revenue	N/A	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	No	No
CONNECT	Connection charge revenue	Your connection charge	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	No	No
CUSTREL	Customer relationship expense	N/A	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	No	No
ADDCHARG	Misc Revenue	N/A	Payoff = Current = Adj. Amt	Yes	No	No

			Refer to ADJT-NM for an example of such an algorithm type			
XFER	Balance transfer clearing	N/A	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	No	No
WO SYNC	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	No	No	No
REFUNDAP	A/P clearing	N/A	Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type	Yes	Yes	No
DPA FIX	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	Yes	No	No
CHARITFX	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	Yes	No	No
BUDG ON	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	Yes	No	No
BUDG OFF	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an	Yes	No	No

			example of such an algorithm type			
BUDG FIX	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	Yes	No	No
DEPOSREF	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type	Yes	No	No
DEPOSIT	Interest expense	N/A	Payoff = Current = Adj. Amt. Refer to ADJT-NM for an example of such an algorithm type. Or Payoff Amt = Adj Amt / Current Amt = 0. Refer to ADJT-TA for an example of such an algorithm type. Use the first method if you want to have the interest reflected as a credit balance on the customer's bill. Use the second method if you roll the interest amount into the customer's existing deposit on hand.	Yes	No	Yes
DEPFXCR	N/A	N/A	Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an	No	No	No

Setting Up Adjustment Type Profiles

Adjustment type profiles categorize your adjustment types into logical groups. When you link a profile to a SA type, you limit the type of adjustments to be linked to the SA type's service agreements. The creation of adjustment profiles and their linkage to SA types prevents inappropriate adjustments from being linked to your service agreements. More than one adjustment type profile may be linked to a SA type.

For example, you can create an adjustment type profile called Miscellaneous Fees and link to it the miscellaneous fee adjustment types. Then, you would link this profile to those SA types that are allowed to levy such fees.

NOTE:

Bottom line. An adjustment can only be linked to a service agreement if its adjustment type is part of an adjustment type profile that is valid for the service agreement's SA type. If an adjustment type is not linked to a profile, it could never be levied.

To set up adjustment type profiles, open **Admin > Financial > Adjustment Type Profile > Add.**

Description of Page

Enter a unique **Adjustment Type Profile** and **Description** for the adjustment type profile.

Indicate the **Adjustment Types** that are part of the profile.

Examples Of Common Adjustment Profiles

The following table shows several classic adjustment profiles used by many organizations (we've displayed some attributes from the adjustment type in the following table to help make it more understandable):

Adjustment Profile	Adjustment Type	Typical Distribution Code	Default Amount	Financial Transaction Algorithm
FEES	NSF	NSF revenue	Your NSF fee	Payoff Amt = Adj Amt / Current Amt = Adj Amt
	LPC	Late payment charge revenue	Your LPC	Payoff Amt = Adj Amt / Current Amt = Adj Amt
	CONNECT	Connection charge revenue	Your connection charge	Payoff Amt = Adj Amt / Current Amt = Adj Amt
MISCEXP	CUSTREL	Customer relationship expense	N/A	Payoff Amt = Adj Amt / Current Amt = Adj Amt
XFER	TRANSBAL	Balance transfer clearing	N/A	Payoff Amt = Adj Amt / Current Amt = Adj Amt

The Big Picture Of Adjustment Approval

Some implementations require adjustments to be approved by one or more managers before they impact a customer's debt and the general ledger. For example, an adjustment used to rebate a credit balance may require managerial approval before the rebate is sent to the customer. The topics in this section describe how to set up the system to support the approval of adjustments.

Approval Is Controlled By Approval Profiles

An approval profile contains the rules that define if and how an adjustment is approved. If an adjustment type does not reference an approval profile, the related adjustments do not require third-party approval before they impact a customer's debt. If an adjustment type references an approval profile, the approval profile's approval hierarchy defines if the adjustment requires approval and who the authorized approvers are. For example, an approval profile can be configured with the following approval hierarchy:

- Adjustments < \$0 require approval by the "credit approvers role"
- Adjustments >= \$0 and <= \$10 do not require approval
- Adjustments > \$10 and <= \$100 require the approval of a user that belongs to the "level 1 approvers role"
- Adjustments > \$100 require two levels of approval: first a user that belongs to the "level 1 approvers role" must approve the adjustment; afterwards, the adjustment must be approved by a user that belongs to the "level 2 approvers role"

NOTE:

Transfer adjustments. The term "transfer adjustment" refers to two adjustments that are used to transfer moneys between two service agreements. The adjustment with the positive amount is considered to be the debit adjustment; the other adjustment is considered the credit adjustment. When a transfer adjustment requires approval, only one of the

adjustments needs to be approved. You control whether the debit side or the credit side of a transfer adjustment is used to control the approval process when you set up the approval profile.

Approval Profiles Can Be Linked To Multiple Adjustment Types

Approval hierarchies are frequently the same for many adjustment types. The system allows an approval profile to be linked to multiple adjustment types to simplify the definition and maintenance of the rules over time.

Adjustments Created In Batch Are Not Approved

The system assumes that no approval is necessary for adjustments created by batch processes even those whose adjustment type references an approval profile.

Approval Inserts A Step Into An Adjustment's Lifecycle

[The Lifecycle Of An Adjustment](#) explains how an adjustment is transitioned from the Freezable state to the Frozen state when it should impact the general ledger and the customer's balance. If an adjustment's adjustment type references an approval profile, the user cannot freeze the adjustment directly. Rather, the user must submit the adjustment for approval when it's ready and only when the last applicable approver approves the adjustment will it become Frozen.

NOTE:

Freeze during bill completion. You can configure the system to only freeze certain types of adjustments when the next bill is completed for the adjustment's account. When the last approver approves such adjustments, they remain in the Freezable. When the next bill is completed for the account, these adjustment become Frozen. Such adjustments that have not been approved at the time of bill completion will remain in the Freezable state. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for more information.

Approval Requests Manage And Audit The Approval Process

Users submit an adjustment for approval using a dedicated button on the [Adjustment](#) page. When an adjustment is submitted for approval, the system creates an "approval request". The approval request determines if the adjustment requires approval and, if so, the list of approvers. If the adjustment does not require approval, the approval request is updated to indicate such and the adjustment is Frozen immediately (if freezing is allowed prior to bill completion). If the adjustment requires approval, the approval request's state becomes Approval In Progress and the approver(s) are notified.

NOTE:

Approval submission logic is customizable. The previous paragraph describes how the base-package works when an adjustment is submitted for approval. This logic resides in an algorithm that's plugged in on the C1-AdjustmentApprovalProfile business object in the Determine Approval Requirements system event. Your implementation can change this logic by developing a new algorithm and plugging it into this business object. If your logic is meant to supersede the base-package algorithm, remember to inactivate the base-package algorithm by adding an appropriate inactivation option to this business object.

To Do Entries Are Created To Notify Approvers

When an approval request detects an adjustment requires approval, it notifies the first approver by creating a To Do entry. The To Do entry is created using the To Do type and To Do role defined on the approval profile. All users who belong to the approving To Do role can see the entry. When a user drills down on an adjustment approval To Do entry, the [Adjustment - Approval](#) portal is opened. This portal contains summary information about the adjustment and the approval history of the adjustment. This portal is also where the user approves or rejects the adjustment.

When the first user in the To Do role approves an adjustment, the To Do entry is Completed and the approval request's audit log is updated. If there are no higher levels of approval required, the adjustment is Frozen (if freezing is allowed prior to bill completion) and the approval request is moved to the Approved state. If there are higher levels of approval required, a new To Do entry is created to the next To Do role in the approval hierarchy.

NOTE:

To Do entries can create email. A To Do entry can be configured to create an email message for every user in the To Do role to inform the user(s) of new adjustments requiring their attention. Refer to [To Do Entries May Be Routed Out Of The System](#) for the details.

Monitoring and Escalating Approval Requests

The base-package is supplied with an algorithm that your implementation can use to monitor approval requests that have been waiting too long for approval. This algorithm can complete the current To Do entry and create a new one for a different role when the timeout threshold defined on the algorithm's parameters is exceeded. If you've configured the system to send email for approval, this algorithm can also send x reminder emails (where x is defined on the algorithm's parameters) before the approval request is escalated to the new To Do role. Refer to C1-APR-TMOUT for more information about this algorithm. If you plan to enable this functionality, plug-in your configured algorithm on the Approval In Progress state on the C1-AdjustmentApprovalRequest business object.

Rejecting Deletes The Adjustment

When an adjustment is being approved, anyone with access to the adjustment can reject it by using the [Adjustment - Approval](#) portal. Users other than the current approver are allowed to reject an adjustment to allow an "in process" an adjustment to be withdrawn.

When an adjustment is rejected, the following takes place:

- The user is prompted for a reject reason.
- The approval request's audit log is updated with the reject reason and the approval request is moved to the Rejected state.
- The adjustment is deleted.

Designing Your Approval Profiles

The following points describe a recommended design process:

- Create logical groups of adjustment types where each group has the same monetary hierarchy and approvers. An approval profile will be required for each of these groups.

- The number of To Do types (if any) that need to be created is dependent on how the adjustment approval To Do entries should be organized on To Do lists. For example, if all approval request To Do entries can appear in the same To Do list, you can use the base-package adjustment approval To Do type. However, if your organization prefers each approval profile's To Do entries to appear in a distinct To Do list, a separate To Do type will be needed for each list. Note that the base-package is supplied with a To Do type called C1-ADAPP that should be used as the basis for any new approval request To Do type.
- The number of To Do roles is dependent on who approves your adjustments. At a minimum, you will require a separate To Do role for each level in your approval profiles. Remember that every user in a To Do role will see its entries (and receive email if you've configured the system to do such).
- Refer to [Monitoring and Escalating Approval Requests](#) for how to configure the system to escalate approval requests that have been waiting too long.
- If your implementation requires email notification when an adjustment requires approval, the following setup is required:
 - Set up an outbound message type, external system, and message sender. Refer to [To Do Entries May Be Routed Out Of The System](#) for the details.
 - Every To Do type referenced on your approval profiles should be configured as follows:
- Define the F1-TDEER batch process as the To Do type's routing process
- Set up an algorithm that references the C1-ADJAREQEM algorithm type and plug it in the External Routing system event.

Implementing Other Approval Paradigms

The above sections describe how the base-package adjustment approval process works. Because adjustment approval has been implemented using the C1-AdjustmentApprovalProfile and the C1-AdjustmentApprovalRequest business objects, your implementation can add additional business rules and change the approval user interface as required. Alternatively, if your implementation has a radically different approval process, you can create a different business objects with their own business rules. To learn how to do this, please enroll in the Configuration Tools training class.

Setting Up Approval Profiles

Approval profiles contain the rules that control how adjustments are approved. To set up an approval profile, open **Admin > Financial > Approval Profile > Add**.

FASTPATH:

Refer to [The Big Picture Of Adjustment Approval](#) for a detailed description of how approval profiles govern the adjustment approval process.

The topics in this section describe the base-package zones that appear on the Approval Profile portal.

Approval Profile List

The Approval Profile [List zone](#) lists every approval profile. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent approval profile.
- Click the Add link in the zone's title bar to add a new approval profile.

Approval Profile

The Approval Profile zone contains display-only information about an approval profile. This zone appears when an approval profile has been broadcast from the Approval Profile List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the approval profile.
- Click the **Delete** button to start a business process that deletes the approval profile.
- Click the **Duplicate** button to start a business process that duplicates the approval profile.

Please see the zone's help text for information about this zone's fields.

Approval Profile's Adjustment Types

The Approval Profile's Adjustment Types zone lists every [adjustment type](#) that is governed by this approval profile. This zone appears when there is at least one adjustment type governed by the approval profile displayed in the Approval Profile zone:

To add an adjustment type to this list:

- Navigate to the Adjustment Type page and display the desired adjustment type.
- Specify the governing approval profile and update the adjustment type.

To remove an adjustment type from this list:

- Navigate to the Adjustment Type page and display the desired adjustment type.
- Change or remove its approval profile and update the adjustment type.

Designing and Defining Budget Plans

If you allow your customers to pay a budget amount each month (as opposed to their actual bill amount), you must set up one or more budget plans. If your company does not offer budget billing options, you can skip this section.

The topics in this section describe how to design and set up budget plans.

The Financial Impact Of Budget Plans

The only difference between a customer who participates in budget billing and one who doesn't is that budget billing customer have bill segments where payoff amount differs from current amount. Why? Because the payoff amount is the actual amount of the bill. The current amount is the amount the customer is expected to pay (i.e., their budget amount).

Let's run through an example of a customer on a budget to illustrate a service agreement where these two balances are not the same. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied:

Date	Financial Transaction	Payoff Balance	Current Balance
1-Jan-19	Bill: \$125, Budget \$150	125	150
15-Jan-19	Payment: \$150	-25	0

2-Feb-19	Bill: \$175, Budget \$150	150	150
14-Feb-19	Payment: \$150	0	0
3-Mar-19	Bill: \$200, Budget \$150	200	150
15-Mar-19	Payment: \$150	50	0

FASTPATH:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

What Do Budget Plans Do?

A budget plan contains the business rules that govern:

- How the recommended budget amount is calculated.
- When and how a customer on an ongoing budget plan will have their budget amount periodically trued up.
- The conditions under which the system will highlight an existing budget amount as being anomalous with the customer's current use patterns.

You may have different budget plans for different customer segments. For example, customers with large bills may have their budget amount recalculated every month, whereas small customers may have their budget amount only recalculated annually. You define which budget plans govern a customer's bills via a **budget plan on the customers' accounts**. An account's initial budget plan is defaulted from its customer class. You may override an account's budget plan at will.

Designing Your Budget Plans

FASTPATH:

Refer to [Budget Billing](#) for background information about budget billing.

A budget plan contains the business rules that govern:

- How the recommended budget amount is calculated.
- When and how a customer on an ongoing budget plan will have their budget amount periodically trued up.
- The conditions under which the system will highlight an existing budget amount as being anomalous with the customer's current use patterns.

You will need multiple budget plans if any of the above rules / conditions differ for different types of customers. For example, if residential customers use a different recommended budget algorithm as compared to commercial customers, you'd need one budget plan for residential and another for commercial.

We'll design budget plans to satisfy the needs of a theoretical company to help you understand how to design your budget plans. The following points describe the budget requirements of our theoretical company:

- The recommended budget amount is the last year's real bill amounts plus any existing debit/credit balance divided by 12. This is true regardless of the type of customer.
- The frequency of budget true up is monthly for commercial customers and annually for residential customers.
- The system should highlight when a residential customer's budget is more than 30% out of whack with what their budget amount would be if it was recalculated.

- The system should highlight when a commercial customer's budget is more than 20% out of whack with what their budget amount would be if it was recalculated.

You'd need the following budget plans to satisfy the above requirement:

Budget plan	Recommended Amount Algorithm	True Up Algorithm	Monitor Algorithm
Residential	Average Bill	True up every 12 months	Highlight when more than 30% out
Commercial	Average Bill	True up every month	Highlight when more than 20% out

Refer to the Page Controls under [Setting Up Budget Plans](#) for a description of the various algorithms defined in respect of a budget plan.

Setting Up Budget Plans

In the previous section, Designing Your Budget Plans, we presented a case study that illustrated a mythical organization's budget plans. In this section, we explain how to maintain your Budget Plans.

Budget Plan - Main

To set up budget plans, select **Admin > Credit & Collection > Budget Plan > Add**.

Description of Page

Enter an easily recognizable **Budget Plan** and **Description**.

If your implementation requires restricting budget plans to accounts by CIS Division, specify a **CIS Division** on the budget plan.

The remaining information on this page is used by the various budget-oriented processes.

Refer to [Budget Plan - Calculation Algorithm](#) for information about the **Calculation Algorithm**.

Refer to [Budget Plan - Monitor Algorithm](#) for information about the **Monitor Algorithm**.

Refer to [Budget Plan - True Up Algorithm](#) for information about the **True Up Algorithm** and **Months for True Up**.

Budget Plan - Calculation Algorithm

On [Budget Plan - Main](#) you must define the **Calculation Algorithm** used by the system when it calculates a customer's recommended budget amount.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates recommended budget amounts.

Budget Plan - Monitor Algorithm

On [Budget Plan - Main](#) you must define the **Monitor Algorithm** used by the [Budget Monitor](#) background process when it determines if a customer's budget plan is out-of-sync with their consumption patterns.

NOTE:

What happens? If the algorithm determines that a customer's budget plan is out-of-sync with its current recommended amount, an entry is added to the [Budget Review](#) page.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that highlights if a customer's current budget amount is out-of-sync with their consumption patterns.

Budget Plan - True Up Algorithm

On [Budget Plan - Main](#) you must define the **True Up Algorithm** used by the [Budget True Up](#) background process when it periodically trues up a customer's budget.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that trues up budget amounts.

The system will automatically true up a customer's budget amount every X months (X is defined in **Months for True Up**).

Tender Management

When a payment is received, a tender is created to record what was remitted (e.g., cash, check, credit card). The topics in this section describe control tables that must be set up in order to remit tenders.

FASTPATH:

We strongly recommend [Tender Management and Workstation Cashiering](#) before setting up the control tables described in this section.

Setting Up Tender Types

Tender types are used to indicate the method in which the tender was made. A unique **Tender Type** must exist for every type of tender that can be remitted. For example, if you allow cash, checks, direct debits from a checking account, and direct debits from a credit card to be tendered, you'd need the following tender types:

Tender Type	Description	Like Cash	Generate Auto Pay	Require External Source ID	Require Expiration Date	External Type
CASH	Cash	Yes	No	N/A	N/A	N/A
CHEC	Check	No	No	N/A	N/A	N/A
OVUN	Cash drawer - over/under	No	No	N/A	N/A	N/A
DDCH	Direct debit - checking	No	Yes	Yes	No	Checking withdrawal

CRED	Direct debit - credit card	No	Yes	No	Yes	Credit card withdrawal
------	-------------------------------	----	-----	----	-----	---------------------------

Go to **Admin > Financial > Tender Type** to define your tender types.

Description of Page

Enter a unique **Tender Type** and **Description** for the tender type.

Turn on the **Like Cash** switch if this tender type is cash or the equivalent of cash. This indicator controls if the system generates a warning if a cash-only account remits a tender other than cash. It is also used to generate a warning for online cashiers to turn in their tenders when the cash-like amount exceeds the maximum amount balance defined for the [tender source](#).

Turn on **Generate Auto Pay** if this type of tender causes an automatic payment request to be routed to a financial institution. For example, this switch will be on if this tender type is used for direct debits from a customer's checking account (because every tender of this type will have an automatic payment request created when the tender is created).

The following fields are only used for tender types associated with automatic payments:

External Type This field is used by the background process that creates the information that is interfaced to the automatic payment source. Specifically, it controls the record type associated with the different types of automatic payments that are routed to the automated clearinghouse (ACH).

NOTE:

The values for this field are customizable using the Lookup table. This field name is EXT_TYPE_FLG.

Require Ext. Src. ID This switch indicates if an Auto-Pay Source that references this type of tender must contain an External Source ID. The External Source ID is the unique identifier of the financial institution to which the automatic payment will be routed.

This switch is typically turned on for tender types associated with checking / saving direct debits. It is turned off for tender types associated with credit card debits (you don't need an external source for a credit card debit, you just need the credit card number).

Expiration Date Required Turn this switch on if an Auto-Pay Option that references an auto-pay source that references this type of tender must also contain an expiration date (e.g., automatic debit / credit cards).

Turn this switch off for tender types associated with checking / saving direct debits.

Tender Authorization Indicates that tenders of a particular type require authorization prior to being created.

Business Object If Tender Authorization has a value of Required, a Business Object must be specified for the tender type. The primary function of this Business Object is to manage the authorization of payment tenders.

FASTPATH:

For more information on authorizing credit card payments, refer to the Tender Type - Credit Card with Authorization business object.

Turn on **Allow Cash Back** if the system should automatically calculate a cash back amount when a tender is remitted for this tender type and the amount tender exceeds the amount being paid.

Setting Up Tender Sources

A unique **Tender Source** must exist for every potential source of funds. For example,

- Every cashiering station will have a unique tender source.

NOTE:

If your organization accepts alternate currency payments online, then a tender source must exist for each currency code accepted at the cashiering station.

- Every lock box will have a unique tender source.
- Your remittance processor will have a unique tender source.
- If you allow customers to pay bills automatically (e.g., via EFT), you'll need a tender source for each institution to which you route automatic payment requests. For example, if you route automatic payment requests to the automated clearinghouse (ACH), you'll need a tender source for the ACH.

For example, if you have 3 lock boxes, 2 cash drawers at an area office A, 2 cash drawers at area office B, and a single remittance processor, you'd need the following tender sources:

Tender Source	Type	External Source ID (Lockbox ID)	Default Starting Balance	Currency Code	Suspense Service Agreement
CASH-A01	Cashiering	N/A	150.00	USD	N/A
CASH-A02	Cashiering	N/A	150.00	USD	N/A
CASH-B01	Cashiering	N/A	150.00	USD	N/A
CASH-B02	Cashiering	N/A	150.00	USD	N/A
LB-INDUS	Lockbox	112910-A	N/A	USD	9291019281
LB-COMM	Lockbox	938219-C	N/A	USD	4739837372
LB-RESID	Lockbox	372829-B	N/A	USD	1912910192
REMIT	Lockbox	N/A	N/A	USD	1920038437
ACH	Auto Pay	N/A	N/A	USD	N/A

To set up a tender source, select **Admin > Financial > Tender Source > Add**.

Description of Page

Enter an easily recognizable **Tender Source** and **Description** for the tender source.

Define the **TenderSource Type**. Valid values are: Ad Hoc, Auto Pay, Online Cashiering and Lockbox. The system uses this information to prevent tender controls from different sources from being included under the same deposit control. In other words, you can't mix ad hoc, automatic payment, cashiering and lockbox tenders under the same deposit control.

FASTPATH:

For more information, refer to [Maintaining Deposit Controls](#).

If the source is an external system (e.g., a lockbox or an automatic payment destination), use **External Source ID** to define the unique identifier of the source. The background process that interfaces tenders from this source uses this information to create the appropriate tender control when it interfaces payments from external sources.

If this source is a cash drawer, define the **Default Starting Balance**. This balance is defaulted onto new tender controls and may be overridden.

NOTE:

The tender type of the **Start Balance** is defined on the installation record.

If this source is a cash drawer, define the **Max Amount Balance**. When the amount of **cash-like** tenders in a cash drawer exceeds this balance, a warning is issued to remind the cashier to turn in some of the funds to a tender control.

Define the **Currency Code** of tenders linked to this source. All tenders in a source must be of the same currency.

If this tender source is associated with payments that are [interfaced from an external source](#) (e.g., a lockbox or a remittance processor), use Suspense **Service Agreement** to define the service agreement whose account will hold uploaded payments with an invalid account. Refer to [Payment Upload Error Segmentation](#) for more information about suspense service agreements. Also note, because the payment upload process simply books payments that reference invalid accounts to the account associated with this service agreement, this account should belong to a customer class with the appropriate payment distribution algorithms. This may entail creating a new customer class that will only be used on these "suspense accounts". This customer class would need the following algorithms:

- We'd recommend using a simple payment distribution algorithm like PYDIST-PPRTY (distribute payment based on SA type's payment priority and the age of the debt).
- We'd recommend using an overpayment distribution algorithm like OVRPY-PPRTY (distribute overpayment to highest priority SA type).

Define the **Bank** and **Bank Account** into which the tender source's moneys will be deposited. The bank account defines the distribution code used to build the GL details for the payment. Refer to The [Source of GL Accounts on Financial Transactions](#) for more information. Note that the bank code and bank account can later be overwritten when entering Tender Deposits on [Deposit Control](#).

Printer IP Address and **Printer Port** are for implementation use, if needed. The base samples for receipt printing do not use these settings, as they are designed for local printers. Refer to the Receipt Printing section of the Optional Products Installation Guide for more details.

If this tender source is associated with payments that are [interfaced from an external source](#), for example tender sources associated with Auto Pay and Lockbox **Tender Source Types**, the information is also used as follows:

- The [payment upload process](#) uses this information to populate the bank and bank account when it creates deposit control records for the tender controls it creates during the interface. Refer to [Managing Payments Interfaced From External Sources](#) for more information.
- The [automatic payment interface](#) uses this information to populate the bank and bank account when it creates deposit control records for the tender controls it creates during the interface.

NOTE:

If your organization accepts alternate currency payments online, then a tender source must exist for each currency code accepted at the cashiering station. When a user adds a tender control the system attempts to default a tender source based on the currency of the deposit control and the tender source(s) define on the user's record.

FASTPATH:

Refer to [Alternate Currency Payments](#) for more information.

Automatic Payment Options

If your customers can pay their bills automatically (via direct debit or credit card debits), you'll need to set up the various control tables described in this section.

IMPORTANT:

Besides the tables described in this section, additional values must also be added to control tables defined under [Tender Management](#). Specifically, refer to [Setting Up Tender Types](#) and [Setting Up Tender Sources](#).

FASTPATH:

Refer to [Automatic Payments](#) for more information about how automatic payments are handled in the system.

Setting Up Auto Pay Route Types

This portal is used to display and maintain an Auto Pay Route Type.

Auto Pay Route Types are used to control when and how automatic payment requests are routed to a financial institution, and when the general ledger is impacted.

You can access the portal from **Admin > Financial > Auto Pay Route Type**.

The information captured on the auto pay route type depends on the business objects supported by your implementation. Refer to the embedded help for more information.

Setting Up Auto Pay Source Codes

A unique **Auto Pay Source** must exist for every bank / credit card company / bill payment service that your customer's use as the source of the funds when they sign up for automatic payment. For example,

- Every bank will have a unique auto pay source.
- Every credit card company will have a unique auto pay source.

To set up an auto pay source, select **Admin > Financial > Auto Pay Source Type > Add**.

Description of Page

Enter an easily recognizable **Auto Pay Source Code** and **Description** for the auto pay source.

The **Source Name** is the name of the financial institution.

When the system creates an automatic payment request, it also creates an associated payment tender. This tender (like all tenders) must have a tender type. This field defines the **Tender Type** associated with this auto pay source's tenders. The **Prenote Tender Type** is also specified on checking and savings tender types. It determines the transaction code to stamp on an auto pay extract records that are sent out for the purpose of debit prenotification. Refer to [Setting Up Tender Types](#) for more information.

The **External Source ID** is the unique identifier of the financial institution to which the automatic payment will be routed (e.g., the bank routing ID of the bank). This field is typically blank on automatic payments routed to credit card companies because the credit card company doesn't have an external source ID (whereas direct debits from banks must have a bank routing number). Whether this field is required is controlled by the **Tender Type**.

The **Auto Pay Route Type** controls when and how automatic payment requests get routed to a financial institution. It also controls when the general ledger is impacted by the automatic payments financial transaction. Refer to [Setting Up Auto Pay Route Types](#) for more information.

The **Work Calendar** defines the financial institution's workdays. This information is used to determine the date on which automatic payment requests will be sent to the financial institution. Refer to [Setting Up External Workday Calendars](#) for more information.

The **Validation Algorithm** defines how the system validates the customer's account ID at the financial institution. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that validates the customer's account ID at the financial institution.

Refer to [Account - Auto Pay](#) for more information.

SEPA Payments

The topics in this section provide background information about the Single Euro Payments Area (SEPA) payment functionality.

NOTE: This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization is participating in SEPA payment transactions such as direct debit collection.

What Is SEPA?

SEPA (Single Euro Payments Area) is a European Union (EU) integration initiative that is aimed at streamlining processes that are related to cross-border payments. SEPA consists of the EU member states plus a few additional countries. In SEPA, customers can make electronic Euro payments within and across these countries under the same rights and obligations. SEPA payment services are based on global ISO (International Organization for Standardization) standards.

SEPA Direct Debit

The SEPA Direct Debit (SDD) scheme allows a creditor to collect money from the debtor, with prior approval from the debtor. The direct participants are the following:

- Creditor
- Creditor's bank
- Debtor
- Debtor's bank

The debtor and creditor must each hold an account with a payment service provider located within SEPA. The accounts may be in Euro or in any other SEPA currency. However, the transfer of funds between the debtor's bank and the creditor's bank always takes place in the Euro currency. The indirect participants are the following:

- Clearing and Settlement Mechanisms (CSMs) such as an automated clearinghouse
- Intermediary Banks that offer intermediary services to debtor banks and/or creditor banks

SEPA Direct Debit Mandate

The mandate is the consent and authorization that the debtor gives to the creditor, to allow the creditor to initiate direct debit collections. The creditor is responsible for storing the original mandates, together with any amendments relating to the mandate or information regarding its cancellation or lapse. The contents of this section describe how mandates are issued and canceled.

Issuing a Mandate

The creditor initiates the issuance of a mandate by sending the mandate form (either paper or electronic) to the debtor with the creditor information filled in. The creditor information includes the creditor's unique identifier as a SEPA creditor. An ISO standard specifies the structure of the creditor identification, which includes country code, a check digit, the creditor's business code and a country-specific identifier for the creditor. The creditor ensures that the mandate form contains the mandatory legal wording and the mandatory set of information, as specified in the standards. The debtor must ensure that the required information is supplied and that the mandate is signed, either in writing or electronically. The mandatory debtor information includes the debtor's international bank account number (IBAN) and bank identifier code (BIC). The creditor

assigns a unique reference for the mandate and provides that reference to the debtor before the first initiation of a collection. The debtor can then use both the unique mandate reference and the creditor identification to verify the bank transactions.

Canceling a Mandate

A mandate can be canceled by either the debtor or the creditor, without the involvement of either bank.

The Lifecycle of a Direct Debit Mandate Task

The following diagram shows the possible lifecycle of the Direct Debit Mandate Task business object:

Pending State: The direct debit mandate starts out in a pending state.

Active State: The direct debit mandate is transitioned manually by a user to the active state. Once a mandate is created and activated in the system, the account's auto pay information must be updated to reflect information on the mandate. This process may be automated within the mandate's lifecycle and a sample algorithm exists in the demo database to achieve this. This algorithm is also included in the export bundle in the demo database.

Canceled State: The direct debit mandate is transitioned manually by a user to the canceled state.

Configuring the System for SEPA Direct Debits

The following sections describe the setup required if your organization intends to process SEPA direct debit transactions.

Define Auto-Pay Route Type

Configure an auto-pay route type for routing direct debit requests to a financial institution. This auto-pay route type must reference the SEPA Direct Debit Payment Extract (C1-SDDCE) batch process.

Refer to [Setting Up Auto-Pay Route Types](#) for more information.

Define Auto-Pay Source Type

Ensure that your auto-pay source codes reference the above auto-pay route type. You must also configure a validation algorithm on the auto-pay source type to ensure the International Bank Account Number (IBAN) defined on the Auto-pay Source of the Account has the correct format.

Refer to [Setting Up Auto Pay Source Codes](#) for more information.

Define a Direct Debit Task Type

Your implementation must configure a **Direct Debit Task Type**. This service task type captures general information that the SEPA extract process needs to create the output file. The base product provides a business object for direct debit task type, **C1-DirectDebitMandateTaskType**.

Note that the direct debit task type is maintained on the Service Task Type portal.

Define SEPA Country Codes

The list of countries and territories that are part of the Single Euro Payment Area (SEPA) must be defined on extendable lookup **C1-SEPACountryCodeLookup**. These country codes are used by the system to validate the creditor identification entered on a direct debit task type.

Note that an export bundle exists in the demo database that includes a sample list of SEPA country codes. This list must be verified by your implementation for accuracy.

Define Mandate Cancel Reasons

A cancel reason is required when canceling a direct debit mandate. Ensure that these status reasons have been configured for the direct debit task business object, **C1-DirectDebitMandateTask**.

Define Navigation Options

The base product includes navigation options for easy access to query and maintain an account's direct debit mandate. To access these portals, add a new menu item to the account context menu (**CI_CONTEXTACCOUNT**). This menu item should include two menu lines:

- A context menu line for navigation to the direct debit mandate that references a navigation option of **c1DirectDebitMandate**. The system uses the account in context and attempts to find the most recent active mandate for the account. If a mandate exists, navigation is to the service task maintenance portal. If an active mandate does not exist, navigation is to the service task query portal.
- A context menu line for adding a new direct debit mandate that references a navigation option of **c1AddDirectDebitMandate**.

Setting Up Account Auto Pay

The SEPA direct debit extract process retrieves banking details from the account's auto pay record. Once a mandate is created and activated in the system, the account's auto pay information must be updated to reflect information on the mandate. This process may be automated within the mandate's lifecycle and a sample algorithm exists in the demo database to achieve this. This algorithm is also included in the export bundle in demo.

Web Debit Account Validation

This section describes Web Debit Account Validation and the steps to enable this functionality.

NOTE: This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization is required to validate bank accounts that are used for the first time in electronic payments initiated over an online channel such as web self-service. This functionality does not cover credit card payment types, which are verified through tender authorization.

Web Debit Account Validation allows your implementation to validate a first-use checking/savings account that is captured through any of the following self-service activity:

- Automatic Payment Setup
- Make One Time Payment
- Manage Payment Options (wallet)

The account validation method is your implementation's choice, based on what regulation prescribes as acceptable account validation options. For instance, the National Automated Clearinghouse Association (NACHA) - that governs the ACH network in the United States - prescribes any of the following options:

- **ACH prenotification.** With this option, a zero-amount checking/savings debit pre-note transaction is sent through the auto pay extract, to verify the bank account information. If a negative response is not received from the bank within a set number of days, the account is considered valid.
- **ACH micro-transaction verification.** With this option, two very small transactions – a debit to deposit the money and a credit to remove the money - are sent to the account. The account holder needs to confirm the amounts on the transactions. The account will only be considered verified if the account holder describes the amounts correctly.
- **Commercially available third party validation service vendors.** Some financial institutions and third parties have access to a large number of accounts and may offer a product that leverages this information. These services can be accessed for verifying that account information is correct and/or verifying the account holder's identity. The responses can be real-time, same-day or next-day.

Web Debit Account Validation is a Plug-in

An algorithm plugged in on Auto Pay Route Type or on CIS Division - Auto Pay Route Type Override Controls (if applicable) is responsible for web debit account validation. Payment methods captured for self-service automatic payment setup and self-service one time payment specify the Auto Pay Source, which in turn, identifies the Auto Pay Route Type.

The base product provides a Web Debit Account Validation Algorithm for ACH prenotification. The algorithm creates an Auto Pay Clearing Staging record with the account number to verify and a zero amount. Refer to the Web Debit Account ACH Prenotification (C1WDAPRENTF) algorithm for details.

Web Debit Account Validation Applies to Self-Service Tasks that Manage Payment Options

The following self-service task business objects include an Account Validation status, where web debit account validation is performed:

- Automatic Payment Task - WX-AutoPayTask
- One Time Payment Task - WX-OneTimePayTask
- Self-Service Payment Option Task - C1-PaymentOptionsTask

The Account Validation status has an enter algorithm that performs the Web Debit Account Validation Algorithm configured in the Auto Pay Source's Auto Pay Route Type (or in the CIS Division's Override Auto Pay Controls, if applicable) when the service task type has Web Debit Account Validation enabled and the account number does not exist in any of the account's saved auto pay options and in any of the saved self-service payment options of persons on the account. The account auto pay option or self-service payment option is not saved until the bank account is deemed valid. The Account Validation Error status includes algorithms for retry processing and wait timeout processing. If the account is deemed invalid, the service task goes to the Rejected status. Refer to the business object for more details.

NOTE: When checking for the existence of a bank account number in person self-service payment options, the system relies on the hash value (in HASH_EXT_ACCT_ID). Implementations must ensure that encryption configuration for this table field includes both the encrypted and hash fields and that legacy data has both fields populated. Refer to [Encrypting Sensitive Data](#) and [Encrypting Legacy Data](#) for more details.

Validating Payment Methods Captured On Add One-Time Payment UI

The Add One-Time Payment user interface allows the capture of first-use checking/savings bank accounts. If a bank account has not been used on any prior recurring bill auto pays and prior self-service one time payments, the system will trigger web debit account validation by creating the One-Time Payment Task (C1-OneTimePaymentTask). Since the Add One-Time Payment UI can handle multiple tenders, a single One-Time Payment Task manages all auto pay tenders that require validation.

Note that the Payment Event is kept in an Incomplete state while web debit account validation is still in progress. Lifecycle processing on the service task will either complete or delete the Payment Event, depending on the result of account validation.

Refer to the C1-OneTimePaymentTask business object in the application, for more information on the service task lifecycle processing.

Specific Transaction Codes for Checking/Savings Debit Prenotification

The APAYACH and C1-APACH batch processes stamp specific transaction codes for checking debit prenotification (28) and savings debit prenotification (38) on the Entry Detail record. The transaction code is retrieved from the prenotification Tender Type's External Type.

Configuring the System for Web Debit Account Validation

The following are the steps to enable Web Debit Account Validation functionality:

- Determine the account validation option(s) that your implementation will use.
 - If opting for ACH prenotification, you can use the base-supplied Web Debit Account ACH Prenotification (C1WDAPRENTF) algorithm.
 - If opting for ACH micro-transaction verification or third party validation, create a Web Debit Account Validation algorithm for your chosen method.
- Plug in the Web Debit Account Validation on your applicable Auto Pay Route Types and CIS Division - Auto Pay Route Type Override Controls (if applicable).
- On your Automatic Payment Setup and One Time Payment Service Task Types, set the Web Debit Account Validation flag to Yes. To use the wait timeout processing built into the Account Validation Error state, configure the Timeout Processing settings. Refer to the service task's embedded help for more details.
- On the Automatic Payment Setup and One Time Payment service task business objects:
 - If using the base-supplied Web Debit Account ACH Prenotification algorithm (or a CM algorithm that allows for a wait period after which the account is considered valid), monitor logic on the Account Validation status should check if the wait time has elapsed - and if so, transition the service task accordingly. Note that the Check Account Validation Status monitor algorithms provided in the base product simply transition the service tasks to the next state (i.e. Process Auto Pay, Process Payment or Process Request) when the wait time elapses. The base algorithms do not check for a negative response because the form of response is implementation-specific. If your implementation needs to check for a negative response, copy the base algorithms and add that processing. Refer to the Check Account Validation Status for One Time Payment (C1OTPACVAST) and Check Account Validation Status for Auto Pay Setup (C1APAYACVAST) algorithms for details.
 - To use the To Do creation algorithm plugged in on the Account Validation Error status, configure a new algorithm parameter instance to specify the Retry Frequency and Discard Cancel Terminate Reason (if applicable).
 - To use the retry processing on the Account Validation Error status, configure a new algorithm parameter instance to specify the Maximum Retry.
- Configure tender types for checking debit prenotification and savings debit prenotification. Use the applicable External Type value on each - i.e. Checking Debit Prenotification (28) or Savings Debit Prenotification (38), The auto pay extract

process uses the Prenote Tender Type's External Type as the transaction code on the Entry Detail record in the extract file.

- Configure the checking and savings Auto Pay Sources with the applicable Prenote Tender Types.
- If your implementation enabled the Add One-Time Payment UI, configure the One-Time Payment Task feature option. Refer to [One Time Payment Options](#) for more details.

One-Time Payment Options

The Add One-Time Payment popup provides the ability to 'quick add' a payment event using existing auto pay methods, new checking/savings auto pay methods, cash and non-cash/non-auto pay methods (like check).

This user interface provides the same capabilities as the [Payment Event - Add Dialog](#), including processing for open-item and non-CIS payor accounts. In addition, it provides the following:

- Ability to specify auto pay tender details within the same popup. No need to navigate to the Payment Event page.
- Ability to select an existing auto pay method from either a currently enrolled Account Auto Pay option or a stored Person Self-Service Payment Option.
- Ability to specify new auto pay methods, with an option to save the payment method for future one-time payments
- Web debit account validation can be enforced for first-use checking and savings accounts. Refer to [Web Debit Account Validation](#) for more details.

Enabling the Add One-Time Payment User Interface

To enable the Add One-Time Payment popup, configure the following options in Financial Transaction Options feature configuration:

- **Enable Add One-Time Payment UI.** Set this to Y, to replace the Payment Event-Add pop-up with the Add One-Time Payment pop-up on all existing launch points of the old pop-up.
- **One-Time Payment UI Navigation.** Specify where the user should be navigated after successful one-time payment creation. This is optional. If not specified, the pop-up simply closes.
- **One-Time Payment Service Task Type.** If your implementation enabled [Web Debit Account Validation](#), add a One-Time Payment service task type using the base-provided C1-OneTimePaymentTaskType and C1-OneTimePaymentTask. Specify your One-Time Payment service task type on this feature option.
- **Override Script for Add One-Time Pmt UI.** If your implementation has additional requirements for the [Add One-Time Payment](#) UI, you can clone the base-owned BPA script (C1OTPayAddNv) and specify your CM script on this feature option. If configured, the system will launch this override script instead of the base-owned script.

FASTPATH:

Refer to [Add One-Time Payment](#) for more information.

Third Party Payment Processing Options

If you allow customers to make one time payments and/or pay bills automatically through a third party payment processing system, you will need to set up a number of control tables to enable these functions in the system.

IMPORTANT: Aside from the tables mentioned in these sections, control tables defined under [Automatic Payment Options](#) must also be configured. Additional values must also be added to control tables defined under [Tender Management](#). Specifically, refer to [Setting Up Tender Types](#) and [Setting Up Tender Sources](#).

FASTPATH: Refer to [Third Party Payment Processing](#) for the big picture of third party payment processing.

Define Service Task Types

The web services used to process one time payment notifications, automatic payment setup and account verification create a corresponding service task record to perform the needed actions.

The following service task types need to be configured and defined on the Third Party Payment Processing Integration master configuration:

- A **Third Party One Time Payment** service task type is used to create an immediate or scheduled third party one time payment. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyOneTimePyTaskType** and **C1-ThirdPartyOneTimePyTask**. Refer to these business objects for details on schemas and processing logic.
- A **Third Party Account Verification** service task type is used to verify an account, which is typically done prior to capturing and processing a one time payment within the third party payment processing system. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyAcctVerifTaskType** and **C1-ThirdPartyAcctVerifTask**. Refer to these business objects for details on schemas and processing logic.
- A **Third Party Auto Pay Setup** service task type is used to add or update an account's ongoing automatic payment option. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyAutoPayTaskType** and **C1-ThirdPartyAutoPayTask**. Refer to these business objects for details on schemas and processing logic.

Refer to [Defining Service Task Types](#) for details on setting up service task types

Define Auto Pay Sources and Auto Pay Route Types

Configure specific auto pay sources for the payment types that your third party payment processing system accepts for one time payment processing and ongoing automatic payment processing. Base-supplied Payment Type values are: Checking Withdrawal, Savings Withdrawal and Credit Card Withdrawal. Your implementation can add payment types. In the Third Party Payment Processing Integration master configuration, each accepted payment type is associated with a Tender Type that is used to create the payment tender associated with a third party one time payment. For checking and savings payment types, the tender type and routing number are used to identify the auto pay source.

Auto pay sources used for ongoing automatic payment processing (i.e. ACH) should be associated with an auto pay route type that specifies C1-TAPEX as the Extract Batch. This ensures that the correct extract batch code is stamped on bill-related auto pay staging records during auto pay activation.

Define Tender Cancel Reason

Configure a Tender Cancel Reason that will indicate that a payment tender was canceled from the third party payment processing system. This cancel reason is configured in the Third Party Payment Processing Integration master configuration and used when a scheduled or processed one time payment is canceled.

Third Party Processing DateTime

The services used in third party payment processing allow for the possibility that the third payment processing system is processing in a different time zone as the utility's. The Third Party Payment Processing Integration master configuration includes the third party's Processing Cutoff Time and Processing Cutoff Time Zone, as well as the local equivalent of the processing cutoff time, based on the Time Zone defined on the Installation record.

The payment datetime that is sent by the third party payment processing system with one time payment notifications and auto pay confirmations is stored as-is as a characteristic on the one time payment's tender. This is done for the purposes of tender controls processing and payments reconciliation (*i.e.*, with reports generated from the third party payment processing system).

As a standard, inbound and outbound communications external systems must use the standard xsd datetime format (yyyy-MM-dd'T'hh:mm:ss[+ or -]hh:mm). The payment datetimes sent with third party one time payment notifications and auto pay confirmations should follow this format.

The Third Party One Time Payment Task also stores the local equivalent of the payment datetime, based on the Time Zone defined on the Installation record. This local datetime is used anywhere third party one time payments (and their payment dates) are displayed in the system (*e.g.*, in the [Scheduled Payments Log](#) in Control Central - Account Information).

Third Party Payment Processing Master Configuration

The integration with a third party payment processing system requires the setup of master configuration data that controls the processing of one time payments and ongoing automatic payments.

To set up the third party payment processing master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Third Party Payment Processing Integration master configuration record.

Refer to the master configuration's embedded help for more details on how each section in this record is configured.

Payment Advices

The topics in this section provide background information about payment advice functionality.

NOTE:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization issues payment advices to the customer instead of initiating electronic funds transfer directly to the customer's bank.

What Is A Payment Advice?

Payment advice is a money order that is established at the initiative of the utility. When a bill is completed, the utility sends the customer a document that indicates a payment amount and the customer's bank details. If the customer agrees to the information on the payment advice, they sign it and return it to the clearinghouse address that is indicated on the payment advice. The clearinghouse, in turn, sends the dated and signed payment advice to the customer's bank, which completes the payment.

Payment Advice vs. Direct Debit

The existing functionality that creates automatic payments is referred to as direct debit processing. Payment advice processing differs from direct debit processing in the way that automatic payments get initiated. With payment advice processing, the usual automatic payment records - *i.e.* payment event, payment, tender and auto pay clearinghouse staging - are not created. Instead, a payment advice is printed and sent to the customer. The customer sends the approved payment advice directly to the clearinghouse.

NOTE:

The system does not provide sample processes for extracting and printing payment advice information. Your implementation team would have to create these.

Setting Up The System To Enable Payment Advices

You must set up a Financial Transaction Options [Feature Configuration](#) to define parameters that control payment advice functionality.

The following points describe the various **Option Types** that must be defined:

- **Payment Advice Functionality Supported.** This option controls whether the system allows for payment advice processing.
 - Enter Y if the system should allow for both direct debit and payment advice processing.
 - Enter N if the system should only allow for direct debit processing.
- **Default Auto Pay Method.** This option is used for defaulting the auto pay method on new account auto pay records.

Refer to [Account - Auto Pay](#) for more information on auto pay method.

NOTE:

The system assumes direct debit processing if the above feature options are not defined.

Credit Card Payments

If your organization accepts credit card payments, you can configure the system to authorize customers' credit card charges in real-time, and perform an authorization reversal (also in real-time) when the credit card payment is canceled. When the authorization web service is not available, you can permit users to enter authorization codes manually so that they can continue processing payments.

Configuring the System for Tender Authorization

The following sections describe the setup required if your organization intends to use the base CyberSource integration tender authorization functionality.

Define the Outbound Message Type

An outbound message type is required for the CyberSource authorization outbound message. This outbound message type must reference the base CyberSource - Credit Card Authorization business object.

An outbound message type is required for the CyberSource reversal outbound message. This outbound message type must reference the base CyberSource - Credit Card Reversal business object.

Define the Message Sender

A Message Sender is required to define how to send messages to CyberSource. Use the context of the Message Sender to define the web service interface.

Define the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each (XAI, Batch or Real Time; Real Time is generally the appropriate choice for credit card authorization). You will also need to select the appropriate XSLs to format both the request and response to the outbound message types for CyberSource.

Define a User

Add a user to hold details required for CyberSource communication. Security information (e.g. Merchant Id, Merchant Reference Code, CyberSource User Name and Password) needed to interface with CyberSource is stored as user characteristics.

Set up the Tender Authorization Algorithm

A Tender Type (BO) - Tender Authorization algorithm must be configured. This algorithm performs a tender authorization or a tender authorization reversal through CyberSource.

Define a Business Object

A business object (BO) must be created for the TENDER TYPE maintenance object. This BO must reference the tender authorization algorithm created.

Define Tender Types

Update the appropriate tender type(s) to denote that authorization is required. The new business object must be specified on the tender type(s).

Tender Authorization - Feature Configuration

If your implementation has a need to prevent users from overriding the automatic tender authorization, then you must set up the Allow Manual Tender Authorization Override option type on the Financial Transaction Options [Feature Configuration](#). The Allow Manual Tender Authorization Override option must have a value of N in order to suppress the Authorization Override checkbox.

FASTPATH:

For more information on credit card payment authorization refer to the Tender Type - Credit Card with Authorization business object.

Non CIS Payments

Payment Templates can be configured for common types of non CIS payment allocations. These templates are used to default the payment distribution and allow non CIS payments to be directly allocated to specific distribution codes.

Setting Up Payment Templates

Payment templates contain the rules that control how non CIS payments are created. You can use a payment template to default the payment distribution for common types of non CIS payments. To set up a payment template, open **Admin > Financial > Payment Template > Add**. The topics in this section describe the base-package zones that appear on the Payment Template portal.

Payment Template List

The Payment Template [List zone](#) lists every payment template. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent payment template.
- Click the Add link in the zone's title bar to add a new payment template.

Payment Template

The Payment Template zone contains display-only information about a payment template. This zone appears when a payment template has been broadcast from the Payment Template List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the payment template.
- Click the **Delete** button to start a business process that deletes the payment template.
- Click the **Duplicate** button to start a business process that duplicates the payment template.
- Click the **Activate** or **Deactivate** button to start a business process that updates the status of the payment template.

Please see the zone's help text for information about this zone's fields.

Alternate Currency Payments

The topics in this section provide background information about alternate currency payments.

NOTE:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization accepts payments tendered in a currency other than the customer's currency. If your organization does not accept alternate currency payments, you need only indicate such on the [Installation Record](#); no other setup is required.

What Is An Alternate Currency Payment?

The currency code on the customer's account defines the currency in which the account's financial transactions are expressed. If the customer remits a payment in a different currency, this is referred to as an alternate currency payment. The system enables conversion of the tendered amount to the account's currency and captures the alternate currency and amount,

as well as the exchange rate used in the conversion on the payment tender. The payment tender is linked to a tender control that references the alternate currency.

Configuring the System for Alternate Currency Payments

Allowing Alternate Currency Payments

You must set the **Alternate Currency** flag on the [Installation Record](#) to Allowed if your organization accepts alternate currency payments. This option controls whether the **Currency Converter** button is displayed when a payment is processed on the payment portal.

Payment Event Business Object

A business object (BO) must be created for the PAY EVENT maintenance object. You must specify this BO as the option value for the CIS Payment Event Add BO option type on the Financial Transaction Options [Feature Configuration](#). This BO must have the Currency Conversion Script BO option defined. This BPA script is invoked when the user clicks on the **Currency Converter** button during CIS payment processing on the payment portal.

NOTE:

Currency conversion logic is customizable. The base product includes a script for currency conversion called C1-ConvCurr that's plugged in on the C1-CISPaymentEvent business object. This script converts an alternate currency amount to the account's currency using a bill factor value. The bill factor to use is derived by concatenating the alternate currency code and the account's currency code. For example, if converting US Dollars (USD) to Barbados Dollars (BBD) the bill factor code to use would be USDBBD. Your implementation can change this logic by developing a new script and plugging it into the payment event business object.

Define the User's Tender Sources

Define the tender source(s) for the location (e.g., the specific cash drawer) in which a user's payment tenders are stored during the day. A tender source should be specified for each currency that payments are accepted in. The tender source(s) on the user record are used by the system when a user adds a new tender control. The system attempts to default a tender source on a new tender control based on the deposit control's currency and the tender source(s) defined on the user's record.

Payment Event Distribution

The base-package, by default, creates a single payment for a payment event. If your business requires potentially many payments to be created when payment events are added, you'll need to set up the various control tables described in this section.

FASTPATH:

Refer to [Distributing A Payment Event](#) for more information about how payment event distribution is handled in the system.

Making Payments Using Distribution Rules

As part of this method, one or more distribution details are provided at payment time along with the usual payment and tender information. Each distribution detail record references a distribution rule and a corresponding value. The distribution rule encapsulates the business rules that govern the distribution of the payment amount into payments using the specified value.

The type of value being captured on the distribution detail and the logic that uses it to create payments are defined on the [distribution rule](#).

Rule Value

The primary use of the rule value is to identify the business entity whose balance is to be relieved by creating payment(s). In most cases where the payor account is the same as the payee account it may also be used to identify the tender account associated with the payment(s).

Determine Tender Account

The very first step in processing a distribution detail is to identify the tender account (i.e. the payor) associated with the payment. To do that the system calls the Determine Tender Account [algorithm](#) defined on the distribution rule providing it with the rule value and other tender information.

Creating Payment(s)

The business logic that distributes a payment amount into one or more payments(s) targeted towards the entity identified by a rule value is held in designated Create Payment [algorithms](#) defined on the distribution rule.

Rule Value Can Capture Additional Information

A rule value can also be used to capture additional information provided at payment time, like address information, comments, etc. Obviously payment distribution details with this type of rule value should have a zero payment amount, as they are not real payments. These distribution details end up being linked to a payment event, but unlike other distribution details they do not contribute any payments. You can think of these details as payment event characteristics.

You don't have to set up a Create Payment algorithm for distribution rules intended solely to capture additional payment information.

Setting Up The System To Use Distribution Rules

Setting Up Distribution Rules

Define a Distribution Rule for each payment event distribution method practiced by your business.

Distribution Rule - Main

To set up a distribution rule, navigate to **Admin > Financial > Distribution Rule > Add**.

Description of Page

Enter a unique **Distribution Rule** and **Description** for the distribution rule.

Provide a short and unique **Distribution Rule Label** to be used as rule's name throughout the system.

Characteristic Type defines the type of entity whose balance is relieved by the payment(s) this rule creates. For example, if this rule targets payments(s) towards a specific service agreement, you'd reference a characteristic that its value identifies a service agreement. We use the term "rule value" for the characteristic value.

Distribution Rule - Algorithms

Navigate to **Admin > Financial > Distribution Rule > Search** and navigate to the **Algorithms** page to set up the algorithms appropriate for your distribution rule.

Description of Page

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Create Payment	Optional	This algorithm is executed to distribute a payment distribution detail payment amount into one or more payments.
Determine Tender Account	Optional	This algorithm is executed to determine the tender account associated with the payment distribution detail. Only one such algorithm may be specified.

Feature Configuration

You must set up a Financial Transaction Options [Feature Configuration](#) to define parameters that control various payment event distribution options.

The following points describe the various **Option Types** that must be defined:

- Always Enable Distribution Rule. This option controls whether the system should only use the distribution rule method to add payment events or rather allow both the default method and the distribution rule method to coexist.

- Enter Y if the system should always use distribution rules. With this setting, navigation to the Payment Event page in add mode opens up the [Payment Event Quick Add](#) page (defaulting it to the single payment event dialog). This dialog is designed to create a payment event using distribution rules
- Enter N if the system should allow both methods. With this setting, navigation to the Payment Event page in add mode opens up the standard [Payment Event - Add Dialog](#) that uses the default method to create a payment event. If you want to use the distribution rule method, navigate to the Payment Event Quick Add page from the menu.
- Default Distribution Rule. This option states your default distribution rule that appears throughout the system.

Cancel Reasons

As described in [The Financial Big Picture](#), the various types of financial transactions can be canceled if their financial impact needs to be reversed from the system. Whenever a financial transaction is canceled, a cancel reason must be specified. This section describes the control tables that contain the cancel reason codes.

Setting Up Bill (Segment) Cancellation Reasons

Open **Admin > Billing > Bill Cancel Reason** to define your bill segment cancellation reason codes.

Description of Page

Enter an easily recognizable **Bill Cancel Reason** and **Description** for the bill cancellation reason.

Only use **System Default** on those reason codes that are placed on bill segments that are automatically canceled by the system. Valid values are: Turn off auto-cancel, Bad estimated read auto-cancel, MDM Corrected Read, and Mass Cancel. The reason code identified as Turn off auto-cancel is placed on bill segments that are automatically canceled when the final bill segment ends before the prior bill (and therefore we have to cancel the prior bill). The reason code identified as Bad estimated read auto-cancel is placed on bill segments that are automatically canceled by the system when it detects that it used an estimated read whose consumption is greater than the next actual read (and therefore we have to cancel the estimated bill segment). The reason code identified as Mass Cancel is placed on bill segments that are canceled as a result of the execution of the Mass Cancellation background process. The reason code identified as MDM Corrected Read is placed on bill segments that are automatically canceled by the system when processing a corrected read notification. Corrected read notifications are received from MDM when reads that were used in bill determinant calculation requests (usage requests) are replaced or modified. This notification may result in the rebill of frozen bill segments. Refer to [Usage Requests](#) for more information.

NOTE:

Required values. You must have one reason code defined for each of the System Default values.

Setting Up Payment Cancellation Reasons

Open **Admin > Financial > Pay Cancel Reason** to define your payment cancellation reason codes.

Description of Page

Enter an easily recognizable **Cancel Reason** and **Description** for the payment cancellation reason.

Turn on the **NSF Charge** switch if the system should invoke the non-sufficient funds (NSF) algorithm when a tender is cancelled using this reason code. Refer to [NSF Cancellations](#) for more information.

The next several fields are used to change an account's credit rating or cash-only points if a tender is canceled using the respective reason code.

- Use **Affect Cash-Only Score By** to define how tenders canceled using this reason will affect the account's cash-only score. This should be a positive number. When a customer's cash-only points exceed the cash-only threshold amount defined on the installation record or the account's CIS Division, the account is flagged as cash only during payment processing and on Control Central.
- Use **Affect Credit Rating By** to define how tenders canceled using this reason will affect the account's credit rating. This should be a negative number. A customer's credit rating is equal to the start credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect.
- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

FASTPATH:

For more information, refer to [Account - Credit Rating](#).

NOTE:

The payor gets the credit rating / cash only hit. When you cancel a tender you must specify a cancellation reason. If the cancellation reason indicates a credit rating / cash only demerit should be generated, the system levies the credit rating transaction on the PAYOR's account.

The **System Default** is specified on those cancellation reasons that are placed on payment segments that are automatically cancelled by the system. Valid values are: Re-opened Bill. The Re-opened Bill value is used as follows:

- Payments are automatically created for accounts who pay their bills automatically when their bills are completed.
- If such a bill is reopened before the automatic payment is interfaced to the paying authority, the system automatically cancels the payment. The Re-opened Bill cancellation reason is placed on such payments.

Setting Up Adjustment Cancellation Reasons

Open **Admin > Financial > Adjustment Cancel Reason** to define your adjustment cancellation reason codes.

Description of Page

Enter an easily recognizable **Cancel Reason** and **Description** for each adjustment cancellation reason.

Miscellaneous Financial Controls

This section describes miscellaneous control tables.

A/P Check Request

Adjustments whose adjustment type is marked with an A/P check request code are interfaced to your A/P system. Your A/P system then cuts the checks.

FASTPATH:

Refer to [Controls The Interface To A/P](#) for more information about the accounts payable interface.

You must set up at least one A/P check request code if you want A/P to cut checks.

To set up A/P check request types, open **Admin > Financial > A/P Request Type**.

Description of Page

Enter an easily recognizable **A/P Request Type** for the accounts payable request type.

Use **Due Days** to define when the check is cut. The cut date is equal to the adjustment date plus due days.

Select a **Payment Method**. Choose from these options:

System Check System check

Billable Charge Line Type

NOTE:

Background information. Before using this page, you should be comfortable with the topics described under [Setting Up Billable Charge Templates](#) and [Uploading Billable Charges](#).

Billable charge line types will simplify the effort required to interface billable charges from an external system. Each line type contains values that will be defaulted onto the line details associated with the uploaded billable charges. Obviously, this defaulting is possible only if you specify a billable charge line type on the billable charge upload staging lines.

To set up billable charge line types, select **Admin > Billing > Billable Charge Line Type > Add**.

Description of Page

Enter an easily recognizable **Billable Charge Line External Type** and **Description**.

Use **Currency Code** to define the currency to be defaulted onto billable charge upload lines that reference this line type.

Use **Show on Bill** to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.

Use **App in Summary** to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.

Use **Memo Only, No GL** to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.

Use **Distribution Code** to define the values to be defaulted into the Distribution Code field on billable charge upload lines that reference this line type.

Payables Cash Accounting

In some areas, taxes and other 3rd party liabilities are not truly payable until the customer remits payment. We refer to this as "payables cash accounting". This practice should be contrasted with "payables accrual accounting" in which the liability is realized when the bill is created (as opposed to when it is paid).

If your organization does not practice payable cash accounting, you may skip this section as accrual accounting is the system default. If you practice payables cash accounting, the contents of this section describe how to configure the system appropriately.

Accrual versus Cash Accounting Example

The following is an example of the financial events that transpire when a customer is billed and payment is received using accrual accounting.

Event	GL Accounting	Tax Payable Balance
Bill segment created	A/R 110	(10)
	Revenue <100>	
	Tax Payable <10>	
Payment received	Cash 110	(10)
	A/R <110>	

In the above example, you'll notice that the payable is booked when the bill is created. Let's contrast this with what takes place if the payable is subject to payables cash accounting.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Payment received	Cash 110	(10)	0
	A/R <110>		
	Tax Holding 10		
	Tax Payable <10>		

Notice that when the bill segment is produced, the liability is not booked, rather, the amount of the liability is placed in a "holding" GL account. When the customer pays, the moneys are transferred from the "holding" GL account to the true tax payable account.

NOTE:

Cash accounting is only applicable for liabilities. In the above example, you'll notice that only the tax payable account had cash accounting implications. This is because organizations that practice cash accounting only do it for liability accounts; they never do it for assets, revenue or expenses.

If the above seems simple, consider the following complications that must be considered:

- What happens if a partial payment is received?
- What happens if there are multiple taxes subject to cash accounting rules?
- What happens if the A/R is relieved via a deposit seizure (or transference of a credit balance from another SA)?
- What if, after payment, the original bill segment is cancel/rebilled resulting in a different amount of tax (keep in mind that the payable got booked when the payment was received)?
- What happens if the payment is cancelled?
- What if the payment isn't received and we have to write-off debt?
- What happens if the customer overpays?
- What happens if the customer is allowed to prepay their tax (this is a common practice in the United Kingdom) and then the tax rate changes at billing time?

The above points, and more, are discussed below.

Distribution Code Controls Cash Accounting For A GL Account

NOTE:

If you do not understand the significance of distribution codes, please refer to [Setting Up Distribution Codes](#).

Whether or not cash accounting is used for a specific GL account is defined on HOLDING GL account's distribution code (i.e., the holding GL account references the true payable account).

It is very important that unique payable and holding distribution codes be used for each type of tax subject to cash accounting rules. For example, if you have cash accounting requirements for both value-added tax (VAT) and a climate levy, you would need four distribution codes:

- VAT Payable.
- VAT Holding.
- Climate Levy Payable.
- Climate Levy Holding.

Without unique distribution codes for each payable and holding account, the system cannot keep track of how much of a given tax is being held, awaiting payment.

Bill Segments and Cash Accounting

The contents of this section describe how cash accounting is implemented when bill segments are created.

Bill Segment Financial Transactions Are Not Affected By Cash Accounting

There are NO changes to rate calculation associated with cash accounting. This is because the rate components that calculate tax reference the HOLDING payable distribution codes.

NOTE:

Prepaid taxes - future functionality. If your organization allows customers to prepay taxes in anticipation of a future tax increase (the customers receive the lower rate if they pay in advance), please speak to your account manager for information about when corresponding functionality will be available.

Payment Segments and Cash Accounting

The contents of this section describe how cash accounting is implemented when payment segments are created.

Payment Segment Financial Transaction Algorithms Transfer Holding Amounts to Payable GL Accounts

Logic exists in the pay segment's FT algorithm that transfers amounts from payable holding distribution codes to their respective payable real distribution codes.

FASTPATH:

Refer to [Setting Up Payment Segment Types](#) for how to define the appropriate FT algorithm.

The following table shows what happens to the financial transaction associated with the payment segment for a cash accounting customer.

Event	GL Accounting
Bill segment is created	A/R 110
	Revenue <100>
	Tax Holding <10>
Payment segment relieves receivables	Cash 110
	A/R <110>
Additional GL details created when the payment segment FT algorithm transfers the holding amount to a payable account	Tax Holding 10
	Tax Payable <10>
Net effect of the above	Cash 110
	A/R <110>
	Tax Holding 10
	Tax Payable <10>

How Does The System Know What Amounts To Transfer From Holding To Payables?

When a payment segment is created for an account that is subject to cash accounting processing, the system determines if there is a CREDIT balance for any holding distribution code in respect of the service agreement. If so, it generates additional GL details to transfer moneys from the holding distribution code to the payable distribution code in proportion to the amount of receivables relieved by the payment. Therefore, if 100% of receivables are relieved by the payment segment, 100% of the holding amounts will be transferred to payable distribution codes. Refer to [Partial Payments Result In Partial Payables](#) for an example of what happens when a partial payment is created.

Partial Payments Result In Partial Payables

The previous example showed the entire tax holding amount being transferred to the tax payable account. The entire holding amount was transferred because the service agreement was paid in full. If a partial payment is received, only part of the holding amount will be transferred to the payable amount (proportional to the amount of receivables reduced by the payment). An example will help make the point.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Partial payment received	Cash 27.50	(2.50)	(7.50)
	A/R <27.50>		
	Tax Holding 2.50		
	Tax Payable <2.50>		

The above example assumes the use of the base product payment segment FT creation algorithm PSEG-AC to transfer the holding amount to the tax payable account. If multiple holding accounts are used, you may want to specify which holding amounts are relieved first. The base product includes an additional payment segment FT creation algorithm C1-FTGL-PSAC that handles booking holding amounts based on a priority.

Partial Payments Using Accounting Priority

To book holding amounts based on a priority, each holding distribution code must be assigned an **Accounting Priority**. When a partial payment is posted, only part of the holding amount will be transferred to the payable amount (proportional to the amount of receivables reduced by the payment). When the holding amount consists of various holding distribution codes with different accounting priorities, the amount to transfer is allocated as follows:

- Holding distribution codes associated with the oldest debt are settled first
- Within the same debt age, holding distribution codes with a higher accounting priority are booked first. If more than one distribution code shares the same priority, the settlement is distributed among them in proportion to the holding account balance

The above logic is handled by the payment segment FT creation algorithm C1-FTGL-PSAC. As an example of how these rules apply, let's assume an implementation practices cash accounting; i.e. revenue, taxes and other third party liabilities are not recognized until payment is received. Also assume the following distribution codes have been configured:

Holding Distribution Code	Description	Cash Accounting Distribution Code	Accounting Priority
HLD-LPC	Late Payment Charge	R-MISC	10
HLD-RGEN	Revenue - Generation Charge	R-GEN	20
HLD-RDIS	Revenue - Distribution Charge	R-DIST	30
HLD-RTRN	Revenue - Transmission Charge	R-TRAN	30
HLD-THRD	3 rd Party Charges	R-THRD	40
HLD-VAT	VAT	A/P-VAT	90

Assume a customer has an outstanding third party charge with an arrears date of 2/Jan/2009:

Event	GL Accounting	SA's Payoff Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Unpaid Amount	A/R 50 HLD-HRD <45> HLD-VAT <5>	50	0	0	0	0	(45)	(5)

A bill is created for a customer and the result of the bill's financial transactions (an LPC adjustment in the amount of 10 and a bill segment in the amount of 127) include the following FT GL lines (both financial transactions have an arrears date of 15/Jan/2009):

Event	GL Accounting	SA's Payoff Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Bill segment created	A/R 127	177	0	(15)	(20)	(55)	(55)	(32)

HLD-RGEN
<15>
HLD-RDIS
<20>
HLD-RTRN
<55>
HLD-THRD
<10>
HLD-VAT
<27>

Adjustment created	A/R 10	187	(10)	(15)	(20)	(55)	(55)	(32)
	HLD-LPC							
	<10>							

No payment is received prior to the next bill. The result of the next bill's financial transaction (a bill segment in the amount of 100) includes the following FT GL lines (this financial transaction has an arrears date of 16/Feb/2009):

Event	GL Accounting	SA's Payoff Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Bill segment created	A/R 100	287	(10)	(30)	(40)	(100)	(65)	(42)
	HLD-RGEN							
	<15>							
	HLD- RDIS							
	<20>							
	HLD- RTRN							
	<45>							
	HLD- THRD							
	<10>							
	HLD-VAT							
	<10>							

The following shows the result if a customer makes a payment on 20/Feb/2009. At payment time we'll build a table of holding amounts by accounting priority and debt age as follows:

Distribution Code & Priority	HLD-LPC	HLD-RGEN	HLD-RDIS	HLD- RTRN	HLD-THRD	HLD- VAT
Debt Age						
4 days old		(15)	(20)	(45)	(10)	(10)
36 days old	(10)	(15)	(20)	(55)	(10)	(27)
49 days old					(45)	(5)

Examples of Partial Payments Using Accounting Priority

The examples below assume a customer has the financial history described above and attempts to illustrate the financial effect when a payment is made.

- [Example 1 - Customer Pays In Full](#)
- [Example 2 - Customer Makes a Partial Payment](#)
- [Example 3 - Customer Makes a Partial Payment](#)

Example 1 - Customer Pays In Full

Assume the customer makes a payment in the amount of 287. This amount is sufficient to satisfy all holding amounts, so the payment will have the following financial effect:

Event	GL Accounting	SA's Payoff Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Payment received	Cash 287	0	0	0	0	0	0	0
	A/R <287>							
	HLD-LPC 10							
	R-MISC <10>							
	HLD-RGEN 30							
	R-GEN <30>							
	HLD- RDIS 40							
	R-DIST <40>							
	HLD- RTRN 100							
	R-TRAN <100>							
	HLD- THRD 65							
	R-THRD <65>							
	HLD-VAT 42							
	A/P-VAT <42>							

[Top of the Page](#)

Example 2 - Customer Makes a Partial Payment

Assume the same financial history described above for a customer and a partial payment in the amount of 70 is made. This amount is not sufficient to satisfy the total holding amounts of 287, so the system will start settling held amounts starting with distribution codes with the oldest debt first from highest priority until the payment amount is exhausted.

A payment in the amount of 70 will be applied in the following sequence

Distribution Code & Priority	HLD-LPC (10)	HLD-RGEN (20)	HLD-RDIS (30)	HLD-RTRN (30)	HLD-THRD (40)	HLD-VAT (N/A)
Debt Age						
4 days old		(15.00)	(20.00)	(45.00)	(10.00)	(10.00)
36 days old	③ (10.00)	④ (15.00)	(20.00)	(55.00)	(10.00)	(27.00)
49 days old					① (45.00)	② (5.00)

The following describes how the holding amounts will be booked as a result of this partial payment:

- Settle oldest debt first (49 days old), i.e. 3rd Party Charges (HLD-THRD) and VAT (HLD-VAT). Note that even though these holding accounts have the lower accounting priorities, they are booked first because they have the oldest debt. An amount of 20 now remains on the partial payment.
- Next, we'll settle the 36 days old debt from the highest priority:
 - Late Payment Charge (HLD-LPC) in the amount of 10. An amount of 10 now remains on the partial payment
 - Revenue - Generation Charge (HLD-RGEN) gets the remaining payment amount of 10
- So, this partial payment in the amount of 70 will result in the following financial effect:

Event	GL Accounting	SA Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Payment received	Cash 70 A/R <70> HLD-LPC 10 R-MISC <10> HLD-RGEN 10 R-GEN <10> HLD-THRD 45 R-THRD <45> HLD-VAT 5 A/P-VAT <5>	217	0	(20)	(40)	(100)	(20)	(37)

[Top of the Page](#)

Example 3 - Customer Makes a Partial Payment

Assume the same financial history described above for a customer and a partial payment in the amount of 220 is made. This amount is not sufficient to satisfy the total holding amounts of 287, so the system will start settling held amounts starting with distribution codes with the oldest debt first from highest priority until the payment amount is exhausted.

A payment in the amount of 220 will be applied in the following sequence

Distribution Code & Priority	HLD-LPC (10)	HLD-RGEN (20)	HLD-RDIS (30)	HLD-RTRN (30)	HLD-THRD (40)	HLD-VAT (NA)
Debt Age						
4 days old		3 (15.00)	10 (20.00)	10 (45.00)	(10.00)	(10.00)
36 days old	6 (10.00)	4 (15.00)	5 (20.00)	6 (55.00)	7 (10.00)	8 (27.00)
49 days old					1 (45.00)	2 (5.00)

The following describes how the holding amounts will be booked as a result of this partial payment:

- Settle oldest debt first (49 days old), i.e. 3rd Party Charges (HLD-THRD) and VAT (HLD-VAT). Note that even though these holding accounts have the lower accounting priorities they are booked first because they have the oldest debt. An amount of 170 now remains on the partial payment.
- Next, we'll settle the 36 days old debt from the highest priority, i.e. Late Payment Charge (HLD-LPC), Revenue - Generation Charge (HLD-RGEN), Revenue - Distribution Charge (HLD-RDIS), Revenue - Transmission Charge (HLD-RTRN), 3rd Party Charges (HLD-THRD) and VAT (HLD-VAT). An amount of 33 now remains on the partial payment.
- Next we'll settle the 4 day old debt from the highest priority:
 - Revenue - Generation Charge (HLD-RGEN) in the amount of 15. An amount of 18 now remains on the partial payment
 - The two holding accounts at the next priority have an outstanding amount of 65. Since the remainder of the payment is not enough to satisfy this amount, the remainder of the payment is prorated amongst HLD-RDIS and HLD-RTRN as follows:
 - $(\text{Remaining Pay Amount} / \text{Total Outstanding Holding Amount}) * \text{Holding Account Amount}$
 - So for the Revenue - Distribution Charge (HLD-RDIS) holding account the amount booked will be $(18/65 * 20) = 5.54$
- So, this partial payment in the amount of 220 will result in the following financial effect:

Event	GL Accounting	SA Balance	Holding Balances					
			HLD-LPC	HLD-RGEN	HLD-RDIS	HLD-RTRN	HLD-THRD	HLD-VAT
Payment received	Cash	67	0	0	(14.46)	(32.54)	(10)	(10)

Adjustments That Behave Like Payments

There are several types of adjustments that behave just like payments (in respect of payables cash accounting). Consider the following events:

- Seizing a deposit (i.e., transferring a credit from a deposit service agreement to a regular service agreement)
- Overpayments transferred from one service agreement to another

The above events should cause the system to transfer holding amounts to true payable amounts (notice that the above examples are all transfer adjustments).

However, there are many other adjustments that should NOT behave like payments. You control how the adjustment works by selecting the appropriate FT algorithm when you [set up adjustment types](#) (refer to ADJT-AC and ADJT-TC for a description of the base package algorithms that cause the holding amounts to be manipulated in proportion to the amount of receivable being adjusted; and to C1-FTGL-ADAC and C1-FTGL-ADTC for the base package algorithms that take **Accounting Priority** into consideration). In other words, there are adjustment FT algorithms that cause the transference of holding payable amounts to real payable amounts when the A/R balance is decreased by the adjustment.

NOTE:

Cash refunds can behave like "anti-payments". In addition to the above examples of transfer adjustments behaving like payments, you should be aware that cash refunds may impact your holding and true payable balances. Refer to [Cash Refunds](#) for more information.

Overpayment Of Taxes Due To Cancel/Rebills

Let's assume a cancel / rebill occurs after a payment is received and the net effect of the cancel / rebill is that the customer has overpaid their taxes.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)

	Revenue <100>		
	Tax Holding <10>		
Payment received	Cash 110	(10)	0
	A/R <110>		
	Tax Holding 10		
	Tax Payable <10>		
Cancel	A/R <110>	(10)	10
	Revenue 100		
	Tax Holding 10		
Rebill	A/R 27.50	(10)	7.50
	Revenue <25>		
	Tax Holding <2.50>		

You'll notice that the amount payable to the taxing authority still indicates \$10 (the amount of tax that was paid by the customer). However, you'll notice that the tax holding balance is 7.50 (debit). This looks a bit odd, but it's correct. Remember that at this point, the customer has a credit balance of \$75 and this will be whittled down as successive bills are produced as shown below. Note: refer to [Cash Refunds](#) for an example of what happens if you refund the credit with a check rather than letting it whittle down.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
		(10)	7.50
Bill segment created	A/R 55	(10)	2.50
	Revenue <50>		
	Tax Holding <5>		
Bill segment created	A/R 110	(10)	(7.50)
	Revenue <100>		
	Tax Holding <10>		

In the unlikely event of a payment being received while the tax holding has a debit balance, nothing will be done in respect of transferring funds from holding to payable (there is nothing to transfer).

Cash Refunds

If you refund moneys to a cash accounting customer, it's important to do the opposite of what was done when the payment was received (i.e., you need to transfer the payable back to the holding account). The following example should help clarify this situation (this example shows a refund due to a credit balance that occurred as a result of a cancel/rebill).

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance	SA's Payoff Balance
Bill segment created	A/R 110	0	(10)	110
	Revenue <100>			
	Tax Holding <10>			
Payment received	Cash 110	(10)	0	0
	A/R <110>			
	Tax Holding 10			

	Tax Payable <10>			
Cancel	A/R <110>	(10)	10	(110)
	Revenue 100			
	Tax Holding 10			
Rebill	A/R 27.50	(10)	7.50	(82.50)
	Revenue <25>			
	Tax Holding <2.50>			
Payment refunded (via an A/P adjustment)	Cash <82.50>	(2.50)	0	0
	A/R 82.50			
	Tax Holding <7.50>			
	Tax Payable 7.50			

We understand this is tricky, but consider this - when a cash accounting customer makes a payment, the system transfers tax holding CREDIT balances to tax payable distribution codes in proportion to the amount of the receivable DEBIT amount that was reduced by the payment. Therefore, when cash is returned to the customer, the system should transfer tax holding DEBIT balances to tax payable distribution codes in proportion to the amount of the receivable CREDIT that was reduced by the refund.

NOTE:

The above takes place when an A/P adjustment is created if the related adjustment type references the appropriate FT algorithm (refer to ADJT-AC and **C1-FTGL-ADAC** for a description of the adjustment FT algorithms used for adjustments that behave like payments).

Overpayments

An overpayment, by definition, does not "match" to open items. However, the match type algorithms supplied with the base package will result in a balanced match event if an overpayment is made. The following points explain how this is achieved:

- The base package's match type algorithms will distribute the payment until the customer's current debt is satisfied.
- The amount of the overpayment will be kept on a separate SA (this only happens if you plug-in the appropriate Overpayment Distribution algorithm on your customer classes). Refer to [Overpayment Segmentation](#) for more information.
- When the payment is frozen, the payment segments that satisfy current debt will be matched against their respective open-items. The payment segment used to book the overpayment (on the overpayment SA) will not be matched.
- When future bills are completed, the credit balance on this "overpayment SA" will be transferred to the "real SAs" when future bills are completed (if you have plugged in the appropriate bill completion algorithm on the overpayment SA's SA type). If the overpayment satisfies all newly calculated charges, a match event is created that matches the new charges against the funds transferred from the overpayment SA. Refer to [When Are Match Events Created](#) for information about how the system creates match events at bill completion time when the new charges on the bill are satisfied by other credits (overpayments, deposit refunds, etc.).
- At some point in the future, the overpayment will be exhausted (i.e., all funds will be transferred to "real SAs"). At that point in time, the overpayment SA will close (assuming you set up the overpayment SA's SA type as a "one time"). At close time, the system creates a match event that matches the original overpayment payment segment with the adjustments that were used to transfer funds to the "real SAs". Refer to [When Are Match Events Created](#) for information about how the system creates match events when a SA closes.

Write Down Adjustment

Writing down debt is very different from [writing off debt](#). When you write down debt, you are removing the receivable with no expectation of it being paid. For example, most organizations write down small debit and credit balances as part of their write-off process (e.g., they don't send a very small amount to a collection agency).

Let's run through an example to illustrate this:

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance	SA's Payoff Balance
Bill segment created	A/R 110	0	(10)	110
	Revenue <100>			
	Tax Holding <10>			
Payment received	Cash 109.50	(9.95)	.05	0.50
	A/R <109.50>			
	Tax Holding 9.95			
	Tax Payable <9.95>			
Write down cash accounting debt	Tax Holding 0.05	(9.95)	0	0
	Write Down Expense 0.45			
	A/R <0.50>			

In order to achieve the above, you must set up an adjustment type that references a special financial transaction algorithm (refer to non-accrual accounting write down algorithms ADJT-AD and **C1-FTGL-AD** for more information). This algorithm will reduce or increase the receivable balance accordingly AND cause any holding amounts to be set to zero. This adjustment type should be referenced on your write-down algorithm that is referenced on your write-off controls.

Write-Offs

At write-off time we may refund credit balances. The refunding of credit balances is handled by A/P adjustments and these have cash accounting processing as described under [Cash Refunds](#).

If we have to write-off debt, holding balances are relieved in proportion to the amount of debt that is written off (as usual). It's important to understand that for this to work, you must set up the system as follows:

- The tax holding distribution codes must have their override distribution switch turned on.
- The distribution code on the SA type associated with the service agreement to which the written-off payables are transferred must be the REAL payable distribution codes. This is important so that if the customer pays after the payables are reversed, we will be able to debit cash and credit the REAL payable distribution code.

Let's run through an example to illustrate this.

Event	Normal SA GL Accounting	Write Off Revenue SA GL Accounting	Reverse Liabilities SA GL Accounting
Bill segment created	A/R 110		
	Revenue <100>		
	Tax Holding <10>		
Write Off Time			

Reverse the held payables	Xfer 10 A/R <10>		Tax Holding 10 Xfer <10> Note, the tax holding only gets debited if you have turned on the override at write-off switch on its distribution code
Write off revenue	Xfer 100 A/R <100>	Write Off Expense 100 Xfer <100>	
If the customer subsequently pays		Cash 100 Write Off Exp <100>	Cash 10 Tax Payable <10> Note, the tax payable only gets credited if the SA type's distribution code has been defined as such

Deferred Accrual Accounting

Some implementations use a hybrid accounting method that combines cash and accrual accounting. In this case revenue, taxes, etc. are recognized on the earlier of the bill due date or the date payment is received. In this scenario, the cash accounting method is used up until the bill's due date, at which time the accrual method is enforced (let's call this "deferred accrual accounting"). A simpler flavor of deferred accrual accounting is when the revenue and liability recognition is done solely at bill due date regardless of when the payment is made.

Deferred accrual accounting affects distribution codes identified as **Use For Non-Accrual Accounting** with an associated **Accounting Method** of either Payable on Earlier of Payment or Due Date or Payable on Due Date. The system accomplishes the holding amount settlement on the bill due date using a customer class post bill completion algorithm C1-CR-BLRVWS that creates a bill review record to be processed on the bill's due date. The bill review batch process then analyzes these bill review records on the bill due date. If a bill review record is due for processing, the algorithm checks the outstanding balance of the holding accounts on each SA linked to the bill and creates a settlement adjustment for each SA.

Deferred Accrual Accounting Examples

The examples below illustrate the financial transactions that transpire under these different scenarios.

Example 1 - Payable On Due Date, Customer Pays In Full

The following is an example of the financial events that transpire when a customer is billed and full payment is received prior to the bill due date. The accounting method in this case is Payable On Due Date.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Payment received	Cash 110	0	(10)

A/R <110>

Adjustment created on bill due date	Tax Holding 10	(10)	0
	Tax Payable <10>		

Example 2 - Payable On Due Date, Customer Does Not Pay

In the following example a customer is billed and no payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Due Date.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Adjustment created on bill due date	Tax Holding 10	(10)	0
	Tax Payable <10>		

Example 3 - Payable On Due Date, Customer Makes A Partial Payment

In the following example a customer is billed and a partial payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Due Date.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Payment received	Cash 27.50	0	(10)
	A/R <27.50>		
Adjustment created on bill due date	Tax Holding 10	(10)	0
	Tax Payable <10>		

Example 4 - Payable On Earlier Of Payment Or Due Date, Customer Pays In Full

In the following example a customer is billed and full payment is received prior to the bill due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		

	GL Accounting	Tax Payable Balance	Tax Holding Balance
Payment received	Cash 110	(10)	0
	A/R <110>		
	Tax Holding 10		
	Tax Payable <10>		

Example 5 - Payable On Earlier Of Payment Or Due Date, Customer Does Not Pay

In the following example a customer is billed and no payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date. Note that if a payment is subsequently received after the settlement adjustment has been created, it's financial transaction(s) will not have any impact on the holding or liability accounts as these have already been booked.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Adjustment created on bill due date	Tax Holding 10	(10)	0
	Tax Payable <10>		

Example 6 - Payable On Earlier Of Payment Or Due Date, Customer Partially Pays

In the following example a customer is billed and a partial payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date. Note that if a payment is subsequently received after the settlement adjustment has been created, it's financial transaction(s) will not have any impact on the holding or liability accounts as these have already been booked.

Event	GL Accounting	Tax Payable Balance	Tax Holding Balance
Bill segment created	A/R 110	0	(10)
	Revenue <100>		
	Tax Holding <10>		
Payment received	Cash 27.50	(2.50)	(7.50)
	A/R <27.50>		
	Tax Holding 2.50		
	Tax Payable <2.50>		
Adjustment created on bill due date	Tax Holding 7.50	(10)	0
	Tax Payable <7.50>		

Payment Cancellations and Deferred Accrual Accounting

If a payment was responsible for transferring moneys from the holding distribution code to the payable distribution code, it stands to reason that if the payment is cancelled, it results in the reversal of this transfer from the holding distribution code to payable distribution code. If deferred accrual accounting is used and the payment is cancelled after the bill due date, the holding amounts that were transferred should remain booked.

Assume, for example, that the payment below was cancelled after the bill due date:

Event	GL Accounting
Payment received	Cash 110
	A/R <110>
	Tax Holding 10
	Tax Payable <10>

At cancellation, the above entry will be reversed, reinstating the balance in the holding account:

Event	GL Accounting
Payment cancelled after bill due date	Cash <110>
	A/R 110
	Tax Holding <10>
	Tax Payable 10

However, since the bill's due date has passed, the holding account needs to be booked. For open item accounts, the system comes with a customer class FT freeze algorithm (C1-PR-CA-RVS) that creates a bill review schedule for the affected bill, if one does not already exist. When the bill review batch process next runs, it checks the outstanding balance of the holding accounts on each SA linked to the bill and creates a settlement adjustment for each SA.

Event	GL Accounting
Adjustment created	Tax Holding 10
	Tax Payable <10>

Note that this solution is only applicable to open item accounting where the bill matched to the payment can be determined. If balance forward accounting is practiced, the bill or bills that the payment applied to cannot be determined. In this case, the next bill review record created for the account as part of billing will cause the balances of the holding accounts to be analyzed and the settlement will catch up at that point.

Open Item Accounting

The topics in this section provide background information about open-item accounting.

NOTE:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization practices open-item accounting. If your organization practices balance-forward

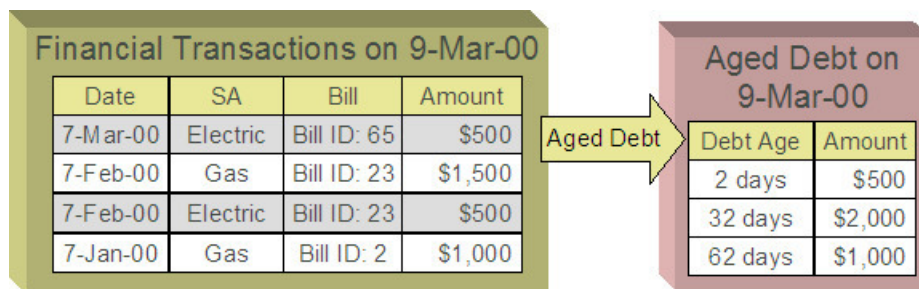

accounting, you need only indicate such on your [customer classes](#); no other setup is required. Refer to [Open Item Versus Balance Forward Accounting](#) for more information about these two accounting practices.

Open-Item Versus Balance-Forward Accounting

If you practice open-item accounting, you match payments against bills. The term "open-item accounting" is used to describe this accounting practice because:

- Payments are matched against "open items" (i.e., unpaid bills and adjustments)
- Only unmatched bills and adjustments (i.e., open items) affect aged debt.

Contrast open-item accounting with "balance-forward" accounting - in a balance-forward world, payments are not matched to bills. Rather, payments implicitly relieve a customer's oldest debt. For example, consider the following unpaid financial transactions that exist for an account and the resultant aged debt.

In a balance-forward world, if a \$1,000 payment was made on 9-Mar-00, the customer's aged debt would look as follows:

Debt Age	Amount
2 days	\$500
32 days	\$2,000

Notice how the \$1,000 payment relieves the 62 day old debt - it does this because, in a balance-forward world, payments payoff oldest debt first.

However, let's assume the customer wants the payment to settle their electric debt (e.g., because they disagree with the gas bills). If you could match the \$1,000 payment to the two electric bills (i.e., open-item accounting exists), the customer's aged debt would look as follows:

Debt Age	Amount
32 days	\$1,500
62 days	\$1,000

In sum,

- In an open-item world, payments are matched to bills and only unpaid bills and adjustments (i.e., open items) affect aged debt.

- In a balance-forward world, payments are not matched to bills and therefore a customer's aged debt is computed by aging debits (bills and adjustments) and then relieving the oldest debits using credits (payments and adjustments).

NOTE:

Financial Transactions and Bills. In an open-item world, only bill segments and adjustments are presented on a bill. When a bill is completed, only those bill segments and adjustments to be presented are swept onto a bill. Payment and payment cancellation FTs, bill segment FTs canceled before bill completion together with their corresponding bill segment cancellation FTs, and adjustment FTs marked as do not show on bill are not swept onto a bill. An adjustment's adjustment type and its algorithms determine if its FT will show on a bill by default.

Accounting Method Defined On Your Customer Classes

You define the type of accounting method that is practiced ([balance-forward versus open-item](#)) on your [customer classes](#). For example, residential customers can practice balance-forward accounting whereas industrial / commercial customers can practice open-item accounting.

Match Events

Match events are used to match open-items (i.e., debit and credit financial transactions) together. The topics in this section provide an overview of match events.

Match Events Match Debit FTs To Credit FTs

For open-item customers, the system matches credit financial transactions (FT's) to debit FT's under a [match event](#). The following is an example of a match event associated with two \$500 payments that satisfy the debt associated with one bill (on February 2000).

Match Event

Account: 10291011

Status: Balanced

Credit FT's: \$1,000

Date	SA	FT Info	Amount
7-Mar-00	Electric	None	\$500
1-Mar-00	Electric	None	\$500

Debit FT's: \$1,000

Date	SA	FT Info	Amount
15-Feb-00	Electric	Bill ID: 22	\$1,000

Notice the following:

- The match event matches 2 credit FT's against a single debit FT. A match event may contain an unlimited number of FT's.
- The match event contains FT's associated with a single account. While the FT's under a match event may belong to multiple service agreements, all FT's under a match event must belong to the same account.
- The match event only contains bill segments that belong to a single bill. If you mix multiple bills under a single match event, then an individual bill balance cannot be properly determined when partial payments exist.
- The status of the match event is balanced. This is because the sum of the debits equals the sum of the credits. If debits do not equal credits, the status of the match event would be open and the various FT's would still affect the customer's aged debt. Refer to [Match Event Lifecycle](#) for more information.

WARNING:

It is strongly encouraged that you refrain from mixing multiple bills on a single match event. If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill (see the [bill page](#), bill summary section). However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate. Algorithm types have been provided which help to enforce this rule of "one bill per match event", please refer to Match By Bill, Pay Oldest Bill First for an example of a matching algorithm that enforces this notion.

When Are Match Events Created?

The following points describe when match events are created for open-item accounts:

NOTE:

Match events are only created for open-item accounts (i.e., those accounts with a customer class that indicates open-item accounting is practiced). Match events may not be created for balance-forward accounts.

- The system can create one or many match events when a payment is added. This match event matches the payment's credit FT's with the debit and credit FT's from bill segments and adjustments. The FT's that are linked to the match event are controlled by the payment's **match type** and **match value** (payments made by open-item customers must reference a match type and match value). Refer to [Payments And Match Events](#) for more information.
- The system may create a match event when any type of financial transaction is cancelled. This match event groups together the original FT with its cancellation FT. Refer to [How Are Match Events Cancelled?](#) for more information.
- The system creates a match event when a bill is completed for customers that pay automatically (i.e., direct debit customers). The match event groups together the bill's new charges against the automatic payment's payment segments.
- The system creates a match event when a bill is completed where the new charges are offset by other financial transactions. For example,
 - Consider a bill that contains a deposit refund. If the sum of the deposit refund equals or exceeds the amount of the bill, the bill's FT's can be matched against the debit refunds FT's. Refer to [Refunding Deposits](#) for more information about deposit refunds.
 - Consider a bill whose new charges are offset by a previous overpayment. Refer to [Over Payments](#) for more information about overpayments.

FASTPATH:

Refer to [Bill Lifecycle](#) for more information about what happens during bill completion.

- The system creates a match event when a service agreement closes and the service agreement has unmatched FT's. For example,

- Consider a deposit service agreement that closes when the deposit is refunded to the customer. The system will create a match event with the deposit SA's FT's (the original credit and the debits used to refund the deposit) when the deposit SA closes (i.e., when its credit balance falls to zero). Refer to [Refunding Deposits](#) for more information about deposit refunds.
- Consider a service agreement for utility debt that is written off. This service agreement closes when the system creates transfer adjustments to transfer the utility debt to a write-off service agreement (or writes down the debt). The system creates a match event to match the original debt to the transfer adjustments used to write-off the debt. Refer to [How Is Debt Financially Written Off](#) for more information about write-off processing.
- A user can create a match event manually at any time. Manual match events would be created under a variety of situations. For example:
 - If a customer disputes a charge. Refer to [Disputing Items](#) for more information about disputes.
 - To handle unusual situations when the system is unable to automatically match FT's together.

Match Event Lifecycle

The following diagram shows the possible lifecycle of a match event:

Match events are initially created in the open state. Financial transactions (FT's) linked to open match events affect arrears, but not in an open-item fashion. Rather, FT's linked to open match events affect arrears in a balance-forward fashion. Refer to [Open Item Versus Balance Forward Accounting](#) for more information about these two accounting methods.

A user may delete an open match event. When an open match event is deleted, its FT's may be linked to other match events.

The system automatically changes an open event's status to balanced when the sum of the debit financial transactions (FT's) equals the sum of the credit FT's for each SA on the match event. It's worth stressing that a match event may contain FT's from many SAs and each SA's FT's must sum to zero before the match event can become balanced.

A user may re open a balanced event (by adding / removing FT's so that the match event becomes unbalanced).

A user may cancel a balanced or open match event. Refer to [How Are Match Events Cancelled?](#) for more information about cancellation.

Payments And Match Events

As described under [When Are Match Events Created?](#), the system creates a match event when a payment is added for an open-item account. The system uses the payment's **match type** and **match value** to determine the FT's (e.g., bill segments and adjustments) that will be matched with the payment's FT's (i.e., the payment segments).

Another way to think of this is as follows:

- When most payments are distributed, the system calls the payment distribution algorithm that is plugged-in on the account's customer class.
- However, a payment that is made in respect of a specific bill requires a different distribution algorithm because the payment should only be distributed amongst the debt associated with the specific bill being paid. This is accomplished by referencing a match type / match value on the payment. The match type references the appropriate payment distribution algorithm. This algorithm is used rather than the customer class distribution algorithm.

For example, if a payment were made in respect of bill ID 192910192101, this payment would reference a match type of bill ID and a match value of 192910192101. At payment distribution time, the system calls the override payment distribution algorithm associated with this match type. The base package bill ID distribution algorithm does several things:

- It distributes the payment amongst service agreements associated with the bill.
- It creates a match event and links the bill's bill segment and adjustment FT's to it.
- Refer to the Bill ID Match Type Algorithm for more information about this algorithm.

NOTE:

The match type's distribution logic is not "hard coded". Because the match type's payment distribution logic is embedded in a plug-in algorithm, you can introduce new algorithms as per your company's requirements.

It's worth noting that payment *distribution* and *freezing* are two separate steps that typically happen in quick succession. The system's standard match event algorithms create the match event during payment distribution. This match event exists in the open state (because the payment segment's FT's have not yet been linked to the match event and therefore debit FT's do not equal credit FT's). The open match event references the debit FT's (the bill segments and adjustments) for which it pays. It is only at payment freeze time that the credit FT's (the payment segments) are linked to the match event thus allowing the match event to become balanced.

If, at freeze time, the payment's credit FT's do not equal the debit FT's on the match event, the match event is left in the open state. An alert will appear on Control Central to highlight the existence of open match events (if the appropriate alert algorithm is plugged in the installation record). In addition, you can also set up a To Do entry to highlight the existence of open match events.

Payments Are Matched To Debit Credit FTs

While the above discussion dealt with the typical situation where the payment's credit FT's are matched against a bill's debit FT's, we want to note that a payment's FT's may be matched against debit and credit FT's. Consider the following example:

Match Event

Account: 10291011

Status: Balanced

Bill 1929: \$2,900

Date	SA	FT Info	Cur Amount
7-Mar-00	Electric	Bill seg	\$1,500
6-Mar-00	Gas	Bill seg	\$1,500
1-Mar-00	Gas	Adj-Credit	\$-100

Pay: \$2,900

Match Type: Bill ID 1929

Date	SA	FT Info	Cur Amount
15-Mar-00	Electric	Pay seg	\$-1,500
15-Mar-00	Gas	Pay seg	\$-1,400

Notice that:

- The \$2,900 payment is distributed amongst two service agreements (electricity and gas).
- The FT's to which the payment segments are matched are both debit and credit FT's. Notice that the debit FT's (the bill segments) and the credit FT (the adjustment) sum to \$2,900.

Credits may result in a situation where the total amount on a bill for an SA is negative. This would be the case if in the above example the credit adjustment were for \$-1600 resulting in the total amount for the Gas SA on this bill to be \$-100 (credit). Assume a full payment of \$1400 is made towards this bill. The Bill ID Match Type Algorithm first allocates negative payment amounts to any SA credit amount on the bill being paid. It then carries over the credit amount to pay off other bill amounts. In this example, a "negative" payment segment is created to match the \$-100 credit of the Gas SA. Using the carried over credit a \$1500 payment segment is created to match the \$1500 debit of the Electric SA.

How Are Match Events Cancelled?

A user can cancel an open or balanced match event at any time. When a match event is cancelled, the event's FT's again effect arrears (and they can be associated with new match events). In other words, when a match event is cancelled, its FT's are released from the match event and become open-items.

In addition to manual cancellation, the system may automatically cancel a match event when the last of its payment FT's, if any, is cancelled (if you plug-in the appropriate FT freeze plug-in on your open-item customer classes).

For example, consider a match event that was created when a payment was made. If the payment is subsequently cancelled, the match event is also cancelled (thus releasing the match event's FT's) if no other payment FT's are linked to the match event. Please be aware that FT cancellation also causes a new match event to be created. This match event matches the original FT (the payment segment) and its cancellation FT. This means that the only "open items" that will exist after a payment is cancelled are the debit FT's that were originally paid.

NOTE:

Reopening bills associated with automatic payment customers. While many payments are cancelled due to non-sufficient funds, please be aware that if you reopen a bill for which an automatic payment was created, the system will cancel the associated payment. If this payment is associated with a match event (because the account is an open-item account), the match event will be cancelled and a new match event will be created to match the original

automatic payment with its cancellation details. This is necessary because a new payment will be created with the bill is subsequently completed and this payment's FT's will be matched to the bill's FT's.

Canceling a payment can result in many match events being created. If a cancelled payment has multiple payment segments, a separate match event will be created for each payment segment.

While payment cancellation is the most common type of FT cancellation, be aware that bill segment or adjustment cancellation may also cause a new match event to be created. We don't necessarily want to always link the cancellation FT and its original FT to the same match event. For example, when the cancellation FT is swept on to the next bill it affects the next bill and not the original FT's bill. For cancellations that will not be swept on to the next bill (payment cancellation, cancellation of an adjustment that is not shown on bill, credit notes, and bill segment cancellation before the bill is completed) the system creates a new match event that matches the original FT and its cancellation FT. This way, neither FT affects aged debt. If the original FT was linked to an existing match event and no other FTs are left on this match event it is automatically canceled.

Current Amount Is Matched, Not Payoff

The system matches the current amount of financial transactions, not the payoff amount.

FASTPATH:

Please refer to [Current Amount versus Payoff Amount](#) for more information about current and payoff amounts.

Disputing Items

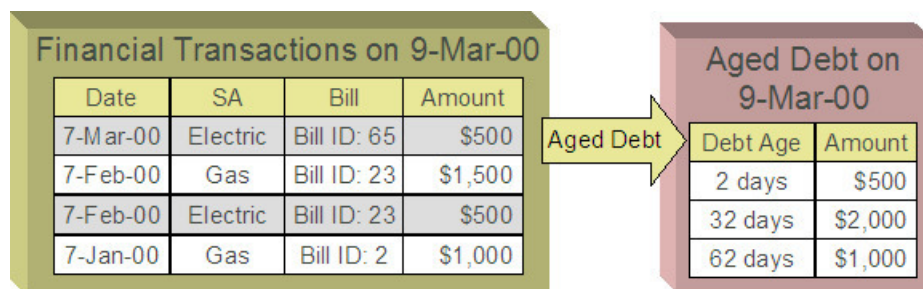

Open-item customers may dispute FT's that they are not comfortable paying. For example, a customer who receives a bill with an anomalous charge may decide to dispute it.

When an open-item customer disputes a charge, a user creates a match event and links the disputed FT(s) to it. This match event will be in the open state (because it does not contain FT's that sum to zero). In addition, the match event's "disputed switch" is turned on.

NOTE:

Alerts. An alert is displayed on control central to highlight the existence of disputed match events (if the appropriate alert algorithm is plugged in). In addition, you can also set up a To Do entry to highlight the existence of disputed match events.

While the dispute is being researched, the disputed amount will not affect aged debt, but it still forms part of the customer's balance. For example, consider the following unpaid financial transactions that exist for an account:

If the customer disputes the two electric bill segments, the customer's aged debt will look as follows:

Notice how a new category of debt appears - Disputed. Also notice how the 2 day old debt disappears and the 32 day old debt is reduced by the disputed amount.

The system shows disputed debt on Control Central. In addition, in all places where aged debt appears in the system, disputed debt is shown as a separate debt category.

If the dispute goes in your company's favor, the disputed match event should be cancelled (thus allowing the FT's to again impact aged debt). For example, if we assume 3 days have passed and the dispute match event is cancelled, the customer's aged debt will look as follows:

If the dispute goes in the customer's favor:

- You may decide to issue a credit note to cancel the offending bill or bill segment(s). As described above, the system in this case will automatically create new match events that match the original FTs with their cancellation FTs and cancel the disputed match event when the last item is unlinked from it.
- You may decide to cancel the offending bill segment(s) / adjustment(s). As described above, these cancellations are going to be swept on to the next bill. The system therefore will not automatically cancel the disputed match event. Notice that the cancellation effect of the disputed items is carried over on to the next bill. This means that the previously disputed items still need to be paid.

NOTE:

Cancel / rebill. If you cancel / rebill an offending bill segment, both the cancel and the rebill will become open-items that will be matched when the next bill is paid.

- You may decide to issue an adjustment to counter the effect of the disputed FT's. In this situation, you would simply link the adjustment FT to the disputed FT's (thus allowing the match event to become balanced). It is important to use in this case an adjustment that does not show on bill.

Pay Plans

You create a [pay plan](#) when a customer agrees to make one or more scheduled payments to satisfy past (or future) debt. These payments cannot be matched to open items because it is unlikely that debit FT's exist that equal the amount of each scheduled payment. However, you must specify a match type on all payments made by open-item customers. Therefore, a conundrum exists - the system requires a match type on payments made by open item accounts, but payments made for

pay plans cannot be matched to existing FT's. This conundrum is solved by the fact that match types do not have to specify an override payment distribution algorithm. The customer class's standard distribution algorithm is used for payments that reference such a match type.

You may wonder how these payments will eventually get matched to open items? If ALL payments associated with a pay plan occur before the next bill is paid (or if the pay plan exists to satisfy future debt), these payments will be swept onto the match event that is created when the customer pays their next bill. However, if the pay plan exists to payoff historical debt and this debt has not been entirely paid by the time of the next bill, an unmatched event will exist when the customer pays their subsequent bills (if the payment amount doesn't match the amount of new charges on the bill). Why? Because, the customer is not paying the entire amount of the bill and therefore the system will not be able to match the payment to open items. If this occurs, we recommend canceling the match events that are created when the customer pays their subsequent bills. When the customer finally pays off all outstanding debt, the system will create a single match event that will contain all payments and bill segments.

Over Payments

If a customer overpays a bill (i.e., we receive more cash than receivables), we strongly recommend you set up the system to NOT keep the excess credit on the customer's regular service agreements. Rather, we recommend you segregate the receivable onto an "excess credit" service agreement. If you do this, the system will transfer any excess credits to the regular service agreements at bill completion time. When this transfer occurs, the same accounting described under [Payments Segment Financial Transaction Algorithms Transfer Holding Amounts To Payable GL Accounts](#) occurs as shown in the following example. Note: this example assumes an excess credit of \$110 was transferred to a normal service agreement and the normal service agreement had \$10 of held payables.

FASTPATH:

Refer to [Overpayment Segmentation](#) for how to set up the system to segregate overpayments on a separate service agreement.

NOTE:

Why not keep excess credits on a customer's regular service agreement? Because the system can't differentiate between a credit that exists as a result of an overpayment and a credit that exists because of cancel/rebills, it would be impossible for the system to know if payables should be realized as a result of the reduced credit balance. However, if you keep overpayments on an excess credit service agreement, the system knows to treat any transference of these credits as "payments" and therefore it can transfer holding balances to true payables.

Event	Normal SA GL Accounting	Excess Credit SA GL Accounting
Bill segment created	A/R 110	
	Revenue <100>	
	Tax Holding <10>	
Payment of \$300 is received	Cash 110	Cash 190

	Tax Holding <10>	

Transfer excess credit amount to normal service agreement (when bill is completed).	Xfer 110 A/R <110>	Overpay 110 Xfer <110>
Because the transfer adjustment is the equivalent of a cash relief outstanding tax holding is relieved in proportion to the amount of receivables that are reduced by the transfer	Tax Holding 10 Tax Payable <10>	
Net effect of the transfer	Xfer 110 A/R <110> Tax Holding 10 Tax Payable <10>	Overpay 110 Xfer <110>

NOTE:

Prepaid taxes - future functionality. If your organization allows customers to prepay taxes in anticipation of a future tax increase (the customers receive the lower rate if they pay in advance), we do not consider this prepayment to be an overpayment. Rather, it is a payment of future taxes that will be remitted to the taxing authorities at payment time (due to cash accounting). Please speak to your account manager for when corresponding functionality will be available.

Setting Up The System To Enable Open Item Accounting

The following section provides an overview of how to enable open-item accounting.

Match Type Setup

The number of match types that you will need is dependent on the number of ways you want payments to be matched to open items. At a minimum, you will probably need the following match types:

- **Bill ID.** This match type should reference an override payment distribution algorithm that distributes the payment based on the bill ID specified on the payment (in match value). Refer to [Payments And Match Events](#) for more information.
- **SA ID.** This match type should reference an override payment distribution algorithm that distributes the payment based on the SA ID specified on the payment (in match value). Refer to [Payments And Match Events](#) for more information.
- **Pay Plan.** This match type should NOT reference an override payment distribution algorithm (if this algorithm is blank, the customer class's payment distribution algorithm is used). Refer to [Pay Plans](#) for more information.

Match Event Cancellation Reason Setup

The number of match event cancellation reasons that you will need is dependent on the number of ways your organization can justify the cancellation of a match event. At a minimum, you will probably need the following match event cancellation reasons:

- **FT Cancellation.** This cancel reason should be referenced on the Customer Class FT Freeze algorithm that is responsible for canceling match events when one of its financial transactions is cancelled.
- **Incorrect Allocation.** This cancel reason should be specified by users when they cancel match events that were created by the system erroneously.

Customer Class Setup

The following points describe [customer class](#) oriented set up functions:

- Turn on the open-item accounting switch.
- Set up the following algorithms for each CIS division:
 - Specify a **payment freeze** algorithm that causes a payment's FT's to be linked to the match event that was created when the payment was distributed. Refer to [Payments And Match Events](#) for more information.
 - Specify a **FT freeze** algorithm that causes match events to be cancelled (and a new match event to be created) when a FT is cancelled. Refer to [How Are Match Events Cancelled](#) for more information about cancellation.
 - We strongly recommend specifying an **overpayment** algorithm that causes overpayments to be segregated onto an "excess credit / overpayment" SA. Refer to [Overpayments](#) for more information.

Overpayment SA Type Setup

Specify a **bill completion** algorithm that causes the credit amount on overpayment SAs to be transferred to newly create debt (created when the bill is created). This algorithm transfers an overpayment SA's balance to regular SAs and creates a match event if the overpayment covers the entire bill. Refer to [Overpayments](#) for more information.

Installation Record Setup

Specify an **automatic payment** algorithm that causes a match event to be created when automatic payments are created for open-item accounts. The base package algorithm will do this for you if you specify the appropriate parameter on the algorithm. Refer to APAY-CREATE for more information about this algorithm.

If you want a Control Central alert to highlight when the current account has any open match events, plug in the appropriate **control central alert** algorithm on your installation record. Refer to C1-OPN-MEVT for more information about this algorithm.

If you want to enable manual pay segment distribution for open item accounts, along with other functions, you will need to plug in an installation algorithm for bill balance calculation. Refer to C1-OI-BI-AMT for more information about this algorithm.

To Do Entry Setup

Two To Do types are supplied with the base package:

- **TD-MODTL**. This To Do type highlights the presence of open, disputed match events.
- **TD-MONTL**. This To Do type highlights the presence of open, non-disputed match events.

Each of the above To Do types should be configured with the roles that work on entries of each type.

In addition, the account management group and/or divisions from which the default roles are extracted should be updated to define the role that should be defaulted for each of the above To Do types.

FASTPATH:

Refer to [The Big Picture Of To Do Lists](#) for more information about To Do lists.

Setting Up Match Types

Most payments are distributed amongst service agreements using the payment distribution algorithm specified on the payment's account's customer class. This algorithm decides how to distribute a payment amongst an account's existing debt if the customer doesn't specify how the payment should be distributed.

A customer can specify how a payment is distributed by specifying a match type and match value on their payments. Consider the following examples:

- Customers that are subject to open-item accounting (this is defined on the account's customer class) tell the system exactly which debt is covered by their payments. For example, an open-item customer might make a payment in respect of bill ID 123919101919.
- Even non open-item customers can direct payments to specific SAs. For example, the system allows a balance-forward customer's payment to be directed to a specific service agreement (however, they cannot direct payments to specific bills as only open-item customers can do this).

Match types are used to define the specific type of debt that is covered by a payment. The match type contains the algorithm that effectively overrides the standard payment distribution algorithm defined on the account's customer class.

NOTE:

Background information. Please refer to [Payments And Match Events](#) and [Match Type Setup](#) for more information about how match types are used.

To set up match types, select **Admin > Financial > Match Type**.

Description of Page

Enter an easily recognizable **Match Type** and **Description**.

Define the **Pay Dist Override Algorithm** used to distribute payments that reference this match type. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that overrides the normal payment distribution algorithm.

Setting Up Match Event Cancellation Reasons

When a match event is canceled, a cancel reason must be supplied.

NOTE:

Background information. Refer to [How Are Match Events Cancelled?](#) and [Setting Up Match Event Cancellation](#) for more information about cancellation.

To set up match event cancellation reasons, select **Admin > Financial > Match Event Cancel Reason**.

Description of Page

Enter an easily recognizable **Match Event Cancel Reason** and **Description**.

Fund Accounting

The topics in this section provide background information about fund accounting.

NOTE:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization practices fund accounting (this type of accounting is typically performed by municipal utilities). If your organization does not practice fund accounting, you need only indicate such on the [Installation Record](#); no other setup is required.

Fund Accounting Overview

Municipal utilities, and not-for-profit organizations in general, often use a form of accounting different from that used by for-profit corporations. Municipal utilities typically practice fund accounting, whereas corporations practice corporate accounting.

Regulations or other restrictions may require a municipal utility to account for the finances of each of its departments as a separate entity. If a municipal utility provides both water and wastewater service, a municipal utility may need to track the receivables, revenue, and liabilities for water service separately from those of wastewater. In contrast, a corporation is free to co-mingle the moneys of the two services.

To track the services separately, the municipal utility sets up a fund for each department. A fund is an accounting entity with its own self-balancing set of accounts. Each fund has its own "sub general ledger" with its own chart of accounts, and within each fund, its debits equal its credits at all times. This allows the utility to report on the financial state of each fund independently.

In addition to having a fund for each department, there is also a general fund, which is used to handle inter-fund transfers as well as shared accounts.

Fund Accounting Example

Consider a municipal utility which provides water and wastewater service. The utility has two departments: water and wastewater. Each department must track their finances separately therefore a fund is setup for each department:

- Water (fund 01).
- Wastewater (fund 02).

In addition, with fund accounting, there is always a general fund (fund 99).

Assume the following bill is generated.

The bill would produce the following GL entries:

For each fund, the GL details of the bill will include a debit to the accounts receivable (A/R) account and credits to the revenue and taxes payable accounts. In organizational terms, each department is owed a portion of the overall bill by the customer, part of which is sales by the department and part of which is owed to the taxing authorities by the department. Each fund is balanced.

Note that the accounting could be identical under corporate accounting if each service is its own division with its own chart of accounts.

The following diagram illustrates the initial GL accounting that would occur when the payment arrives:

The utility's general cash account is debited, and the departmental funds' A/R accounts are credited. In other words, the cash is held by the utility as a whole but the receivables are reduced for the individual departments.

If the accounting were left in this state, the fund accounting principal - that each fund represents an independent entity with a self-balancing chart of accounts - would be violated. This violation is caused due to the fact that cash is recorded on the general fund, not the departmental funds, causing the general fund to have an excess debit and the departmental funds to have an excess credit.

From an organizational viewpoint, to make each department whole, the departments need to note what portion of the cash they own, and correspondingly, the utility needs to note what portion of the cash is owed to each department. The following diagram illustrates this point.

To maintain a balance of debits and credits within each fund, the departmental funds have an "equity in pooled cash" (EPC) account and the general fund has a liability account for each departmental fund. In addition to debiting the general fund's cash account and crediting the departmental funds' A/R accounts, the departmental funds' EPC accounts are debited and the general funds liability accounts are credited.

And so, with the additional GL entries, all funds have matching debits and credits.

An Example Of A Bill Segment That References Multiple Funds

Consider a municipal utility that primarily supplies water service but is also responsible for maintaining the city's fire hydrants. The costs for fire hydrant maintenance are borne by the water customers and make up just a small portion of the overall bill. These costs are simply added to the water bill as a line item. The utility has two departments:

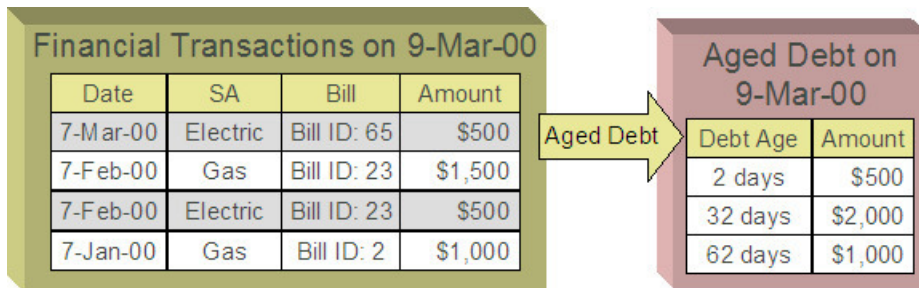

- Water service (fund 01)
- Hydrant maintenance (fund 39).

In addition, there is a general fund (fund 99).

Assume the following bill is generated for water and hydrant services.

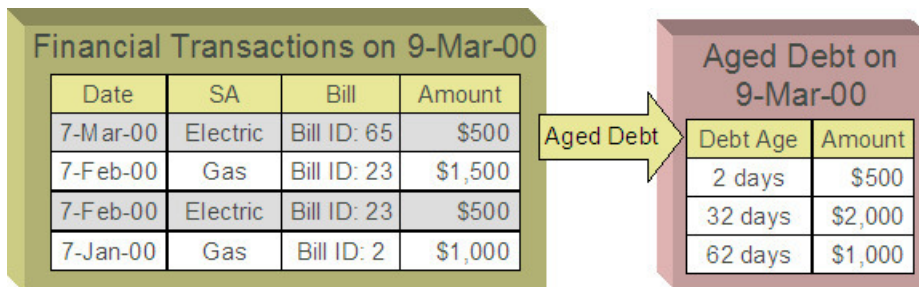

The following diagram illustrates the initial GL entries for the bill:

In accounting for the bill, the water fund's A/R is debited, the water and hydrant funds' revenue accounts are credited, and the water's taxes payable account is credited.

If left at this, the funds would be out of balance; the water fund would have an overall excess debit and the hydrant fund would have an equal excess credit. In organizational terms, the hydrant fund has recorded sales but that amount is recorded as being owed to the water department.

To balance each department, the water department accepts the responsibility for collecting the hydrant charges from the customer but immediately remunerates the charges to the hydrant fund.

This transfer is done using the general fund. The water fund's EPC account is credited and the liability to water is debited with the amount of the hydrant revenue. Also, the hydrant fund's EPC account is debited and the general fund's liability to

hydrant account is credited by the hydrant revenue. In effect, the water department owes the hydrant charges to the general fund, and the general fund owes the hydrant charges to the hydrant fund.

The following diagram illustrates the initial GL accounting that would occur when the payment arrives:

When the payment arrives, the cash is debited to the general fund's cash account, and the water fund's A/R is relieved. Again, the funds would be unbalanced if left in this condition; the water fund would have an excess of credits and the general fund would have an excess of debits.

To maintain each fund's balance of debits and credits, the general fund's liability to the water fund is credited by the amount of the department's share of the cash, and the water fund's EPC is debited. Note that the payment has no effect on hydrant fund's EPC and the general fund's liability to the hydrant fund. The hydrant department "received" its money from the water department when the bill was created.

And so, all funds have matching debits and credits.

Accounting Method Is Defined On The Installation Options

You must turn on a switch on the [Installation Record](#) to enable fund accounting.

Fund Controls Fund-Balancing Entries

There are two levels of debit and credit balancing in fund accounting. There is the balancing required by double entry accounting: the total debits in the entire GL must equal the total credits. This is required regardless of whether fund or corporate accounting is used. The distribution codes for these entries come from varying sources, depending on the type of financial event.

FASTPATH:

Refer to [The Source Of GL Accounts On Financial Transactions](#) for information on the sources of the distribution codes.

The second level of balancing is specific to fund accounting. Within each fund-not just across the GL-the total debits must equal the total credits. The original distribution code from the financial event has a fund specified. For example, a bill would

cause a debit to a fund's A/R distribution code, and included in that A/R distribution code is the fund. It is the definition of the fund that specifies whether fund-balancing entries are required and provides the distribution codes for these entries.

For a departmental fund, the fund-balancing debit and credit would be specified. When a debit is applied to a departmental fund's GL account, an additional account (typically the general fund's liability to the departmental fund) is debited and an account (typically the departmental fund's EPC) is credited. When a credit is applied to a departmental fund's account, an additional account (typically the general fund's liability to the departmental fund) is credited and an account (typically the department's EPC) is debited.

For the general fund, no fund-balancing debits and credits are specified.

Building Fund-Balancing GL Details

Building the GL details for a financial event is a two-step process.

- First, the system generates the regular GL details for a financial transaction (FT). This is done regardless of whether corporate or fund accounting is used.
- Second, if fund accounting is activated (by turning on a switch on the [Installation Record](#)), the system analyzes the distribution code on each GL detail associated with the FT. If a **fund** is specified on a distribution code, the system checks the definition of the fund. If fund-balancing entries are specified on the fund, two additional GL entries are added to the FT:
- An offsetting entry to the Equity in Pooled Cash account is created for the departmental fund (e.g., if the FT is debiting a given fund, an offsetting credit is created in the funds EPC account).
- Another entry to the departments Liability account is created for the general fund.

The result is a consolidated set of GL entries for the FT, incorporating the regular entries as well as the fund-balancing entries.

The topics in this section illustrate the generation of the GL details for the earlier examples.

FTs Whose GL Details All Reference The Same Fund Do Not Impact the General Fund or EPC Accounts

In [Fund Accounting Example](#), where the bill's bill segments reference a single fund, the system creates a fund-balancing GL entry for each GL entry applied to a departmental fund:

- A debit to a departmental GL account triggers a debit to the general fund's liability-to-departmental-fund account and a credit to the departmental fund's equity-in-pending-cash account.
- A credit to a departmental GL account triggers a credit to the general fund's liability-to-departmental-fund account and a debit to the departmental fund's equity-in-cash account.

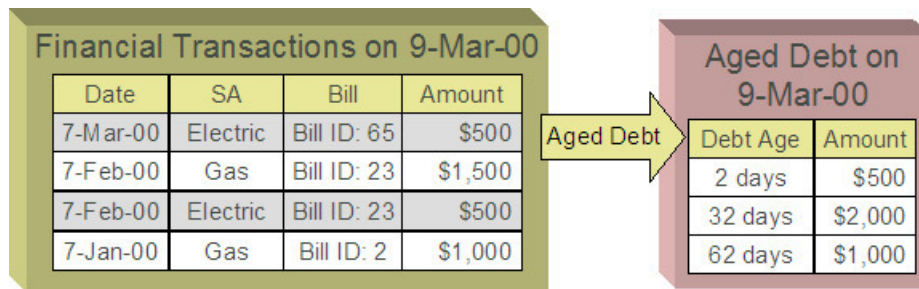

The net effect on the individual equity-in-cash and general fund's liability accounts is zero because the debits and credits net to zero for each GL account. In other words, the yellow boxes net to zero and therefore fund accounting does not impact the bill segment's financial transactions. Refer to [Fund Accounting Example](#) for the resulting consolidated GL entries.

An FT Whose GL Details Reference Multiple Funds

In [An Example Of A Bill Segment That References Multiple Funds](#), where the bill's bill segments reference multiple funds (water and hydrant), the system also creates fund-balancing GL entries for the financial transaction:

- A debit to a departmental GL account triggers a debit to the general fund's liability-to-departmental-fund account and a credit to the departmental fund's equity-in-pending-cash account.
- A credit to a departmental GL account triggers a credit to the general fund's liability-to-departmental-fund account and a debit to the departmental fund's equity-in-cash account.

The net effect of the bill on the GL is that the water fund's EPC has a credit of \$0.80, the hydrant fund's EPC has a debit of \$0.80, the general fund's liability to the water fund has a debit of \$0.80, and the general fund's liability to the hydrant fund has a credit of \$0.80. Note that, overall, the general fund's overall liability to the departmental funds nets to zero. Refer to [An Example Of A Bill Segment That References Multiple Funds](#) for the resulting consolidated GL entries.

Setting Up The System To Enable Fund Accounting

The following section provides an overview of how to enable fund accounting.

Turn On Fund Accounting

On the [Installation Record](#), indicate that fund accounting is Practiced.

Defining Funds

A fund must be setup for each specific fund in your organization. Don't forget to also set up a fund for the general fund. Navigate using **Admin > Financial > Fund**.

Description of Page

Enter a **Fund** and a **Description** to identify the fund.

If this fund is used to balance other funds or to hold cash, indicate a **Fund Type** of General, otherwise indicate that it is Specific.

If the fund type is Specific, specify the **Equity Distribution Code** and **Liability Distribution Code**. These codes are used to balance financial transactions that span funds. The equity distribution code should belong to the same **Fund** as the one you are defining. The liability distribution code should belong to the general fund.

Distribution Codes Must Include Fund ID

All of your distribution codes must include their respective fund ID.

FASTPATH:

For more information, refer to [Setting Up Distribution Codes](#).

Update Your Funds With Their Respective Equity and Liability Distribution Codes

After distribution codes have been setup, you must update your funds to indicate the equity and liability accounts used to balance inter-fund financial transactions.

Bill Taxation Threshold

Some implementations only apply taxes if the accumulated tax amount at the bill level exceeds some specified threshold amount.

Taxation Threshold Examples

The following examples show how taxation thresholds affect a customer's bill. In the examples a tax rate of 5% and a threshold amount of \$21.30 is used.

Example 1 - Account With Taxes Under Threshold

This example shows the bill for an account where the accumulated tax amount is less than the threshold amount. Since the accumulated tax amount of \$10.50 is less than the threshold amount, taxes are not applicable and the account's bill should be adjusted to exclude the tax amount of \$10.50.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ \$0.10	200.00
Tax @ 5% on \$210.00	10.50
Total	220.50
Adjusted Total	210.00

Example 2 - Account With Taxes Above Threshold

This example shows the bill for an account where the accumulated tax amount is greater than the threshold amount. Since the accumulated tax amount of \$27.92 is greater than the threshold amount, taxes are applicable and the account should be billed for the total amount.

Bill Line	Amount
Standing Charge	10.00
4,000 units @ \$0.10	400.00
Additional Charge	148.45
Tax @ 5% on \$558.45	27.92
Total	586.37

Example 3 - Account With Rounding Discrepancy

This example shows the resulting bill segment calc lines for an account with 3 service agreements. Here the accumulated tax amount at the bill level is \$21.29 with taxes calculated and rounded for each SA's bill segment. However, if the same taxes were calculated for each SA's bill segment and then accumulated and rounded at the bill level, the accumulated tax amount would be \$21.30 implying that taxes are applicable and the account should be billed for the tax amount of \$21.30 accounting for the discrepancy of \$0.01.

Bill Segment	Bill Line	Amount	Pre-rounding Amount
Bill segment for SA 1	964.70 units @ \$0.10	96.47	96.47000
	Tax @ 5% on \$96.70	4.82	4.82350
	Bill Segment Total	101.29	
Bill segment for SA 2	2222.90 units @ \$0.10	222.29	222.29000
	Tax @ 5% on \$222.29	11.11	11.11450
	Bill Segment Total	233.40	
Bill segment for SA 3	1072.40 units @ \$0.10	107.24	107.24000
	Tax @ 5% on \$107.24	5.36	5.36200
	Tax Discrepancy	0.01	
	Bill Segment Total	112.61	

NOTE:

Pre-rounding amount. Rate application captures two calculated amounts on the resulting bill segment calc lines. The first is the calculated amount rounded to two decimal places, and the second is a raw calculated amount with a five decimal precision. The base package algorithm that calculates taxation thresholds uses both amounts to account for any rounding discrepancy; however, only the raw calculated amount is used to compare against the taxation threshold.

Billing and Taxation Thresholds

The following sections describe how taxation threshold rules are implemented when a bill is produced.

Calculation of Taxation Thresholds

When taxation thresholds are applied at the account's bill level, it means that the system must calculate taxes for each of the account's service agreements, then sum these tax amounts and apply any applicable rounding rules. This accumulated tax amount is compared to a threshold amount and if the accumulated tax amount is less than the threshold amount, then taxes should not be applied to the customer's bill. To ensure the accumulated tax amount is accurate, all service agreements for an account whose tax amounts should be taken into consideration when comparing to the specified threshold should be billed together and the threshold comparison should take place after the bill segments have been generated. In addition, all bill segments whose tax amounts should be taken into consideration when comparing to the specified threshold must be for the same bill period.

NOTE:

Bill segments from different periods may not appear on the same bill. If a bill segment is canceled, all bill segments associated with that bill must be canceled and re-billed together. You cannot re-bill the bill segment on a bill for a different period.

An algorithm type is supplied with the base package that checks for taxation thresholds at bill completion time. The base bill completion algorithm type accumulates identified tax calc line amounts (accomplished using a bill segment calc line characteristic), and compares this to a specified threshold amount to determine if taxes apply for the account. If taxes do not apply, it sets a bill characteristic indicating this and regenerates the bill segment. Refer to the C1-CPBC-TAXT algorithm type for more information on how this type of algorithm operates.

NOTE:

Calculated adjustments are included in the evaluation against taxation thresholds. Adjustments that use a rate to calculate the adjustment amount may be included in the taxation threshold evaluation if their rate's components are set up to do so. The base algorithm C1-CPBC-TAXT looks at adjustments that are about to be swept onto the bill and, if applicable, includes them in the calculation.

The calculation rule(s) that calculate taxes make use of calculation rule eligibility criteria to ensure that taxes are only computed if the bill does not have the characteristic indicating that taxes are not applicable. Note that during the initial generation of each bill segment, the characteristic will not exist and taxes will be applied. This means that if you look at a bill before it is complete, taxes may not be accurately reflected.

Tax Amount Discrepancies

Since tax calculation rules are calculated and rounded at the bill segment level, it's possible that rounding discrepancies may occur if rounding of these tax amounts occurs at the bill level instead as illustrated in the example above. To account for this, the system uses both the two decimal precision and the five decimal precision calculated amounts that rate application captures on bill segment calc lines; however, only the raw calculated amount is used to compare against the taxation threshold. If there is a discrepancy in the tax amount (as shown in example 3 above), the system captures this amount as an entry in one of the bill segment's SQ collections prior to regenerating the bill segments. This is depicted in example 3 above where the tax discrepancy SQ resulted in an additional bill segment calc line on one of the bill segments for the rounding amount of 0.01. Note that a calculation rule is configured to bill for this discrepancy amount SQI.

NOTE:

Pre-rounding amount. Rate application captures two calculated amounts on the resulting bill segment calc lines. The first is the calculated amount rounded to two decimal places, and the second is a raw calculated amount with a five decimal precision. The base package algorithm that calculates taxation thresholds uses both amounts to account for any rounding discrepancy; however, only the raw calculated amount is used to compare against the taxation threshold.

Setting Up The System For Bill Taxation Thresholds

This section provides an overview of how to configure the system to calculate taxes at the account's bill level.

Installation Option

Select Freeze at Bill Completion as the bill segment freeze option. The system compares tax amounts calculated to a specified threshold amount and based on this determines if taxes should apply at bill completion time. If taxes should not be applied for the account, the system has to regenerate the bill segments as necessary.

Adjustment Types

Select Freeze at Bill Completion as the adjustment freeze option. The system compares tax amounts calculated to a specified threshold amount and based on this determines if taxes should apply at bill completion time. If taxes should not be applied for the account, the system has to regenerate the adjustments as necessary.

Bill Factors

Tax Threshold. Set up a separate bill factor for each distinct tax threshold amount.

Characteristic Type

Set up a characteristic type and value to identify the tax calculation rules and bill segment calculation lines that the system will use to compare to the specified threshold amount. Specify this characteristic type and value as parameters to the algorithms that apply the taxation threshold. This characteristic type and value must also be specified on each of your tax calculation rules that should be included in the threshold comparison.

Set up a characteristic type and value to use for the bill characteristic that indicates when bill level taxes apply. Specify this characteristic type and value as parameters to the algorithms that apply the taxation threshold.

Service Quantity Identifiers

Optional service quantity identifiers may be configured to capture the following:

- **Tax Amount.** The system compares the accumulated bill's tax amount to the specified threshold amount to determine if taxes are applicable. If taxes should not be applied for the account, the system regenerates the bill segments as necessary. If you wish to capture the tax amount computed for informational purposes, then a tax amount SQI should be set up and specified as a parameter on the algorithms that apply the taxation threshold.

- **Tax Discrepancy Amount.** Since tax calculation rules are calculated and rounded at the bill segment level, it's possible that rounding discrepancies may occur if rounding of these tax amounts should take place at the bill level. If you wish to account for these rounding discrepancies, then a tax discrepancy amount SQI should be set up and specified as a parameter on the algorithms that apply the taxation threshold. Your rates should also be configured to cater for this rounding discrepancy. The system adds an entry for the discrepancy amount to one of the bill segment's SQ collections prior to regenerating the bill segments.

Algorithms

Apply Taxation Threshold. Define an algorithm for each distinct tax threshold amount. Plug the algorithm(s) in on the appropriate customer class for the Pre Bill Completion system event. Refer to the C1-CPBC-TAXT algorithm type for more information about the base package algorithm.

Adjustment Generation - Apply Rate. Define an algorithm for each rate to be used by calculated adjustment types that are to be included in the tax threshold evaluation. Plug the algorithm(s) in on the appropriate adjustment type for the Generate Adjustment system event. Refer to the ADJG-RT algorithm type for more information about the base package algorithm.

Calculation Rules For Bill Taxation Thresholds

Your calculation rules that bill for taxes require the following:

- A characteristic that identifies them as calculation rules to include in taxation threshold comparisons
- Calculation rule eligibility criteria to ensure that taxes are not calculated if the taxation threshold algorithm dictates this

Only one eligibility group on the calculation rule is required. It would look as follows:

Group No.	Group Description	If Group is True	If Group is False
1	Tax applies if total accumulated tax amount at the account's bill level exceeds the threshold amount	Apply calculation rule	Skip calculation rule

The following criteria will be required for this group:

Seq	Field to Compare	Comparison Method	If True	If False	If Insufficient Data
10	Bill characteristic: Characteristic type = Tax Not Applicable indicator	= YES	Group is false	Check next condition	Group is true
20	Characteristic Collection: Characteristic type = Tax Not Applicable	= YES	Group is false	Group is true	Group is true

NOTE:

The second criterion included above is used to evaluate the applicability of the tax on calculated adjustments. Since these adjustments are not yet linked to the bill, the first criterion cannot be used to evaluate the applicability of the tax threshold. The pre-bill completion algorithm C1-CPBC-TAXT instead adds the characteristic to the characteristic

collection for use by the rate application when evaluating the adjustment's rate's eligibility rules. Refer to the ADJG-RT algorithm type for more information about the base package algorithm.

FASTPATH:

For more information, refer to [Designing Calculation Groups and Rules](#).

An additional calculation rule is required to bill for the tax rounding discrepancy as follows

- Calculation Rule type = Service Quantity
- UOM/TOU/SQI = the identifier of the service quantity containing the tax discrepancy amount
- Value Type = Unit Rate
- Value Source = Value
- Value = 1

Other Financial Transaction Topics

Various topics about financial transactions are discussed in this section.

The Source Of GL Accounts On Financial Transactions

The following table lists the major financial events, their standard accounting, and the source of distribution codes used to derive the GL accounts sent to your general ledger.

Financial event	GL Accounting	Source Of Distribution Code
Create a normal utility bill segment. Bill Segment FT Algorithm is Payoff Amt = Bill Amt / Current Amt = Amt Due	Debit: A/R	SA Type
	Credit: Revenue / Taxes Payable	Calculation Rule
Create a bill for company usage. Bill Segment FT Algorithm is Payoff Amt = 0 / Current Amt = 0	Debit: Company Usage Expense	SA Type
	Credit: Revenue / Taxes Payable	Calculation Rule
Create a bill for charity. Bill Segment FT Algorithm is Payoff Amt=0 / Current Amt = Bill Amt	N/A - charity bills have no effect in the GL	N/A
	N/A	N/A
Create a payment segment for a normal utility service agreement	Debit: Cash	Bank Account on the Tender Source of the Tender Control for the Payment Segment's Tender.
	Credit: A/R	SA Type
Create a payment segment for a charitable contribution service agreement	Debit: Cash	Bank Account on the Tender Source of the Tender Control for the Payment Segment's Tender.

	Credit: Charity Payable	SA Type
Create a payment segment for auto-pay at bill completion time	Debit: Cash	Bank Account on the Tender Source on the Auto-pay Route Type of the Auto-pay Source.
	Credit: A/R	SA Type
Canceling a payment	Debit: A/R	SA Type
	Credit: Cash	Bank Account specified by the user on the cancel tender page. Note that this defaults to the original tender's bank account.
Create an adjustment to levy a charge	Debit: A/R	SA Type
	Credit: Revenue	Adjustment Type

The bottom line is as follows:

- If a bill segment has a financial effect, the distribution code to debit comes from the distribution code on the SA Type, the distribution code to credit comes from the calculation rule(s) used to calculate the bill segment.
- Payment segments always have a financial effect; the distribution code to debit comes from the bank account on the tender source of the tender control of the tender, the distribution code to credit comes from the SA type.
- If an adjustment has a financial effect, the distribution code to debit and credit comes from the SA type and adjustment type. If the adjustment is positive (i.e., the customer owes your organization more money), the distribution code to debit comes from the SA type; the distribution code to credit comes from the adjustment type. Vice versa if the adjustment is negative.

Defining Customer Options

The definition of a customer is someone (or something) with financial obligations with your company. These obligations ensue because the customer has agreed to purchase goods or services at an agreed price.

You may be surprised to learn that there is no "customer" record in the system. Rather, the system subdivides customer information into the following records:

- **Person.** The person record holds demographic information about your customers and every other individual or business with which your company has contact. For example, in addition to customers, person records also exist for landlords, contractors, accountants at corporate customers, guarantors of customers, energy distributors, collection agencies, etc.
- **Account.** Accounts are the entities for which bills are produced and therefore you must create at least one account for every person who has financial obligations with your company. The account record contains information that controls when the bills are created and how the bills are formatted.
- **Service Agreement.** Think of a service agreement as a contract between your company and the customer. The service agreement contains the terms and conditions controlling how the bill details are created. Every account will have at least one service agreement (otherwise, nothing will appear on the account's bills).

Before you can define persons, accounts, and service agreements, you must set up the control tables defined in this section.

FASTPATH:

For more information about how persons, accounts and premises are used by your customer service reps, refer to [Understanding The "V"](#).

NOTE:

The tables in this section are only some of many tables that must be set up before you can bill your customers for the service(s) they consume. In this section, we limit the discussion to those tables that control basic demographic

and financial information. In later sections, we describe the tables that control other billing-related functions like bill creation algorithms, meter reading and rates. It is only after all of these tables are set up that you will be able to generate bills and record payments.

Customer Overview

This section describes how the person, account, and service agreement records are used to record your customers' demographic and billing options.

A Simple Example Of Two Customers

The following picture illustrates two customers: Joe Smith and Pam Jones. Joe is the "main customer" on the first account. Pam is the "main customer" on the second account. Pam is also the "third party guarantor" on Joe's account.

A Simple Example Of Two Customers

Persons

Person records hold demographic information about the individuals and businesses with whom your organization communicates. Demographic information includes phone number(s), names and aliases, identification numbers, life support equipment needs, employment information, etc.

In the above example, 2 person records would be needed; one for Pam Jones and another for Joe Smith.

A new person is added when you first have contact with a person; the person does not have to be a customer before it is added. So, for example, if your company is starting a new marketing campaign, you can add information about potential customers the moment they are identified.

NOTE:

Businesses are persons too. In addition to humans, you use person records to maintain basic information about the businesses with which your organization has contact.

FASTPATH:

For a description of the control tables that must be set up before you can define a person, refer to [Setting Up Person Options](#).

Accounts

An account is analogous to an account at a bank:

- A person or business with no financial dealings with a bank will have no account (but the bank may choose to keep demographic information about the person as part of their marketing efforts). The exact analogy exists in this system.
- Individuals with financial dealings with a bank will have one or more accounts. The number of accounts is up to the customer. The exact analogy exists in this system.

A simple way to determine the number of accounts a customer will have is to ask "how many bills do they want each period?" because a customer receives one bill for each account. For example:

- A residential customer who also owns a small business may choose to receive two bills each month; one for the residence, the other for the business. This way, the charges for their business would be segregated from their personal charges. This customer would have two accounts.
- A conglomerate that owns several factories may want their transportation gas charges to appear on a single bill rather than have a separate bill for each factory. This customer would have a single account.

Account ID Is Non-Intelligent

The unique number of an account is referred to as the "account ID". You are probably very comfortable with this concept. You may, however, have difficulty dealing with the fact that the account id in this system has no intelligence built into it (e.g., many systems include the bill cycle and geographic location in the account id). In this system, the account ID is a random, system-assigned value.

Because the account ID contains no meaning, it can remain with a customer for life, regardless of where they live, when they are billed, the type of service they receive, etc. This is important because it means that all of the financial history linked to the account remains with the customer for life.

NOTE:

The non-intelligence of the account ID is also important from the perspective of the parallel processing that takes place when the system creates bills. Because the collection of accounts to be billed in any given bill cycle will be randomly

distributed through the number spectrum, the system can distribute account number ranges to parallel threads and each thread will process roughly the same number of accounts.

Account / Person Cross-Reference

A person may be linked to zero or more accounts. A person won't be linked to an account when they have no financial relationship with your organization. A person will be linked to multiple accounts when they have financial relationships with more than one account.

An account must reference at least one person (i.e., the main customer), but may reference an unlimited number of individuals. Multiple persons are linked to an account when several parties have some type of financial relationship with the account (e.g., third party guarantors, account contact, bill copy recipients, etc.).

When Is An Account Created?

A person can exist without an account until such time as the person formally requests the commencement of service. The moment the customer requests service, an account must be created (and the person must be linked to the account).

When Is An Account Expired?

Accounts never expire. Once a customer has an account, the account remains in the system forever. Linked to the account are service agreements that define the price and conditions of a service supplied to the customer. When an account has active service agreements, the system produces bills for it. If the account doesn't have active service agreements, the system will not produce a bill for it. You can think of an account without active service agreements as being "dormant", waiting for the day when the customer again starts service. If the customer never restarts, the account (along with its financial history) remains dormant forever.

Service Agreements

A service agreement is a contract (either formal or implied) between your organization and a customer. Every service agreement contains the price and conditions of a service supplied to a customer.

A service agreement is linked to an account. There is no limit to the number of service agreements that may be linked to an account.

When Is A Service Agreement Created?

A service agreement is created when the customer requests service (not when service commences). Typically, service agreements are created in the pending state and field activities are generated to connect service. When the field activities are complete, the service agreement becomes active and the billing process starts generating bill segments for the service agreement.

FASTPATH:

For more information about starting service, refer to [The Big Picture Of Starting Service](#). For more information about bill segments, refer to [Bill Details](#).

Financial Transactions Are Linked To Service Agreements

FASTPATH:

For more information about how financial transactions are linked to service agreements, refer to [The Financial Big Picture](#).

When Is A Service Agreement Expired?

A service agreement is expired when the customer requests service be stopped. At that time, the service agreement is transitioned to the pending stop state and field activities are generated to stop service (these activities might involve simply reading the meter or they could involve disconnecting or removing the meter). When the field activities are complete, the system transitions the service agreement to the stopped state and the billing process generates a final bill for the service agreement. When the customer pays the final bill, the system transitions the service agreement to the closed state

FASTPATH:

For more information about stopping service, refer to [The Big Picture Of Stopping Service](#).

Setting Up Person Options

This section describes tables that must be set up before you can define persons.

Person Identifiers

This section describes the setup and use of person identifiers.

Setting Up Person Identifier Types

When you set up a person, you may define the various types of identification associated with the person, e.g., their driver's license number, their tax identity, etc. Every piece of identification associated with a person has an identification type.

NOTE:

How are person identifiers used? The reason why identifiers are defined on a person is so that users can look for a customer using one of their person identifiers (see [Control Central - Search Facilities](#) for more information). In addition, person identifiers help prevent duplicate persons from being added to the database. The base product provides an algorithm type C1-PERSONVAL that can issue a warning or error to a user before they add a new person or update an existing person when another person exists with the same identifier. This is a BO validation algorithm on the person MO's identifying BO.

Person identifier types are optional. An [installation option](#) controls whether at least one identifier type is required on every person.

You can access the portal from **Admin > Customer > Person Identifier Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Understanding Person Identifiers

Person Identifiers have many uses in the system. Their main use is to help uniquely identify persons and businesses. Another use is to store other non-uniquely identifying attributes about a person that are better suited to identifiers than they are to person contacts or characteristic. An example is a customer provided password or PIN that is verified before account details are provided.

The installation record defines if and when at least one person identifier is required on persons and businesses. Identifiers can be required when the record is created (always), when linked to an account, when linked to an account as financially responsible, or when linked to an account as the main customer. The system enforces these rules when a person is added or maintained or when persons linked to accounts are maintained. The installation record also defines the default identifier types for person and business records.

When a person identifier is required, the person identifier collection requires that one and only one record is marked as the primary identifier. Identifier types indicate if they can serve as the primary ID and also if they are validated for duplicates. Typically only ID types that should have unique values are configured to validate or duplicates.

Identifier types can be setup to indicate a format such as prefix, delimiter, and value. For example, an identifier for passport can indicate that the country code is the prefix followed by a dash then the passport number. A validation algorithm is provided to ensure all entered data conforms to this format.

Most organizations prefer that the primary identifier is uniquely identifying or a high-quality ID. However, it is not always possible to obtain such an identifier from all customers. The following are two common ways this is handled:

- An identifier type, such as a PIN, is configured and allowed to be the primary identifier, even if it considered a lesser quality or non-uniquely identifying identifier. These types should not be configured to validate for duplicates as their values are not uniquely identifying.
- The desired identifier is used, but a value such as all zeros or all nines is entered, indicating that the customer did not provide the value. In this scenario, the system cannot distinguish between an entry with a quality value and an entry with all zeros since the same ID type is used.

NOTE: Note: the customer service request-based start service process has configuration that allows your organization to differentiate between identifier types that can be primary and those that represent a high-quality ID. Refer to [Verifying Identity, Checking Credit and Requiring Deposits](#) for more information on how the start service process uses person identifiers.

Setting Up Contact Routings

Base values for Contact Routing are supplied. You can add your specific contact routings using the **Contact Routing** extendable lookup. You can add more contact routings, but the ones supplied with the system cannot be edited or deleted.

NOTE: Person contacts that reference the CSS routing type cannot be added by a user, and are not permitted to be edited or deleted. As well, records with this contact routing are only visible in the Person - Main page and are not displayed in the Account Portal or other places in the system.

Refer to [Defining Extendable Lookups](#) and for more information on lookups.

If your implementation is using notification preferences, you may need to set up delivery types before setting up contact routings. Refer to [Setting Up Delivery Types](#) for more information.

Setting Up Person Contact Status

Person contacts can have a status; for example, the status of an email contact could be pending, verified, or bounced. The product is delivered with statuses that are used in conjunction with opt-in functionality. When new person contacts are added, the initial status can be defaulted from the person contact type. See [The Person Contact Status Can Be Controlled By A Process](#), [System Person Contact Statuses](#) and [Opt-in Process](#) sections for more information.

Your implementation may choose to introduce other logic to update the status. See [The Person Contact Status Can Be Controlled By A Process](#) for more information. You can add your specific person contact statuses by updating the value for the CND_VERIF_STATUS_FLG lookup field.

When new person contacts are added, the initial status can be defaulted from the person contact type. Refer to the Person Contact zone's help text for more information.

Setting Up Person Contact Type Algorithms

Format Validation

Person contact information can be subject to format validation such as ensuring a phone number is entered in a particular format.

The base product provides the algorithms C1-VALEMFMT (Validate Email Format), C1-VALPHFMT (Validate Phone Format), and C1-VALANYFMT (Any Format Valid), which your implementation may use (and if so, no further configuration is needed). If your implementation's business rules require additional format validation algorithms, you may introduce your own.

NOTE: These algorithms confirm that a specific format exists and do not reformat or apply formatting to the corresponding field; for example, the *C1-VALEMFMT* (Validate Email Format) algorithm confirms that the email address contains required features (such as an @ symbol and domain). It will not, however, insert these features.

If your implementation's business rules require additional format validation algorithms, you may introduce your own.

Setting Up Person Contact Types

Person contact types define the format for entering person contacts and information about the person contact.

To set up contact types, select **Admin > Customer > Person Contact Type > Add**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Choosing to Use Person Contact or Person Phone

Person contact is an updated and more configurable alternative to person phone and email. In this release, a feature is introduced that some system processes use to determine if person contact or person phone and email is being used. Person phone and email are referred to as legacy behavior. Legacy behavior is enabled when the Legacy Person Phone and Email **Option Type** on the Customer Information Options is set to Y. When set to N or not set legacy behavior is not enabled.

If your implementation uses functionality that has not been updated to use the feature, such as campaigns and order, you may wish to enable legacy behavior and continue to use person phone and email. It is important to note that Person Contacts are required for notifications.

The following system processes have been updated to alter functionality based on whether legacy behavior is enabled or not.

System Process	Behavior When Feature is Not Set	Behavior When Feature is Set
Person	The Person Phone Grid and the Person Email field are not shown	The Person Phone Grid and the Person Email field are shown. Person Contact is always shown.
Person	The functionality to maintain person contacts from person phone is not triggered even when a person contact type is associated with a phone type.	The functionality to maintain person contacts from person phone is enabled.
Account/ Person	When an email or fax bill or quote route type is chosen, then information displayed is related to person contacts.	When an email or fax bill or quote route type is chosen, then information displayed is related to person phone or email.
Start/Stop	The Person Contact collection is shown and can be edited.	The Person Phone collection and Person Email are shown and can be edited.
Case	The Preferred Contact Methods associated with legacy person phone and email are not shown.	The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available.
Customer Contact	The Preferred Contact Methods associated with legacy person phone and email are not shown.	The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available.

Person Contact Status Can Be Controlled By A Process

Overview

Person contact types can be configured to allow a status. For some person contact types, your implementation may want to control the status through a process instead of allowing the status to be set manually. An example of this is using person contact status to capture opting in for receiving text messages, which is required in some jurisdictions. Opt-in is seeking permission from a customer to use a person contact for a purpose such as sending a customer text messages.

Opt-in works in conjunction with the functionality to enable opt-in for a delivery type. Each can function independently, but together they offer a complete solution. Since they can function apart from each other, each is described independently. See [Enabling Opt-in for a Delivery Type](#) for more detail on this logic.

To control a person contact status with a process, the person contact type must first be configured to allow status. The person contact type must then be set up in the opt-in section of the [Notification Preferencesmaster configuration](#). By defining a Status Script, the person contact status can only be changed by the logic contained in or initiated from the script. The product is delivered with a script that creates an opt-in service task. This is designed specifically to support opting in to receiving notifications via text messages (SMS).

Opt-In Process

To use the delivered functionality, configure a new service task type for opt-in. This task type should reference the Notification Preference Opt-In Task Type Business Object (C1-NotifPrefOptInTaskType). The product is delivered with a service task business object The service task is responsible for initiating an opt-in request, updating the person contact status, and logging the user response. An inbound web service receives responses and transitions the service task. These components are designed to integrate with Notification Center. When a customer is sent an opt-in request, they are asked to confirm. The content of the message explains the commands to the user. Examples are CONFIRM or STOP. Notification Center is configured to interpret the specific commands and map them to those expected by the inbound service, which transitions the service task appropriately.

Aside from the initial opt-in request, users can stop or unsubscribe from notifications at any time. The delivered solution supports two modes for this functionality: unsubscribing from all notifications for a particular person contact or unsubscribing from a specific notification type for a particular person contact. This is controlled through configuration, and relies on the external system such as Notification Center to determine the notification type.

The [Notification Preferencesmaster configuration](#) help text contains detailed information about the configuration required to control person contact status and setting up opt-in processes.

It is important to note that while the delivered process to control person contact status was designed to work in conjunction with the opt-in process, your implementation can design a custom process that can create a service task or do something

completely different. Also, it can be independent of opt-in and notifications. For example, the process can be used to verify that an email address is valid by sending the customer a verification request.

There is another concept, which is enabling opt-in for a delivery type. This is closely related to the functionality described here, but has different implications in the system. See [Enabling Opt-in for a Delivery Type](#) for more information.

There is a limitation worth noting. A person contact type may be set up to allow multiple delivery types, however the delivered solution only allows a single delivery type to be associated with the process used to automate person contact status. Without this limitation, different processes would be responsible for updating a single person contact status and those updates could be conflicting.

The System Person Contact Statuses

The opt-in solution delivered with the product utilizes the three delivered status values. They are: **Pending**, **Approved**, and **Rejected**. Your implementation can add your own person contact statuses, but they will not work with the solution delivered with the product. See [Setting Up Person Contact Status](#).

How the System Automates Person Contact Status

There are many ways that the process that controls person contact status can be invoked. For all of these, the person contact type must be set up in the **Notification Preferences** master configuration to have its status controlled by a process and, unless noted otherwise, the person contact is not already *Approved*.

- The primary way to initiate the process to control person contact status is when a person contact is used to add a contact preference and the contact preference's delivery type matches the delivery type associated with the person contact type as defined in the Notification Preferences master configuration. This method relies on enabling opt-in for a delivery type. This is how the two processes work with each other. See [Enabling Opt-in for a Delivery Type](#) for more information. An example of this scenario is that a person contact exists and is of a type that can receive text messages, such as "Mobile Phone". Until the person contact is used on a contact preference to receive a notification, there is no reason to initiate an opt-in process.
- This process can be automatically initiated by configuring a person contact to default to an initial status of *Pending*. When a person contact is added, the process is initiated. An example of this scenario is an email person contact initiating a process to verify the email address as soon as it is added to the system.
- When the value of an approved person contact is changed, the process is reinitiated. For example, even though the approval is attached to a specific person contact in the system, which has a unique ID, externally the approval was for a particular phone number or email address. When the person contact value (i.e. the phone number or email address) is changed, the prior approval is no longer valid. The person contact status is changed to *Pending*.

A user can manually initiate the process. A button is provided on the Person Contact row on Person - Main. The button can be used to reinitiate the process when the customer does not have the request and needs it resent. It can also be used to manually initiate the process upfront - before the person contact is used on a contact preference.

Maintaining Person Contact via Person Phone

Person phone is referenced extensively throughout the system. All system processes have been updated to determine if phone data and email data is being maintained on person contacts or being maintained on person phone and email. See [Choosing to Use Person Contact or Person Phone](#) for more information.

To keep person contacts records in sync with a person phone, you should consider which phone types should be stored as contacts, configure the person contact type corresponding to each phone type, and update the person contact type to reference the corresponding phone type. Many phone types may be associated with a single person contact type, but a single phone type may only be associated with one person contact type.

The base product provides a batch process C1-INPUS (Create Person Contact from Person Phone/Email) that creates a person contact for all person phone records whose phone type is associated with a person contact type. The batch process can also create person contact records for the email address on the person. You would run this process to create person

contact records if you already have phone or email data for persons, and you wanted to start leveraging person contact as the repository for phone and email information. See the batch process description for more information.

NOTE:

There is a primary switch on person contact records; one person contact for each unique contact routing must be set as the primary contact. When the batch process creates person contacts from person phone data, the first person contact added for each unique contact routing is set as primary. This can be controlled to some extent by your implementation by associating phone types with person contact types sequentially and running the batch process multiple times. For example, you may prefer that a home phone be the primary over a cell phone if both exist. To ensure this happens, associate the home phone with a person contact type and run the batch process. Then associate the cell phone with a person contact type and run the batch process again. This will force all home phone records to be processed first. It is recommended that regardless of how many times the batch processes run, they are run back to back. This should be thought of as a conversion of data and should be treated as such.

When a phone type is associated with a person contact type the following occurs:

- When a phone record is added, a corresponding person contact is added if one does not already exist.
- When a phone record is updated, corresponding updates are made to the person contact.
- When a phone record is deleted, the system tries to delete the corresponding person contact. All business rules for person contacts are enforced. If the person contact is associated with a contact preference, the person contact cannot be deleted, and in turn the phone record cannot be deleted.
- Person contacts associated with phone types cannot be deleted directly. The delete function is disabled.
- Contact information on person contacts associated with phone types cannot be updated directly. The contact information and extension are disabled.
- Person contacts whose person contact type is associated with a phone type cannot be added from the account contact information zone in the account portal. These need to be added through person phone.

There is no direct association between a person phone record and person contact (i.e. there are no foreign keys on either record pointing to the other). The system uses the association between phone type and person contact type and the specific phone number in order to find the associated person contact.

Your implementation may decide to use person contacts to store phone data and not associate them with phone types. Functionality related to the system use of person phone will not be available such as updating a phone number through an order.

If your implementation associates phone types with person contact types and wishes to remove this association, it is best to remove all phone types from all person contact types.

WARNING: Making changes to the association of phone type to person contact type can have serious implications for your data. Changing the person contact type associated to a phone type will likely result in difficulty maintaining both person phone and person contact data.

Setting Up Statement Construct Options

This section describes tables that must be set up before a statement construct can be set up for a person to begin receiving financial statements.

FASTPATH:

For more information, refer to [The Big Picture of Complex Statements](#).

Setting Up Statement Route Types

Statement route types define the method used to route statements to persons. To define a statement route type, open **Admin** > **Billing** > **Statement Route Type**.

Description of Page

Enter a unique **Statement Route Type**, **Description** and **Statement Routing Method** for every statement route type.

NOTE:

The values for Statement Routing Method are customizable using the Lookup table. This field name is STM_RTG_METH_FLG.

The next two fields control how statements that are routed using this route type are printed (both in batch and online). Refer to [Technical Implementation Of Batch Statement Production](#) for more information about producing statements in batch. Refer to [Technical Implementation Of Online Statement Production](#) for more information about online statement production.

- Use **Batch Control** to define the process that creates the flat file that is passed to your statement printing software. If you use an **Extract Algorithm** to construct the downloaded information, you can use the STMDWLD process.
- Use **Extract Algorithm** to define the plug-in component that constructs the "flat file records" that contain the information to be merged onto statements routed using this route type. This algorithm is called when a user requests an online image of a statement on [Statement - Main](#) and it may also be called by the batch statement extraction process defined above.

Setting Up Account Options

This section describes tables that must be set up before an account can receive a bill.

Setting Up Account Management Groups

Users are informed that something requires their attention by entries that appear in To Do lists. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error - meter read cannot be found.
- This error bill segment, in turn, triggers the creation of a To Do entry.
- The To Do entry is addressed to a role. A role is one or more users who can "action" the To Do entry.
- When a user views their To Do entries, they see all entries addressed to all roles of which they are part.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and a given To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to [Assigning A To Do Role](#) for more information..

NOTE:

Account management groups are optional. You need only set up account management groups (and link them to accounts) if you wish to address specific To Do entries associated with specific accounts to specific roles.

Account management groups are defined using **Admin > Customer > Account Management Group > Add**.

Description of Page

Enter an easily recognizable **Account Management Group** code and **Description** for each account management group. Use the grid to define the **To Do Role** to be assigned to entries of a given **To Do Type** that are associated with accounts that reference the **Account Management Group**.

NOTE:

Only To Do entries that are account-oriented take advantage of the roles defined for an account management group (because only accounts reference an account management group).

Setting Up Account Relationship Codes

When you link a person to an account, you must define in what way the person is related to the account by using an account relationship code. These codes are defined using **Admin > General > Account Relationship Type**.

Description of Page

Enter an easily recognizable **Relationship Type** and **Description** for each relationship type.

Setting Up Alert Types

Account based alerts that appear in control central have an **AlertType**. To define valid alert types, navigate to **Admin > Customer > Alert Type**.

Description of Page

Enter an easily recognizable **Alert Type Code** and **Description** for each alert type. Specify the **Alert Days** to indicate the amount of time that alerts of this type will be effective by default. Specify a value of zero to indicate that alerts of this type will be effective indefinitely by default.

Setting Up Bill Messages

There are various informational and warning messages that may appear on an account's bills. Each message is identified with a bill message code. To define a bill message, open **Admin > Billing > Bill Message > Add**.

Description of Page

Enter a unique **Bill Message** and **Description** for every bill message.

The following attributes control how and where the bill message appears on the customer's bill:

Priority controls the order in which the message appears when multiple messages appear on a bill.

NOTE:

The values for this field are customizable using the Lookup table. This field name is MSG_PRIORITY_FLG.

Insert Code controls whether a document should be inserted into the bill envelope when the bill message appears on a bill.

Message on Bill is the actual verbiage that appears on the customer's bill. If the message text is not static (e.g., field values need to be substituted into the body of the message), you can use the % *n* notation within the **Message on Bill** to cause field values to be substituted into a message. Refer to [Substituting Field Values Into A Bill Message](#) for more information.

Setting Up Bill Route Types

Bill route types define the method used to route bills to accounts. To define a bill route type, open **Admin > Billing > Bill Route Type**.

Description of Page

Enter a unique **Bill Route Type** and **Description** for every bill route type.

Bill Routing Method controls the type of information that may be defined when the respective **Bill Route Type** is selected on [Account - Person Information](#). The following options are available:

- **Postal**: Use this method if the routing is via the postal service.
- **Fax**: Use this method if the routing is via fax.
- **Email**: Use this method if the routing is via email.

NOTE:

The values for **Bill Routing Method** are customizable using the [Lookup](#) table. This field name is BILL_RTG_METH_FLG.

The next two fields control how bills that are routed using this method are [printed](#) (both in batch and online).

- Use **Batch Control** to define the background process that performs the actual download of the billing information. Refer to [Technical Implementation of Printing Bills In Batch](#) for more information about these processes.
- Use **Extract Algorithm** to define the algorithm that constructs the records that contain the information that appears on a printed bill. Refer to [Printing Bills](#) for more information.

Setting Up Bill Cycles

FASTPATH:

Refer to [Defining Bill and Measurement Cycles](#) for a description of how to set up bill cycles.

Setting Up Customer Classes

When you set up an account, you must assign it a customer class. The topics in this section describe the customer class control table.

Customer Class - Main

To set up customer classes, navigate to **Admin > Customer > Customer Class > Add** and use the **Main** page to define your Customer Class.

Description of Page

Enter a unique **Customer Class** code and **Description** for every customer class.

Use **Collection Class** to define the collection class that defaults onto new accounts that belong to this customer class. An account's collection class may be subsequently modified if the account has special collection problems or needs.

FASTPATH:

For more information about the significance of collection class, refer to [Designing Your Collection Classes](#).

Turn on **Business Activity Required** if service agreements linked to accounts with this customer class require a Business Activity description to be entered.

Turn on **Open Item Accounting** if accounts belonging to this customer class are subject to open-item account. Refer to [Open Item Accounting](#) for a complete explanation of the significance of this switch.

Turn on **Non CIS Payment** if accounts belonging to this customer class are used for payments made to reduce non-CIS debt. For example, assume your company accepts payments for a county assessor and you don't want to set up a separate account for each person who pays their assessment bill. You should set up the following information to accept such payments:

- Create a new customer class called "Non CIS Customer".
 - Create a SA type for each type of non-CIS payment that customers can make. Make sure to enter a distribution code on each SA type that references the appropriate revenue (or payable) account. Don't forget to indicate that each SA type is not billed.
-

NOTE:

Payment Templates can be used for common types of non-CIS payment allocations. These templates are used to default the payment distribution and allow non-CIS payments to be directly allocated to specific distribution codes.

FASTPATH:

For more information about using Payment Templates to process non-CIS payments, refer to [Non-CIS Payments](#).

- Create an account to which you'll book such payments. Have this account reference the new customer class. We recommend creating a separate account for each SA type that you created in the previous step.
- Create and activate a service agreement for the new account(s).

When someone pays for non-CIS debt, the operator will add a payment for the above account. On the payment, the operator should record reference information in order to know exactly why the payment was made. Refer to [Payment Event - Main](#) for more information.

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division. You do this on the [Customer Class - Controls](#) page. The grid that follows simply shows the CIS divisions for which business rules have been set up.

Customer Class - Bill Messages

When a customer class has bill messages, the system will sweep these messages onto bills created for accounts belonging to the customer class. Use this page to define a customer class's bill messages. Navigate to **Admin > Customer > Customer Class > Search** and then navigate to the **Bill Messages** page to maintain this information.

Description of Page

Use the bill messages collection to define **Bill Message** codes that should appear on bills that created for accounts that belong to a given customer class. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps customer class bill messages on a bill during bill completion. For more information about bill messages, refer to [The Source Of Bill Messages](#).

Customer Class - Controls

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division in respect of the residential customer class. Open **Admin > Customer > Customer Class > Search** and then navigate to the **Controls** page to maintain this information.

Description of Page

The **Customer Class Controls** scroll contains business rules governing accounts that belong to a **CIS Division** and **Customer Class**. The following fields should be defined for each **CIS Division**:

- Use **Days Till Bill Due** to define the number of days after the bill date that the customer's bill is due. If the due date is a weekend or company holiday, the system will move the due date forward to the next workday (using the workday calendar defined on the account's CIS division).
- Specify the **Budget Plan** that defaults onto new accounts belonging to this customer class. Please note that an account's budget plan may be subsequently modified if the account has special budget processing needs. Refer to [Setting Up Budget Plans](#) for more information.
- Use **Min Credit Review Freq (Days)** to define the maximum number of days that can elapse between the reviews of an account's debt by the [account debt monitor](#). Note, a value of zero (0) means that accounts in this customer class will be reviewed every day.
- Use **Credit Review Grace Days** to define the number of days after the bill due date that an account should be reviewed by the [account debt monitor](#).
- Turn on the **Late Payment Charge** if customers in the class / division combination are eligible for late payment charges.
- Use **LPC Grace Days** to define the number of days after a bill's due date that a late payment charge will be generated (if the various LPC algorithms allow such - refer to [How Late Payment Charges Get Calculated](#) for the details). If the grace date falls on a weekend or holiday, the system moves the grace date to the next available workday (using the workday calendar defined on the account's CIS division).
- Specify an **Access Group** to default an access group onto an account based on the account's CIS Division and customer class. This will override the access group defaulted from the user's default access group. Note: the access group defined here will not apply if a Customer Class Control - Determine Access Group algorithm is defined and successfully returns an access group.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

WARNING:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
--------------	---------------------	-------------

Auto Pay Amount Over Limit	Optional	<p>This algorithm is called to handle the situation when a system-initiated automatic payment is created that exceeds the customer's maximum withdrawal limit. Specifically, this algorithm is called when:</p> <ul style="list-style-type: none"> - The account has a maximum withdrawal limit on their automatic payment options - The system attempts to create an automatic payment that exceeds this amount - The automatic payment algorithm that's plugged into the installation record has logic that invokes this algorithm when the above conditions are true <p>If you do not plug-in this type of algorithm and the above situation is detected, the automatic payment will be created and no error will be issued.</p> <p>Refer to How To Implement Maximum Withdrawal Limits for more information.</p>
Bill Completion	Optional	<p>When a bill for an account is completed, bill completion algorithms are called to do additional work.</p> <p>Refer to the description of the Complete button under Bill Lifecycle for a description of when this algorithm is called during the completion process.</p>
Bill Eligibility	Optional	<p>Algorithms for this plug-in spot are called when generating a bill in batch billing. It provides the ability to determine if an account is ineligible for billing and should therefore be skipped from further processing.</p> <p>If an eligibility algorithm is not used, a bill is created for any account in the open bill cycle and is later deleted by the billing process if it detects that there is no information linked to the bill.</p>
Bill Segment Freeze/Cancel	Optional	<p>When a bill segment for an account in this customer class / division is frozen or canceled, an algorithm of this type may be called to do additional work.</p> <p>Refer to Bill Segment Lifecycle for more information about freezing and canceling bill segments.</p>
Cancel Bill	Optional	<p>This algorithm provides the ability to include additional cancel logic when canceling online.</p> <p>Algorithms of this type can be called in two modes: D (Determine Bill Page Buttons) and X (Cancel Bill). Mode 'D' governs whether an action button to cancel the bill will appear on</p>

		the Bill page and mode 'X' performs the actual cancellation logic.
Determine Access Group	Optional	<p>When an account is added or an account's CIS Division or customer class is changed, this plug-in spot can be used to determine the appropriate access group. This plug-in spot allows more complex logic to be defined, such as checking the access group on the main person's others account's.</p> <p>If a determine access group is not used, the access group can be defaulted from the customer class control or the user.</p>
FT Freeze	Optional	<p>When an FT is frozen, this algorithm is called to do additional work.</p> <p>For example, if you practice Open Item Accounting, you will need such an algorithm to handle the cancellation of match events when a financial transaction is canceled that appears on a match event. Refer to How Are Match Events Cancelled? for more information about cancellation.</p>
LPC Eligibility	Required if the customer class / division is eligible for late payment charges	<p>This algorithm is called by the late payment process to determine eligibility for late payments.</p> <p>Just because an account's customer class allows late payment charges to be calculated doesn't mean the account's delinquent service agreements will be levied late payment charges. In addition, a delinquent service agreement's SA type must reference a late payment charge algorithm. Refer to SA Type - Main for more information about SA type late payment charge issues. Refer to How Late Payment Charges Get Calculated for more information about late payment charges in general.</p> <p>NOTE: Only One Algorithm. Only one late payment charge eligibility algorithm may be defined for a customer class / CIS division combination.</p>
Levy NSF Charge	Optional	<p>This algorithm is called when a payment is canceled with a cancellation reason that indicates an NSF.</p> <p>Refer to NSF Cancellations for more information about what happens when a payment is canceled due to non-sufficient funds.</p> <p>NOTE:</p>

Only One Algorithm. Only one algorithm to levy an NSF charge may be defined for a customer class / CIS division combination.

Order Completion	Optional	When an order is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when an order is completed for customers who belong to this customer class.
Overpayment Distribution	Required	When a customer pays more than they owe, this algorithm is called to determine what to do with the excess funds. Refer to Overpayment Segmentation for a description on how to configure the system to handle your overpayment requirements. NOTE: Only One Algorithm. Only one overpayment distribution algorithm may be defined for a customer class / CIS division combination.
Override Due Date	Optional	An account's bill due date will be equal to the bill date plus its customer class' Days Till Due. If you need to override this method for accounts in a specific customer class, specify the appropriate algorithm here. NOTE: Only One Algorithm. Only one due date override algorithm may be defined for a customer class / CIS division combination.
Payment Cancellation	Optional	Algorithms of this type are called when a payment is canceled.
Payment Distribution	Required	This algorithm is called to distribute a payment amongst an account's service agreements. Refer to Payment Distribution for more information about how payment distribution works. NOTE: Only One Algorithm. Only one payment distribution algorithm may be defined for a customer class / CIS division combination.
Payment Freeze	Optional	When a payment is frozen, this algorithm is called to do additional work. If you practice Open Item Accounting , you will need such

an algorithm to link the payment's financial transactions to the match event that was originally created when the payment was distributed. Refer to [Payments and Match Events](#) for more information.

Post Bill Completion	Optional	<p>When a customer class has algorithms of this type, they are called after the completion of a bill for an account linked to this customer class.</p> <p>Refer to the description of the Complete button under Bill Lifecycle for a description of when this algorithm is called during the completion process.</p>
Pre Bill Completion	Optional	<p>When a customer class has algorithms of this type, they are called immediately before completion starts for an account linked to this customer class. These algorithms have the potential of:</p> <ul style="list-style-type: none">• Deleting a bill. You might want a pre completion algorithm to delete a bill if a condition is detected that should inhibit the sending of a bill to a customer (e.g., the bill just contains information about recent payments).• Aborting the completion process and creating a bill exception. If the algorithm indicates this should be done, the bill is left in the pending state and a bill exception is created describing why completion was aborted. You might want a pre completion algorithm to do this if, for example, integrity checks detect there is something wrong with the account or its service agreements. If the integrity check fails, the bill can be left in the pending state and a bill exception created describing why. <p>Refer to the description of the Complete button under Bill Lifecycle for a description of when this algorithm is called during the completion process.</p>
Quote Completion	Optional	<p>When a quote is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when a quote is completed for customers who belong to this customer class.</p>
Write Off Method	Required if you allow users to write-off debt real time using the write off transaction	<p>When a user presses the create button on the write off transaction, this algorithm is executed to write-off the selected debt. Refer to The</p>

Setting Up Collection Classes

FASTPATH:

Refer to [Setting Up Collection Classes](#) for a description of how to set up collection classes.

Setting Up Customer Information Options

When you add a new person, the system is set up by default to add an account for the person and go to the Start Service page when you save the new person information. You can change this functionality by configuring the following option types on the Customer Information Options feature configuration:

- **Add Account and Start Service Default:** Indicates whether the Add Account and Start Service option is selected on the person page, by default. If this option is not configured, the Add Account and Start Service option is selected by default.
- **Post Add Person BPA Script:** Indicates a BPA script to invoke when a user successfully adds or changes a person on the person page.

When you use control central to search for accounts, the system limits your search results based on your access rights. You can change this functionality by configuring the following option type.

- **Search All Accounts:** Indicates whether a Control Central search should allow a user to search all accounts without validating the user's access rights. If the user tries to select an account without having the required access, they will not be able to navigate to the Account Information tab on Control Central for the selected account.

For more information about Feature Configurations, see [Defining Feature Configurations](#).

Setting Up Customer Contact Options

This section describes tables that must be set up before you can define customer contacts.

FASTPATH:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Setting Up Customer Contact Classes

Every customer contact record has a contact type that classifies the record for reporting purposes. And every contact type, in turn, references a customer contact "class". The class categorizes customer contacts into larger groupings for reporting purposes.

Open **Admin > Customer > Customer Contact Class** to define your customer contact classes.

Description of Page

Enter a unique **Contact Class** and **Description** for each customer contact class.

After you have created your customer contact classes, you'll be ready to setup your [customer contact types](#).

Setting Up Customer Contact Types

Every customer contact record has a contact type that controls the behavior of the customer contact.

FASTPATH:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Open **Admin > Customer > Customer Contact Type > Add** to define your customer contact types.

Description of Page

Every customer contact type is identified by a unique combination of **Contact Class** and **Contact Type**.

Enter a brief **Description** of the customer contact type.

Only specify a **Contact Shorthand** if customer contacts of this type can be added in the [Customer Contact Zone](#). The value you specify in this field is what the user selects to add a customer contact in this zone.

If your implementation requires restricting customer contact types by CIS Division, specify a **CIS Division** on the customer contact type.

Person Usage controls the applicability of a person on customer contacts of this type. Select **Required** if a person must be defined on this type of customer contact. Select **Optional** if a person can optionally be defined on this type of customer contact. Select **Not Allowed** if a person is not allowed on this type of customer contact.

Account Usage controls the applicability of an account on customer contacts of this type. Select **Required** if an account must be defined on this type of customer contact. Select **Optional** if an account can optionally be defined on this type of customer contact. Select **Not Allowed** if an account is not allowed on this type of customer contact.

Premise Usage controls the applicability of a premise on customer contacts of this type. Select **Required** if a premise must be defined on this type of customer contact. Select **Optional** if a premise can optionally be defined on this type of customer contact. Select **Not Allowed** if a premise is not allowed on this type of customer contact.

NOTE:

Person usage and premise usage cannot both be set to not allowed, as the customer contact must at least one of them. Account usage is dependent on person usage.

Entity Relationship controls the validation of relationships on customer contacts of this type. *All* ensures that the account belongs to the person and that the account and premise are related. *Person and Account Only* disables the account and premise validation. *Premise and Account Only* disables the person and account validation. *None* disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

Use **Contact Action** if something should be triggered when customer contacts of this type are added or if the contact has a special use. When set to *Send Letter*, you must also specify a **Letter Template**. Refer to [Printing Letters](#) for more information about how letters are produced. Set to *Record Notification* if this contact type is used on template-based notification types as a record of the communication.

The **Business Object** defined here controls how customer contacts of this type are show on the customer contact portal. The system is delivered with three customer contact business objects. The value is defaulted based on the contact action.

NOTE: Unlike many objects, the customer contact business object is not stored directly on the customer contact. The system obtains it from the type and uses it to control how the customer contact is displayed, such as which fields are shown. It does not impact the behavior of the customer contact.

Set the **Custom Archive Eligibility Criteria** flag to *Applicable* if customer contacts of this type require additional custom eligibility criteria checks when being evaluated for archiving.

NOTE: The base product provides an ILM Eligibility algorithm for Customer Contact (C1-CCILMELIG) that marks a customer contact as eligible for archiving based on the customer contact's age and the state of the related person's information. This algorithm will not mark the customer contact as eligible for archive if the customer contact type's Custom Archive Eligibility Criteria flag is Applicable. Your implementation is responsible for providing the additional criteria checks for customer contact types that require custom eligibility criteria.

Use the **Customer Contact Type Characteristics** collection to define characteristics that can be defined for contacts of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on customer contacts of a given type. Turn on the **Default** switch to default the **Characteristic Type** when customer contacts of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Notification Preference Options

The topics in this section provide background information about notification preferences.

Notification Preferences Overview

The Notification Preferences functionality is comprised of two main components: sending messages out of the system and maintaining customers' communication preferences for receiving these messages.

Notifications are created by an algorithm plugged into the Create Notification plug-in spot on the Notification Type (BO). The base product provides the C1-CRE-NTF algorithm, which creates the notification via an outbound message.

The following sections describe specific notification preference concepts and how to configure the system to use notification preferences.

Setting Up Notification Event Types

This portal is used to display and maintain a Notification Event Type.

Notification Event Types are system events used to send communications or notifications to customers.

You can access the portal from **Admin > Customer > Notification Event Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Template-Based vs. Message-Based Notification Types

The application supports two different notification formats: template-based and message-based. For message-based notifications, the outbound message contains the message that is delivered. It contains the fixed and variable information and comes from the message catalog. For template-based, the outbound message contains the data necessary for an external system to create the notification. In this model, the external system owns the message format and fixed content and uses the data from the system for the variable information. The notification type's business object has an option that indicates the format. This business object option is used by the programs that initiate notifications from the application. The programs that initiate a notification and need to know the notification type's format and must have the responsibility to populate the correct elements before calling the create notification plug-in spot. These programs know how to prepare notification information based on the format before calling the notification type's BO create notification plug-in spot. That plug-in spot's API has elements that support both notification formats.

Push vs. Subscription Notification Types

Notification types are defined as either push – which means that a customer need not sign up to receive notifications of this type, or subscription – which means that a customer must sign up to receive this type of notification. As you can tell, they have different uses and different behaviors.

Push notification types allow users to specify communication preferences for a general type of notification, which are referred to as parent push notification types. These preferences include contact preferences and opt-out preferences, which are applied to individual notifications belonging to the parent type. For example, “Products and Offers” may be the parent type, and the individual notification types may include several different types of product and offers notifications that contain different messages and are targeted at different customers. Refer to [Parent vs. Individual Push Notification Types](#) for more information.

In the absence of any contact preference or opt-out preference, push-based notifications can determine a default contact and send the notification using it. The logic to determine a default contact is defined via an algorithm plugged into the Determine Default Contact plug-in spot on the Notification Type (BO). The base product provides the C1-NTF-DFPRF (Determine Default Contact for Notification Type) algorithm, which looks to retrieve a default contact from the account’s main person.

Subscription notification types define a particular notification and its message. Customers must have an active contact preference to receive these notifications. Subscription-based notification types can use an underlying service task. Refer to [Some Notification Types Use Service Task](#) for more information. A subscription-based notification type can also be set up to allow routing of bills or quotes to multiple destinations.

NOTE: For template-based notifications, there are distinct business objects for subscription, parent push and individual push notification types. For message-based notifications, there is a single business objects and the behavior of the notification type must be defined when configuring the notification type.

Parent vs. Individual Push Notification Types

Push notification types are configured as either a parent or individual notification type. An individual notification type references a parent notification type; a parent cannot reference another parent. Customers define communication preferences for parent push notification types. Notifications are sent out for individual push notification types. The preferences defined for parent push notification types are applied to the associated individual push notification types.

This means that customers do not have to supply their preferences for every individual notification that your implementation may send. Storing customer preferences for a parent notification type permits those preferences to be inherited for individual notification types added later in time under the same parent. The parent push notification types can be thought of as categories of notifications for which your customers define contact preferences and opt-out preferences.

When system processes or your custom processes attempt to send out a push notification, it should be for an individual notification type. The system will retrieve the parent notification type from the individual notification type when checking for communication preferences.

One function available to push-based notifications as described in [Push vs. Subscription Notification Types](#) is the ability to determine a default contact in the absence of a contact preference or opt-out preference. If your implementation wants to take advantage of this function, but would like the customer to supply preferences for receiving an individual notification, a parent push notification type can be set up with only one individual push notification type.

Delivery Type

Delivery Type is the channel used to send a notification. Examples are email, text message (SMS), fax, and outbound IVR. Delivery type is used throughout notification preferences. If your implementation is not using notification preferences, you would not utilize delivery type.

- Notification types list the supported delivery types. For example, a bill ready notification type may support email and SMS while a notification type to encourage customers to enroll in a budget plan may only support email. The message subject and body are configured for each notification type's supported delivery type.
- Person contact types list the allowable delivery types. For example, a cell phone person contact type may allow SMS while a home phone person contact type may not allow any delivery types. An email person contact type would allow an email delivery type unless the person contact type exists to capture a customer's email address and not to be used in conjunction with notification preferences. Note: the delivery types that can be specified on a person contact type are restricted to those defined on the person contact types contact routing. Refer to [Setting Up Contact Routings](#) for more information.
- A contact preference for a customer consists of the combination of notification type, delivery type, and person contact.

Enabling Opt-In for a Delivery Type

Overview

Opt-in can be enabled for a delivery type and is configured using the **Notification Preferences** [master configuration](#); for example, opt-in can be enabled for SMS, but not email.

To help clarify some terminology, as explained in [Person Contact Status Can Be Controlled by a Process](#), the product is delivered with a process that initiates a service task to request opt-in or permission to use a person contact. This solution requires that opt-in is enabled for the delivery type associated with the person contact type. In this regard, the two concepts are intertwined, but enabling opt-in for a delivery type can function independently.

Enabling opt-in is centered on the person contact status, while the process that controls the status can vary; therefore, it is possible to use enable opt-in for a delivery type while manually controlling the person contact status. Enabling opt-in for a delivery type has two key impacts system behavior.

- When a contact preference is added and the delivery type is enabled for opt-in, there is logic that checks if the person contact associated with the contact preference is in the **Approved** status. If it is not, and the person contact type is associated with a process to control the status, that process is initiated. If the person contact type is not associated with a process to control its status, a To Do Entry is created. The To Do Type is configured on the **Notification Preferences** master configuration. The system is delivered with To Do Type Opt-In Errors (C1-OPTIN) for this purpose.
- Notifications will not be delivered to person contacts that are not **Approved**. When a system process initiates an outbound notification based on an active preference, if the person contact associated with the contact preference is not **Approved**, a flag is set in the notification indicating that it should not be delivered. It is up to the receiving system, such as Notification Center, not to deliver the notification based on this flag. This is designed so that a record of the notification being generated is still captured. Also, C1-NTF-DFPRF (Determine Default Contact for Notification Type) will not choose a person contact that is not approved.

The **Notification Preferences** [master configuration](#) help text contains detailed information about the configuration required to enable opt-in for a delivery type.

Some Notification Types Use Service Task

Prior to the introduction of notification preferences functionality, the system supported notifications set up through self-service. These notifications used service tasks to store customer preferences and in some cases trigger notifications. The destination information for the notification existed outside of the system. Notification preferences, and more particularly communication preferences, define the user's preferences on how to be notified for each notification type and where the notification is to be sent. This reduces, but does not eliminate, the need to use a service task to store a customer's preference. These service tasks will not contain the self-service information when created internally by the system

There are four existing notification types that rely on service tasks to trigger a notification. Additionally, one of the prepaid notifications uses a service task type business object with specific fields for that notification type. Refer to [Designing Notification Types](#) for information regarding the configuration requirements for certain notification types.

Notification Preferences supports configuring notification types with or without a service task and only subscription-based notification types can be configured with an underlying service task.

Designing Notification Types

Some notification types require a specific configuration in order for the system to create notifications for that type.

Service Task Based Notification Types

There are system processes that rely on a hard-coded notification type lookup, referred to as notification type (legacy) on the notification type configuration. The system identifies the user-defined notification type from the lookup value.

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on service tasks.

Notification Type (User Defined)	Push/Subscription	Controlled By	Notification Type (Legacy)	Service Task Type
Prepaid billing new charge	Subscription	Service Task	C1PC	Self-Service Task Type with BO C1-NotifyTaskType
Prepaid billing payment request	Subscription	Service Task	C1PP	Self-Service Task Type with BO C1-PPBPaymentNotifyTaskType
Payment Received	Subscription	Service Task	WSPR	Self-Service Task Type with BO C1-NotifyTaskType
Bill Ready	Subscription	Service Task	WXBR	Self-Service Task Type with BO C1-NotifyTaskType
Bill Due	Subscription	Service Task	WXBD	Self-Service Task Type with BO C1-NotifyTaskType
Late Payment	Subscription	Service Task	WSLP	Self-Service Task with BO C1-NotifyTaskType

Non-Service Task Based Notification Types

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on the user-defined notification type to be configured.

NOTE:

Marketing and forms notification types can be set up one of two ways: as subscription-based or as push-based. For it to be push-based, it would be an individual push, meaning that it references a parent push notification type specified by the implementer.

Notification Type (User Defined)	Push/Subscription	Controlled By	Notes
Marketing Preference (Lead Event)	Subscription or Individual Push	N/A	Notification type configured on lead event type of BO C1-LeadEvtTypeNotificationPref
Forms Update	Subscription or Individual Push	N/A	Notification type configured on form task type of C1-FormTaskTypeForNotification

Bill and Quote Routing

Notification types can also be used to define contact preferences for bill and quote routing for email and fax. This can enable a bill or quote to create a routing for each active contact preference. For example for a single person on an account that receives a copy of the bill, the bill can be sent to more than one email address.

Some specific configuration is needed to support this.

The notification types are to be set up as follows and must use the message-based notification type business object.

Notification Type (User Defined)	Push/Subscription	Controlled By	Bill/Quote Route Type	Algorithm
Bill Route	Subscription	Bill Route	Specify the Bill Route Type	Use the Suppression Algorithm for Bill/Quote Route
Quote Route	Subscription	Quote Route	Specify the Quote Route Type	Use the Suppression Algorithm for Bill/Quote Route

Configure only the delivery type that corresponds with the bill or quote route's routing method. For example, if the bill route type's routing method is email, configure the email delivery type on the notification type.

Configure only person contact types whose contact routing corresponds with the bill or quote route's routing method. For example, if the bill route type's routing method is email, configure only person contact types with a contact routing of email. Ensure that the person contact type allows only the delivery type specified on the notification type.

This very specific configuration is needed because the system will override the existing logic that creates bill and quote routings when a notification type exists as described above and there are active contact preferences for that notification type with the specified delivery type and the person contact's person contact type.

Collection Events

The system is delivered with a collection event algorithm type that supports template-based notifications. To send collection based notifications, define individual push notification types for each collection notification. These notification types should reference a parent notification type such as "Collection Notices". Configure algorithm(s) using the delivered algorithm type, specifying the individual push notification type(s) in the algorithm parameter. Create collection event types using these algorithms and incorporate them into your collection process templates.

Setting Up Notification Type Algorithms

Suppression Criteria

Notification types can be suppressed from appearing in a list for a particular customer. This is done by plugging in a suppression criteria algorithm on the notification type.

The base product provides the C1-ALWY-SUP (Always Suppressed) algorithm, which suppresses the notification type for all customers. This does not impact active contact preferences for the notification type, nor does it prevent processes from creating notifications of this type. This should be used with business process changes to stop sending notifications of this type. This can also be used temporarily after a notification type has been configured, but before it should be used.

The base product provides the C1-CKSP-PPB (Check Prepaid Biller Suppression) algorithm, which suppresses the notification type if the customer does not have an active prepaid biller task. This should be used on prepaid related notification types so that only customers on prepaid billing receive these notifications.

If your implementation's business rules require additional notification type suppression rules, you may introduce your own algorithm.

Override Do Not Disturb

Do not disturb information can be captured on person contacts. Person contacts are associated with a notification type to define a contact preference. When notifications are sent out, do not disturb information is included in the message to the receiving system. Some notification types might be important enough to not honor the customer's do not disturb information. For example, a notification might be sent to a subset of customers to warn of a gas leak and evacuation and needs to be sent regardless of the customer's do not disturb wishes. This is done by plugging in an override do not disturb algorithm on the notification type. Note: this does not actually override the customer's information, but sends an indicator in the message to the receiving system that the do not disturb information should be overridden or ignored.

The base product provides the C1-OVR-DND (Override Do Not Disturb) algorithm, which returns a value of true that is passed to the receiving system in the notification.

If your implementation has more specific business rules related to overriding a customer's do not disturb preference, you may introduce your own algorithm.

Setting Up Delivery Types

Base values for Delivery Type are supplied. You can add your specific delivery types by updating the value for the C1_SS_DELIVERY_TYPE lookup field.

Setting Up Notification Types

Each notification type defines the controls and behavior for defining communication preferences and sending out notifications of that type.

There are two main categories of notification types: subscription and push. These behave differently. Refer to [Push vs. Subscription Notification Types](#) for more information.

Push notification types are configured as either parent or individual push notification types. A parent push notification type is used to define communication preferences and an individual push notification type is used to send notifications. Refer to [Parent vs. Individual Push Notification Types](#) for more information.

The base product supplies one Notification Type business object for message-based notification types and distinct business objects for template-based notification types. Refer to [Template-Based vs. Message-Based Notification Types](#) for more information. For more details, refer to the specifications for these business objects.

Some notification types require specific configuration. Refer to [Designing Notification Types](#) for more information.

To set up notification types, select **Admin > Customer > Notification Type +**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Setting Up the Outbound Message Type

An outbound message type is required for the notification outbound message. This outbound message type must reference the base C1-NotifPrefOutboundMessage (Notification Preference Outbound Message) business object.

Setting Up the Message Sender

A Message Sender is required to define how to send notifications. Use the context of the Message Sender to define the web service interface.

Setting Up the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each (XAI, Batch, or Real Time); Real Time is generally the appropriate choice notifications).

Setting Up Notification Preferences Master Configuration

General configuration details for the notification preferences functionality is captured in the **Notification Preferences**[master configuration](#).

For more information about specific fields in the master configuration, refer to the embedded help.

Other Edge Application Notification

Other applications such as *Oracle Utilities Network Management System* or *Oracle Utilities Meter Data Management* may initiate notifications; for example, the network management product can create notifications for outages or restoration information. The customer's preferences to receive these notifications will reside in Oracle Utilities Customer Care and Billing, since this is where their contact information exists. The other applications need to be notified when an active contact preference is created for one of their notifications. The **Notification Preferences**[master configuration](#) provides the section to indicate if a Notification Type is owned by another edge application. When a contact preference is created or inactivated for one of these notification types, an outbound message is sent to notify the other edge product. When the system event in another edge application occurs that initiates a notification, that application calls and inbound web service that creates the notification.

The **Notification Preferences**[master configuration](#) help text contains detailed information about other edge applications.

Setting Up Service Agreement Options

This section describes tables that must be set up before you can define service agreements.

Setting Up Standard Industry Codes (SIC)

A service agreement for non-residential service should reference a standard industry code (SIC). This code is used to categorize service agreements for reporting purposes. To define a SIC, open **Admin > Customer > SIC Code**.

Description of Page

Enter a unique **SIC** and **Description** for the SIC.

Setting Up Tax Exempt Types

Your rates will probably have provisions for the calculation of taxes of one type or another. Frequently you will have customers who are completely or partially exempt from these taxes. The service agreements for these customers will need to have tax exemption information in order for them to be billed properly. Tax Exempt Type is used to define the precise nature of the applicable exemption. To define the Tax Exempt Types you will use, open **Admin > Customer > Tax Exempt Type**.

Description of Page

Enter a unique **Tax Exempt Type** and **Description** for each type of tax exemption.

Setting Up Contract Quantity Types

You may have customers whose contracts (service agreements) have contractual consumption limits. The service agreements for these customers must have information regarding this quantity in order to be billed properly. Contract Quantity Type is used to precisely define the nature of the quantity. To define the Contract Quantity Types, open **Admin > Rates > Contract Quantity Type**.

Description of Page

Enter a unique **Contract Quantity Type** and **Description** for each type of contract quantity.

SA Type Controls Everything

Every service agreement references a SA type. The SA type controls all aspects of a service agreement's behavior including how service is started, how bills are created, how its financial transactions are booked in the general ledger, and much more. We don't explain how to set up SA types in this section because it's only after you have set up all of the control tables in this manual that you'll be able to finally define your SA types.

FASTPATH:

For more information about SA types, refer to [Defining Service Agreement Types](#).

Financial Controls

FASTPATH:

There are also a number of control tables that must be set up to control the bills, payments, and adjustments that are linked to a service agreement. For more information about these tables, please refer to [Defining Financial Transaction Options](#).

Setting Up Order Options

This section describes tables that must be set up before orders can be used to start service.

FASTPATH:

For more information, refer to [The Big Picture of Campaigns, Packages and Orders](#).

Setting Up Column References

A column reference must be created for each miscellaneous field that's captured on an order that doesn't reside in a characteristic. Refer to [Determine The Properties Of Every Miscellaneous Field](#) for more information.

Open **Admin > Sales & Marketing > Column Reference > Add** to define your column references.

Description of Page

Enter an easily recognizable **Column Reference** code and **Description** for each column reference.

Specify the **FK Reference** to use if this column reference uses field values from another table. Use **Long Description** to describe the data that fields using this column reference capture.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated. You can define algorithms for the following system events: Post when order completed, Retrieve current value, Validate field value, Service task order processing, and Pre-process field value. Refer to [Extract Column References](#) for a description of these events.
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

WARNING:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

Setting Up Order Cancellation Reasons

An order cancellation reason must be supplied when an order is cancelled. Open **Admin > Sales & Marketing > Order Cancel Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Cancel Reason** and **Description** for each order cancellation reason.

Where Used

Cancellation reasons are used when an [order is canceled](#).

Setting Up Order Hold Reasons

An order hold reason must be supplied when an order is held. Open **Admin > Sales & Marketing > Order Hold Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Hold Reason** and **Description** for each order hold reason.

Where Used

Hold reasons are used when an [order is held](#).

Setting Up Order Feature Configurations

Defining a [feature configuration](#) with a feature type of Order Configuration can increase performance of the Order page when campaigns have a large number of packages or criteria. Open **Admin > Feature Configuration > Add** to define a configuration for the feature type Order Configuration.

NOTE:

Only one. The system expects only one order configuration feature configuration to be defined.

Description of Page

The following points describe the various **Option Types** that may be defined:

- Eligibility Tree - Suppress Error Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages with errors in their eligibility criteria. This is an optional setting. If the option type is not defined, the error packages node is displayed, if applicable.
- Eligibility Tree - Suppress Ineligible Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages that are not applicable to the customer based on the eligibility criteria. This is an optional setting. If the option type is not defined, the ineligible packages node is displayed, if applicable.
- Eligibility Tree - Suppress Other Campaigns node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains other eligible campaigns. This is an optional setting. If the option type is not defined, the other campaigns node is displayed, if applicable.

Setting Up Program Management Options

This section describes how to set up the system for program management.

For more information about program management, see [The Big Picture of Program Management](#)

Designing Initiative Eligibility Criteria

The following describes guidelines for designing initiative eligibility criteria. These guidelines apply when using the base-supplied business objects and any additional business objects that the implementation defines.

There are two general types of initiative eligibility criteria business objects provided in base: specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

NOTE: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies the category to use through a business object option called Initiative Criteria Type. Eligibility criteria business objects are defined with an Initiative Criteria Type of either C1EC (Eligibility Criteria) or C1BT (Both Eligibility Criteria and Participation Criteria).

Specific Criteria Business Objects

Most of the base-supplied business objects are designed to perform comparisons to a specific field. The algorithm type for retrieving/determining the value to compare with is already preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Communication Channel Criteria
- Conservation Program Criteria
- Contract Option Criteria
- Rate Schedule Criteria
- SP Type Criteria
- Service Type Criteria
- Is Account Current Criteria
- Account is on Autopay Criteria
- Account is on Budget Criteria
- Number of Days Since Last Lead Criteria

- Account Customer Class Criteria
- Average Service Quantity Criteria
- Premise Cities Criteria

To add similar business objects:

- Identify the specific value for comparison. This could be a reference to an object or entity in the system, or a character string; such as, true/false.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Criteria Business Object

The Freeform Criteria business object, on the other hand, is designed to perform comparisons for different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. A number of these Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

NOTE: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific value for comparison. It could be a reference to an object or entity in the system, a character string (such as, true/false), or a scalar value (such as, number of days or number of kwh).
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Designing Related Object Criteria

The following describes guidelines for designing related object criteria. These guidelines apply when using the base-supplied business objects and additional business objects that the implementation defines.

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes this object nomination algorithm after executing initiative eligibility criteria. The base supplied parent Initiative business object (C1–Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account’s active and pending start service agreement’s service points. This algorithm applies the related object criteria, which is configured on the initiative, to each premise. If the premise is determined to be eligible, it is returned as a related object for the lead. To override the base object nomination algorithm, add another instance of the Object Nomination System Event and specify your own algorithm.

The base product supplies related object criteria business objects that look for one or more premise to associate with a lead.

There are two general types of related object criteria business objects provided in base - specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

NOTE: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies the category to use through a business object option called Initiative Criteria Type. Related object criteria business objects are defined with an Initiative Criteria Type of C1EO (Related Object Criteria).

Specific Criteria Business Objects

The base product supplies two business objects that perform comparisons to a specific premise-related field. The algorithm type for retrieving or determining the comparison value is preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Premise SP Type Criteria
- Geographic Value Criteria

To add similar business objects:

- Identify the specific comparison value. It could be a reference to an object or entity in the system (such as, SP Type), or any other attribute that can be used to find the related object.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Premise Criteria Business Object

The Freeform Premise Criteria business object, on the other hand, is designed to perform comparisons to different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

NOTE: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Premise Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific comparison value.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Premise Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Setting Up Lead Event Types

Each initiative can define a structured marketing effort for the events that take place during the life of a lead. For example, one event could be that a letter or an email is sent to the customer.

Each event references a lead event type. An initiative defines a lead event type profile that specifies one or more lead event types and the sequence in which those event types should occur. Refer to [The Big Picture of Initiatives](#) for more information.

Some types of lead events may also involve sending outbound messages to an external system (*e.g.*, to notify a third party representative about a customer who has signed up). The lead event type business object can specify the outbound message type(s) to use.

Event types that involve additional workflow activities can define one or more steps; for instance, when work is outsourced to a third party representative (after customer sign-up), the third party lead event includes a list of steps to complete. Each event step has information (such as, completion date) that can be used to track progress.

The base product supplies a number of Lead Event Type business objects. For more details, refer to the specifications for these business objects.

To set up lead event types, select **Admin > Sales & Marketing > Lead Event Type**.

The Lead Event Type portal contains the following zones:

Lead Event Type List

The Lead Event Type List zone lists all lead event types. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent lead event type.
- The standard actions of **Edit**, **Delete** and **Duplicate** are available for each lead event type.

Click the **Add** link in the zone's title bar to add a new lead event type.

Lead Event Type

The Lead Event Type zone contains display-only information about the Lead Event Type. This zone appears when a Lead Event Type has been broadcast from the Lead Event Type List zone or if this portal is opened via drill down from another page.

Please see the zone's help text for information about this zone's fields.

Overriding Initiative Sign Up Options

The behavior of the Sign Up action on Lead maintenance is controlled by two business object options on the initiative:

- Sign Up UI Map
- Sign Up Service Script

When invoking a lead's Sign Up action, the system retrieves these options and displays or executes them accordingly.

The base-owned parent initiative business object, C1-Initiative, is supplied with the Sign Up Service Script option referencing the C1-IntvSignU script. To override this, add another *Sign Up Service Script* option with a higher sequence number.

The Sign Up UI map, on the other hand, is not plugged in on the base BO, because this could vary across implementations. The Sign Up UI map C1-SignUpResponseCh provided in base simply prompts for a Response Channel. Implementations can use this map or their own specific map.

NOTE: The system does not issue an error if the Sign Up UI map is not specified. It proceeds with executing the Sign Up Service Script and, if there are no problems, displays a sign up confirmation. The base-supplied C1-IntvSignU script includes logic to recheck the account's eligibility for the initiative and update the *Has Signed Up* indicator on the lead.

Program Management Master Configuration

The master configuration business object for Program Management defines general configuration details for the program management functionality.

Navigate using **Admin > General > Master Configuration**. In the Master Configuration list, scroll to Program Management Configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Setting Up Letter Templates

You can set up a customer contact type to generate a form letter whenever a customer contact of this type is added. In fact, this is the only way to generate a letter in the system.

FASTPATH:

Refer to [Printing Letters](#) for more information about how letters are produced.

Every customer contact that causes a letter to be sent must reference a unique letter template. To define a letter template, open **Admin > Customer > Letter Template**.

NOTE:

Document composition application users. If you use the document composition software to produce letters, there will be a template in the software associated with each letter. The name of the template must be the same as the code associated with the letter template set up in the system.

Refer to the embedded help for details on the letter template fields.

Setting Up Customer Service Request Types

This portal is used to display and maintain a Customer Service Request Type.

A Customer Service Request Type controls how a specific customer service request is processed.

Refer to [Understanding Customer Service Requests](#) for more information.

To maintain customer service request types, open **Admin > Customer > Customer Service Request Type**.

You are brought to a query portal with options for searching for a specific customer service request type. Once a question is selected, you are brought to the maintenance portal's Main tab, to view and maintain the selected record.

Refer to the zone's embedded help for more information.

The Questions tab is used to configure one or more questions to ask during the flow of a start/stop/transfer service request. Refer to [Setting Up Customer Service Request Questions](#).

The Service Eligibility tab is used to configure one or more service eligibility criteria that are applied using question responses and existing information for the customer or premise request. Refer to [Setting Up Service Eligibility Criteria](#).

The Related Updates tab is used to configure how question responses should be stored when the service request is processed and/or completed. Refer to [Setting Up Response-Related Updates](#).

Setting Up Consumer Contract Request Types

A consumer contract request type is a Customer Service Request Type that controls how a contract change request is processed.

Refer to [Understanding Customer Service Requests](#) for more information on customer service requests.

For contract change requests, the Consumer Contract Request Type also defines the service location business object that is applicable to a market and action (i.e. Add to Contract, Remove from Contract, Meter Change, etc.)

Setting Up Start, Stop and Transfer Request Types

The following sections describe how the request types and process flow types provided in the base product can be extended for your specific business rules.

Verifying Identity, Checking Credit and Requiring Deposits When Starting Service

The Start Service Request Type (request type) provides controls to help verify customers' identity and/or check their credit. The start service process provided with the system can begin with or without a person being passed into the process. The process orchestrates the following:

- When there is no person passed into the process, the assumption is that this is a new customers, but the first step is to ensure they are not already in your system. This is done by performing a person search using, name, phone, e-mail or person identifiers. The search options are configured on the start service type. When a record is not found, the last search criteria are retained to minimize asking the customer for the same information again. If an existing person is found, the record can be selected and the process continues as if the process began with an existing customer. For this purpose, existing customers are simply those in your system before beginning the start service process. They may be long-standing customers with current service, or a person record added moments before beginning the start service process. For this reason, the start service process follows the same steps after choosing to add a new customer or selecting an existing one.
- Ensuring customers are who they say they are is often an important step in starting service, especially for new customers. This is often done by asking the customer for a unique identifier such as a government issued ID like a driver's license, or Social Security number. This information is often verified with a third-party and is sometimes combined with a credit check.

The start service process allows you to configure what identifier types your organization accepts when both new and existing customers are starting service. This may be a subset of all of the person identifier types defined in your system. Refer to [Understanding Person Identifiers](#) for more information. Note: This help topic pertains to the primary identifier; the start service process supports additional, non-primary identifier types separately.

When setting up the start service type and configuring the primary identifier types, you need to indicate their usage. The usage for most uniquely identifying identifiers is probably **New & Existing**. These are identifier types that you accept and can uniquely identify a person or business and are probably the primary ID type on the person record. If there is an identifier that was once accepted and is still considered valid for existing customers, but is not used for new customers, these can be set to **Existing Only**. Lastly, some identifier types such as a PIN or password are used when an identifier is required, but the customer is not willing or is unable to provide a high-quality unique ID. These identifier types should be set to **New & Non-Identifying**. This allow agents to input an ID when one is required, but the process knows that the record is not a unique identifier.

For existing customer, the start service process sets an indicator when an existing identifier is found from the list of identifiers valid for existing customers. Note: the identifier need not be the primary, although it is likely that it is. For new and existing customers, a different indicator is set when a new uniquely identifying identifier is provided during the start service process. ID types that are configured as non-identifying are not considered when setting the indicator. It is

not possible for both indicators to be set since the user is not prompted to enter a new ID when a valid existing one is found. These indicators are passed into plug-in spots called during the start service process.

- Your business rules, might include asking customers for their date of birth. This could be used when deciding whether or not to perform a credit check or ID verification or if it does not factor into the decision, it could be passed to the third party as part of the credit check or ID verification process. If date of birth is not part of the credit or ID process, it may be requested only if the customer is eligible for service and may be used when determining if a deposit is required. Since this could be considered sensitive data, it is possible that is used during the start service process, but not saved on the person record.

To support a wide range of business rules, the start service process provides options for capturing and saving date of birth. When the use of date of birth is enabled, there are options to determine when the date of birth field is shown. It can be show always. It can be show only if a credit check or ID verification is going to be performed. This means the presence of the date of birth cannot factor into the decision to perform a credit or ID check. Lastly it can be shown only if service can start. There is also an option to save the date of birth as a person characteristic. For existing persons, if the date of birth already exists, it is shown, but cannot be updated during the start service process. Note: the date of birth functionality is only available for persons and not businesses.

- After the data entry is complete, the start service process calls the algorithm(s) plugged into the ID/Credit Check Should be Performed plug-in spot, passing the two ID indicators and the date of birth if enabled, to determine if an identity or credit check should be performed. This can be used to ensure the customer has provided the necessary information to pass to an external service to check credit or verify ID. This can also check the indicator that person has an existing ID and no further checking is needed. This is a multi plug-in spot so you can configure as many business rules as necessary. Each algorithm can indicate if the next algorithm should be called. The system is delivered with a sample algorithm that chooses to run a credit check based on the availability of a unique ID and a sample algorithm that bases the decision on the account history. Refer to the algorithm types for this plug-in spot for more details.
- If a credit check should be performed, the user is prompted to perform the credit check or ID verification. The algorithm plugged into the ID/Credit Check plug-in spot is then called. The user is shown if the credit check passed or failed, but the process relies on subsequent plug-in spots to determine use the results of the credit check or ID verification.
- After checking the credit or verifying ID, the next step is ensuring the criteria has been met for starting service and, if so, identifying if the person or business has existing accounts that eligible for service. This is done by calling the algorithm(s) plugged into the Start Service Eligibility plug-in spot. These algorithms receive ID indicators, date of birth if enabled, and the output from the ID/credit check plug-in spot, which can be used to determine if service can start. Algorithms in this plug-in spot are also responsible for returning the eligible accounts if there are any. For example, accounts previously used for bankruptcy or those dormant too long might not be eligible for new service based on your business rules. This is a multi plug-in spot so you can configure as many business rules as necessary. Each algorithm can indicate if the next algorithm should be called. When there are existing accounts that are eligible for service, a control on the start service request type indicates if new accounts are also allowed. You would set the control if a new account can be created even when there are existing eligible accounts. Algorithms in this plug-in spot also support returning a list of ineligible accounts that are shown on the start service process to show information about all of the customer's accounts. If your business rules do not support using existing accounts for new service, your algorithms would not return any eligible accounts. The system is delivered with a sample algorithm that determines start eligibility and account eligibility. Refer to the algorithm type for this plug-in spot for more details.
- Your business rules may require a deposit before a customer starts service. If so, the deposit functionality should be enabled for the start service process and optionally for the transfer service process. There is a control on the customer service request type that allows you to define if a deposit is always required or if the determination is situational, in which case algorithms in the Determine Deposit Required plug-in spot are called. The following explains the plug-in spot.

Since deposits can be based on more than one factor, this is a a multi plug-in spot. When the plug-in spot is called, the deposit required indicator is not set and a generic message is set that a deposit is not required. The system then relies on the algorithms plugged into the plug-in spot to indicate that a deposit is required, or update the message with a specific reason that a deposit is not required.

When called from within the Start Service process flow, the ID indicators, date of birth if enabled, and the results of the ID verification or credit check are passed into this plug-in spot and can be used in determining if a deposit is required.

Note: the transfer service process uses the same plug-in spot, but is not passed any date of birth, ID or credit information since transfer only applies to accounts with current service and the transfer process does not contain the identifier and credit check logic.

There are four sample algorithms provided to determine if a deposit is required. The following illustrates how these algorithms can be used to support both new and existing customers. When a specific condition requiring a deposit or exempting a customer from a deposit is met, the reason is output from the algorithm and displayed to the user in order to communicate with the customer. As mentioned, the system's default assumption is not required and a default message would be shown to the user if none of the algorithms output a more specific message explaining why the deposit is or is not required. Refer to the algorithm type descriptions for more detail information about each.

- C1DEPEXBAGE illustrates how an algorithm is used to waive a deposit when a condition is met, which in this case is the customer's age. This sample indicates that other algorithms in the plug-in spot should not be performed when the condition is met. If your business rules waive deposits when a condition is met and no further checking is required, you'd plug-in the algorithm(s) that check for this first. These algorithms should tell the system not to perform the additional algorithms in this plug-in spot.
- C1REQDEPAID uses the results from the ID or credit check to determine if a deposit is required. This algorithm has logic for both new and existing customers. It uses inputs including an indicator if an ID or credit check was run and, if run, the results of the ID or credit check. Based on the results, this algorithm can require a deposit. This algorithm tells the system not to perform the subsequent algorithms in this plug-in spot when a deposit is required.
- C1REQDEPBACR is intended for existing customers and uses the account's internal credit rating to determine if a deposit is required. It's possible that you'd not verify ID nor run an external credit check for existing customers, so the preceding algorithm would not have required a deposit, leaving downstream algorithms such as this one to make the determination. If the customer's internal credit rate is too low, a deposit is required, and this algorithm tells the system not to perform the subsequent algorithms in this plug-in spot.
- C1DEPEXMPBAH is the last sample and is based on account history. If the customer has recent or current service, the algorithm indicates that a deposit is not required and updates the message explaining that a deposit is not required. If there is no recent account history, the algorithm indicates that a deposit is required. In this example, this is the last algorithm, but it could be performed before other algorithms. To accommodate calling it in any sequence, this algorithm tells the system not to perform the subsequent algorithms only when a deposit is required.

NOTE: If your business follows the model where a deposit is required unless there is a reason to waive it, then your algorithms will behave in the inverse from the delivered samples. Your first algorithm plugged into the plug-in spot must set the deposit required indicator and update the default message. Subsequent algorithms or subsequent steps in the first algorithm can then clear the deposit required indicator when conditions to waive the deposit are met.

The delivered algorithms for these four plug-in spots work with each. You can design the algorithms in these four plug-in spots to work together or independently to implement your business's rule for adding new customers or ensuring existing persons or businesses meet the requirements for verifying ID or credit, starting service, choosing an account, and checking if a deposit is required.

Introducing Your Business Rules For Starting Or Transferring Service

The Start Service and Transfer Service requests are designed to allow you to define pre-requisites before customers start service. Each request has an "Waiting for Additional Actions" status where you can plug-in your business rules that define the actions required to start service. The requests have monitor algorithms to transition into and out of the waiting status.

For example, if you require a deposit to be paid before starting service, you can plug-in your business rule that ensure that the deposit is paid before our process starts the customer's service.

Understanding UI Override Controls

Process flow type panels are made up of a data area or UI map fragment. The delivered start, stop, and transfer process flow type panels are built using data areas. Instead of a single data area, these panels are built using nested or included data areas. This is done to facilitate custom extension of the data area at the lowest. This is useful when your business rules include adding something at the end of one of the delivered sections. However, there are times when your business rules are more complex than just adding on to a delivered section. Some of the UI sections that are delivered can be overridden with a custom replacement UI section. This logic is enabled through UI Override Controls on the request types.

The start, stop, and transfer processes each contain a summary header that is shown at the top of each step in the process that can be overridden. By overwriting this, you can create a custom header that is displayed throughout the process flow.

When starting service, especially for a new customer, business rules can differ between different organizations or within different operating units of the same organization. For example, a utility with customers in different states may have different requirements around verifying identity or checking credit. The sections responsible for new customer and existing customer identification can be replaced with a custom experience using the UI override controls.

When the request type indicates that the UI section is overridden, the extension data area replaces the UI component of the delivered data area that it extends. It does not override or replace the data area's schema.

Displaying More Details for the Move-to Premise

When starting or transferring service, additional scrutiny may be given to the move-to premise. Some of the pertinent information might be related to knowing if the premise has had frequent move-ins and move-outs and what the outstanding balance is on the previous account(s). Perhaps the meter information or usage history is important.

The system is delivered with a feature that is not enabled by default. On the start and transfer customer service request type business objects, you can specify a BPA script in the **Move-To Premise Details BPA Script** BO Option type. This script should invoke a map that contains the additional premise information that is relevant to your business. The Move-To Premise steps on the start and transfer service processes display an icon next to the selected premise when this option is configured. The system is delivered with a sample BPA script (**C1SSDisPrDe**) that can be used as a guide for any custom script you wish to introduce.

Capturing Custom Elements in the Start, Stop, and Transfer Processes

Your business rule may require capturing information beyond what is delivered in the start, stop, and transfer processes. Additional elements can be added to specific places in the processes and the values then made available to the requests and therefore the request's lifecycle algorithms.

To create custom extensions in the processes, create a new data area to hold the custom elements that extends the Panel Extension Data Area where you want to make the extension. The data areas need to use UI Hints or map fragments.

To pass the custom elements values from the process to the request, make the identical extension to the corresponding Request Extension Data Area. The system handles copying the values using "move by name".

Process	Panel	Panel Extension Data Area	Request Extension Data Area
Start	Move-To Premise Address	C1-StartMoveToPremPanelExtend	C1-StartMoveToPremCSRExtend
	Customer Identification	C1-StartCustIDPanelExtend	C1-StartCustIDCSRExtend
	Services to Start	C1-StartSvcToStartPanelExtend	C1-StartSvcToStartCSRExtend
	Person and Account Details	C1-StartAcctDetailPanelExtend	C1-StartAcctDetailCSRExtend
Stop	Services to Stop	C1-StopSvcToStopPanelExtend	C1-StopSvcToStopCSRExtend
	Person and Account Details	C1-StopAcctDetailPanelExtend	C1-StopAcctDetailCSRExtend
Transfer	Move-To-Premise Address	C1-TransferMoveToPremPanelExt	C1-TransferMoveToPremCSRExt

Services to Start	C1-TransferSvcToStartPanelExt	C1-TransferSvcToStartCSRExt
Services to Stop	C1-TransferSvcToStopPanelExt	C1-TransferSvcToStopCSRExt
Person and Account Details	C1-TransferAcctDetPanelExtend	C1-TransferAcctDetCSRExtend

Adding Custom Text to the Start, Stop, and Transfer Processes

When using the start, stop, or transfer processes, agents or CSRs users may need specific instructions or may need to provide specific information to customers, such as how their information such identifiers or email are used. This functionality is referred to as “Agent Contact Scripting” and the system is delivered with specific places in the processes where custom text can be added. These places are called “Script Points” and are maintained as extendable lookup values.

When setting up start, stop, and transfer customer service request, you can configure the text that appears for the provided script points. Refer to the embedded help on the Agent Contact Scripting sections for more information on how to configure this feature.

If your implementation has added custom elements through data area extensions, those extensions can reference custom script points. To implement this, you need to ensure your map fragment’s class attribute is set to “contact-script-point” and the scriptPoint attribute is set to the CM script point extendable lookup value. Here is the sample syntax: <div class="contact-script-point" scriptPoint="CM-NewScriptPoint"/>.

Questions and Response Processing

A customer service request type defines the questions to ask the customer during the flow of self-service start / stop / transfer service requests. Questions are presented, based on the applicability to the customer and / or the premise(s) / SP(s) / SA(s) being started / stopped.

The responses to questions can be inputs to service eligibility criteria processing, to determine: start options (for new/ additional services), additional SAs to start (e.g. non-SP-based SAs) and changes to whether or not selected services (for start / stop) are eligible to be started/stopped.

Questions can also be configured to update person / account / premise attributes and characteristics with the captured responses when the start / stop / transfer service request is processed or completed.

The following sections describe question configuration and response processing.

Understanding Customer Service Request Questions

One or more questions can be asked during the flow of a self-service New Service / Add Service / Stop Service / Transfer Service request. The questions can vary across customer service request types. For instance, the questions asked during a self-service New Service / Add Service request differ from the questions asked during a Stop Service request. Transfer Service requests ask questions for both stopping service and starting service.

The base product provides a Customer Service Request Type Question business object (**C1-CSRTQuestion**) for configuring questions. Refer to the business object in the application for more information

The following describes the functionality that this business object supports:

Question Structure and Valid Answers

A Customer Service Request Type Question references a Customer Question that defines the structure of the question - i.e., question text, answer style (i.e., data type), and valid answers (if applicable).

Refer to [Defining Customer Questions](#) for more details.

Question Applicability

The questions to ask during the flow of a customer service request can be determined using any of the following applicability criteria:

- The customer starting/stopping service is a Person or Business
- Account's Customer Class
- Start / Stop Premise's Premise Type
- SP Type(s) on the Premise(s) being started / stopped

Applicability criteria is optional. General questions can be configured to be always applicable.

Questions are marked as either Required or Optional. When marked as Optional on the CS Request Type Questions, it can be overridden as Required for certain SP Type(s) or Premise Type(s) or any other custom applicability criteria.

Your implementation can extend applicability criteria by:

- Adding elements to the CS Request Type Question - Main (**C1-CSRTQuestionMain**) data area, and / or
- Adding lookup values for Question Related Object Type (QSTN_REL_OBJ_TYPE_FLG)

Note that if you choose to extend the Question Related Object Types, you will also need to customize the **Read Questions** algorithm plugged in on the Customer Service Request Type BOs, to handle your additional applicability criteria.

Answer-Based Question Relationships (Conditional Questions)

A question can have one or more valid answers. Each valid answer, in turn, can determine the next question to ask.

A Customer Service Request Type Question can reference a related question for each Valid Answer. The related question must be one that is already configured on the Customer Service Request Type. Therefore, questions configuration should be a two-step process:

- Add all questions to the Customer Service Request Type.
- For each question, set up the related question(s) based on its valid answer(s).

The system has validation in place to ensure that question relationships do not result in recursion.

Question Placement Groups

A customer service request type can logically group questions based on where they are shown on the user interface. For instance, with a Transfer Service Request, the questions for stopping service are shown separately from the questions for starting service.

A Customer Service Request Type Question can be designated with a Question Placement Group, which is an extendable lookup (**C1-QuestionPlacementGrpLookup**) field. Base-owned lookup values are provided for Self-Service Start Service and Self-Service Stop Service. Each lookup value defines the customer service request type business objects that can use the Question Placement Group. Your implementation can define additional lookup values, if the groupings need to be more specific / granular.

Retrieving Applicable Questions

The **Read Questions** plug-in on the Customer Service Request Type BO is responsible for retrieving the questions that are applicable to a customer service request type. Given the inputs (Customer Service Request Type, Person ID, Account ID and Premise ID), the questions are read based on applicability criteria: Person / Business, Customer Class, Premise Type, SP Type(s) and/or any implementation-specific question applicability criteria (configured in Question Related Objects).

The **Read CS Request Type Questions By Applicability (C1RDCSRTQSTN)** base algorithm will apply Person / Business, Customer Class, Premise Type and SP Type criteria. Additional applicability criteria will require a custom algorithm type.

The Read Questions plug-in spot is invoked using a common service script, **Read CS Request Type Questions By Applicability (C1RDCSRTQSTN)**. The Service Questions operation of the **Start Stop Transfer Tasks IWS** calls this script to read the applicable questions to show on the self-service user interface. Refer to this IWS' specifications for more details.

Understanding Service Eligibility

A service eligibility criterion has four components:

- The value to compare.
- The comparison method, which consists of an operator and a comparison value.
- Action to take, based on the comparison results. The result can be any of: True, False or Insufficient Data. For each result, the possible actions are: Eligible, Not Eligible, Check Next Condition.
- The SA Type(s) and any applicable Start Options that are eligible for start / stop when the comparison results in an Eligible action.

The base product provides a CS Request Type Svc Eligibility Criteria business object (**C1-CSRTSvcEligCriteria**) for configuring service criteria. Refer to the business object configuration in the application for more information

The following describe the functionality that this business object supports:

Criteria Basis and Comparison Method

The **Criteria Basis** on CS Request Type Service Eligibility Criteria determines the value to compare:

- **Question Response** uses the response to a question that is configured on the CS Request Type.
- **Derive Value Algorithm** retrieves a field or characteristic value from an existing object, such as Person, Account or Premise. The base product provides algorithms to retrieve: an attribute from Account, an attribute from Premise and a characteristic value from Person / Account / Premise / SP / SA. Refer to the algorithm types for the **CS Request Type Svc Criteria - Derive Value** algorithm entity, for details.

The **Criteria Comparison** defines the operator to use and the value to compare with either question response or algorithm-derived value. The base product supports the operators: =, <>, >, >=, <, <=, Between and In. The comparison value is a free-form string, which should contain comma-separate values when the operator is Between or In.

Configuring Eligible SA Types and Start Options

At least one Eligible SA Type must be configured on a service eligibility criterion. If configuring multiple SA Types, designate one of them as the default. Configure any applicable Start Option(s) and designate one as the default.

Applying Service Eligibility Criteria

The **Apply Svc Criteria** plug-in on the Customer Service Request Type BO is responsible for processing service eligibility criteria, given input: the selected SPs and SAs to start / stop, list of question responses and the service task ID.

The **Apply Service Eligibility Criteria (C1CSRTAPSEC)** base algorithm reads the service eligibility criteria and performs the criteria comparisons for each.

The **Apply Svc Criteria** plug-in spot is invoked from the common service script for response processing, **Process Question Responses (C1ProQstnRsp)**. The Process Services to Start and Process Services to Stop operations of the **Start Stop Transfer Tasks IWS** calls this script to apply the service eligibility criteria using the question responses capture from self-service. Refer to this IWS' specifications for more details.

Enabling Service Eligibility Criteria

To enable service eligibility criteria:

- Identify the CS Request Type Questions, for which the responses will be used as the values to compare on service eligibility criteria.
- Determine the 'Derive Value' processing that your implementation needs
 - To use the base-provided **CS Request Type Svc Criteria - Derive Value** algorithms:
 - Configure algorithm instances for the **Retrieve Account Attribute (C1SCRETACCT)** algorithm type.
 - Configure algorithm instances for the **Retrieve Premise Attribute (C1SCRETPREM)** algorithm type.
 - Configure algorithm instances for the **Retrieve Effective-Dated Characteristic Value (C1SCRETEFFCH)** algorithm type.
 - Identify and develop any additional **CS Request Type Svc Criteria - Derive Value** algorithms.
- Configure the Service Eligibility Criteria for your implementation's self-service New Service, Add Service, Stop Service and Transfer Service customer service request types. For each criterion, specify:
 - The criteria comparison details - criteria basis, question or algorithm (depending on the criteria basis), operator and comparison value.
 - The actions to take for comparison results True, False and Insufficient Data.
 - The eligible SA Types and any applicable start options.

Refer to [Setting Up Service Eligibility Criteria](#) for more details.

Understanding Response-Related Updates

The questions configured on the customer service request type can be set up to perform related updates when the start / stop / transfer service request is processed and / or completed.

A response-related update can store the response value in a specific attribute or characteristic on objects such as Person, Account, Premise, SP and SA. In other cases, the the response value can be used to derive the actual value to store on a particular attribute (e.g. when the attribute is a foreign key to an admin table or a lookup).

The base product provides a CS Request Type Related Update business object (**C1-CSRTRelUpd**) for configuring response-related updates. Refer to the business object configuration in the application for more information

The following describes the functionality that this business object supports:

Related Update Entity Defines The Object To Update

A response-related update specifies a Related Update Entity, which identifies the maintenance object (i.e. Account, Person, Premise, etc.) and the specific part of the object to update - i.e., table field, characteristic or a custom element in the CLOB/XML.

Related Update Entity is an extendable lookup (**C1-CSRTRelUpdEntity**) that has several base-supplied values, to support updates to fields and characteristics on Person, Account, Premise, etc.. Your implementation can add other objects to update by adding values to this lookup.

Response-Related Updates Are Staged For CS Request Processing

Response-related updates are staged into the CS Request Person / Account / Premise or directly on the CS Request, so that all updates to each object are done at the same time - i.e. when the CS Request transitions to a specific status. For instance, with a Start Service Request, the Person(s) and Account are updated when the request transitions to the Service Processing state. An algorithm on that state transitions the CS Request Person and CS Request Account staging records, that will in turn, update the Person(s) and Account. The CS Request SA records are also created and transitioned at that point. The CS Request Premise(s) are transitioned when the CS Request is transitioned the Completed state. Updates to SP attributes and characteristics need to be staged directly on the CS Request, as there is no staging object for SP.

Each response-related update specifies a Processing Algorithm that is responsible for staging the update on the applicable CS Request staging object. The base product provides processing algorithms for the Related Update Entities that are supported in base. Refer to the algorithms types for the **CS Request Type Related Update - Process** algorithm entity, for more details.

Staging Related Updates

The **Stage Related Updates** plug-in on the CS Request Type (BO) is responsible for invoking a customer service request type's response-related updates. It reads the Response-Related Update configuration and invokes the associated **CS Request Type Related Update - Process** algorithms.

The **Stage Related Updates** plug-in spot is invoked using a common service script, **Process Related Updates (C1ProcRelUpd)**.

When a self-service start / stop / transfer request is finalized, an enter algorithm on the service task's Service Processing state calls the Process Related Updates service script before transitioning the CS Request (that in turn, transitions CS Request Person, Account, etc). Refer to the Self-Service Start/Stop/Transfer Task (C1-SSStartStopXferServiceTask) business object, for details on this lifecycle processing.

Enabling Response-Related Updates

To enable response-related updates for configured CS Request Type Questions:

- Determine the Related Update Entities that your implementation needs to support:
 - To use the base-provided Related Update Entities, configure the **CS Request Type Related Update - Process** algorithm instances for the specific fields and / or characteristics that should be updated from the responses.
 - Configure any additional **Related Update Entity** lookup values and develop the corresponding **CS Request Type Related Update - Process** algorithms for them.
- Identify the CS request type questions that will trigger response-related updates. Configure a Response-Related Update for each of these questions, specifying the applicable Related Update Entity and Processing Algorithm. Refer to [Setting Up Response-Related Updates](#) for more details.

Setting Up Customer Service Request Questions

A customer service request type can define one or more questions to ask during the flow of customer service requests, such as self-service New Service, Add Service, Stop Service and Transfer Service.

Refer to [Understanding Customer Service Request Questions](#) for more information.

To configure questions, open **Admin > Customer > Customer Service Request Type** and navigate to the **Questions** tab page.

The Questions List zone displays all questions that are configured for the customer service request type. Search filters are provided, to allow specific search using any of the following criteria: Person/Business, Customer Class, Premise Type (applicability), SP Type (applicability), Sort Sequence (range) and Status.

The Question zone displays when a record is broadcast from the Questions List. Refer to the zone's embedded help for more details.

Setting Up Service Eligibility Criteria

A customer service request type can define one or more service eligibility criteria to apply, using the responses to questions and/or information that is already stored in the system (e.g. person / account / premise attributes and characteristics).

Service eligibility criteria processing can determine one or more of the following:

- Applicable start option(s) for SP-based service agreements that are selected for starting service.

- Additional service agreements that are eligible to start. For example, non-SP-based service agreements, such as charitable contributions, equipment rentals, loans, etc.
- A change in whether or not a selected SP-based service agreement can be started/stopped.

Refer to [Understanding Service Eligibility](#) for more information.

To configure service eligibility criteria, open **Admin > Customer > Customer Service Request Type** and navigate to the **Service Eligibility** tab page.

The Service Eligibility Criteria List zone displays all service eligibility criteria that are configured for the customer service request type. Search filters are provided, to allow specific search using any of the following criteria: Sort Sequence range, Question text and Status.

The Service Eligibility Criteria zone displays when a record is broadcast from the Service Eligibility Criteria List. Refer to the zone's embedded help for more details.

Setting Up Response-Related Updates

Question responses can trigger updates to Person, Account and / or Premise attributes and characteristics, when the request is processed or completed. A Response-Related Update defines: the object to update, the object's attribute / field to update and the algorithm that will process the update. The base product provides algorithms that store question responses in: characteristics, a table fields (on the object's primary table), or a custom element in the object data area (CLOB) field (on Person).

Refer to [Understanding Response-Related Updates](#) for more information.

To configure Related Updates, open **Admin > Customer > Customer Service Request Type** and navigate to the **Response-Related Updates** tab page.

The Response-Related Updates List zone shows all questions that are currently configured for the customer service request type. Each can be configured with a related update that stores the response to the question in a field / attribute / characteristic on Person, Account or Premise. Click **Add Related Update** or **Edit Related Update** to configure the related update.

The Respons-Related Update zone displays when a record is broadcast from the Response-Related Updates List. Refer to the zone's embedded help for more details.

Defining Customer 360 Options

The following section provides an overview of how to enable Customer 360.

FASTPATH:

Refer to [Customer 360](#) for more information on this functionality.

Setting Up The System To Enable Customer 360

To set up the system for Customer 360, do the following:

- Define Display Icon Override Configuration settings.
- Define Billing and Usage Configuration settings.

Display Icon Override Configuration

This section describes the process for configuring display icons that are used within the various zones for Customer 360. For example, icons that appear alongside nodes within the Premise Context tree, as well as icons that appear within records of the Customer Activity and Financial History zones.

By default, display icon references are configured at the Maintenance Object or Business Object level using the **Default Icon Reference** Option Type. For certain Maintenance Objects, these icons can be overridden based on their type fields. For example, a Customer Contact can have an override icon based on its Contact Class or Contact Type, a Service Agreement can have an override icon based on the SA Types Service Type, etc.

Display icon overrides are configured by adding or changing a Master Configuration. You can access the portal through **Admin > General > Master Configuration**.

From the Master Configuration list, add or edit the **Display Icon Override Configuration** record. Use the Add button to configure for the first time. If a record has already been added, click the Edit button instead. Use the embedded help to guide you through the options.

Billing and Usage Display Configuration

There are several options available to tailor your Customer 360 Billing & Usage data display via Master Configuration - Billing and Usage Display Configuration. The units of measure, the specific service quantities to display per rate, the default time period, as well as the summarization of the data within the bar chart can all be adjusted per your organization's needs.

Billing and Usage display settings are configured by adding or changing a Master Configuration. You can access the portal through **Admin > General > Master Configuration**.

From the Master Configuration list, add or edit the **Billing and Usage Display Configuration** record. Use the Add button to configure for the first time. If a record has already been added, click the Edit button instead. Use the embedded help to guide you through the options.

Defining Service Order Options

Service orders manage the activities that are required to enable service, disable service, and perform other operations. These activities can range from simple events (such as, a meter read) to complex events (such as, installing a power line and a new meter). They can also include both fieldwork and smart commands.

Service Orders

This section provides an overview of service order activities.

SOM Options Overview

Understanding Service Order Management

At a high level, service order management handles requests for service as follows:

Receive / Create Service Order Request

A service order request is created and/or received. This can be as a result of a customer requesting a change to their service such as enabling or disabling service when moving into or out of a residence, but can also be the result of other business processes, such as a request to cut service due to non-payment.

Regardless of the origin of the request, a service order request is created in a customer information system (CIS) such as Oracle Utilities Customer Care and Billing), which in turn is sent to Service Order Management.

Create Service Order Activity

When Service Order Management receives the service order request, it creates a service order activity. This activity will manage and orchestrate any/all other activities needed to fulfill the original service request.

Evaluate Service Point and/or Meter

The service order activity then evaluates the current state of the service point, meter, or item, and determines the appropriate action(s) to take to fulfill the service request.

Create Activities as Needed / Appropriate

Based on the evaluation of the service point/meter/item, the service order activity creates one or more activities as needed.

- Service order field activities involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.
- Command activities are smart meter commands used to remotely change the state of the meter. This can include connect, disconnect, checking the device status (ping), or requesting an on-demand reading.

Following each of activities, the orchestration activity re-evaluates the state of the service point/ meter/item to determine the next appropriate action(s) required to fulfill the original service request.

For example, when enabling service at a service point with a smart scalar meter, a typical scenario might involve the following:

1. Service Order Field Activity - Install Meter
2. Command Activity: Commission Device
3. Command Activity: Remote Connect
4. Command Activity: On Demand Read - Scalar

Update Requesting System

When the service order activity determines that everything necessary to satisfy the service order request is ready, the service order activity will inform the requester and complete the original request.

Send Notification to Subscribing Systems

The service order activity can also be configured to send notifications to other subscribing systems regarding the status of the service point/meter/item.

Supported Service Order Processes

Service Order Field Activity supports the following service order processes as part of the base package.

- [Enable Service](#)
- [Disable Service](#)

- [Cut for Non-Payment](#)
- [Reconnect for Payment](#)
- [Meter Exchange](#)
- [Back-to-Back](#)
- [Cancellation Service Order Requests](#)
- [Update Service Order Requests](#)

Enable Service

Enable Service is a request to start service for a particular service point. It is typically initiated by a *Start Service* field activity request, but can also be initiated by another CIS application.

A Start Service field activity request results in the creation of an Enable Service orchestration activity. The Enable Service orchestration activity then initiates the necessary field activities and smart meter commands to change the state of service at a service point to Enabled and confirm that an initial measurement exists; for example, an enable service orchestrating activity could involve the following service order field activities and smart meter commands based on the state of the service point:

- If there is no meter at the service point and the service point is not connected at the source, a service order field activity will be created to connect the service point to its source and install a meter.
- If a smart meter exists at the service point and it is in a disconnected state, a smart meter command will be sent to the appropriate head-end system to connect the meter.
- If there is a non-smart (manual) meter at the service point and it's On, a service order field activity will be created to request a read on or near the start date (depending when the next read is scheduled).

Disable Service

Disable Service is a request to stop service for a particular service point. It is typically initiated by a *Stop Service* field activity request, but can also be initiated by another CIS application.

A Stop Service field activity request will result in the creation of a Disable Service orchestration activity in Service Orders. The Disable Service orchestration activity will initiate the necessary field activities and smart meter commands to change the state of service at a service point to Disabled and confirm that a final measurement exists; for example, a disable service orchestration activity could invoke the following service order field activities and smart meter commands based on the state of the service point:

- If there is a non-smart (manual) meter at the service point and it's on, a service order field activity will be created to turn off the meter.
- If a smart meter exists at the service point and its state is connected or commissioned, a smart meter command will be sent to the appropriate head-end system to perform a remote disconnect of the meter.

Cut for Non-Payment

Disconnect for non-payment is a type of field work that is most often initiated from a collections process that has been created from within the Credit & Collection module. A collections process is created when the customer's current balance has been determined to be past due. One of the methods for eliciting payment is to issue a disconnect. A *Disconnect for Non-Payment* field activity request will result in the creation of a Cut Service for Non-Payment orchestration activity in Service Orders. The Cut Service for Non-Payment orchestration activity will initiate the field activities and/or smart meter commands necessary to change the state of service at a service point to the disabled state.

For a Cut for Non-Payment service order, the orchestrations steps will include determining if a smart meter command can be executed, or if a request to a mobile field work application (such as Oracle Utilities Mobile Workforce Management) to dispatch a truck needs to be executed. Another example might be to determine if a disconnect can be executed for a service point. These rules might include determining if there is life support equipment at the premise, or if the service point can be

disconnected at the current time of year or business hours based on utility defined rules taking into account predominant weather conditions (for instance, the utility cannot disconnect someone in the dead of winter or the service point resides at a postal code that is affected by extreme cold weather).

Reconnect for Payment

Reconnect Service for Payment is a request to restart service for a particular service point after customer has paid off their past due balance. It is typically initiated from the Credit & Collection's Severance Process.

A Reconnect for Payment field activity request will result in the creation of a Reconnect Service for Payment orchestrator activity in Service Orders. The Reconnect for Payment orchestration activity will initiate the field activities and/or smart meter commands necessary to change the state of service at a service point to the enabled state; for example, a service order request to reconnect service could involve the following service order field activities and smart meter commands based on the status of the service point:

- If there is a non-smart (manual) meter at the service point and it's turned off, a service order field activity will be created to turn on the meter.
- If a smart meter exists at the service point and it is in a disconnected state, a smart meter command will be sent to the appropriate head-end system to connect the meter.

Meter Exchange

Meter Exchange service is basically an exchange of an old meter with a new meter. A meter exchange request may be initiated as the result of:

- A smart meter rollout.
- A customer opting-out of having a smart meter.
- A meter no longer working correctly.
- A meter reaching the end of its life expectancy.
- A customer with a manual meter enrolling in a program that requires a smart meter.
- A need to upgrade measurement capabilities.

Meter exchanges can be initiated in a variety of ways, including:

- Within service order field activities (internally)
- By an external CIS or asset management system such as Oracle Utilities Operational Device Management
- A pick-up order from a field work application such as Oracle Utilities Mobile Workforce Management

Meter Exchanges involving smart meters will include smart meter commands in addition to field activities. A request can optionally include information on the type of meter needed, depending on the requesting system; this information could be specific (the type of configuration) or general (smart or manual).

Back-to-Back

Back to Back service is service disablement and enablement in single step; for example, one customer moving out while another moves in. The main purpose of this service is to minimize dispatching field work to obtain readings for both a start and stop event.

Another example of a back-to-back scenario would involve an tenant moving out and another moving into the same premise. As long as the gap between tenants (vacancy) is within the utility company's threshold, the change would be considered as a back-to-back event. In this situation, a single field task is used for this event to take the meter reading.

A Back-to-Back Service field activity request will result in the creation of a Back-to-Back Service orchestration activity in Service Orders. The Back-to-Back Service orchestration activity will initiate the field activities and smart meter commands necessary to change the state of the service of both customers at a service point to the desired state and confirm that measurements exists for that period.

Canceling Service Order Requests

A cancellation request basically cancels any orchestration and/or specific activities that are in progress. If the cancellation request is for an orchestration activity then that orchestration activity along with corresponding activities will be discarded. If the cancellation request is for a specific activity then only that specific activity will be discarded.

Depending on the status of a specific activity, a Cancel orchestration activity will either discard the activity or an outbound communication will be sent to the field work system to request a cancel the specific activity. Once the cancellation sent to the field work system is confirmed as successful, the Cancel orchestration activity will also cancel the parent orchestration activity and/or specific activities. If the cancellation sent to the field work system is not successful then the Cancel orchestration activity will be discarded. When it is discarded, it will send a response message to the requester indicating the cancellation was unsuccessful. A cancellation request can be initiated in a variety of ways, including by cancelling a field activity request , within Service Orders itself (internally), and by an asset management system such as Oracle Utilities Operational Device Management. Cancellation requests can also be created as pick-up orders from a field work application such as Oracle Utilities Mobile Workforce Management.

Update Service Order Requests

An update request handles requests for updates to an existing enablement, disablement, cut for nonpayment, and reconnect for payment orchestration activity and their related specific field activities.

The types of data available for update include the following:

- Instructions
- Comments
- Start Date/Time
- Contact Name
- Main Phone

Additionally, an update request can check to see if appointment information is different between the specific activity and the update orchestration activity. Depending on the status of the specific activity, direct updates will be made to the activities and communications within Service Orders or an outbound communication will be sent to the field work system to request an update of the specific activity fields that have been changed. Once that update to the field work system is confirmed as successful the Update orchestration activity will update the effected orchestration activity. If the updates are not successful the Update orchestration activity will be discarded. When it is discarded, it will send a response message to the requester indicating the update was unsuccessful.

Update service requests can be initiated by a field activity request or within Service Orders itself (internally).

Defining Disconnect Locations

When a service point is disconnected from the supply source, a disconnect location must be specified. This location defines where service was severed.

To define disconnect location codes, open **Disconnect Location** page.

Description of Page

Enter a **Disconnect Location** and **Description** for every disconnect location.

Defining Field Activity Profiles and Types

A field activity request initiates a service order to perform a task at a service point. Every field activity request references a field activity type.

Most field activity requests are created:

- When a customer service representative starts or stops service at a premise. When this happens, the system automatically creates field activity requests for each service point.
- When service is cut due to lack of payment.

If you set the system up correctly, your CSRs won't have to create these field activity requests. Rather, the system creates field activity requests based on the information you set up in your field activity type profiles.

- Refer to [Starting Service & Field Activities](#) for a description of how field activity requests are created to start service.
- Refer to [Stopping Service & Field Activities](#) for a description of how field activity requests are created to stop service.
- Field activities used to cut service due to non-payment are created by two modules:
 - If you use severance process to stop a service agreement due to nonpayment, refer to [Field Events And Their Activities](#) for a description of how these field activity requests are created.
 - If you use cut processes to stop a service agreement due to nonpayment, refer to [Field Activities To Cut and Reconnect Service](#) for a description of how these field activity requests are created.

The topics in this section describe how to design your field activity profiles and field activity types.

How Does A Field Activity Type Profile Get Used?

A field activity type profile contains:

- A list of the types of field activity requests that can be made for service points.
- A matrix defining the specific activity type(s) to generate in order to start service, stop service, or disconnect due to nonpayment.

You may wonder how field activity type profiles get related to your service points. It's a little indirect, but the indirection provides a great deal of flexibility:

- Every service point references an SP type.
- Every SP type references the specific field activity type profile used by the start/stop and credit and collections process to generate field activity requests.

An example will help illustrate how this works:

- When you start service at a specific service point, the system extracts the service point's SP type.
- Then, the system determines the field activity type profile that is to be used on this SP type.
- And finally, it generates the appropriate field activity request.

Designing Field Activity Type Profiles

With Service Order Management typically only a single field activity type profile will be needed for the meter and item related service points. This profile should have a template for each of the following with a service point condition of *External Fieldwork Orchestration* to indicate that Service Order Management is orchestrating the field work:

- Start Service
- Stop Service
- Start/Stop

- Cut for Non-Payment
- Reconnect for Payment

Designing Field Activity Types

A field activity type is required for the following events:

- Start service
- Stop service
- Cut for non-payment
- Reconnect for payment
- Back-to-back

Setting Up Field Activity Types

The topics in this section describe how to set up field activity types.

FASTPATH:

For more information about field activity types, refer to [Defining Field Activity Profiles and Types](#).

Field Activity Type - Main

You begin to define a field activity type by opening **Admin > Field Work > Field Activity Type > Add**.

Description of Page

Enter an easily recognizable **Activity Type** and **Description** for each field activity type.

Use **Field Activity Priority** to define the priority associated with field activity requests of a given type.

NOTE:

The values for this field are customizable using the Lookup table. This field name is FA_PRIORITY_FLG.

Turn on **Display as Alert** if Control Central should display an alert if its premise has a completed field activity request of this type. If this switch is on,

- Use **Nbr Days Alert Active** to define the number of days the alert should appear on Control Central. The field activity request's scheduled date is used as the start date for the alert period.
- Enter the **Alert Information** to appear on Control Central.

NOTE:

Recommendation. We recommend only using this feature on unusual field activity types (e.g., cut for non-payment) so that a CSR is not presented with an alert for every field activity request.

Enter the **Business Object** for this FA Type if the FA type will need access to the BO plug-in spots. If the FA type has a business object specified, the system applies the business object's rules when the FA is added, changed, or deleted. This includes the business object's validation algorithms (only executed after the "core validation" specified on the maintenance object is done), post-processing algorithms, and audit algorithms. The maintenance object for the FA should specify an

algorithm that finds its business object using its FA Type. Refer to the base package Determine Standard Business Object algorithm for an example of this type of algorithm.

Field Activity Step is not applicable when Service Order Management is used.

Use the **Characteristic** collection to define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics that are common to all field activity requests of this type.

NOTE:

You can only choose characteristic types defined as permissible on the field activity type record.

Field Activity Type - FA Characteristics

Description of Page

Use the **Characteristics** collection to define characteristics that can be defined for field activity requests of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on field activity requests of a given type. Turn on the **Default** switch to default the **Characteristic Type** when field activity requests of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

NOTE:

Field activity requests created by the system. When setting the Required switch, remember that most field activities are created by the system. Only turn on the required switch for these types of activities if a default characteristic value can also be indicated

Field Activity Type - FA Completion Control

Description of Page

NOTE:

These algorithms are optional. The use of completion algorithms on a field activity type is optional. You would only use them if you have special functions that should be executed when a given field activity type is completed.

The **Field Activity Completion Controls** tab is used when an algorithm should be executed when a field activity request is completed. The type of algorithm may differ based on the CIS division in which the service point's premise is located. The following fields must be defined:

CIS Division Defines the division associated for which the algorithm will be executed. The system will only execute the algorithm when a field activity request is performed at a service point whose premise is governed by the division.

FA Completion Algorithm Defines the algorithm that will be executed when a field activity request is performed at a service point whose premise is governed by the associated division.

Field Activity Type - SP Type Review

Not applicable when Service Order Management is being used.

Setting Up Field Activity Type Profiles

The topics in this section describe the pages used to define a field activity type profile.

NOTE:

When a new profile is added. When you introduce a new field activity type profile, you must define the SP types that use it. Refer to [Understanding Service Point Types](#) for more information.

FASTPATH:

For more information about field activity type profiles, refer to [Designing Your Field Activity Profiles & Types](#).

Field Activity Type Profile - Main

Description of Page

Enter a unique **Field Activity Type Profile** and **Description** for the activity type profile.

The **FA Type Profile Templates** indicate the templates that exist for this field activity type profile. Use the drill down button to go directly to the desired template. Alternatively, you can go to the **Template** tab and scroll until you find the correct template.

Field Activity Type Profile - Template

Description of Page

The information in the **Field Activity Profile Template** collection defines the field activity request(s) created for each situation identified by the **Customer Event**. The possible customer events are Cut for Non-payment, Disconnect Warning, Reconnect for Payment, Reread, Stop Service, Start Service, and Start/Stop.

NOTE: Field activity requests do not need to be defined for Reread when Service Order Management is being used.

Other customer events can be defined on the [Look Up](#) page (search for the CUST_EVT_FLG field name). Refer to the following sections for more detail about customer events included with the base product.

The fields defined for each event are common. You define the field activity request(s) to be generated given the condition of the service point. The following fields display:

SP Field Condition Define the condition of the service point associated with the field activity. Define *External Fieldwork Orchestration* when Service Order Management is being used.

Sequence You will typically have a single field activity request for any specific combination of SP Field Condition and Disconnect Location. Therefore you'll just have a single sequence (say 10) for each combination. If you need to generate multiple field activities based on a given combination, use a unique sequence number for each activity.

No Activity Turn on this switch if no field activity should be generated for the condition.

Disconnect Location this is not applicable when Service Order Management is being used.

Activity Type Define the type of field activity request to be generated. You should take care to ensure that the activity type is defined as valid for the SP type (on the last page).

Where Used

Refer to the following sections for information about where each template is used.

Field Activity Requests Initiated To Start Service

Use the customer event Start to define the field activity request(s) used to start service at a service point whose SP type references this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start service process uses this information to determine the type of field activity requests to create to start service at a service point.

WARNING:

Warning. Field activity requests will only be created for starts if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activity Requests Initiated To Stop Service

Use the customer event Stop to define the field activity request(s) used to stop service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The stop service process uses this information to determine the type of field activity requests to create to stop service at a service point.

WARNING:

Warning. Field activity requests will only be created for stops if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activity Requests Initiated For Back-to-Back Service

Use the customer event Start/Stop to define the field activity request(s) used to stop service for one customer and start service for another at a service point whose SP type uses this profile.

NOTE:

Terminology. We use the term **back-to-back** to describe the situation when a single field activity request supports both the stop and start service requests. The system sets up a back-to-back situation by default when it is aware of both the start and stop customers at a premise.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start/stop service process uses this information to determine the type of field activity requests to create to start service at a service point.

Field Activity Requests Initiated To Cut Service Due To Non-Payment

Use the customer event Cut for Non-Payment to define the field activity request(s) used to cut service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to cut service at a service point.

Field Activity Requests Initiated To Place A Disconnect Warning At A Service Point

Use the customer event Disconnect Warning to define the field activity request(s) used to place a disconnect warning at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to leave a disconnect warning at a service point.

Field Activity Requests Initiated To Reconnect Service At A Service Point

Use the customer event Reconnect for Payment to define the field activity request(s) used to reconnect service (after being cut) at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to reconnect service at a service point.

Field Activity Requests Initiated To Reread A Meter At A Service Point

This template is not applicable when Service Order Management is being used.

Defining A Profile's Valid Field Activity Types

Description of Page

The **Field Activity Type** collection shows the field activity requests that may be created for at service points whose SP type references the field activity type profile.

Where Used

This information is used to control the types of field activity requests that may be created for at a service point.

Setting Up Fieldwork Cancellation Reasons

Description of Page

Enter a **Cancel Reason** and **Description** for every field activity request cancellation reason.

Only use **System Default** on those reason codes that are placed on field activity requests that are automatically canceled by the system. The following table lists the valid values and the condition where this cancel reason is used.

System Default	System Condition
Cut Process canceled	Placed on field activity requests that are canceled when a Cut Process is canceled.
SA Start/Stop canceled	Placed on field activity requests that are canceled when a pending start/stop is canceled.
Severance Process canceled	Placed on field activity requests that are canceled when a severance process is canceled .

NOTE:

Required values. You must have one reason code defined for each of the System Default values that corresponds to an event that may occur in your implementation.

Setting Up Field Activity Remarks

NOTE: Field work remarks are typically processed by Service Order Management; therefore, field activity request remarks are not required.

Description of Page

Enter a unique **Field Activity Remark** and a **Description** for every field activity request remark.

Turn on **Eligible for Processing** if field activity requests marked with a given remark code should cause one or more algorithm to execute.

The grid contains **Algorithms** associated with the field activity request remark. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
--------------	---------------------	-------------

Setting Up Outage Call Types

When you create an outage call, you must supply an outage call type. Outage call types contain a great deal of information that is defaulted onto the outage call, including the outage category group codes or trouble codes. To set up outage call types, open **Admin > Field Work > Outage Call Type > Add**.

FASTPATH:

Refer to [The Big Picture of Outage Care Integration](#) for more information about how trouble calls are created and sent to NMS

The topics in this section describe the base-package zones that appear on the Outage Call Type portal.

Outage Call Type List

The Outage Call Type [List zone](#) lists every outage call type, i.e. every service task type that has a service task type class of Outage Call. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent outage call type.
- Click the Add link in the zone's title bar to add a new outage call type.

Outage Call Type

The Outage Call Type zone contains display-only information about an outage call type. This zone appears when an outage call type has been broadcast from the Outage Call Type [List zone](#) or if this portal is opened via a drill down from another page. The following functions are available:

- **Edit:** to start a business process that updates the outage call type.
- **Delete:** start a business process that deletes the outage call type.
- **Duplicate:** to start a business process that duplicates the outage call type.

Please see the zone's help text for information about this zone's fields.

Setting Up Service Call Communication Types

A Service Call Communication Type defines the rules and controls for creating service call communications.

Refer to [Asset Management System Integration](#) for more information.

To set up service call communication types, open **Admin > Field Work > Service Call Communication Type > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service call communication type depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Setting Up Service Categories

A service category represents a broad category of services.

Refer to [Asset Management System Integration](#) for more information.

To set up service categories, open **Admin > Field Work > Service Category — CCB > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service category depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Setting Up Service Codes

Service Codes are used to create the appropriate work record from the service call

Refer to [Asset Management System Integration](#) for more information.

To set up service codes, open **Admin > Field Work > Service Code — CCB > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service code depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Service Order Management External Applications

The external systems used with Service Order Management must be defined as External Applications using the "External Application" (D1-ExternalApplication) business object. Examples of external systems can include:

- A customer information system (such as Oracle Utilities Customer Care and Billing)
- A field work system
- An asset management system (such as Oracle Utilities Operational Device Management or Oracle Utilities Work and Asset Management)

Information defined for external system service providers used by Service Order Management include:

- **Our Name/ID in Their System:** This is the value that the field work system uses to identify our system.
- **Utility Device ID Type:** This is the Device ID Type that will be used when communicating with the external application and it will be the assumed Device ID Type for any device identifiers sent from the external application.
- **Utility Service Point ID Type:** This is the Service Point ID Type that will be used when communicating with the external application and it will be the assumed Service Point ID Type for any service point identifiers sent from the external application.

Refer to [Understanding External Applications](#) and [Configuring External Applications](#) for more information about external applications.

Processing Roles

The external application's processing roles define how data relevant to the field work system is sent and/or created.

Field work service providers can use the following processing roles:

- **Activity Notification:** Used to send notifications to subscribing and/or requesting systems about the status of orchestration and/or service order field activities.
- **Appointment Request:** Used to send a request for an appointment to the field work system.
- **Cancelation Activity:** Used to send notifications to requesting systems when canceling orchestration and/or service order field activities.
- **Collection Details:** Used to retrieve details about collections processing (used with "Cut Service for Non-Payment" and "Restore Service for Payment" orchestration activities).
- **Customer Contact:** Used to send a contact to a customer regarding a service request
- **Field Activity:** Used to send a service order field activity to the field work system.
- **Field Activity Completion:** Used to send a notification regarding completion of a service order field activity.
- **Interim Status Update:** Used to send updates regarding the status of orchestration and service order field activities to requesting systems.
- **Meter Exchange Mapping:** Used to define how to define different types of meter exchanges based specific roles and device configurations. This can provide context to field crews to help ensure they install the correct type of device and device configuration when exchanging a meter.
- **Response - Appointment:** Used to send a request for an appointment to the field work system.
- **Response - Fail:** Used to send a response to an external system when Service Order Management fails to respond.
- **Response - Missed Appointment:** Used to send a response to the field work system when notification of a missed appointment is received.
- **Response - Negative Acknowledgement:** Used to send a negative acknowledgement response to an external system in the event that a request is rejected.
- **Response - Received:** Used to send a response to an external system to acknowledge receipt of a request.
- **Response - Success:** Used to send a response to an external system when Service Order Management successfully processes a request.
- **Send Field Activity Remark:** Used to send a service order field activity remark to a subscribing system
- **Update Activity:** Used to send notifications to requesting systems when updating orchestration and/or service order field activities.

Service Order Activities

Understanding Service Order Activities

This section describes service order activities and how they manage the service order process.

Service order activities coordinate a large number of child transactions that represent the communication to and from an external application. The below diagram depicts a service order activity:

Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- **Orchestrating Activity:** controls the overall intent of the communication. For example it may "Enable Service" which would include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- **Specific Activity:** can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- **Communication Out:** orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- **Outbound Message:** represents the message payload sent to the external system and the synchronous response.
- **Communication In:** orchestrates the handling of an asynchronous or unsolicited response from an external system.
- **Completion Event:** carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The base package provides the following types of service order activities:

- **Enable Service:** Used to enable service at a service point.
- **Disable Service:** Used to disable service at a service point.
- **Cut for Non-Payment:** Used to cut off service at a service point due to non-payment of past due amounts.
- **Reconnect Service for Payment:** Used to restore service at a service point after receipt of past due payment.
- **Exchange Meter:** Used to orchestrate the exchange of meters at service point, such as in the event that a customer upgrades their meter.
- **Back to Back Service:** Used to orchestrate a change of service when the customer at a service point changes (such as when owners/tenants change).

Service Order Activity Processing

To understand how service order activities manage the service order process, it's important understand the lifecycle of orchestration activity business objects.

Service Order Orchestration Activity Lifecycle

All service order orchestration activity business objects share a common parent business object that defines their lifecycles. This is the Service Point Activity Orchestration business object (DI-SPActivityOrchestration). The table below outlines the lifecycle for this business object.

State	Description
Pending	<p>The initial state for orchestration activities.</p> <p>An Enter algorithm sends an acknowledgement to the requesting system.</p> <p>The activity is transitioned to the next state via a monitor process.</p>
Validate	<p>Enter algorithms perform the following:</p> <p>Validate Activity Type</p> <p>Validate Service Point</p> <p>Check for a non-final duplicate service order request activity for the same service point.</p>
Validation Error	<p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Activities in this state can be corrected and retried.</p>
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Validate that non-final child activities can be discarded without the need for a cancel activity</p> <p>Cancel non-final child activities</p> <p>Send a failure notification to the requesting system</p>
Waiting for Effective Date	<p>If an orchestration activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time).</p>
Are SP and Device Ready?	<p>Each type of orchestration activity business object has a unique set of Enter algorithms that perform operations as appropriate for the type of service order request.</p> <p>See Service Order Activity Algorithm Types for more information about these algorithms.</p>
Activity in Progress	<p>Orchestration activities remain in this state while their child activities are processed.</p> <p>A Monitor algorithm transitions the activity to the "Are the SP and Device Ready?" state if there are no non-final child activities related to the current activity.</p> <p>A Monitor algorithm validates that the orchestration activity has not been in its current state for too long, based on the Expiration Days parameter on the orchestration activity's type and the Expiration Date/Time on the orchestration activity</p> <p>An Exit algorithm resets the Expiration Date/Time on the orchestration activity such that each time the activity exits this state its Expiration Date/Time is updated.</p>
Activity Error	<p>If one or more child activities enters an Error state, the orchestration activity enters this state.</p> <p>Activities in this state can be corrected and retried.</p>
Retry	<p>When an orchestration activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Check to determine if there are child field activities in progress that have outbound communications awaiting a response.</p> <p>Transition any non-final child activity to the "Reject" state (the state defined as "Reject" on the child activity business object lifecycle. This is most often the "Discarded" state).</p>

State	Description
Completed	Orchestration activities enter this state when all child activities have successfully completed. An Enter algorithm send a success notification to the requesting system.

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Cancel / Update Orchestration Lifecycle

The Cancel Orchestration (D1-CancelOrchestration) and Update Orchestration (D1-UpdateOrchestration) business objects have a similar lifecycle, with the following exceptions:

- There is no "Waiting for Effective Date" state.
- In place of the "Are SP and Device Ready?" state, they have "Cancel Specific Activity" / "Update Specific Activity" states. Enter algorithms on these states attempt to cancel or update a specific child activity.
- In the place of "Activity In Progress" and "Activity Error" states, they have "Communication in Progress" and "Communication in Error" states.

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Throttling Commands Issued from Service Order Activities

Service order management can be configured to limit, or "throttle", the number of smart meter command activities initiated by a service order activity that are executed within a specified time range. For example, in a situation in which a utility initiates dozens (or hundreds) of cut for on-payment service activities on a single day, this feature allows the execution of the related remote disconnect commands to be spread out over a number of hours rather than executing all of those commands in the first hour of the day.

NOTE: Throttling is only supported for Cut Service for Non-Payment service order activities and Remote Disconnect smart meter command activities.

Configuring throttling of command processing is done via parameters on the service order activity type and the related smart meter command activity type.

Service Order Activity Type

The following **Business Hours** parameters on the Cut Service for Non-Payment activity type are used to define the business days and hours during which remote disconnect commands can be executed:

- **Ensure Business Hours:** Indicates if commands should be processed during specified business hours as defined by the **Work Calendar**, **Start Hour**, and **End Hour** parameters.
- **Work Calendar:** The work calendar used to determine work days on which commands can be processed.
- **Start Hour:** The start hour of the day during which commands can be processed.
- **End Hour:** The end hour of the day during which commands can be processed.

Refer to the **Business Hours** embedded help on the Cut Service for Non-Payment activity type for more details.

Smart Meter Command Activity Type

The **Throttle Parameters** on the Remote Disconnect activity type are used to define if throttling is enabled, and if so, the number of commands that can be processed during specific time ranges during each business day. These parameters include:

- **Throttle Option:** Specifies if throttling is allowed. If set to "Allowed", one or more time ranges must be defined in the **Schedule** list.
- **Schedule:** Defines one or more time ranges (defined by the **From** and **To** columns) and the number of records that can be processed during each (defined by the **Number of Requests** column).

Batch Processing

Processing of commands configured for throttling is performed using the Command Request Wait Monitor with Throttle Option batch control (D1-CRWTO).

This batch control monitors command activities in the "Wait For Effective Date/Time" state, and if the Throttle Option parameter (enableThrottle) is set to "Y", it will only process up to the number of records specified in the current time range defined in the **Schedule** section on the command activity type. For example, if there are 50 Remote Disconnect commands in the "Wait For Effective Date/Time" state and this batch control (with **Throttle Option** set to "Y") is run during a time range for which the **Number of Requests** is set to 30, only 30 of the commands will be transitioned to the Connection Ready state.

This batch control can be used for all commands, with the **Throttle Option** parameter set as appropriate based on the type of command activities. As of this release, throttling is only available with Remote Disconnect smart meter command activities.

Notes:

- This batch control can be used only with command activity business objects whose "Wait For Effective Date/Time" state does NOT have a monitor process defined.
- If this batch control is run more than once during a specific time range, it will process up to the number of records specified for that time range during each run. In the previous example, if the batch control were to be run twice during the same time range, the first run would process 30 records, and the second would process the remaining 20 records.

See the **Detailed Description** of this batch control for more information.

Service Order Activity Algorithm Types

When an orchestration activity enters the "Are SP and Device Ready?" state, a set of Enter algorithms are used to evaluate the state of the service point / meter / item to determine which actions are required to complete the service request. These algorithms are based on the following algorithm types.

Customer-Device Compatibility Check (D1-DVCOMCHK)

Algorithms of this type execute the "Customer-Device Compatibility Algorithm" defined on the orchestration activity's activity type. Algorithms of this type uses the following parameters:

- **Activity BO To Create If Compatibility Detected:** Specifies the activity business object to instantiate if the algorithm detects an in compatibility between the customer/service point and device.

Note: The base package does not include algorithm types for the "Activity Type - Customer Device Compatibility" algorithm entity.

Connect Only If Previously Connected (D1-CONPRECON)

Algorithms of this type check if the "Connect New Device" flag has a value. If the flag is not populated, the algorithm sets the value of the flag based on the connection status of the device prior to the meter exchange (used only with Meter Exchange requests).

For additional information, refer to the D1-CONPRECON Algorithm Type.

Create Meter Exchange Field Activity (D1-CREMTREXC)

Algorithms of this type create a service order field activity based on details provided in the algorithm's parameters. Algorithms of this type uses the following parameters:

- **Activity and Specific Field Task to Create:** Specifies the type of activity business object and field task type to create for meter exchange service order field activities, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create.
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup.

For example, to create a service order field activity based on the D1-FieldActivity business object and the Exchange Meter field task type, these mnemonics would be configured as follows:

```
activityBOToCreate=D1-FieldActivity specificFieldTask=D1-ExchangeMeter
```

For additional information, refer to the D1-CREMTREXC Algorithm Type.

Decommission Removed Meter (D1-DCRMMTR)

Algorithms of this type create a decommissioning command for a removed meter (used only with Meter Exchange requests). Algorithms of this type uses the following parameters:

- **Decommission Activity BO to be created:** Specifies the type of activity business object to create when decommissioning a meter. The specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create.

For example, to create a smart meter command activity based on the D1-DeviceDecommission business object, this parameter would be configured as follows:

```
activityBOToCreate=D1-DeviceDecommission
```

For additional information, refer to the D1-DCRMMTR Algorithm Type.

Create Specific Activity (D1-CRSPACT)

Algorithms of this type determine if a specific activity needs to be created based on the state of the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created:

- **Field Activity BO:** Specifies the field activity business object to instantiate if the algorithm creates a field task type (see next parameter).
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. This parameters uses the following mnemonics to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
servicePointConnected	Specifies if the service point is currently connected Valid values are "true" and "false".
disconnectLocation	Specifies the "Disconnect Location" for the service point.

Mnemonic	Description
	Valid values are "D1SR" (source) and "D1DV" (device).
deviceInstalledAtSP	Specifies if there is a device currently installed at the service point. Valid values are "true" and "false".
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the unique combination of these mnemonics, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the field task type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.
executeOverrideAlgorithm	Specifies whether or not to execute the algorithm specified for the Override Device/Task Algorithm on the service order orchestration activity type. This allows the activity business object to create to be dynamically determined based on an algorithm instead of the "activityBOToCreate" or "specificFieldTask" mnemonics. Valid values are "true" and "false".

For example, the following parameter configuration would create a "Connect Service Point and Install Meter" service order field activity given the following conditions:

- Service Point Connected: False
- Disconnect Location: Source
- Device Installed at Service Point: False
- Service Point Category: Meter

```
servicePointConnected=false disconnectLocation=D1SR deviceInstalledAtSP=false specificFieldTask=D1-ConnSPAtSrceAndInstMtr spTypeCategory=D1MT
```

NOTE: Additional values for the **SP State and Activity BO to Create** parameter can be defined using the **Field Task By Service Point Condition** zone on the [Activity Type](#) portal.

For additional information, refer to the D1-CRSPACT Algorithm Type.

Update Device (D1-UPDDVC)

Algorithms of this type determine if an activity needs to be created to update the device based on the state of the service point and device installed at the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created.

- **Error if SP Not Connected or no Device Installed (Default is Yes):** Indicates if the algorithm should return an error if the service point is not connected or if a device is not currently installed. Valid values are "Yes" and "Con" (continue)
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. This parameters uses the following mnemonic to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the value of this mnemonic, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values in include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.
alternativeFieldTask	Specifies an alternative Field Task Type to use when creating a service order field activity in the event that the device does not support the command indicated by the "activityBOToCreate" mnemonic. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create. A value of 'skip' will continue the evaluation of the algorithm's next parameter

For example, the following parameter configuration would create a "Turn On Meter" service order field activity given the following conditions:

- Installation Status: Manual Off

- Service Point Category: Meter

```
installEventStatusOverride=ManualOff specificFieldTask=D1-TurnOnMeter spTypeCategory=D1MT
```

NOTE: Additional values for the **SP State and Activity BO to Create** parameter can be defined using the **Field Task By Device Condition** zone on the [Activity Type](#) portal.

Other parameters used by algorithms of this type include:

- **Field Activity BO:** Specifies the field activity business object to instantiate if the algorithm creates a field task type (see above parameter).
- **XPath of Activity Element controlling Activity creation:** Defines an element within the activity business object schema that can be used to control whether or not this algorithm should create an activity. For example, to specify that the value of the "Connect New Device" flag be used to determine whether or not the algorithm should create an activity, this parameter could be set to "connectNewDevice".
- **Element value indication that Activity creation should not proceed:** Specifies a value for the element defined in the "XPath of Activity Element controlling Activity creation" parameter that would indicate that the algorithm should not create an activity. Valid values are based on the element defined for the "XPath of Activity Element controlling Activity creation" parameter. For example, to specify that an activity should not be created if the "Connect New Device" flag is set to "Do Not Connect / Turn On", this parameter should be set to "D1NC" (from the D1_CONNECT_NEW_DEVICE_FLG lookup).

For additional information, refer to the D1-UPDDVC Algorithm Type.

Remote Turn Off Turn On (D1-REMONOFF)

Algorithms of this type remotely turn a device off and on for a Back to Back service request. Algorithms of this type use the following parameters:

- **Device Incompatibility Detected Activity BO:** Specifies the activity business object the algorithm will look for. If the algorithm finds an activity of this business object, the algorithm terminates.
- **Remote Connect BO:** Specifies the activity business object to instantiate when creating a remote connect command.
- **Remote Disconnect BO:** Specifies the activity business object to instantiate when creating a remote disconnect command.
- **Installation Event Status Override for Connect:** The override status to which the Installation Event Status is set after performing a remote connect command.
- **Installation Event Status Override for Disconnect:** The override status to which the Installation Event Status is set after performing a remote disconnect command.

For additional information, refer to the D1-REMONOFF Algorithm Type.

Check for Measurement (D1-CHKMSMT)

Algorithms of this type determine if measurements exist on activity's service point as of the service date/time. If no measurement is found, algorithms of this type create an activity to either obtain or wait for a measurement. The specific type of activity is based on the type and configuration of the device and service point. Algorithms of this type use the following parameters:

- **Activity BO To Wait For Measurement:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a measurement for the service point.
- **Activity BO For Field Read:** Specifies the field activity business object to instantiate when the algorithm logic indicates it should request a meter reading from the field.
- **Specific Field Task:** Specifies the field task type when creating a service order field activity for a meter reading from the field.

- **Activity BO To Wait For Scheduled Read:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a scheduled read for the service point.
- **Activity BO For On Demand Read - Scalar:** Specifies the activity business object to instantiate when the algorithm logic indicates it should issue an on-demand read (scalar) smart meter command.
- **Start Range for Normal Measurement Condition:** The start of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **End Range for Normal Measurement Condition:** The end of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **Minimum Range for bottom Measurement condition:** The minimum measurement condition used when searching for measurements for the service point. Used only when no measurements are found in the "normal" range defined by the "Start/End Range Normal Measurement Condition" parameters.

The following parameters on the orchestration activity type are also used by algorithms of this type when searching for measurements for the service point:

- **Look for Measurement within the Day:** Limits the search to the reference date (the service date).
- **Minimum and Maximum Offset Number of Days:** Numbers of days added to /subtracted from the reference date to expand the search period.

For additional information, refer to the D1-CHKMSMT Algorithm Type.

Algorithm Types and Orchestration Activity Business Objects

Each of the orchestration activity business objects uses a different set of these algorithm types. The table below lists which of these algorithm types are defined for each of the service order orchestration activity business objects.

	Enable Service	Disable Service	Cut for Non-Payment	Reconnect for Payment	Meter Exchange	Back-to-Back
Customer-Device Compatibility Check	X					X
Connect Only If Previously Connected					X	
Create Specific Activity	X					
Create Meter Exchange Field Activity					X	
Update Device	X	X	X	X	X	X
Remote Turn Off Turn On						X
Decommission Removed Meter					X	
Check For Measurement:	X	X	X			X

Cancel / Update Orchestration - Algorithm Types

Enter algorithms on the "Cancel Specific Activity" and "Update Specific Activity" states attempt to cancel or update a specific child activity. These algorithms are based on the following algorithm types.

- **Cancel Specific Activity:** Algorithms of this type cancel the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.

- **Update Specific Activity:** Algorithms of this type update the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.

Algorithm Type	Algorithm(s)
Cancel Specific Activity (D1-CANSPACT)	Cancel Specific Activity (D1-CANSPACT)
Update Specific Activity (D1-UPDSPAC)	Update Specific Activity (D1-UPDSPAC)

Use the Algorithm Type and Algorithm portals to view additional details about these algorithms.

Understanding Service Order Field Activity Types

Service order activity types must be configured for each type of service order activity.

Service order activity types are assigned to the following Activity Type Categories:

Service Order Activity	Activity Type Category
Back-to-Back	Service Request Orchestration
Cancel Orchestration	Orchestration Maintenance
Cut Service for Non-Payment	Request Orchestration
Disable Service	Request Orchestration
Enable Service	Request Orchestration
Exchange Meter	Request Orchestration
Reconnect Service for Payment	Request Orchestration
Update Orchestration	Orchestration Maintenance

Refer to [Understanding Activity Types](#) for more information about activity types.

Configuring Service Order Activity Types

You use the **SOM Activity Type** portal is to view and maintain service order activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, SOM Activity Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order activity types as well as service order activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type

- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order activity types supported by Service Order Management:

Service Order Activity	Activity Type (Business Object)
Enable Service	Enable Service (D1-EnableServiceType)
Disable Service	Disable Service (D1-DisableServiceType)
Cut Service for Non-Payment	Cut Service for Non-Payment (D1-CutServiceForNonPaymentType)
Reconnect Service for Payment	Reconnect for Payment (D1-ReconnectForPaymentType)
Meter Exchange	Exchange Meter (D1-ExchangeMeterType)
Back-to-Back Service	Back-to-Back Service (D1-BackToBackServiceType)
Cancel Orchestration	Cancel Orchestration (D1-CancelOrchestrationType)
Update Orchestration	Update Orchestration (D1-UpdateOrchestrationType)

The demonstration database contains examples of each of these service order activity types.

Service Order Field Activities

Understanding Service Order Field Activities

This section describes service order field activities and how they communicate with field work management systems.

Service order field activities are activities that involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.

Service order field activities send messages to a field work system, which in turn assigns them to crews to be completed in the field.

Field Activity Information

All service order field activities are based on the Field Activity (D1-FieldActivity) business object, and include the following user-accessible information:

- **Status:** The current status of the service order field activity.
- **Service Date/Time:** The date and time the service order field activity was created.
- **Service Point:** The service point associated with the service order field activity.
- **Field Task Type:** The field task type for the service order field activity. This defines the type of task and other processing details regarding how Service Order Management processes the service order field activity. See [Field Task Types](#) for more details about field task types.
- **Recipient:** The field work system service provider to which the service order field activity is sent for scheduling and assignment.
- **Device ID:** The device related to the service order field activity (if applicable).
- **Request Information:** Details of the service order request, including requester and external system information.
- **Contact Details (or Customer Information):** Contact details for the customer associated with the service order request.
- **Address Information:** The address of the service point associated with the service order field activity.

The field activity business object also contains other information that is populated by algorithms and scripts as the service order field activity is processed by the system.

How Do Service Order Field Activities Work?

At a high level, service order field activities work as follows:

Create Field Activity

A service order orchestration activity creates a service order field activity based on the current state of the service point/meter/item.

Retrieve Required Data

The service order field activity uses a set of pre-processing algorithms to derive and populate data needed by the activity, such as the device, service point, address, effective date, and others.

Request Appointment (Optional)

If the service order field activity task type specifies that field tasks of this type require an appointment, the service order field activity checks for available appointment slots in the field work system and sends a notification to the appointment handling system.

Create Outbound Communication

The service order field activity creates an outbound communication to send the service order field activity to the field work system. The outbound communication gathers the information required by the field work system before being sent. This information is retrieved by a set of processing scripts defined on the field task type.

Receive Inbound Communication

When the service order field activity has been completed, the field work system sends an inbound communication back to Service Order Management.

Inbound communications can contain Field Activity Remarks (entered by field resources when they perform and complete their field work. If the Field Activity Remarks reference completion events, they are executed.

The inbound communications create completion events as defined on the field task type. If the service order field activity was successfully completed, it creates the "Completion Events When Successful" completion events. If the service order field activity was canceled, it creates the "Completion Events When Canceled" completion events.

Execute Completion Events

After receiving the inbound communication, a service order field activity algorithm transitions any active completion events into their executed state.

Complete Processing

The service order field activity completes its processing by doing the following:

- Updating the parent orchestration activity
- Sending a success response to the requester
- Transitioning the parent orchestration activity to the next state in its lifecycle
- Sending a service order field activity completion outbound communication to subscribing systems.

Service Order Field Activity Processing

This section outlines how service order field activities are processed.

Pre-Processing, Validation, and Post-Processing Algorithms

When service order field activities are first instantiated, a set of pre-processing algorithms populate and derive information needed for the activity, such as the activity type, service point, device, address, effective date, and other information.

Validation algorithms validate this information when first retrieved and when updated.

When service order field activities are completed, a post-processing algorithm populates the activity end date/time.

Service Order Field Activity Lifecycle

As a service order field activity moves through its lifecycle, it triggers various business processes based on the type of service order field activity. The table below outlines the lifecycle for the Field Activity (D1-FieldActivity) business object.

State	Description
Pending	The initial state for service order field activities. An Enter algorithm sends an acknowledgement to the requesting system. The activity is transitioned to the next state via a monitor process.
Validate	Enter algorithms perform the following: Validate Activity Type (and transition to error if invalid) Derive and validate service order field activity recipient Validate duplicate and conflict service order field activities Derive and validate service order field activity service point Derive and validate service order field activity device Validate address constituents Check for any existing cut service restrictions

State	Description
Validation Error	<p>The activity is transitioned to the next state via a monitor process.</p> <p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes".</p> <p>This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Activities in this state can be corrected and retried.</p>
Waiting to Request	<p>If a service order field activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time).</p> <p>An Enter algorithm sets the "Allow Child to Transition Parent Activity Based On Effective Date" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p>
Waiting for Appointment	<p>If the service order field activity passes its validations and the effective date has been reached, the activity enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Evaluate if an appointment is required for field tasks of this type. If not, the activity transitions to the "Communication in Progress" state.</p> <p>Create a To Do if an appointment is necessary but the system is not able to send an appointment request.</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes".</p> <p>This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Send a notification to the appointment handling system.</p> <p>Monitor algorithms perform the following:</p> <p>Verify if an appointment has been supplied.</p> <p>Send a notification to the appointment handling system.</p> <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Waiting for Appointment for more information about this state.</p>
Communication in Progress	<p>Service order field activities enter this state following the "Waiting for Appointment" or "Retry" states.</p> <p>Enter algorithms perform the following:</p> <p>Create an outbound communication for the service order field activity (see Communication in Progress for more information).</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes".</p> <p>This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Monitor algorithms perform the following:</p> <p>Check for existing child communications.</p> <p>Check that the activity hasn't timed out.</p>

State	Description
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Cancel outstanding outbound communications.</p> <p>Cancel outstanding completion events.</p> <p>Populate the cancel reason.</p> <p>Send a failure notification to the requesting system.</p> <p>Transition the parent activity to the "Activity Error" state (see Service Order Orchestration Activity Lifecycle for more information).</p> <p>Check if a Cancel Orchestration activity is required.</p>
Communication Error	<p>If an outbound or inbound communication an Error state, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <p>Check that the activity hasn't timed out.</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role.</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Activities in this state can be corrected and retried.</p>
Retry	<p>When a service order field activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Check to determine if there are associated outbound communications in progress.</p> <p>Cancel any outstanding outbound communications.</p>
Execute Completion Events	<p>After an inbound communication is received, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Executes completion events defined on the field task type (these completion events were initially created by the inbound communication).</p> <p>Evaluates the "Field Activity Completed" flag on the service order field activity. If this is set to "No", the service order field activity is transitioned to the "Canceled In Field" state.</p> <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Execute Completion Events for more information about this state.</p>
Completion Event Error	<p>If an error occurs during completion event processing, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <p>Check that the activity hasn't timed out.</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role.</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p>

State	Description
	Activities in this state can be corrected and retried.
Completed	<p>Service order field activities enter this state when all completion events have successfully completed.</p> <p>Enter algorithms perform the following:</p> <p>Update the parent orchestration activity.</p> <p>Send a success response to the requester.</p> <p>Transition the parent orchestration activity to the next state in its lifecycle.</p> <p>Send a service order field activity completion outbound communication to subscribing systems.</p>
Canceled in Field	<p>If the "Field Activity Completed" flag on the field activity is set to "No", the service order field activity enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Send a failed response to the requester.</p> <p>Transition the parent orchestration activity to the "Activity Error" state.</p> <p>Create a To Do to notify users that the service order field activity has been canceled.</p>

Waiting for Appointment

When a service order field activity enters the "Wait for Appointment" state, it first determines if an appointment is necessary for the service order field activity. If not, the activity moves on to the "Communication in Progress" state (see below).

If an appointment request cannot be sent for some reason, the service order field activity creates a To Do item to alert a user to attempt to manually request an appointment. Otherwise, the service order field activity sends an outbound message to the field work system requesting an appointment. based on the appropriate processing role defined on the "Send Notification to Appointment Handling System - Enter" algorithm.

Processing Role	Outbound Communication Business Object
Appointment Response (default)	Send Appointment Response Outbound Message (D1-SendApptRespOutboundMsg)
Used if: An appointment is required and needs to be scheduled Appointment has been set	Note: An outbound message must be created based on this business object.

The response from the field work system can be received by creating an Inbound Web Service that references the "Book selected appointment to Field Activity" (D1-BookAppt) service script.

While in this state, monitor algorithms verify if an appointment has been supplied and send notifications to the field work system.

Communication in Progress

Service order field activity communications are records of messages sent between Service Order Management and an external field work system. Communications can flow both outbound and inbound.

See [Service Order Field Activity Communication](#) for more information about service order field activity communication.

Manually Completing Service Order Field Activities

Service order field activities in the "Communication in Progress" state can be manually completed or canceled by clicking **Complete** in the **Record Actions** section of the **Activity** zone. This opens the **Field Activity Manual Completion** page where the user can enter appropriate details to manually complete the field activity (such as completion information, service point information, device information, and so on). When submitted, this page creates an inbound communication and transitions the field activity to the next state as appropriate.

Note: Implementations can define custom service scripts for each field task type in the **Manual FA Completion Controls** section on the Field Task Type extendable lookup to customize the sections displayed on the **Field Activity Manual Completion** page.

Execute Completion Events

After receiving the inbound communication, the service order field activity enters the "Execute Completion Events" state.

The inbound communication will have previously created completion events for the service order field activity, based on those defined on the field task type or those referenced by field activity remarks. These creation events begin in the "Pending" state.

An Enter algorithm transitions completion events associated with the service order field activity into their "Executed" state.

Service Order Field Activity Communication

This section outlines how service order field activities communicate with field work systems.

When a service order field activity enters the "Communication in Progress" state, it sends an outbound communication to the field work system, and waits for an inbound communication response.

See **Understanding the Service Order Field Activity Communication Process** below for more information about the role of communications in the service order field activity communication process.

Outbound Communications

Outbound Communications represent messages sent from Service Order Management to an external field work system. Outbound communications use the following types of objects:

Outbound Communication Business Objects

An outbound communication business object exists for each type of message to be sent to an external system. For service order field activities, the following base package outbound communication objects can be used.

Type of Outbound Communication	Outbound Communication Business Object
--------------------------------	--

Initial service order field activity outbound communication	Field Activity Outbound Communication (D1-FieldActivityOBComm)
---	--

Modify outbound communication	Field Activity Outbound Communication (D1-ActivityModifyOBComm)
-------------------------------	---

Used to send an update to a service order field activity previously sent to the field work system.

Outbound Message Types

A outbound message type must also be created for each type of message to be sent to an external system. Again, this is based on the types of messages the system is designed to accept. For service order field activities, the following outbound message types are needed:

Type of Outbound Communication	Outbound Message Type
Initial Service Order Field Activity Message	Field Activity Outbound Message
Modify Existing Service Order Field Activity	Modify Field Activity Outbound Message

Refer to the Oracle Utilities Application Framework documentation for more information about outbound message types.

External Systems

You must also create an External System for each external system to which Service Order Management will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch, XAI, or Real-time)
- Message Sender (if Processing Method is set to Real-time or XAI)
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

To continue the example above, you might create the following external system:

Outbound Message Type	Processing Method	Batch Control
Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)
Modify Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)

Refer to the Oracle Utilities Application Framework documentation for more information about external systems.

Inbound Communications

Inbound Communications represent messages sent from an external field work system to Service Order Management. Inbound communications are typically sent in response to a service order field activity. Inbound communications use the following types of objects:

Inbound Communication Business Objects

An inbound communication business object must be created for each type of message to be received from an external system. For service order field activities, the following base package inbound communication object can be used.

Inbound Communication Business Object
Field Activity Inbound Communication (D1-FieldActivityIBComm)

Inbound Web Service

You must also create an Inbound Web Service for each type of message to be received from an external system. Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send. To continue the example above, you might create the following inbound web services:

Inbound Web Service	Schema (Inbound Communication Business Object)
Field Activity Inbound Communication	Field Activity Inbound Communication D1-FieldActivityIBComm

Refer to the Oracle Utilities Application Framework documentation for more information about Inbound Web Services.

Field Activity Remarks

Inbound communications can contain activity remarks, which represent notes entered by the field worker as they perform and complete their field work. These can be solely informational, or can reference completion events via the "Remark Processing" section of the Field Activity Remark Type extendable lookup. This allows information sent with the inbound communication to initiate business processing if necessary.

Completion events specified on this extendable lookup are created by the inbound communication, and then executed when the service order field activity enters the "Execute Completion Events" state.

Understanding the Service Order Field Activity Communication Process

This section provides an overview of the communication process that takes place when a service order field activity is initiated. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used by Service Order Management

Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Base Package Objects
1.	An orchestration activity creates a service order field activity as part of its processing. A service order field activity business object is instantiated for the command.	Field Activity Business Object: Field Activity (D1-FieldActivity)
2.	When the service order field activity enters the Communication in Progress state, it creates an outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
3.	A Enter algorithm on the "Awaiting Response" state of the outbound communication retrieves information needed by the outbound message to be sent to the field work system based on processing scripts specified on the field task type.	Enter Algorithm: Populate Send Detail for Field Activity (D1-POPSNDDTL)
4.	A Enter algorithm on the "Awaiting Response" state of the outbound communication creates an outbound message.	Enter Algorithm: Create Outbound Message (D1-COUTMSG) Note: An outbound message type for this message is not included in the base package.

Step	Process	Base Package Objects
5.	<p>The outbound message is sent to middleware components via an External System and Batch Control.</p> <p>Middleware components utilize Business Process Execution Language (BPEL).</p>	<p>External System: MWM</p> <p>Batch Control: Sync Request Monitor (F1-SYNRQ)</p>
6.	<p>The middleware converts the outbound message from SOM format into the format used by the field work system, and sends the message to the field work system.</p>	
7.	<p>When the field work system sends a response, the middleware receives the response message from the field work system, and converts it from the format used by the field work system to SOM format and invokes an Inbound Web Service.</p>	<p>Inbound Web Service: D1-FieldActivityIBComm</p>
8.	<p>The Inbound Web Service picks up the message, and creates a corresponding inbound communication.</p> <p>The specific type of inbound communication business object created is determined by the Inbound Web Service.</p>	<p>Inbound Web Service: D1-FieldActivityIBComm</p> <p>Inbound Communication Business Object: Field Activity Inbound Communication (D1-FieldActivityIBComm)</p>
9.	<p>The inbound communication identifies the parent outbound communication.</p>	<p>Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)</p>
10.	<p>The inbound communication creates the completion events defined on the field activity field task type (Successful or Canceled, as appropriate) in the "Pending" state.</p> <p>If the inbound communication contains field activity remarks, it also executes any field activity remark completion events.</p>	<p>Inbound Communication Business Object: Field Activity Inbound Communication</p> <p>D1-FieldActivityIBComm</p>

Unrelated Pickup Orders

When field work crews are out performing field work, it's possible that they will encounter other work unrelated to their current task that needs to be done. This type of work can be as simple as trimming a tree whose branches are too close to power lines, or the replacement of a meter for a different customer or service point. These types of task are referred to as "unrelated pickup activities." Crews can either work the field activity or leave it to be assigned to another crew at a later date.

When the crew creates an unrelated pickup activity in the field work system, it is sent to Service Order Management, and a corresponding service order field activity is created in the system.

Unrelated pickup activities can be created via one of the following Inbound Web Services:

- Field Activity Asynchronous Req Inbound (D1-FARequestAsynchronous)
- Field Activity Synchronous Req Inbound (D1-FARequestSynchronous)

Once created, they are processed like any other service order field activity. If the pickup activity was completed in the field before being sent to Service Order Management, it will quickly move through its lifecycle (as no further action is needed) until it reaches the "Completed" state.

Retrieving Service Point Information

If the unrelated pickup activity is customer-related it will require service point information to be created. This information can be queried by the field work crew via the "Field Work Service Point Query" (D1-FieldWorkSPQuery) Inbound web service.

This service uses a set of service point criteria to allow the field crew to search for a service based upon either service point or device information. The service returns a list of service points that is configurable in length. If the number of results is larger than the configured maximum length the service indicates that additional records exist and the crew can request another set of results allowing them to identify the proper service point to associate to the activity.

There are times when an unrelated pick-up activity is identified but the field crew is out-of-coverage (i.e. no network connection) and they will not be able to immediately verify service point information. In this type of situation, the crew can input the service point criteria fields and create the activity, which, when imported into Service Order Management, will attempt to identify the service point based upon the information provided. If the service point can be uniquely identified everything should operate as normal. If the service point cannot be uniquely identified then the service order field activity is set to the error state.

Setting Up Service Order Field Activity Types

Understanding Service Order Field Activity Types

A single service order field activity type must be configured to support communication with external field work systems such as Oracle Utilities Module Workforce Management. Service order activity types are assigned to the "Field Activity" Activity Type Category.

Refer to [Understanding Activity Types](#) for more information about activity types.

Service Order Field Activity Types and Divisions

Service order field activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

See [Understanding Divisions](#) for more information about divisions.

Configuring Service Order Field Activity Types

You use the **SOM Activity Type** portal to view and maintain service order field activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, SOM Activity Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order field activity types as well as service order field activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as "Install Device" or "Connect SP", based on the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order field activity type supported by Service Order Management:

Field Activity	Activity Type (Business Object)
Field Activity	Field Activity (D1-FieldActivityType)

The demonstration database contains examples of each of these service order activity types.

Configuring Service Order Field Activity Reschedule Reasons

The Reschedule Reason (D1-RescheduleReasonLookup) extendable lookup can be used to define reasons for rescheduling field activities. Reschedule reasons are captured on field activities, as well as their parent service order activity and an update orchestration activity.

Use the following steps to define service order field activity reschedule reasons:

1. Select **Admin, General, Extendable Lookup** to access the **Extendable Lookup Query** portal.
2. Enter “D1-RescheduleReasonLookup” in the **Business Object** field (or enter “Reschedule Reason” in the **Description** field) and click **Search**.
3. Click the “Reschedule Reason” link in the **Description** column of the search results.
4. Click **Add**, and enter the following details for the reschedule reason (fields not listed below are optional):
 - **Reschedule Reason:** A code used to designate the reschedule reason.
 - **Status:** The status of the reschedule reason.
 - **Description:** A description of the reschedule reason. This is what will appear in **Reschedule Reason** drop-down list on the service order field activity.
5. Click **Save**.

Field Task Types

Understanding Field Task Types

A service order field activity’s field task type defines details about the type of task to be performed and how the system will process the activity.

Field Task Type Information

Field task types are values for the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup. Each field task type value includes the following information:

- **Routing:** Indicates if field tasks of this type can only be performed at a service point. Valid values are "SP Required" and "Pass-Through".
- **Appointment Option:** Indicates if an appointment (via a mobile workforce application) is required or applicable to field tasks of this type. Valid values are "Not Applicable", "Optional", and "Required".
- **Completion Events When Successful:** One or more completion events that are executed upon successful completion of field tasks of this type.
- **Completion Events When Canceled:** One or more completion events that are executed upon cancellation of field tasks of this type.
- **Duplicate Task Type Information:** Defines processing rules for handling potential duplicate field tasks, including:
 - **Allow Duplicates:** Specifies whether or not duplicate field tasks are allowed.
 - **Duplicate Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a duplicate.
 - **Field Task Types:** A list of one or more field task types that are considered to be duplicates of the field task type.

- **Conflict Task Type Information:** Defines processing rules for handling potentially conflicting field tasks, including:
 - **Allow Conflicts:** Specifies whether or not conflicting field tasks are allowed.
 - **Conflict Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a conflict.
 - **Field Task Types:** A list of one or more field task types that are considered to conflict with the field task type.
- **Processing Scripts:** Defines one or more processing scripts to extract supplemental information needed by the mobile workforce application to schedule field tasks of this type.
- **Manual FA Completion Controls:** Defines an optional Service Script used to customize the sections displayed on the **Field Activity Manual Completion** page when manually completing service order field activities.

Configuring Field Task Types

Field task types are configured using the extendable lookup portal.

You can access the extendable lookup portal from the **Admin > General > Extendable Lookup**.

Use the **Extendable Lookup Search** zone to search for and select the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup.

The following zones may appear as part of the portal's **Main** tab page:

- **Extendable Lookup List:** This zone displays a list of values for the Field Task Type extendable lookup.
- **Extendable Lookup List:** This zone provides information about the selected value.

Service Order Management Configuration

The following table outlines the field task types that must be configured to support each of the service order activity types supported by Service Order Management:

Service Order Activity	Field Task Types
Enable Service — Meters	Connect SP at Source: D1-ConnectSPAtSource Connect SP at Meter: D1-ConnectSPAtMeter Connect SP at Source and Turn On: D1-ConnectSPAtSourceAndTurnOn Connect SP at Meter and Turn On: D1-ConnectSPAtMeterAndTurnOn Connect SP at Source and Install Meter: D1-ConnSPAtSrceAndInstMtr Connect SP at Meter and Install Meter: D1-ConnSPAtMtrAndInstMtr Install Meter: D1-InstallMeter Turn On Meter: D1-TurnOnMeter
Enable Service — Items	Connect SP at Source: D1-ConnectSPAtSource Item - Connect SP at Device: D1-ConnectSPAtDevice Item - Connect SP at Source and Turn On: D1-ConnSPAtSrceAndTurnOnDvc Item - Connect SP at Device and Turn On: D1-ConnectSPAtDvcAndTurnOn Connect SP at Source and Install Device: D1-ConnSPAtSrceAndInstDvc Connect SP at Device and Install Device: D1-ConnSPAtDvcAndInstDvc Item - Install Device: D1-InstallDevice

Service Order Activity	Field Task Types
	Turn On Item: D1-TurnOnItem
Disable Service — Meters	Turn Off Meter: D1-TurnOffMeter
Disable Service — Items	Turn Off Item: D1-TurnOffItem
Cut Service for Non-Payment — Meters	Cut for Non-Payment: D1-CutForNonPayment
Cut Service for Non-Payment — Items	Item - Cut for Non-Payment: D1-CutItemForNonPayment
Reconnect Service for Payment — Meters	Reconnect for Payment: D1-ReconnectForPayment
Reconnect Service for Payment — Items	Item - Reconnect for Payment: D1-ReconnectItemForPayment
Meter Exchange	Exchange Meter: D1-ExchangeMeter
Item Exchange	Exchange Device: D1-ExchangeDevice
Back-to-Back — Meters	Read Meter: D1-ReadMeter

Defining Credit & Collections Options

NOTE:

The functionality described in this section is meant to handle the collection of unpaid balances. If your organization practices [open-item accounting](#) and collects on unpaid bills, you will not use this functionality. Rather, you will use the functionality described under [Defining Overdue Processing Options](#).

The system periodically monitors how much your customers owe to ensure they haven't violated your collection criteria. When a violation is detected, the system generates the appropriate responses (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). This section describes how to set up the tables that control your credit & collections processing.

WARNING:

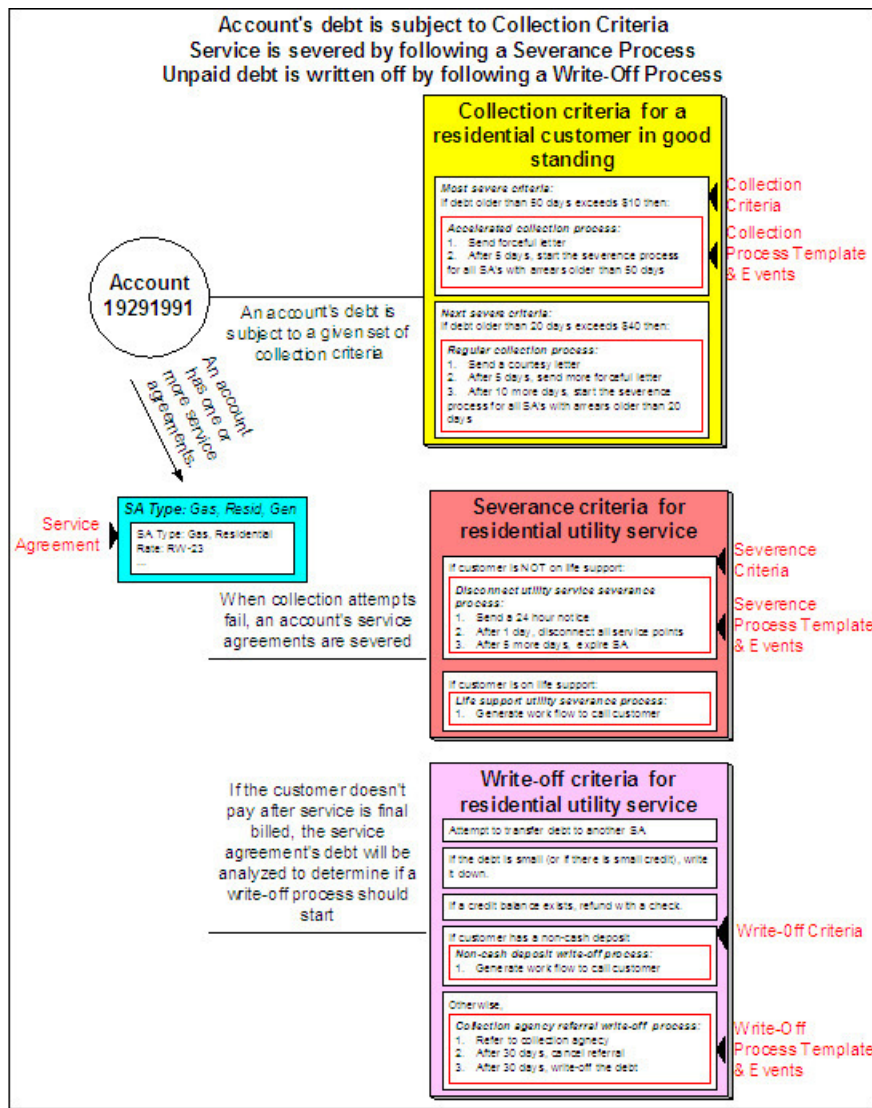

Setting up the credit & collections control tables is as challenging as your organization's collection rules. If you have simple rules then your setup process will be straightforward. If your collection rules are complicated (e.g., they differ based on the type of customer, the type of debt, the age of debt, the type of service, etc.), then your setup process will be more challenging.

The Big Picture Of Credit & Collections

This section provides an overview of important C&C concepts with which you should be familiar before you set up your C&C control tables.

Collection Criteria vs. Severance Criteria vs. Write Off Criteria

The following diagram introduces important concepts related to the C&C processes:

There are many important concepts illustrated above:

An account's debt comes from its service agreements

An account's debt is managed at the service agreement level, i.e., the system keeps track of how much a customer owes in respect of each service agreement. In order to determine an account's balance, the system must add up the debt on each of the account's service agreements.

Collection criteria define intolerable debt

Collection criteria are control data that define intolerable debt. Most criteria are defined using a combination of number of days in arrears and a dollar amount.

Collection criteria may be compared to an account's total debt or to subsets of debt

If your organization has simple collection procedures, you will probably target collection criteria at an account's total debt. However, you have the option of segregating an account's debt into debt classes and targeting the collection criteria at each class. For more information about debt classes, see [Different Collection Criteria For Different Customers And Different Debt](#).

Collection criteria also define what to do when the level of intolerable debt is exceeded	When you define collection criteria, you also define how the system should respond if an account violates your criteria. These collection events are defined in respect of a "collection process template".
There are usually several collection events that take place when criteria are violated	A collection process template usually has several collection events. Each event is meant to prod the customer to pay. The initial collection events are typically letters. If payment is not received after several such attempts, the last collection event typically starts a severance process for each service agreement in arrears.
A severance process template defines how to sever a service agreement	A "severance process template" defines how to sever a given type of service agreement. A severance process template usually contains several severance events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received.
Severance criteria define how to sever service agreements	Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer (or premise). For example, you may have a different severance process if the customer has life support equipment.
After a service agreement is severed, it will be final billed	When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.
If a customer doesn't pay their final bill, the account's debt will be analyzed to determine if the system can reduce the debt to zero using a variety of mechanisms	<p>The system will look at an account's finaled debt on its next scheduled credit review date (typically a few days after the bill's due date). The system will attempt to reduce the service agreement's debt to zero using all of the following methods:</p> <ul style="list-style-type: none"> • If the account has active service agreements, it will transfer the finaled debt to an active service agreement. • If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit). • If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).
If a customer's finaled debt cannot be reduced via any of the previous methods, the system creates a write-off process	<p>A write-off process contains one or more write-off events. These events can generate a letter, send a To Do entry to a CSR, send a referral to a collection agency, etc.</p> <p>When you set up the system, you define the type of write-off process to use for every collection class / write-off debt class combination. In addition, you can also indicate when the type of write-off process should differ depending on some attribute of the customer (or premise). For example, you may have a different write-off process if the customer has a non-cash deposit.</p>
The last write-off event typically causes the debt to be written off	Ultimately, if the write-off events fail, the debt will have to be written off. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life and will have to be paid off if the customer ever returns.

NOTE:

Checkpoint. At this point, you should be familiar with the concept that an account's debt is compared to user-defined collection criteria. If the account violates the criteria, a series of events will ensue that prod the customer to pay. If the customer doesn't respond, every service agreement in arrears will be severed (i.e., disconnected). If lack of service doesn't inspire payment, the service agreement will be expired and a write-off process will be created to manage the write-off activities.

The C&C Monitors

Your collection, severance and write-off criteria described in the previous section exist to support the processes that manage the collection of overdue debt: The following diagram illustrates, at a high level, the major processes that manage the collection of overdue debt:

There are many important concepts illustrated above:

Bills, payments and adjustments affect an account's debt	An account's debt is the accumulation of all bills, payments and adjustments.
The Account Debt Monitor creates a collection process when an account violates collection criteria	Periodically, a background process referred to as the Account Debt Monitor determines if an account's debt violates your collection criteria. If so, a collection process is created using the violated criteria's collection process template. Refer to When Is An Account's Debt Monitored? for a description of when an account's debt is compared against collection criteria.
A collection process contains one or more collection events	The collection process contains a series of collection events. These events correspond with the collection event types associated with the collection process template. The initial collection events are typically letters. If payment is not received after several such communications, the last collection event typically starts a severance process for each service agreement in arrears.
The Collection Process Monitor cancels a collection process when warranted	The Collection Process Monitor cancels a collection process when its service agreements satisfy your cancellation criteria (e.g., when the service agreements have less than \$10 of debt older than 20 days). Refer to How Are Collection Processes Cancelled for more information about the cancellation process.
The last collection event starts one or more severance processes	The last collection event typically starts one or more severance processes. A severance process contains the activities necessary to sever a service agreement. The service agreement(s) that are severed may be all SAs that are associated with the collection process. Alternatively, you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). The algorithm on the collection event that starts severance will control which service agreement(s) are severed. Refer to How To Nominate A Single Service Agreement To Sever for more information.
Each service agreement has its own severance process	Every service agreement that is severed has a severance process. The type of process is dependent on the severance criteria linked to the service agreement's SA type.
A severance process contains one or more severance events	The severance process contains a series of severance events. The events correspond with the severance process template's severance events.
The system cancels a severance process when warranted	The system cancels a severance process when its service agreement satisfies your cancellation criteria (note, it is possible to set up the system so that all service agreements in the debt class must satisfy your cancellation criteria before a severance process is cancelled). It's important to note that the cancellation is real time (as opposed to the cancellation of collection processes, which happens in a background process). Refer to How Are Severance Events Canceled? for more information.
The last severance event should expire the service agreement	The last severance event typically expires its service agreement. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).
If you nominate a single SA to sever when multiple SAs are in arrears...	Earlier we indicated that you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). If you do this, you also need

a severance event that will sever all other service agreements in the debt class if the severance of the nominated service agreement doesn't inspire payment. A severance event algorithm to do such is supplied with the base package. Refer to [How To Nominate A Single Service Agreement To Sever](#) for more information.

The Write-Off Monitor creates a write off process to collect stopped, unpaid debt

The Write-Off Monitor reviews stopped and reactivated service agreements after their closing bill's due date (plus grace period). The Write-Off Monitor attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to an active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).
If the system is unsuccessful in reducing the account's debt to zero, a write-off process will be created using the appropriate write-off process template. Refer to [The Big Picture Of Write Off Processing](#) for more information about the write-off process.

A write-off process contains one or more write-off events

The write-off process contains a series of write-off events. These events correspond with the write-off event types associated with the write-off process template. The initial write-off events are typically collection agency referrals and/or letters. If payment is not received as a result of such efforts, the last write-off event typically writes off the customer's debt.

The system cancels a write-off process when warranted

The system cancels a write-off process when its service agreements no longer have debt (i.e., they become closed).

Another write-off process will be created if a closed service agreement ever reactivates

If a service agreement becomes reactivated (e.g., because the final payment bounces), the service agreement will be processed by the Write-Off Monitor and the whole write-off process starts again.

NOTE:

Checkpoint. At this point, you should be familiar with the concept that a collection process will be created for an account that violates collection criteria. The collection process consists of a series of events that typically generate letters and / or To Do entries. If the customer doesn't respond, a severance process will be started for one or more service agreements. A severance process consists of a series of events that typically generate letters and/or disconnection field activities. If lack of service doesn't inspire payment, the last severance event expires the service agreement (and a final bill will be scheduled when the last service agreement is expired). If the customer doesn't pay the final bill, a write-off process will be created for each type of unpaid debt. The write-off process consists of a series of events that ultimately result in the write-off of the customer's debt. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life (because the write-off service agreement is linked to the account) and will have to be paid off if the customer ever returns.

The Big Picture Of Collection Processes

The topics in this section describe how collection processes are created and cancelled.

FASTPATH:

For more information refer to [The Lifecycle Of A Collection Process And Its Events](#).

How Does The Account Debt Monitor Work?

This section describes how the Account Debt Monitor uses your collection criteria and collection process templates to collect overdue debt.

Different Collection Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different collection criteria for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different regulator-imposed criteria applied to each state's debt. You differentiate your debt in respect of the collection process via the **CIS division code on each customer's account**.
- You probably have different collection criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different collection criteria for different classes of debt. For example, if a single customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have the freedom to apply stricter criteria to the unregulated debt. You differentiate your debt in respect of the collection process via a **debt class code on the customers' service agreements** (note: the debt class is actually defined on the service agreement's SA type).
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

Given the above, you should understand that different collection criteria will exist for every combination of CIS division, collection class, debt class, and currency code. If you're confused, consider the following matrix (where we assume you have a single currency and division and therefore avoid the third and fourth dimensions):

SA's Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, commercial customer debt.	Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers.

Charitable Contribution

Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process.

Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process.

Also, notice that there can be multiple criteria for each cell in the matrix. What differentiates one collection criteria from another is its priority. The higher priority criteria will be compared first. If the debt meets the criteria, the collection process is initiated and no further comparisons are performed.

FASTPATH:

For more information about maintaining this matrix, refer to [Setting Up Collection Class Controls](#). For more information about how the system handles an element in this matrix that has multiple criteria, see [How Is An Account's Debt Monitored?](#).

Override Conditions

WARNING:

Your credit & collection requirements may not require any overrides and therefore this section may not be relevant for your organization.

The matrix presented in the previous section showed:

- You can have different collection criteria for different categories of debt and customers.
- When a collection criteria is violated, the system generates a specific collection process.

This works great for many organizations, but if your organization has other factors that affect either the collection criteria OR the collection process that is initiated when the criteria is violated, you may need to use override collection criteria. For example,

- If you have a different collection process for regulated, residential debt during the winter months, you'll need to use override collection criteria (where the override criteria is "if it's winter").
 - If you have different collection criteria for customers with a poor credit score, you'll need to use override collection criteria (where the override criteria is "if the customer's credit rating is poor").
-

FASTPATH:

Refer to [Designing Your Collection Class Control Overrides](#) for more information.

This section describes how and when the Account Debt Monitor analyzes an account's debt.

When Is An Account's Debt Monitored?

The account debt monitor (ADM) analyzes an account's debt at least every X days, where X is defined on the [customer class control](#) associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, an account's debt will also be monitored as follows:

- The ADM looks at an account's debt X days after an account's bill due date (X is defined on the account's customer class in the field Collection Grace Days).
- The ADM looks at an account's debt after a payment is canceled when the cancellation reason indicates NSF (non-sufficient funds).

- The ADM looks at an account's debt after a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to [Monitoring Payment Arrangements](#) for more information.
- The ADM looks at an account's debt after a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information.

How Is An Account's Debt Monitored?

Assume the following collection control matrix exists for your organization:

SA's Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, large customer debt	Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers.

This matrix contains the information used by the Account Debt Monitor.

FASTPATH:

For more information about the information in this matrix, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

This matrix can be overwhelming when viewed as a whole. So let's consider how to use it for a specific account's debt and things will become clearer.

First, because an account belongs to a unique collection class, we only have to worry about a single column in the matrix when monitoring an account's debt.

Next, we accumulate the total amount of aged debt for each unique debt class associated with the account's service agreements.

Next, we subject the accumulated aged debt to the override aged debt algorithm (plugged in on the debt class). This algorithm can cause aged debt to be reduced. This is an optional algorithm and is only used if you set up pay plans for customers. Refer to [How Pay Plans Affect The Account Debt Monitor](#) for more information.

Next, we determine if the debt for the debt class violates the collection criteria in the respective matrix element. If so, we kick off a collection process and link the offending service agreements to it. The logic associated with the determination of whether to kick off a collection process is rather sophisticated. The following flowchart explains the exact details.

NOTE:

Important. If a service agreement is part of an ongoing severance process, it will NOT be considered by the Account Debt Monitor (it's already being severed). If a service agreement is stopped, closed, or reactivated, it also will NOT be considered by the Account Debt Monitor (it's already severed).

NOTE:

Multiple collection processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple debt classes, a collection process will be started for each offending debt class.

One collection process per debt class. A given debt class for an account may only have one ongoing collection process at any point in time.

What Happens When A Collection Process Is Started?

When you define collection criteria, you must define the collection process template to use if the criteria are violated. The system uses this template to create the account-specific collection process.

Every service agreement that is part of the offending debt class that has debt older than X days will be linked to the collection process (where X is the debt age on the collection criteria).

Also linked to the collection process will be one or more collection events. These events are typically a series of letters meant to prod the customer (you can also create an event that sends a To Do entry to a user to highlight the offensive debt). You define exactly which letters are generated and when they are generated when you set up the events on your collection process templates.

It's important to note that all of the collection events will be created when the collection process is created. Each of these collection events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for information that describes how the trigger date is set.

A separate process, Activate Collection Events, is responsible for activating collection events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a severance processes, etc.)

If adequate payments / credits are recorded in the system, the collection process will be cancelled.

FASTPATH:

For more information about collection process templates, see [Setting Up Collection Process Templates](#). For more information about collection events, see [The Big Picture Of Collection Events](#). For more information about how a collection process is cancelled, see [How Are Collection Processes Cancelled](#).

Experimenting With Alternative Collection Process Templates

The system allows you to determine the efficacy of proposed collection process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing collection process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" collection process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Collection Processing [Feature Configuration](#) for every champion template. Each option's value defines:
 - the "champion" collection process template code
 - the "challenger" collection process template code
 - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing collection process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, the [Account Debt Monitor](#) will use the challenger template X% of the time rather than the champion template.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination).

How Are Collection Processes Cancelled?

A collection process may be cancelled via the mechanisms described in this section.

The Collection Process Monitor Can Cancel A Collection Process

The Collection Process Monitor (CPM or C1-CPM) is a background process that reviews a collection process when the debt associated with one of its service agreements is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

The review performed by the CPM occurs as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the collection process's debt class must be less than a given threshold amount for a collection process to be cancelled. If so, the collection process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the customer's debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Please be aware that this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

NOTE:

The above logic is not "hard coded". The CPM calls the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm will cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

-
- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - All service agreements that are in arrears in a given debt class are linked to the collection process.
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears on the collection process (the alternative is to [Nominate A Single Service Agreement To Sever](#)).
 - If you use the Start Severance collection event, you would want to remove a service agreement from a collection process when it no longer has intolerable debt (regardless of the state of the debt class's entire debt). You'd want to do this because, if you don't, the system would start a severance process for the paid up service agreement and if it's paid up, you wouldn't want a severance process created for it.
 - To "remove" service agreements from a collection process when they no longer have intolerable debt, you should plug-in a Service Agreement-Oriented Cancel Criteria Algorithm on your collection process templates. The CPM will call this algorithm if you've plugged it in.

NOTE:

When all service agreements are "removed" from a collection process, the CPM cancels all pending collection events and cancels the collection process.

WARNING:

Checking if individual service agreements should be removed from a collection process is optional (meaning that you don't have to plug one in on the collection process template).

A New Payment Plan Can Cancel A Collection Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

NOTE:

Real time cancellation. Please be aware that the system will cancel a collection process real time when a pay plan is created (if the pay plan's scheduled payments are enough to pay-off the customer's outstanding debt).

A User May Cancel A Collection Process At Their Discretion

A user may cancel a collection process at their discretion.

Stopping A Service Agreement May Cancel A Collection Process

The system will "remove" a service agreement from a collection process when it is stopped (i.e., when the service agreement's status becomes Stopped). When the last service agreement is "removed" from the collection process, the collection process will be cancelled.

The Big Picture Of Collection Events

This section describes the various types of collection events and their lifecycle.

How Are Collection Events Created?

Collection events may be created as follows:

- The Account Debt Monitor creates a collection process when an account violates collection criteria. The collection process has one or more collection event(s). The number and type of events is controlled by the collection process template associated with the collection process.
 - Collection events are created when a user creates an ad hoc collection process. The number and type of events is controlled by the collection process template defined when the collection process is created.
 - An ad hoc collection event may be created and linked to an existing collection process by a user at their discretion.
-

NOTE:

Bottom line. Most collection events are created by the system when it creates a collection process for delinquent accounts. If you need to create an ad hoc collection event, you can either create a collection process whose template contains the desired event OR link the desired event to an existing collection process.

FASTPATH:

For more information about the creation of events by the Account Debt Monitor refer to [What Happens When A Collection Process Is Started?](#). For more information about creating ad hoc collection processes, refer to [Collection Process Maintenance](#). For more information about creating ad hoc events, refer to [Collection Process - Events](#).

Types Of Collection Events

The following table describes the various types of collection events and what happens when they are completed:

Type Of Collection Event	What Happens In The System
Send Letter	<p>A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p>
Create To Do Entry	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the collection event type.
Cancel Budget	Every service agreement linked to the account that is on a budget is "removed" from the budget (i.e., the recurring charge amount for the service agreement is set to zero). In addition, a syncing adjustment is issued to cause each SA's current balance to be set equal to their payoff balance (the adjustment type is defined on the SA's SA type). Also, the Budget Plan field on the Account - Budget page is cleared.
Generic Algorithm	The algorithm defined on the event's event type is executed.
Start Severance Process	A severance process is created for every service agreement linked to the collection process. The type of severance process is defined on the SA type table (every service agreement references an SA type).

FASTPATH:

Refer to [Setting Up Collection Event Types](#) for more information.

Collection Event Lifecycle

The following diagram shows the possible lifecycle of a collection event:

Collection events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

FASTPATH:

For more information about a collection event's trigger date, see [Collection Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the account's debt no longer violates the collection criteria that sparked the event's collection process. A pending event may also be cancelled by a user at their discretion. Refer to [How Are Collection Processes Cancelled](#) for more information about how the system will cancel a collection process (and its events).

Collection Event Trigger Date

When a collection event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Collection Events Completed

A background process runs periodically (at least daily) that looks for collection events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Collection Event Activator](#) for more information.

The Last Collection Event Should Kick Off Severance Process(es)

The last collection event will typically kick off the severance process for every service agreement linked to the collection process. This will only happen if you set up the collection process template accordingly (i.e., the last event type in the process template is the kind that starts a severance process for every service agreement linked to the collection process).

NOTE:

Nominating a service agreement to sever. Many organizations that have multiple services in arrears will NOT sever every service agreement that's in arrears. Rather, they will nominate one service agreement and use it to encourage the customer to pay for the other services. If your organization works this way, then your last collection event should call the Nominate A Service Agreement To Sever Algorithm.

How Are Collection Events Canceled?

Users can cancel a collection event at their discretion. In addition, the system can cancel a collection event when it automatically cancels a collection process. Refer to [How Are Collection Processes Cancelled](#) for the details.

The Big Picture Of Severance Process Cancellation

The topics in this section provide high level information about the cancellation of severance processes.

FASTPATH:

For more information refer to [The Lifecycle Of A Severance Process And Its Events](#).

How Are Severance Processes Cancelled?

A severance process may be cancelled via the mechanisms described in this section.

FASTPATH:

Refer to [What Happens When A Severance Process Is Cancelled?](#) for what happens when a severance process is cancelled.

The Freezing Of Certain Financial Transactions Can Cancel A Severance Process

NOTE:

The system will only cancel a severance process if its severance process template indicates that **Auto Cancel** is allowed. Typically, this switch is set on all severance process templates except for the odd ones that are used to [reconnect service](#).

The system reviews a severance process real-time whenever its service agreement's debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
 - The creation of a payment segment.
 - The creation of an adjustment that credits a service agreement.
-

NOTE:

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no background process that monitors severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person

for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered.

The review takes place as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the severance process's debt class must be less than or equal to a given threshold amount for a severance process to be cancelled. If so, the severance process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

NOTE:

The above logic is not "hard coded". The system calls the Severance Process Cancel Criteria Algorithm defined on the [debt class](#) that is associated with the severance process. This algorithm cancels a severance process if the sum of ALL service agreements in the debt class have debt less than or equal to a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears. Note: you would only use this type of collection event if you do not Nominate A Single Service Agreement To Sever.
 - If you use the Start Severance collection event, then you would want to cancel a severance process when its service agreement no longer has intolerable debt (regardless of the state of the debt class's entire debt).
- To cancel a severance process when its related service agreement no longer has intolerable debt, you should plug-in a Cancel Criteria Algorithm on your [severance process templates](#). The system will call this algorithm if you've plugged it in.

NOTE:

Manual Creation. A user can create a severance process for an account that does not qualify to be on severance according to the cancel criteria algorithm. For example, perhaps your cancel criteria algorithm cancels a severance process when the account's debt falls below a threshold amount. A user can create a severance process for an account whose debt is already below this threshold. Because cancellation is real time, there is no action that will cause this severance process to be canceled. When a manual severance process is created, the system executes the appropriate cancellation criteria algorithm. If the algorithm indicates that the system would have canceled this severance process, a warning is issued.

A New Payment Plan Can Cancel A Severance Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

NOTE:

Real time cancellation. Please be aware that the system will cancel a severance process real time when a pay plan is created that pays off enough debt.

A User May Cancel A Severance Process At Their Discretion

A user may cancel a severance process at their discretion.

Stopping A Service Agreement Will Cancel A Severance Process

The system will cancel a severance process if its service agreement is stopped (i.e., when the service agreement's status becomes Stopped).

What Happens When A Severance Process Is Cancelled?

The following takes place when a severance process is canceled by the system:

- The system cancels all pending severance events and deactivates the severance process.
- If there are any field activities linked to the severance process, an optional plug-in spot defined on the installation record allows you to plug in an algorithm to cancel these field activities.
 - The base package Severance Process Cancellation Algorithm will cancel all pending field activities that were created as a result of the severance process that are not linked to a dispatched field order.
- If there are any pending field activities left associated with the severance process, it is marked to trigger the creation of a To Do entry to highlight that field activities exist for a canceled severance process. (This happens if you have not plugged in an algorithm to perform the cancellation or if the algorithm detected a condition that prevented cancellation.) To create the To Do entry, you must run the background process [TD-SPRO](#).
- There is an optional plug-in spot defined on the severance process' template. If an algorithm is plugged-in, it is called. The base package algorithm will create a reconnect process if there are completed field activities for a cut for nonpayment severance event associated with the severance process. Refer to Severance Post Cancellation Algorithm for more information about this algorithm.

The Big Picture Of Severance Events

This section describes the various types of severance events and their lifecycle:

How Are Severance Events Created?

Severance events may be created as follows:

- The process that completes (i.e., executes) collection events creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The number and type of events is controlled by the severance process template associated with the severance process. Refer to [The Collection Event Activator](#) for more information about this process.
- Severance events will be created when a user creates an ad hoc severance process. The number and type of severance events is controlled by the severance process template associated with the severance process.
- An ad hoc severance event may be created and linked to an existing severance process by a user at their discretion.

NOTE:

Bottom line. Most severance events are created by the system when it creates a severance process for delinquent service agreements. If you need to create an ad hoc severance event, you can either create a severance process whose template contains the desired event OR link the desired event to an existing severance process.

FASTPATH:

For more information about creating ad hoc severance processes and events, refer to [How To Perform Common Severance Process Functions](#).

Types Of Severance Events

The following table describes the various types of severance events and what happens when they are completed:

Type Of Severance Event	What Happens In The System
Send Letter	<p>A customer contact is created for every financially responsible person linked to the service agreement's account. It is the customer contact that causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p>
Create To Do Entry	<p>A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.</p>
Create Field Activities	<p>A field activity is created for each service point associated with the service agreement being severed. The type of activity is defined on the service point's SP type's field activity type profile.</p>
Generic Algorithm	<p>The algorithm defined on the event's event type is executed.</p>
Expire Service Agreement	<p>The service agreement is expired and, if earlier severance events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point.</p>
Affect Credit Rating/Cash-Only	<p>An account credit rating demerit record is created. The number of demerits is defined on the collection event type.</p>

FASTPATH:

Refer to [Setting Up Severance Event Types](#) for more information.

Field Events Versus Office Events

Severance events are considered either field or office events. Office events are just like collection events in that they don't involve any type of field activity in their completion. Field events, however, are not like collection events because they create one or more field activities. These activities cause these events to have a different lifecycle. Refer to [Severance Event Lifecycle](#) for more information.

Severance Event Lifecycle

The following diagram shows the possible lifecycle of a severance event:

The following points explain the lifecycle of severance events of the office variety:

- Office events are initially created in the pending state.
- A pending office event becomes complete when the system sees that its trigger date is on or before the current date. At this time, the system executes the event's activity (e.g., create a letter, create To Do entry).

FASTPATH:

For more information about a severance event's trigger date, see [Severance Event Dependencies & Trigger Date](#).

- A pending office event will be cancelled automatically by the system when the debt associated with the severance process's service agreement is sufficiently reduced. A pending office event may also be cancelled by a user at their discretion. Refer to [How Are Severance Processes Cancelled](#) for more information about how the system will cancel a severance process (and its events).

The following points explain the lifecycle of severance events of the field variety:

- Field events are initially created in the pending state.
- A pending field event becomes awaiting field activity completion when the system sees that its trigger date is on or before the current date. At this time, the system creates the field activities associated with the given event (e.g., disconnection warning, disconnect for nonpayment, etc.).

FASTPATH:

For more information about a severance event's trigger date, refer to [Severance Event Dependencies & Trigger Date](#). For more information about the field activities that are created for a field severance event, refer to [Field Events And Their Activities](#).

- An awaiting field activity completion field event becomes complete when the system sees that its field activities are all complete or cancelled.
- A pending field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits. A pending field event may also be cancelled by a user at their discretion.
- An awaiting field activity completion field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits if the field activity has not been dispatched (refer to [Designing Your Reconnection Procedures](#) for information on how the system handles the situation if the field activity is completed or dispatched). An awaiting field activity completion event may also be cancelled by a user at their discretion.

Severance Event Dependencies and Trigger Date

When a severance event is created by the system, its trigger date cannot be set. This is because, unlike collection events, the trigger date on severance events can only be set when ALL of the preceding severance events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a standard severance process and its events:

Event Number	Severance Event	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Preceding Events
10	Field activity - Disconnect for non-payment warning	N/A - first event	0
20	Field activity - Disconnect for non-payment	10	2
30	Create To Do entry	20	0
40	Send letter to customer	20	0
50	Expire service agreement	20	10

This severance process is meant to execute as follows:

- On the first day, generate a 48-hour warning of impending disconnection. This is a field event as most organizations deliver this warning in person.
- After 2 days (i.e., 48 hours) have passed, create a field activity to disconnect for non-payment.
- When this is completed, generate a To Do entry to let a CSR know about the cutoff. Also, send a letter to the customer.
- If after 10 days from the cutoff, we still don't have payment, expire the service agreement.

As can be seen from the above example, the later events are dependent on the completion of the field activities in the earlier events. This means that when you set up a severance event, you must indicate the events on which it depends (and the number of days after their completion that the event should be triggered).

NOTE:

Bottom line. The system sets the trigger date on severance events when it detects that all of its dependent events are complete (this is the responsibility of the SED background process). Refer to [Calendar vs Work Days](#) for a description of your choices in respect of how the trigger date is calculated.

Field Events And Their Activities

When the system is told to start a severance event that creates field activities (e.g., disconnect for non-payment), it will generate a field activity for every service point linked to the service agreement.

The question is, where does it get the field activity type associated with the field activities? The answer is explained below:

- Every service point has an SP type.
- Every SP type references a field activity type profile.
- A field activity type profile contains a matrix defining activity types to generate under various situations. Some of these situations are those associated with severance.

FASTPATH:

For more information, refer to [Setting Up Field Activity Type Profiles](#).

Severance Event Activation & Completion

A background process runs periodically (at least daily) that looks for severance events with a trigger date on or before the current date. This process executes the activity associated with each event. If the event is an office event, the event then becomes complete. If the event is a field event, the event becomes "awaiting field activity completion" until the field activities are complete. At this time, the severance event is completed. Refer to [Severance Event Activator](#) for more information.

How Are Severance Events Canceled?

Users can cancel a severance event at their discretion. In addition, the system can cancel a severance event when it automatically cancels a severance process. Refer to [How Are Severance Processes Cancelled](#) for the details.

The Big Picture Of Write Off Processing

Before you financially write-off debt, most companies go to some effort to collect the past due funds. You control exactly what happens by setting up the various write-off control tables. The topics in this section provide background information that will help you understand how the information in these control tables is used.

How Is Debt Financially Written-Off?

Before debt can be written-off, a write-off service agreement must exist for the account. Why? Because when you write-off a normal service agreement's debt, you are actually transferring its debt to a write-off service agreement.

A write-off service agreement is just like other service agreements in that:

- It holds debt.
- When a payment is received, the service agreement's debt is reduced.

Debt is transferred to a write-off service agreement (WO SA) from the customer's uncollectable service agreements (SAs). The following points highlight important characteristics about the uncollectable SAs and the WO SA:

- The WO SA and the uncollectable SAs should be linked to the same account (note: this isn't a strict rule, it just makes sense because an account's written off funds should be linked to the account).
- Debt may be transferred to a WO SA from any type of service agreement regardless of debt class, i.e., a WO SA can contain debt that originated in any debt class.
- When you transfer debt from the uncollectable SAs to the WO SA, the debt is removed from the uncollectable SAs (and their status becomes closed - assuming their balance becomes zero).
- If you use the system's automated write-off processing, the system will create WO SAs for you. The system's automated write-off processing can write-off revenue in a different manner than is used to write-off liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for more information.
- WO SAs are immune from the account debt monitor (assuming their debt class is marked as not being subject to collection activities).
- WO SAs are not billed (assuming their SA type is marked as being not billable).

- WO SAs start their life with a non-zero payoff and current balances (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose uncollectable debt necessitated the creation of the WO SA.
- If the customer pays off the write-off debt, the WO SA remains active in case you ever need to write-off debt in the future. If you don't like the WO SA remaining active after it's paid off, you can indicate on the WO SA's SA Type that it is a "one time charge", this will cause the WO SA to be automatically closed when it's paid off.
- You can transfer additional uncollectable debt to the WO SA.

NOTE:

Bankruptcy write-offs. If you have to write-off debt because a customer declares bankruptcy, everything stated above is true. The only thing you have to do is use a different SA type for bankruptcy write-offs as compared to "normal" write-offs. On the bankruptcy write-off SA type, simply leave the payment segment type blank - this way the system will never distribute a payment to the bankrupt debt (because bankrupt debt is legally uncollectable).

The Ramifications of Write Offs in the General Ledger

WARNING:

If you practice cash accounting, refer to [Cash Accounting and Write-Offs](#).

When you write-off unpaid debt, you shouldn't book it all to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you typically want to:

- Book the written off revenue to a write-off expense account, and
- Reduce the liabilities (you don't owe the liability if you don't get paid).

Consider the following example of a simple electric service agreement with two financial transactions:

Event	GL Accounting
Customer is billed	A/R 1000
	Revenue <900>
	State Tax Payable - Taxing State - California <80>
	City Tax Payable - Taxing City - San Francisco <20>
Customer is levied a late payment charge	A/R 50
	Late Payment Revenue <50>

After these two financial transactions are booked, the customer has debt of \$1050. Of this \$1,050; \$950 is revenue and \$100 is liability (money you owe the taxing authorities).

If the customer doesn't pay, you will eventually have to write-off this debt. Most organizations would issue the following types of financial transactions to do this:

Event	GL Accounting
Write-off the bill	Write-off Expense 900
	State Tax Payable - Taxing State - California 80
	City Tax Payable - Taxing City - San Francisco 20
	A/R <1000>
Write-off the late payment charge	Write-off Expense 50

Notice in the above transactions, the two separate revenue accounts are written off by booking to an expense account. However, the liability accounts are reversed. Why is revenue treated differently from liabilities at write-off time? There's a good reason for it (if you're an accountant), for the time being, just accept that this is how it works.

And finally, we need to worry about what happens if the customer eventually pays off their written off debt. If this happens, most organizations would pay off the write-off first, and, if there was still money left, they'd reimburse the taxing authorities. If we assume the customer pays off the entire written off debt, the following financial transactions would be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900
	Write-off Expense <900>
Reinstate the liabilities	Cash 100
	State Tax Payable - Taxing State - California <80>
	City Tax Payable - Taxing City - San Francisco <20>

While the reinstatement of liabilities at payment time is possible in the system, the ramifications of doing such make this approach impracticable (the ramifications are a) if the check bounces, we would not be able to reduce the liabilities, and b) if there was a partial payment of the liabilities, the remaining unpaid amount could get written down). Therefore, when a write-off is paid the following financial transactions should be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900
	Write-off Expense <900>
Reinstate the liabilities	Cash 100
	Reinstated liabilities <100>

Notice that rather than reinstating the individual liabilities, we simply reinstate all liabilities into a single account. This means your accountants will have to distribute this money to the appropriate liabilities manually.

So, how do we achieve the above in the system? This explanation is a little complicated, but it'll make sense if you keep the above financial transactions in mind:

- First of all, you'll need two different SA types - one to hold the written off revenue and another to hold the reduced liabilities.
 - On the SA type that holds written off revenue, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference your Write-off Expense account.
 - On the SA type that holds the reduced liabilities, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference a the "reinstated liabilities" GL account.

Next, you need to understand how the system's standard write-off logic works:

- The system accumulates the distribution codes from GL details associated with recent financial transactions linked to the service agreement being written-off.
- When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement(s). The number and type of service agreements to which the bad debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for how to define the type of write-off service agreement

associated with a distribution code. In our example, we'd need the two SA types described above - one for the revenue accounts, the other for the liability accounts.

- At write-off time, for those distribution codes associated with revenue, the system will create a transfer adjustment from the normal service agreement to the write-off revenue service agreement. This will reduce (credit) the receivable on the normal service agreement and increase (debit) the expense account defined on the write-off revenue service agreement.
- However, if we do the above for the distribution codes associated with liabilities, we have a problem. The problem is a bit hard to explain unless you understand tax accounting, but it basically comes down to this - if we simply transfer the portion of the receivable balance associated with the liabilities to the write-off liability SA, we will always be debiting the distribution code defined on the SA type. This isn't correct because we really want to debit the liability account (and reference the characteristic type and value from the original credit) when we reduce the liability. So how do we do this? For those distribution codes associated with liabilities, you need to indicate that you want to override the distribution code on the "transfer to" side of the transfer adjustment with the distribution code / characteristic type / characteristic value that was originally booked. Refer to [Setting Up Distribution Codes](#) for how to indicate you want to override the distribution code at write-off time. If you do the above, then at write-off time the transfer adjustment will reduce (credit) the receivable on the normal service agreement and increase (debit) the original liability accounts from the original financial transactions.

If you followed the above, you'll see that we now have everything debited and credited appropriately. And, if a payment materializes for the written off debt, we will simply debit cash and credit the distribution code on the respective SA (either Write Off Expense or Reinstated Liabilities).

NOTE:

Batch and real-time write-offs may use the above processing. The above logic is executed real time when a user writes off debt using the [write-off transaction](#) (assuming the base package write off algorithm is plugged into the account's [customer class](#)). The above logic is executed in batch when a write-off event that references a Write Off Using Distribution Codes [event type](#) is executed. Write-off events are described in detail below.

Automated versus Manual Write Offs

The system will automatically create write-off SAs and transfer uncollectable debt to them during the automated write-off processing described below.

If necessary, you can write-off debt outside of the automated write-off process using either of the following methods:

- You can transfer bad debt from any service agreement to a write-off service agreement using a transfer adjustment.
- You can use the [write-off transaction](#) to write-off debt real-time. When this transaction is used, the system executes the logic embedded in the Write Off Method algorithm that's plugged in on the account's [customer class](#).

How Does The Write-Off Monitor Work?

This section describes how the [Write Off Monitor](#) uses your write-off criteria and write-off process templates to collect overdue debt.

Different Write-Off Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different write-off criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**.

An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.

- You probably have different write-off criteria for different classes of debt. For example, if a customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have control over how to write-off unregulated debt. You differentiate your debt in respect of the collection process via a write-off **debt class on the customers' service agreements** (note the write-off debt class is actually defined on the SA type and every service agreement has a SA type).

NOTE:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt.

Given the above, you should understand that different write-off criteria will exist for every combination of collection class and write-off debt class. If you're confused, then consider the following matrix:

SA's Write-Off Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, commercial customer debt.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for regulated debt.
Unregulated	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt / credit is < \$10 and > \$-10, write down the debt using a write-down adjustment. If the debt / credit is <= \$-10, create an A/P adjustment to refund the credit to the customer. If debt still remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for unregulated residential debt.

Otherwise, create the default write-off process
for unregulated commercial debt.

Notice that each cell in the matrix has the same pattern:

- The system first attempts to reduce the SA's current and payoff balances to zero using the following methods (assuming you have set up the write-off control appropriately):
 - Sync the current balance with the payoff balance. If the SA's payoff balance is zero, this will cause the current balance to become zero and therefore close the SA.
 - If there's a debit balance, transfer the debt to any pending start or active SA in the same write-off debt class.
 - If there's a credit balance, transfer the debt to any non-closed / non-cancelled SA in the same write-off debt class
 - If the remaining debit / credit balance is within a user-defined tolerance (this is defined on the respective algorithm on the write-off control), create an adjustment to write-down the small balance.
 - If a credit balance remains, create an A/P adjustment to refund the balance with a check (the adjustment type is defined on the respective algorithm on the write-off control).
- All of the above points will cause the SA to close. If debt remains, the system starts some type of write-off process. The type of process is dependent on the respective criteria. What differentiates one write-off criteria from another is its priority. The higher priority criteria will be compared first. If the customer / debt meets the criteria, the write-off process is initiated; no further comparisons are performed.

FASTPATH:

For more information about maintaining this matrix, refer to [Setting Up Write-off Control](#).

When Is Debt Monitored For Write Off Purposes?

The write-off monitor only reviews a service agreement when the following conditions are true:

- The service agreement is stopped and reactivated.
- If the service agreement is a "billable charge" SA (as identified on its SA type), all of its billable charges must appear on a bill segment AND the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is not a "billable charge" SA AND it is billable (as identified on its SA type), the SA must have a closing bill segment (i.e., it must be final billed) and the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is a sub SA, its master SA must abide by the above conditions.
- If the service agreement is not billable, it is possible that adjustments, which affect the SA's debt, exist. The write-off monitor will only review a non-billable SA if all FTs for this SA that have been marked to include on a bill have been swept onto a bill and the bill for any of these FTs has a bill due date plus grace period on or before the business date.

NOTE:

Postponing write-off processing. You can prevent the write-off process from processing an eligible service agreement by populating the account's C&C Postpone Date with a future date.

Attempt To Close The SA Before Creating A Write Off Process

Before the write-off monitor creates a write-off process for a stopped and reactivated service agreement, it attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to a pending start or active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

NOTE:

Plug-in algorithms do the work. Algorithms that are plugged-in on the [write-off control](#) responsible for managing the service agreement's debt actually perform the above effort. You can customize these algorithms to behave exactly how your collections staff desires.

If the algorithms responsible for the above effort are successful in reducing the service agreement's debt to zero, then the service agreement closes and will not be subject to write-off processing. If the above algorithms don't result in the service agreement's debt being reduced to zero, a write-off process will be started (as describe below).

What Happens When A Write-Off Process Is Started?

When you define write-off criteria, you must define the write-off process template to use if the criteria are violated. The system uses this template to create the account-specific write-off process.

Every stopped or reactivated service agreement that is part of the offending write-off debt class will be linked to the write-off process.

Also linked to the write-off process will be one or more write-off events. These events are meant to prod the customer. You define the types of events and when they are generated when you set up your write-off process templates.

It's important to note that all of the write-off events will be created when the write-off process is created. Each of these write-off events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for a description of how the trigger date is calculated.

A separate process, Activate Write-off events, is responsible for activating write-off events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do to an operator, refer debt to a collection agency, etc.)

NOTE:

Multiple write-off processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple write off debt classes, a write-off process will be started for each offending write off debt class that has stopped or reactivated service agreements.

FASTPATH:

For more information about write-off process templates, see [Setting Up Write Off Process Templates](#). For more information about write-off events, see [The Big Picture Of Write-off Events](#). For more information about how a write-off process is cancelled, see [How Does A Write-Off Process Get Cancelled?](#).

How Does A Write-Off Process Get Cancelled?

The system "removes" a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-

off process. When the write-off process is deactivated, all collection agency referrals associated with the write-off process are cancelled.

NOTE:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

How Do Collection Agency Referrals Work?

The following points describe how collection agency referrals work.

- A write-off process has one or more events. One type of event causes overdue debt to be referred to a collection agency.
- When a referral write-off event is activated, the system marks the event for processing by the event's Collection Agency Referral Algorithm (refer to [Setting Up Write Off Event Types](#) for more information).
- The next time the Collection Agency Referral process executes (the frequency is dependent on your background process schedule), it will refer the process' debt to a collection agency. The specific agency to which the debt is referred is controlled by the event type's Collection Agency Referral Algorithm. The sample algorithm supplied with the system simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must write your own algorithm.
- Regardless of the manner in which a collection agency is selected for an account's debt, the referral involves the creation of a collection agency referral history record. Refer to [Collection Referral](#) for more information.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that, in turn, triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to [Setting Up Collection Agencies](#) for more information.
- If the collection agency is successful in obtaining the funds, simply add a payment. If the payment causes the SA's balance to become zero, the system will automatically close the service agreement. When the system closes a service agreement, it is "removed" from the write-off process. When a write-off process no longer contains active service agreements, the system cancels the write-off process. When a write off process is cancelled, all collection agency referrals are automatically cancelled.
- Collection agency referrals get cancelled by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you design your write-off process to generate a collection agency cancellation X days after the referral. Refer to [Setting Up Write Off Process Templates](#) for how to do this. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).

FASTPATH:

When you enable the Control Central alert algorithm, C1-COLL-REF, an alert displays when an account has an active collection agency referral. This algorithm is plugged-in on the [installation record](#).

The Big Picture Of Write-off Events

This section describes the various types of write-off events and their lifecycle.

How Are Write-off Events Created?

Write-off events may be created as follows:

- The Write-Off Monitor creates a write-off process when an account has unpaid, final billed service agreements. The write-off process has one or more write-off event(s). Refer to [How Does The Write-Off Monitor Work?](#) for more information about how the system creates write-off processes and their events.
- Write-off events are created when an operator creates an ad hoc write-off process. The number and type of events is controlled by the write-off process template defined when the write-off process is created.
- An ad hoc write-off event may be created and linked to an existing write-off process by an operator at their discretion.

NOTE:

Bottom line. Most write-off events are created by the system when it creates a write-off process for unpaid, finalized service agreements. If you need to create an ad hoc write-off event, you can either create a write-off process using a template that contains the desired event OR link the desired event to an existing write-off process.

FASTPATH:

For more information about creating ad hoc write-off processes and events, refer to [How To Perform Common Write-off Maintenance Functions](#).

Types Of Write-off Events

The following table describes the various types of write-off events and what happens when they are completed:

Type Of Write-off Event	What Happens In The System
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the write-off event type.
Cancel Agency Referral	All collection agency referrals associated with the write-off process will be cancelled.
Refer to Agency	The debt associated with the SAs linked to the write-off process will be referred to a collection agency.
Send Letter	A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced. The type of letter is defined on the customer contact type control table. The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).
Send To Do	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.
Write Off using Distrib Code	This type of event is used to write-off bad debt in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. You'd use this method for example if you want to write-off revenue differently than you write-off liabilities. The system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-

off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement. The type of service agreements to which the debt is transferred is defined on the distribution codes.

Write Off using SA Type

The service agreements linked to the process will be written-off by transferring their debt to a new or existing write-off service agreement. Note: the SA type of the write-off service agreement is defined on the algorithm defined on events of this type.

Generic Algorithm

The system calls the algorithm defined on the write-off event type. This type of event is used when what you need to do isn't handled by one of the above event types.

FASTPATH:

Refer to [Setting Up Write Off Event Types](#) for more information.

Write-off Event Lifecycle

The following diagram shows the possible lifecycle of a write-off event:

Write-off events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

FASTPATH:

For more information about a write-off event's trigger date, see [Write-off Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the service agreements linked to the process are all closed (i.e., they no longer have debt - either because it was paid or transferred to a write-off service agreement). A pending event may be cancelled by an operator at their discretion.

Write-off Event Trigger Date

When a write-off event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Write-off Events Completed

A background process runs periodically (at least daily) that looks for write-off events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Write Off Event Activator](#) for more information.

The Last Write-off Event Should Write Off All Debt Associated With All SAs

The last write-off event will typically transfer all debt from the service agreement's linked to the process to a write off service agreement (linked to the account). This will only happen if you set up the write-off process template accordingly (i.e., the last event in the write-off process template is the kind that writes off debt for every service agreement linked to the write-off process).

How Are Write-off Events Canceled?

The system removes a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). Be aware that any type of financial event could cause an SA's balance to fall to zero (e.g., the creation of an adjustment, the application or cancellation of a payment, the cancellation of a bill, ...). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process.

NOTE:

Real time cancellation. Unlike collection processes, the system cancels write-off processes real time when the service agreement becomes closed (i.e., there is no background process that monitors write-off processes).

Besides the automated cancellation process, an operator may cancel a write-off event at will.

NOTE:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

Calendar vs. Work Days

When you set up your collection, severance and write-off process templates, you supply information that controls how the system determines the trigger date of each event in the related process. There are two different mechanisms for doing this:

- When you set up your severance process templates, you must define the number of days between each event. For example, the second event (send cutoff warning) may need to be triggered 7 days after the first event (send reminder letter).
- When you set up your collection and write-off process templates, you must define the number of days after the start of the process when each event should be triggered. For example, the second event (send cutoff warning) may need to be triggered 7 days after the start of the collection process.

The system uses this information in conjunction with the account's division's work calendar when it allocates a trigger date to the various collection, severance, and write-off events in your processes. The system offers you the following choices in respect of how it calculates an event's trigger date:

- You can indicate that the trigger date should be set to the next possible workday. For example, if you indicate that the second event is triggered 7 days after the first event, the system will add 7 days to the first event's completion date. It then checks if this is a workday (and not a holiday), if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.
- You can indicate that the trigger date should be calculated by counting workdays. For example, if you indicate that the second event is triggered 7 days after the first event, the system will count 7 workdays (using the account's division's work calendar), and set the trigger date accordingly.

You must define which of the above methods is used in the following processes:

- Account Debt Monitor (ADM). Refer to [The Account Debt Monitor](#) for more information.
- Collection Event Trigger (CET). Refer to [The Collection Event Activator](#) for more information.
- Severance Event Set Trigger Date (SED). Refer to [Set Trigger Date](#) for more information.
- Write-off Monitor (WPM). Refer to [The Write Off Monitor](#) for more information.

The Big Picture Of Payment Arrangements and Pay Plans

The topics in this section describe two different mechanisms that allow a customer to payoff overdue debt in installments.

The Big Picture Of Payment Arrangement Requests

A Payment Arrangement Request is used to manage the process of starting a payment arrangement. It is a step-by-step process that can include:

- Checking the account's eligibility for payment arrangement
- Capturing the terms of the payment arrangement such as the included service agreements, down payment amount, number of installments and installment amount
- Evaluating whether or not the payment arrangement request requires approval
- User approval / rejection of the payment arrangement request
- Monitoring for the down payment, if applicable
- Creating the payment arrangement service agreement

The topics in this section describe how payment arrangement requests work.

Lifecycle Of A Payment Arrangement Request

The base product provides a Payment Arrangement Request (**CI-PARrequest**) business object that supports the functions needed to create a payment arrangement. Its lifecycle allows for managing and monitoring of the prerequisites of a payment arrangement:

- The first step in the payment arrangement request process is typically to check that the account is eligible for a payment arrangement. One or more eligibility criteria are executed and an overall assessment is made on the results, to determine the account's eligibility/ineligibility. The request goes into the **Eligibility Checked** state. The results are shown on the user interface, for the user to determine the next step.
- If the account is ineligible for a payment arrangement, the request process ends. The payment arrangement request goes into the **Denied** state.

- If the account is eligible, the process can proceed with setting up the terms of the payment arrangement. The agreed upon terms are submitted and the request proceeds to the next step. If there are no prerequisites (approvals, down payment etc.), the request can automatically go to the **Granted** state, where the payment arrangement service agreement is created
- A payment arrangement request may be subject to prior approval if it meets certain criteria — e.g. the payment arrangement amount exceeds a threshold amount. The payment arrangement request goes into the **Approval In Progress** state, where an authorized user will need to review the request and **Approve** or **Reject** it accordingly.
 - If the user approves the request, the request will proceed to the next step — i.e. either another prerequisite (such as a down payment) or granting the request.
 - If the user rejects the request, the request will automatically go to the **Denied** state.
- If a down payment must be paid prior to starting the payment arrangement, the request will stay in the **Waiting for Down Payment** state until the payment is received or until the down payment due date.
 - If the down payment is paid (i.e. according to implementation-specific criteria for considering it paid), the payment arrangement request goes into the **Granted** state, where the payment arrangement service agreement is created. The account's SA balances to include in the payment arrangement are recalculated, based on the actual down payment that was received.
 - On the other hand, if the down payment is not received or is received but insufficient, the payment arrangement request goes into the **Unpaid Down Payment** state.
- A payment arrangement in a **Waiting for Down Payment** or **Approval In Progress** state can be **Withdrawn**. This is for cases where a customer decides to not proceed with the payment arrangement.
- Any issues encountered during the recalculation of the SA balances or during the creation of the payment arrangement service agreement can put the request into the **Error** state.

Refer to the Payment Arrangement Request business object, for more details on these lifecycle rules.

Payment Arrangement Eligibility

An account's eligibility for payment arrangement is typically checked at the start of the request process. Based on the results of these eligibility checks, a user can determine whether or not the payment arrangement request can proceed.

Since the eligibility rules can vary across implementations, the base product provides plug-in spots on the Payment Arrangement Request Type (**C1-PARequestType**) business object for eligibility checking:

- The **PA Request Type – Eligibility Criteria** algorithm spot is responsible for checking specific conditions or activity on the account, to determine payment arrangement eligibility. Algorithms of this type commonly return a simple Pass/Fail result. The base product supplies a sample algorithm that checks the account's past broken payment arrangements.
- The **PA Request Type — Criteria Assessment** algorithm spot is responsible for taking the results of the execution of **PA Request Type – Eligibility Criteria** algorithms and determining the overall result, which is whether or not the account is eligible for payment arrangement. The base product supplies two sample algorithms for this spot:
 - One algorithm type checks for at least one Fail result from the **PA Request Type – Eligibility Criteria** algorithms and if it finds one, returns an *Ineligible* result
 - Another algorithm type simply returns an *Eligible* result. This is for implementations that do not need **PA Request Type – Eligibility Criteria** algorithms. This default algorithm would be the only algorithm to plug in.

Payment Arrangement Request Approval

A payment arrangement request may require prior approval, based on the terms specified on the request. For instance, if the total payment arrangement amount exceeds a set threshold amount, the request may have to be routed to another user for approval. That user will need to review the request and Approve or Reject accordingly.

Since the approval requirements are implementation-specific, the base product provides a **PA Request Type — Determine Approval Requirement** plug-in spot on the Payment Arrangement Request Type (**C1-PARequestType**) business object. Algorithms of this type return an indicator of whether or not approval is needed. If the algorithm indicates that approval is needed, the payment arrangement request will go into the **Approval In Progress** state until a user reviews and approves/rejects the request.

Your implementation must configure an algorithm with your specific approval criteria. The base product does not currently supply an algorithm type for this spot.

Payment Arrangement Down Payments

A down payment may be required/applicable as a prerequisite for starting the payment arrangement.

A setting on the Payment Arrangement Request Type controls whether down payments are required/optional/not applicable. If down payments are required or optional, the payment arrangement request type defines the down payment options, which are percentages of the total payment arrangement amount or a flat amount.

The down payment due date is calculated based on settings in the Payment Arrangement Request Type – e.g. number of days till due.

The down payment is monitored for the actual payment:

- If the down payment is paid, the request is granted. The SA balances are recalculated based on the down payment amount that was paid and the payment arrangement service agreement is created.
- If the down payment is unpaid or is insufficient (based on the implementation's rules), the request is denied and the payment arrangement service agreement will not be created.

Refer to the Payment Arrangement Request Type (**C1-PARequestType**) business object for more details on down payment option configuration and to the Payment Arrangement Request (**C1-PARequest**) business object, to see the monitor algorithm that checks if the down payment was made.

Setting Up Payment Arrangement Request Control Tables

This section describes the control tables needed to set up payment arrangement requests.

Setting Up Payment Arrangement Request Types

A payment arrangement request type defines properties that control how a request for payment arrangement is processed.

Refer to [The Big Picture Of Payment Arrangement Requests](#) for an overview of payment arrangement request functionality.

To maintain payment arrangement request types, open **Admin > Credit & Collection > Payment Arrangement Request Type > Search**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information on the fields.

Setting Up Payment Arrangement Request Reasons

A payment arrangement request can capture the specific reason why a customer is asking to go on a payment arrangement. This reason is optional if using the base-owned Payment Arrangement Request (**C1-PARequest**) business object and the Payment Arrangement Request Process Flow Type (**C1-PAREQUEST**) on your Payment Arrangement Request Types.

To use Payment Arrangement Request Reasons, configure your specific values on the **C1-PARequestReasonLookup** extendable lookup. No base values are supplied for this lookup.

Setting Up Payment Arrangement Request Status Reasons

The Payment Arrangement Request (**C1-PARequest**) base business object provides the option to specify the reason for the request going into the **Denied** or **Canceled** state.

A few base-owned status reasons are supplied. To add other reasons for payment arrangement request cancellation/denial, go to the Status Reason portal and update the **C1-PARequest** business object's status reasons for the Denied and Canceled states.

Automatically Cancelling Inactive Payment Arrangement Requests

The system is delivered with a batch process, Cancel Inactive PA Requests (C1-ACPAR), that can be used to cancel payment arrangement requests that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the payment arrangement request. Adjust the batch parameters according to your custom logic, if needed.

The Big Picture Of Pay Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

NOTE:

Nomenclature. Some people refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the customer's bill only contains charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed.

- When a payment is received, the service agreement's debt is reduced.
- If the service agreement becomes delinquent, a collection process is initiated to collect the overdue debt.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent service agreements (SAs) at the inception of the payment arrangement.

When you transfer delinquent debt from the delinquent SAs to the PA SA, the debt is removed from the delinquent SAs. If you transfer all debt from the delinquent SAs, the customer will no longer be in arrears in a given debt class (and if the customer is no longer in arrears, active collection and severance processes will be cancelled).

NOTE:

Use the Payment Arrangement Request Transaction. You could do the above functions by adding a new service agreement and creating transfer adjustments. However, this is tedious. Rather, use the [Payment Arrangement Request process](#). This process is recommend when requests for payment arrangements require eligibility checking and other prerequisites such as down payments and approvals. When a payment arrangement request is granted, it creates the PA SA, transfers debt to it, and sets up the installment amount.

You can also create the payment arrangement service agreement directly using the [Payment Arrangement](#) transaction if you don't require any prior eligibility checks, down payments or approvals. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

WARNING:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, neither the original service agreements nor the PA SA have delinquent debt. If the customer neglects to pay their payment arrangement, the PA SA will fall into arrears and a collection process will ensue. If the customer neglects to pay their previously delinquent SAs, they will again fall into arrears and a collection process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes \$500 on their electric and water service agreements and they want to pay this off in 10 installments, you'd set up the installment amount to be \$50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their normal service agreements, you can transfer additional delinquent debt to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off \$500 with 10 installments of \$50 would have an initial payoff balance of \$500 and a current balance of \$0. After the first bill, the PA SA would still have a payoff balance of \$500, but its current balance would be \$50. When the customer pays, the PA SA's payoff balance would fall to \$450 and its current balance would return to \$0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff \$1,000 of debt in \$10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance

Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed (\$50 for new debt and \$10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays \$60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Monitoring Payment Arrangements

The PA SA should belong to its own debt class (let's call it Payment Arrangement Debt) so that you can have stricter collection criteria for payment arrangement debt (as compared to normal SAs). Because there will be a new debt class, there will be a unique collection class control (CCC) for payment arrangements. This CCC will have debt criteria associated with payment arrangement debt. If these criteria are violated, we will kick off a collection process that should have 1 collection event - Start Severance.

The severance process template for PA SAs will have 1 severance event that calls the Break Payment Arrangement Event algorithm. This algorithm does the following:

- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement (identified by the XFER adjustment type on the PA SA's SA type). When these are cancelled, the original arrearage will be reinstated under the original SAs - this debt should be rather old by this point.
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the account's debt using the standard distribution algorithm. Because the payment arrangement debt that was reinstated should be rather old, it should get relieved first. This relief will occur via transfer adjustments from the PA SA to the original SAs.
- If there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), the debt will be transferred back to one of the SAs from which the arrangement was originally created.
- Inserts a characteristic under the PA SA to indicate that it has been broken (we need this for the account debt monitor (ADM) a few steps down).
- Inserts a row on the account debt monitor trigger. This trigger will cause the account to be reviewed by the ADM the next time it runs.

NOTE:

The PA SA must final bill before it closes. The PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the ADM next runs, it will analyze the account's reinstated debt. We recommend creating a new override collection criteria for the normal debt class that will return a value of true if the account has a closed payment arrangement that has been broken in the last X days (where X is a parameter of the override collection criteria's algorithm). If this algorithm returns a true, kick off a unique collection process template (that has nasty events). A sample algorithm of this type is supplied in the base package - COLL COND PA.

To complete this discussion, we have to worry about the situation when the final bill of a payment arrangement goes unpaid. In this situation, the payment arrangement is stopped and will therefore not be processed by the ADM. In this case, the write off monitor will process the PA SA after its final bill's due date and a write-off process will start. This write off process will have a single event that calls the Break Payment Arrangement algorithm (described above). After the FT's are issued in this event, the SA will close (because it's been final billed and its balance will go to zero).

The Big Picture Of Pay Plans

A pay plan (PP) is an agreement with a customer to make payments on specific dates. Pay plans differ from payment arrangements in that pay plans have user-defined scheduled payment dates, which are independent from the customer's billing dates. In other words, payment arrangements appear on the customer's bills, pay plan scheduled payments do not.

If a customer is in arrears and you want to receive payments on specific dates (as opposed to with the customer's regular bills), you would set up a pay plan and define the dates on which you expect the payments.

The topics in this section describe how pay plans work.

A Pay Plan Has One Or More Scheduled Payments

When you create a pay plan for an account, you must define the number of scheduled payments and their respective amounts. There is no limit to the number of scheduled payments that may be set up under a pay plan.

Automatic Payments Can Be Created On The Scheduled Payment Dates

The system will create automatic payments on a pay plan's scheduled payment dates if:

- The account is set up for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)), and
- The payment method defined on the pay plan indicates automatic payment is being used

The background process called PPAPAY is responsible for creating these automatic payments. It does this by calling the automatic payment creation algorithm plugged in on the installation record.

NOTE:

If the **Autopay Creation Option** on the [installation record](#) is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated). Refer to [Automatic Payments](#) for more information.

A Pay Plan Insulates Overdue Debt From The Account Debt Monitor

A pay plan's scheduled payments are used by the account debt monitor as "pseudo payments" that relieve the account's debt before it is subjected to the collection criteria (refer to [How Does The Account Debt Monitor Work](#) for more information about collection criteria).

It's important to understand that a pay plan only insulates the account's debt that belongs to the pay plan's debt class. Therefore, if a customer has debt that belongs to two debt classes (e.g., normal debt and 3 rd party pass through debt), you would need to set up a separate pay plan for each debt class (assuming both types of debt are covered by a pay plan). Refer to [Different Collection Criteria For Different Customers and Different Debt](#) for more information about debt classes.

A Pay Plan Must Reference A Pay Plan Type

When you create a pay plan, you must define its pay plan type. The pay plan type controls the following functions:

- The debt class whose debt is insulated by the pay plan.
- The type of algorithm (if any) that is executed when the pay plan is broken. You might use such an algorithm to affect the customer's credit rating when the pay plan is broken.

A Pay Plan May Reference A Third-Party Payor

In addition to referencing the account whose debt is insulated by the pay plan, the pay plan must also reference the account that is responsible for making the payments. We refer to this second account as the pay plan's "payor".

While the payor's account is typically the same as the account whose debt is insulated by the pay plan, you can indicate a third-party payor (e.g., a social service agency) is responsible for making the pay plan's scheduled payments.

If your organization allows third-party payors, you can define each on the third-party payor control table. This control table exists to simplify the data-entry effort when you create a pay plan (as it defines the account associated with the third-party payor).

NOTE:

If a pay plan does not reference a third-party payor, any non-third-party payor (i.e., any account that is not defined in the third-party payor control table) can make payments on behalf of the customer. If a pay plan references a third-party payor, only payments made by the third party on behalf of the customer are counted towards the fulfillment of the pay plan.

The Lifecycle Of A Pay Plan

The following diagram shows the possible lifecycle of a pay plan:

The following points explain this lifecycle:

- Pay plans are initially created in the active state. Active pay plans are monitored for compliance by [The Pay Plan Monitor](#).
- A pay plan may be cancelled as follows:
 - A user can cancel a pay plan at will.
 - When a SA is stopped AND there are no other active SAs in the same debt class, all **Active** pay plans associated with the account and debt class will be will be **Canceled** .
 - The activation of a collection event that calls the "cancel pay plan" algorithm will cancel all active pay plans associated with the collection process's debt class. You may want to use such a collection event if your organization cancels active pay plans when new debt causes a collection process to kick-off. Note, the base package algorithm that performs this function will not cancel the pay plan if it's associated with a 3rd party payor.
- [The Pay Plan Monitor](#) causes active pay plans to become broken if sufficient payments have not been made to satisfy the pay plan's scheduled payments.
- [The Pay Plan Monitor](#) causes active pay plans to become kept when it detects that sufficient payments have been made to satisfy the pay plan's scheduled payments.

Highlighting The Existence Of Broken / Kept / Active and Denied Pay Plans

You can define on the installation record plug-in algorithms that format alert messages. (Refer to [Installation Options - Algorithms](#) for additional information.) We recommend that you take advantage of the following algorithms to highlight pay plans:

- Highlight pay plans in a given status. This algorithm is used to highlight pay plans in a given state (broken, kept, cancelled) that were started within the last X days.
- Highlight customer contacts of a given type. This algorithm would be used to highlight customer contacts of a given type that were created within the last X days. This would be useful if you create a specific type of customer contact when you deny a pay plan. Some utilities do this to prevent customers from shopping around.

In addition, you can define account-specific alerts to highlight customers that should never be allowed to have a pay plan (for whatever reason).

A Pay Plan Must Reference A Payment Method

When you create a pay plan, you must define how the customer will make the payments by referencing a payment method. Examples of payment methods include: In Person , Wire Transfer, By Post, Express Mail, etc.

The payment method is more than just documentation as it defines the number of grace days the customer has to make the pay plan's scheduled payments. For example, if you set up the payment method control table to indicate that payments made By Post have 3 grace days, then the customer has up to 3 days after each scheduled payment date to make the payment. If payment is not received by the scheduled payment date plus the grace days, the pay plan will be marked as broken (and the ADM will be triggered).

The Pay Plan Monitor

FASTPATH:

Please understand the concepts described in [The Lifecycle Of A Pay Plan](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading this section.

The Pay Plan Monitor background process (referred to as PPM) is responsible for monitoring active payment plans. This process can cause a pay plan (PP) to become kept or broken (or being left as active).

NOTE:

When is a pay plan marked as broken / kept? It's important to understand that only the PPM can cause a pay plan to become kept or broken. This means that if a customer makes a payment that satisfies a pay plan, the pay plan will only be marked as kept when the pay plan monitor next runs. Analogously, if a payment is cancelled, nothing will happen to an active pay plan until the PPM next runs. When the PPM next runs, it will see that the scheduled payment was not kept and it will break the pay plan and schedule the ADM to be executed. When the ADM next executes, it will create a collection process (because the customer's debt will no longer be insulated by the pay plan's scheduled payments).

NSF Cancellations After A Pay Plan Is Kept. If a payment is cancelled due to non-sufficient funds (NSF) after a pay plan is marked as kept, the pay plan will remain kept. But keep in mind that the pay plan's account is scheduled for review by the ADM when a payment is cancelled due to NSF. When the ADM reviews the account's debt, it will no longer have an active pay plan to insulate it and the account's debt will likely trigger a new collection process. Refer to [How Pay Plans Affect The Account Debt Monitor](#) for more information.

The following points describe, at a high level, how the PPM monitors a pay plan (PP) for compliance.

- The system selects all frozen, non-cancelled payment segments associated with the PP's account and debt class where:
 - The payment date is after the start date of the pay plan, and
 - The payment's pay event has at least one tender that references the pay plan's payor.
- The system logically reduces / removes past and current scheduled payments (starting with the earliest scheduled payment) until the total amount of payment segments is exhausted (or there are no more historical / current scheduled payments).

NOTE:

Paying pay plans in advance. Scheduled payments with a future date are not logically removed / reduced. This means that if a customer makes advance payments on a pay plan, it will not be marked as kept until all scheduled payment dates are in the past.

- If all scheduled payments have been logically removed, the pay plan is marked as kept.
- If there exist scheduled payments where the pay date + grace days (grace days are defined on the pay plan's payment method) is before the current date (i.e., a payment doesn't exist for a scheduled payment):
 - The pay plan is marked as broken.

- The PP's break algorithm (if any) is called (note, for European / Australian pay plans, there are scenarios where the break algorithm can cause the pay plan to become unbroken - when there aren't at least two missed, historical scheduled payments).
- An ADM trigger is stored for the PP's account. This will cause the account to be reviewed by the ADM the next time it runs. And because the pay plan is broken, its scheduled payments will no longer insulate the account's arrearage.

IMPORTANT:

It's important that you schedule the PPM to run before the ADM so that it can break unpaid payment plans prior to the ADM subjecting the account's debt to collection criteria. Refer to [How Pay Plans Affect The ADM](#) for more information.

How Pay Plans Affect The Account Debt Monitor

As described under [A Pay Plan Insulates Overdue Debt From The Account Debt Monitor](#), a pay plan's scheduled payments insulate an account's debt from the ADM. This section describes how this is accomplished.

WARNING:

You should understand the concepts in [How Does The Account Debt Monitor Work](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading the following.

NOTE:

The ADM will be triggered when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for an explanation of how the ADM is triggered when a pay plan is broken.

Before the ADM subjects an account's debt to the collection criteria, it calls the debt's debt class's Override Arrears Algorithm (this is an optional plug-in spot on [Debt Class](#)). This algorithm is passed the debt class's aged debt and manipulates it as follows:

- First, a list of all past, present and future scheduled payments associated with the account and debt class's active pay plans is constructed.
 - If multiple payors are encountered (because the customer has multiple pay plans and these have different payors), a separate list of scheduled payments is maintained for each payor.
- Next, for each payor, retrieve the total amount of frozen, non-cancelled payment segments made on behalf of the pay plan's account and debt class.
 - Select all frozen, non-cancelled payment segments associated with the pay plan's account and debt class whose pay date is \geq pay plan's start date and the pay segment's event has at least one tendering account associated with the pay plan's payor.
- Next, logically reduce / remove past and current scheduled payments (starting with the earliest scheduled payment) until the payor's payment amount is exhausted (or there are no more historical / current scheduled payments). Future scheduled payments cannot be remove / reduced.
- Finally, reduce the passed in aged debt with any unpaid scheduled payments.

NOTE:

This logic is not "hard coded". Rather, the mechanism used to use a pay plan's scheduled payments to reduce debt is defined in an algorithm defined on the pay plan's debt class. The contents in this section describe how a base package algorithm works. Because it's an algorithm, you can introduce whatever logic you please.

The following is an example of how pay plans affect aged debt.

Date	Event	SA's Arrears	SA's Balances	Scheduled Payments
Prior to creation of the PP 1/18/2000		\$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old	Current: \$4,500 Payoff: \$4,500	
1/18/2000	Pay Plan created. The \$4,500 in future scheduled payments offsets the existing \$4,500 of aged debt.	\$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old De facto ADM debt: \$0	Current: \$4,500 Payoff: \$4,500	1/20/2001 \$1,500 2/01/2001 \$1,500 2/07/2001 \$1,500
1/20/2001	The customer pays \$1,500. There exists \$3,000 of future scheduled payments that offset the arrears	\$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0	Current: \$3,000 Payoff: \$3,000	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
1/20/2001	ADM runs. The \$3000 in future scheduled payments offsets the Current Balance of \$3000, so CC events not created.	\$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0	Current: \$3,000 Payoff: \$3,000	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
1/24/2001	A new bill is created for \$400	\$1,100 - 62 days old \$1,900 - 32 days old \$400 - 1 day old De facto ADM debt: \$400 - 1 day old	Current: \$3,400 Payoff: \$3,400	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
2/2/2001	Pay Plan Monitor runs. PP marked as Broken because the 2/1/2001 scheduled payment has not been paid (assuming no grace period on the pay plan's payment method)	\$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old	Current: \$3,400 Payoff: \$3,400	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 "Late" 2/07/2001 \$1,500 Future
2/2/2001	ADM runs. There are no active pay plans and therefore there is nothing to insulate the customer's debt. Therefore the aged debt will be subjected to the collection criteria and an appropriate collection process will be created.	\$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old De facto ADM debt is the same as above (i.e., rather old)	Current: \$3,400 Payoff: \$3,400	Pay plan is broken and therefore its scheduled payments cannot be used.

Collection Process / Severance Process Cancellation

When a pay plan (PP) is created, the system determines if it can cancel active collection and severance processes associated with the pay plan's account and debt class. It does this because a pay plan's scheduled payments act as "pseudo payments" that relieve the account's debt (temporarily). The following points describe how this works:

- The system attempts to cancel collection processes by calling the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm is meant to cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.
- It attempts to cancel severance processes by calling the Severance Process Cancel Criteria Algorithm defined on the debt class that is associated with the severance process. This algorithm is meant to cancel a severance process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

If collection / severance processes still exist for the account / debt class associated with the pay plan, a warning is issued.

Interesting Pay Plan Facts

The following points describe a variety of interesting facts about pay plans (PP):

- An account may have many active pay plans. However, only 1 pay plan may be active for a given account / debt class / payor at any point in time.
- The existence of a pay plan has no impact on payment distribution.
- When a SA is stopped, if the SA's debt class has an active PP AND there are no other active SAs in the same debt class, the PP will be cancelled
 - The cancel reason will be "cancelled by system" (as opposed to "cancelled by user")
- If necessary, different collection / severance processes can be triggered if a broken PP is detected (via the override algorithms on CCC and write-off control - we do NOT provide such algorithms).

Setting Up Pay Plan Control Tables

This section describes the control tables needed to set up pay plans.

Setting Up Pay Plan Types

Pay plan types control what is done by a given pay plan. Open **Admin > Credit & Collection > Pay Plan Type** to define your pay plan types.

FASTPATH:

For more information refer to [The Big Picture Of Pay Plans](#) for more information.

Description of Page

To modify a pay plan type, simply move to a field and change its value. To add a new pay plan type, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Plan Type The name of the pay plan type.

Description A meaningful description of the pay plan type.

Broken Algorithm This algorithm is called when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information about how pay plans are broken.

If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that breaks a pay plan.

Debt Class The debt class covered by pay plans of this type. Refer to [Setting Up Debt Classes](#) for more information.

Setting Up Payment Methods

Payment methods are used to describe how a customer intends to make their pay plan's scheduled payments. Open **Admin > Credit & Collection > Pay Method** to define your payment methods.

FASTPATH:

For more information refer to [A Pay Plan Must Reference A Payment Method](#) for more information.

Description of Page

To modify a pay method, simply move to a field and change its value. To add a new pay method, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Method The name of the payment method.

Description A meaningful description of the payment method.

Grace Days The number of days added to the scheduled payment date. The ADM will consider the pay plan to be broken if payment is not made by the scheduled date plus the grace days.

Auto Pay If the pay method is marked as being for **Auto Pay**, the PPAPAY background process will automatically create an automatic payment on the pay plan's scheduled payment dates IF the account has been set up for automatic payment.

Setting Up Third Party Payors

Pay plans support optional third-party payors. Open **Admin > Credit & Collection > Third Party Payor** to define your third-party payors.

NOTE:

A third-party payor refers to an account. You must set up the account before you can create a third-party payor.

FASTPATH:

Refer to [A Pay Plan May Reference A 3rd Party Payor](#) for more information.

Description of Page

The following fields display for each third party payor:

Third Party Payor Provide a meaning id for the third-party payor that can be easily recognized when setting up a pay plan.

Description A meaningful description of the payor.

Account ID The account that is used for this payor. It is this account that is tracked as the "payee" of any payments made towards a third party payor's pay plan.

Active Check this box if the payor is currently available to participate in pay plans.

Creating Collection, Severance & Write-Off Procedures

Your collection procedures define how your organization collects overdue debt. Your severance procedures define how your organization severs service agreements when collection attempts fail. Your write-off procedures define how your organization writes off finalized debt. In this section, we describe how to set up the data that controls these procedures.

FASTPATH:

For more information about collection, severance and write-off procedures, see [The Big Picture Of Credit & Collections \(C&C\)](#).

WARNING:

There are innumerable ways to design your collection, severance and write-off procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production collection, severance and write-off procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Your Collection Procedures

The design of your collection procedures is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the collection process control tables.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

FASTPATH:

For more information about how the information in this matrix is used to monitor your customers' debt, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

Designing Your Debt Classes

Multiple debt classes are needed when you have different collection procedures for different types of service agreements. If all service agreement debt is collected the same way, then you'll have just one debt class (call it Generic). However, if you're like many organizations, you will have multiple debt classes. The following points will help you understand why:

- If you have both regulated and unregulated service, you probably have different debt classes for each type of service. Why? Because your local regulators control how you collect and cutoff overdue, regulated debt. For unregulated debt, your organization controls how overdue debt is collected.
- If your customers make charitable donations, you will have a charitable contribution debt class. Why? Because you probably send a different type of letter when the customer falls into arrears on their charitable contributions. You also can't cut off their water service if they don't make their charitable contributions.

- If you levy deposits, you will probably have a deposit debt class. Why? Because you probably respond differently if the customer doesn't pay their deposit (e.g., you may decide to cut off their electric service until the deposit is paid).
- If you allow customers to make payments on Non-Billed Budgets, you will probably have a Non-Billed Budget debt class. Why? Because you probably respond differently if the customer doesn't pay their Non-Billed Budget (e.g., you may decide to expire the Non-Billed Budget but not affect their other service since the Non-Billed Budget is a way for customers to prepay for upcoming bills).
- If you write-off uncollectable debt, you will need another debt class for write-off service agreements. Why? Because when you write-off debt in the system, you transfer the uncollectable debt from the original service agreement(s) to a write-off service agreement. The write-off service agreement holds this debt forever (or until it is paid). You need to use a different debt class for the write-off service agreements because they aren't subject to collection criteria.
- If you use the system to charge your organization's company usage, you'll need another debt class (we refer to it as the "N/A" debt class below). Why? Because all service agreements must have a debt class, even those that will never have debt.

SA's Debt Class	Account's Collection Class	Account's Collection Class
Regulated		
Unregulated		
Charitable Contribution		
Deposit		
Non-Billed Budget		
Write Off		
N/A		

Designing Your Collection Classes

Multiple collection classes are needed when any debt class has different collection rules depending on the type of customer. If all customers within all debt classes are collected the same way, then you'll just have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

Consider unregulated debt. For commercial/industrial customers, you probably don't worry until they owe you more than, say, \$100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, \$5 after 20 days. In this situation, you will have at least two collection classes: one for large customers, the other for residential customers.

In our example, we are assuming you have two collection classes: Residential and Commercial/Industrial.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:
	Residential	Commercial/Industrial
Charitable Contribution		
Regulated		
Unregulated		
Write Off		
Company Usage		

Designing Collection Class Controls

At this point we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Each cell should have a "collection class control" that defines its collection criteria and what to do if the criteria are violated. If a cell doesn't have a collection class control, this means you don't have any debt associated with that combination of collection class and debt class. So, we'll mark each cell without debt with "N/A".

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off		
N/A		

Next, we'll mark each cell for debt classes whose debt isn't collectable (i.e., the write-off and N/A debt classes).

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off	N/A	N/A
N/A	N/A	N/A

NOTE:

If the Account Debt Monitor encounters debt associated with a non-existent collection class control, it will issue an error.

Determining the collection criteria in each remaining cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For charitable debt, if the customer is more than \$0 in arrears by more than 20 days, kick off the "charity reminder" collection process. We'll talk more about this collection process later.
- For regulated / residential debt, if the customer is more than \$15 in arrears by more than 20 days, kick off the Normal Regulated collection process. We'll talk more about this collection process later.
- For unregulated / residential debt, if the customer is more than \$5 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For unregulated / commercial-industrial debt we have multiple criteria:
 - Highest priority. If the customer is more than \$10,000 in arrears by more than 20 days, kick off the Large Overdue Debt collection process. We'll talk more about this collection process later.

- Lower priority. If the customer is more than \$100 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For deposit debt (regardless of collection class) we have multiple criteria:
 - Highest priority. If the customer is more than \$5 in arrears by more than 50 days, kick off the Deposit Severely Overdue collection process. We'll talk more about this collection process later.
 - Lower priority. If the customer is more than \$15 in arrears by more than 20 days, kick off the Deposit collection process. We'll talk more about this collection process later.

Given the above, our matrix will look as follows:

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Charitable Contribution	If > \$0 is older than 20 days, start Charity Reminder collection process.	N/A
Regulated	If > \$15 is older than 20 days, start Normal Regulated collection process.	N/A
Unregulated	If > \$5 is older than 20 days, start Normal Unregulated collection process.	Highest priority: If > \$10,000 is older than 20 days, start Large Overdue Debt collection process. Lower priority: If > \$100 is older than 20 days, start Normal Unregulated collection process.
Deposit	Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process.	Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process.
Write Off	N/A	N/A
N/A	N/A	N/A

Designing Your Collection Class Control Overrides

WARNING:

Your collection needs may not require any overrides for your collection class control matrix and therefore this section may not be relevant.

The following matrix will help you design your collection class overrides. When the matrix is complete, you're ready to set up the collection class control tables.

Notice that the matrix has two dimensions: one is dependent on collection condition algorithms; the other is dependent on the collection class controls designed in the previous section. Collection condition algorithms are confusing. Think of them as optional conditions that, if met, will subject the collection class control's debt to different collection criteria.

Each cell in the matrix contains the collection criteria that will be applied to the account's debt when the collection condition is met (i.e., the same type of criteria - dollars and days and collection process - are defined in each cell).

We label the first collection condition as the Default. The collection criteria associated with this column will be used to analyze an account's debt when none of the other conditions applies. We'll start by indicating the Default collection criteria (this was defined in the previous section).

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

If a different collection process OR criteria should be used when other conditions are met, you should indicate such by defining the collection criteria in the cell. For example, if we assume that all unregulated residential debt has a different collection process when the account's credit score is less than the threshold credit rating on the installation record or the account's CIS Division, our matrix will look as follows:

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	Override: If Credit Rating is lower than the credit rating threshold: If > \$5 is older than 15 days, start Risky Unregulated collection process.
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

Once the matrix is complete, you're ready to design your collection process and collection event types.

NOTE:

The collection conditions are limited by your imagination (and business requirements). We have provided the collection conditions you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors. For example, if you have different collection criteria that apply during winter months, you should add a new collection condition (called Winter Season). Or if you have different criteria based on years of service, you could have another condition.

New collection conditions may require programming. See [How To Add A New Algorithm](#) for more information.

Designing Collection Process Templates & Collection Event Types

The following table shows the collection process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Collection Process Template	Collection Event Template	Triggered X Days From Start Of Collection Process
Charitable Contribution Reminder	Charity courtesy reminder letter	0
	Start severance	15
Normal Regulated	Regulated courtesy reminder letter	0
	Regulated second notice letter	10
	Start severance	15
Large Overdue Debt	Large debt courtesy reminder letter	0
	To Do for large overdue debt	3
	Large debt second notice letter	10
	Start severance	15
Normal Unregulated	Unregulated courtesy reminder letter	0
	Unregulated second notice letter	5
	Start severance	10
Risky Customer Unregulated	Unregulated risky letter	0
	Start severance	5
Deposit	Deposit reminder	0
Deposit Severely Overdue	Create To Do entry	0

If we extract each unique event type from the above table, we end up with the following:

Collection Event Type	Event Type
Charity courtesy reminder letter	Send Letter - CHARIT REMIN
Start severance	Start Severance Process
Regulated courtesy reminder letter	Send Letter - REGUL REMIN
Regulated second notice letter	Send Letter - REGUL second
Large debt courtesy reminder	Send Letter - LARGE REMIN
Risky debt courtesy reminder	Send Letter - RISKY REMIN
To Do for large overdue debt	Issue To Do
Large debt second notice letter	Send Letter - LARGE second
Unregulated courtesy reminder letter	Send Letter - UNREG REMIN
Unregulated second notice letter	Send Letter - UNREG second
Deposit reminder	Send Letter - DEPOS REMIN

Now you're (almost) ready to set up your collection procedures.

Defining Cancellation Process Auto Cancellation Criteria

The topics in the section [How Are Collection Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Collection Process Templates](#).

Setting Up Collection Procedures

In the previous section, [Designing Your Collection Procedures](#), we presented a case study that illustrated a mythical organization's collection procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Collection Event Types

Collection event types control what is done by a given collection event. Open **Admin > Credit & Collection > Collection Event Type > Add** to define your collection event types.

Description of Page

Enter a unique **Collection Event Type** and **Description** for the collection event type.

Enter the **Collection Event Type**. Permissible values are: Affect Credit, Rating/Cash-Only, Cancel Budget, Generic Algorithm, Send Letter, Create To Do Entry, Start Severance Process. The following discussion describes the parameters that must be defined for each type of collection event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Credit Rating Points** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Credit Rating Months** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

FASTPATH:

For more information, refer to [Account - Credit Rating](#).

The Send Letter collection event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.

- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

NOTE:

Letter creation is triggered via a customer contact. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the collection event. Refer to [Setting Up Letter Templates](#) for more information.

The Cancel Budget collection event type cancel an account's budget plan (if the account is on such a plan). When a budget plan is cancelled, adjustments are issued to synchronize every service agreement's current balance with its payoff balance and each applicable SA's recurring charge amount (i.e., budget amount) is set to zero.

The Generic Algorithm collection event type causes the algorithm defined in the **Collection Event Alg** to be executed. You use this type of algorithm when the standard types of collection events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type of activated.

The Create To Do Entry collection event type causes a To Do entry to be issued. A good example of where this is used is when the collection event requires that the customer be called on the phone. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-CEVT for the type of To Do entry that's created).

The Start Severance Process type will start a severance process for every service agreement linked to the collection process. No parameters are needed for this type of event.

Enter a **Long Description** to fully describe the collection event type.

Setting Up Collection Process Templates

Collection process templates define the collection events that will be executed when a collection criteria rule is violated. Open **Admin > Credit & Collection > Collection Process Template > Add** to define your collection process templates.

Description of Page

Enter a unique **Collection Process Template** and **Description** for the collection process template.

Select a **Cancel Criteria Algorithm** if your organization allows individual service agreements to be "removed" from a collection process regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM. If this algorithm is specified, it is executed by the collection process monitor when it detects that a credit has been applied to a service agreement linked to an active collection process. This algorithm will indicate if the specific service agreement that has been credited no longer has debt that warrants a collection process. Refer to [How Are Collection Processes Cancelled](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that "removes" a service agreement from a collection processes if the service agreement's debt so warrants.

The **Response** grid contains an entry for every collection event that will be created when a collection process that references this template is created. The following information must be defined for each event:

Event Sequence controls the order in which the collection event types appear under the collection process template. The sequence number is system-assigned and cannot be changed. If you have to insert a collection event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Collection Event Type Specify the type of collection event to be generated.

Days After Process Creation Specify the number of days after the creation of the collection process that the related collection event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective collection events.

FASTPATH:

For more information about collection event types, see [Setting Up Collection Event Types](#). For more information about trigger dates, see [Collection Event Trigger Date](#).

Setting Up Collection Classes

Every account has a collection class. This class is one of several fields that control the collection method applied to the account's debt. Open **Admin > Credit & Collection > Collection Class** to define your collection classes.

FASTPATH:

For more information about collection classes, see [Designing Your Collection Classes](#).

Description of Page

Enter a unique **Collection Class** code and **Description** for each collection class.

Indicate which method is used to monitor the member accounts' unpaid debt:

- If you practice [balance-forward accounting](#) for accounts belonging to this collection class, select Collection, Severance & Write-Off. This method of collection is described throughout this chapter.
- If you practice [open-item accounting](#) for accounts belonging to this collection class, select Overdue. This method of collection is described under [Defining Overdue Processing Options](#).
- If accounts belonging to this collection class are not subject to either of the above collection methods, select Not Eligible For Collection. Please be aware that these accounts will NOT be reviewed for overdue debt.

Setting Up Debt Classes

Every SA type has a debt class. This class is one of several fields that control the collection criteria applied to the service agreement's debt. Open **Admin > Credit & Collection > Debt Class > Add** to define your debt classes.

FASTPATH:

For more information about debt classes, see [Designing Your Debt Classes](#).

Description of Page

Enter a unique **Debt Class** and **Description** for the debt class.

Turn on **Eligible for Collection** if service agreements belonging to this debt class have their debt monitored by the collection process. This should only be turned off if this debt cannot be collected, e.g., write-off debt.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to an arbitrary number as only one algorithm for each system event is allowed in this case.

WARNING:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
Collection Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a collection process can be canceled, and if so, it cancels it. Refer to How Are Collection Processes Cancelled for more information.
Severance Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a severance process can be canceled, and if so, it cancels it. Refer to How Are Severance Processes Cancelled for more information.
Override Arrears Due to Pay Plan	Required if you use Pay Plans	<p>This algorithm is called to temporarily override a customer's arrears using a pay plan's scheduled payments when the system looks at an account's debt from a credit & collections perspective (i.e., the ADM calls this algorithm before it subjects a customer's debt to the collection criteria and when a pay plan is created). It does not actually change any data, but overlays the current arrears with the pay plan scheduled payments.</p> <p>This algorithm is also called by the above algorithms when a pay plan is created in order to evaluate if the scheduled payments actually cover the arrears (if so, the collection / severance processes are cancelled). It is also called periodically by the ADM in order to establish if the current state of the pay plan still covers the arrears. Refer to How Pay Plans Affect The Account Debt Monitor.</p>

Setting Up Collection Class Controls

The topics in this section describe the windows on which you set up your collection class control information.

WARNING:

The information in this page is what controls how the system analyzes your customer's debt. The flexibility of this control information provides you with almost unlimited options. This is very powerful, but it requires careful analysis. Refer to [Designing Your Collection Procedures](#) for more information.

Collection Class Control - Main Information

The information on this transaction defines the conditions that will be checked by the [Account Debt Monitor](#) when it checks if an account has violated your debt criteria.

Open **Admin > Credit & Collection > Collection Class Control > Add** to define this information.

FASTPATH:

For more information about collection class control, refer to [Designing Collection Class Controls](#).

Description of Page

Enter a unique **Collection Class Control** code and **Description** for the collection class control (CCC).

Enter the **CIS Division** to which the CCC's criteria applies.

Enter the **Collection Class** to which the CCC's criteria applies.

Enter the **Debt Class** to which the CCC's criteria applies.

Enter the **Currency Code** in which the CCC's criteria are denominated.

Use **Long Description** to further describe the CCC.

FASTPATH:

The information in the following grid is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

The grid which follows contains the conditions that are checked by the [Account Debt Monitor](#) (ADM) to determine the type of criteria (defined on the next tab) that will be applied against an account's debt. In other words - the ADM will check each condition (from highest to lowest **Priority**). The first condition that returns a value of true will cause the system to compare the account's debt against the debt criteria defined on the next tab.

Multiple conditions may be defined if different conditions result in a different type of debt thresholds (or a different type of collection process). The following fields are required for each condition:

Collection Condition Priority The priority controls the order in which the ADM checks if a collection condition applies (the lower the number, the higher the priority). Higher priorities are checked before lower priorities.

NOTE:

The values for this field are customizable using the Lookup table. This field name is COLL_CAT_PRIO_FLG.

Condition Algorithm Define the algorithm used to check if an account should be subject to the collection criteria defined on the next tab. If the algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** (defined on the next tab) and start a collection process if the account has debt that violates these criteria.

You must have at least one collection condition; otherwise the system will not have criteria against which to compare the account's debt. This entry should have the lowest priority code and reference the "default" algorithm. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references the "default" collection condition algorithm type (COLL COND DF).

If you have other conditions that should be checked before the default condition, you must create an entry for each in this grid. Each entry should have a priority consistent with your business requirements (and this priority should be higher than the default condition's priority). In addition, you should reference an algorithm that contains the conditions that will be checked to determine if the account should be subject to the debt criteria (defined on the next tab). The system is supplied with many additional algorithm types. In order to take advantage of them, you will need to create an algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references one of the collection condition algorithm types.

Where Used

Collection class controls contain the data that controls the Account Debt Monitor. Refer to [How Does The Account Debt Monitor Work?](#) for more information.

Collection Class Control - Debt Criteria

The information on this page defines the debt and age thresholds used by the [Account Debt Monitor](#) when it checks if an account has violated your acceptable levels of debt. Open **Admin > Credit & Collection > Collection Class Control > Search** and navigate to the **Debt Criteria** page to define this information.

NOTE:

The information on this page is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

Description of Page

The **Debt Criteria** scroll contains an entry for each collection criteria algorithm defined on the **Main** tab. The following information appears

The **Collection Condition Priority** controls the order in which the Account Debt Monitor (ADM) checks if a collection condition applies. Higher priorities are checked before lower priorities.

The **Condition Algorithm** is called by the ADM to determine which collection criteria should be applied to the account's debt. If this algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** defined below. If the account violates any criteria, a collection process will be started (using the respective **Collection Process Template**).

The grid that follows contains the debt age and amount of debt that must be violated by the account in order for the ADM to create a collection process template. The following fields should be defined:

Arrears Priority controls the order in which the arrears criteria will be checked by the Account Debt Monitor (the lower the number, the higher the priority). The first criteria, if any, that is met will cause a collection process to be created (using the **Collection Process Template**).

Collection Process Template If the Account Debt Monitor determines that the account's debt violates the corresponding criteria, it creates a collection process using the specified collection process template.

Arrears Amount When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than "> Number of Days" (the next field) AND the debt exceeds "> Arrears Amount". If so, a collection process is started.

Days When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than **Days** AND the debt exceeds **Arrears Amount**. If so, a collection process is started.

Where Used

Collection class controls contains the data that controls the [Account Debt Monitor](#).

Designing Your Severance Procedures

The following matrix will help you design your severance procedures. When the matrix is complete, you're ready to set up the severance process control tables.

Notice that the matrix has two dimensions: one is dependent on severance criteria algorithms; the other is dependent on the SA type of the service agreement being severed. The number and type of SA types is dependent on how your organization sets up the SA type table (the SA types shown below are characteristic of those used by a simple utility).

SA Type	Severance Criteria Algorithm:	Severance Criteria Algorithm:
	Default	Customer On Life Support

Electric Residential

Electric Commercial

Gas Residential

Gas Commercial

Charitable Contribution

Once you know the values of each dimension, you fill in each cell with its respective severance events. We've completed the sample matrix with some characteristic events.

SA Type	Severance Criteria Algorithm:	Severance Criteria Algorithm:
	Default	Customer On Life Support
Electric Residential	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p>	<p>Create a To Do entry asking a collection rep to call the customer.</p> <p>5 days later, create a 72-hour warning field activity.</p> <p>2 days after completion, create a To Do entry telling collection rep of impending life support cutoff.</p> <p>3 days after completion of warning, create a disconnect service field activity AND generate a To Do entry informing a collection agent of such.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection expire the service agreement.</p>
Electric Commercial	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p>	N/A
Gas Residential	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p>	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p>
Gas Commercial	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p>	N/A

Immediately after completion of the disconnect field activity, send a letter to the customer.

10 days after completion of disconnection, expire the service agreement.

Charitable Contribution	Expire service agreement	Expire service agreement
-------------------------	--------------------------	--------------------------

Once the matrix is complete, you determine the severance process templates needed to implement your severance procedures. The following table shows the severance process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Utility severance - default	10	Field activity - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Electric life support residential severance	10	Generate delinquent life support customer To Do entry	N/A - first event	0
	20	Field activity - 72 hour disconnect for non-payment warning	10	5
	30	Generate impending life support cutoff To Do entry to C&C rep	20	2
	40	Field activity - cut for non-payment	20	3
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Just expire severance	10	Expire service agreement	N/A - first event	

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
48-hour warning	Generate Field Activity - Disconnect Warning
72-hour warning	Generate Field Activity - Disconnect Warning
Disconnect for non payment	Generate Field Activity - Cut For Non-Payment
Delinquent life support customer	Create To Do Entry - C&C Rep Role
Impending life support cutoff	Create To Do Entry - C&C Rep Role

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

Now you're (almost) ready to set up your severance procedures.

Defining Severance Process Auto Cancellation Criteria

The topics in the section [How Are Severance Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Severance Process Templates](#).

Designing Your Reconnection Procedures

If a customer pays for a service agreement after the service has been cut for non-payment AND BEFORE THE SA HAS BEEN EXPIRED, they need to be reconnected. Counter-intuitively, you must set up a severance process to initiate the field activities to reconnect service.

NOTE:

Why do you use a severance process to reconnect service? Because a severance process is nothing more than a series of events that take place one after another. Some of the events create field activities, others send letters, others create To Do entries. So, why not use a severance process? You just have to send different letters and perform different field activities.

WARNING:

The system will automatically create a reconnection process if a severance process is cancelled as a result of a payment (or other credits). Please note that this will only happen if you plug-in the appropriate post cancellation algorithm on your severance process templates. Refer to [What Happens When A Severance Process Is Cancelled?](#) **for more information.**

While you don't define the reconnect procedures for an SA type, we recommend you think about the reconnection steps for each of your SA types that can be disconnected for nonpayment. We've completed the sample matrix with some characteristic events.

SA Type	Steps
Electric Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Electric Commercial	Create a reconnect service field activity.

	Immediately after completion of the reconnect, send a letter to the customer.
Gas Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.

Once the matrix is complete, you determine the severance process templates needed to implement your reconnection procedures. Notice each SA type has the same reconnection steps. This means you just need one severance process. The following table shows this severance process template and its events.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Reconnect	10	Field activity - reconnect service	N/A - first event	0
	20	Service has been reconnected letter	10	0

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
Reconnect	Generate Field Activity - Reconnect
Service has been reconnected letter	Send Letter

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

IMPORTANT:

If you want the system to automatically create a reconnection process if a customer pays after they have been cut, you must specify the appropriate post cancellation algorithm on your severance process templates.

And now you're ready to set up your severance (and reconnection) procedures.

Setting Up Severance Procedures

In the previous section, [Designing Your Severance Procedures](#), we presented a case study that illustrated a mythical organization's severance procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Severance Event Types

Severance event types control what is done by a given severance event. Open **Admin > Credit & Collection > Severance Event Type > Add** to define your severance event types.

FASTPATH:

For more information refer to [Designing Your Severance Procedures](#).

Description of Page

Enter a unique **Severance Event Type** code and **Description** for the severance event type.

Enter the Severance **Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Send Letter, Generic Algorithm, Create To Do Entry, Create Field Activities, Expire Service Agreement. The following discussion describes the parameters that must be defined for each type of severance event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- account debt monitor.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

The Send Letter severance event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Generic Algorithm severance event type causes the algorithm defined in the **Sev. Event Algorithm** to be executed. You use this type of algorithm when the standard types of severance events won't do what you need done.

The Create To Do Entry severance event type causes a To Do entry to be created. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-SEVT for the type of To Do entry that's created).

The Generate Field Activities severance event type causes one or more field activities to be generated. Enter the following **Parameters** for this type of event:

- Select the **Customer Event** associated with the field activity. Valid values are: Cut For Non-Payment (CNP), Disconnect Warning (Disc Warn), Reconnect for Payment (Reconn), Start Service (Start) , Start/Stop Service (Start/Stop), Stop Service (Stop), Reread (Reread).
- The system uses the **Customer Event** to select the appropriate field activity type(s) from the field activity type profile associated with the service points linked to the service agreement.

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter off) and the desired customer event (e.g., Disconnect Warning, Cut

For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

The Expire Service Agreement severance event type causes the service agreement to be moved to the pending stop state (it also populates the service agreement's stop date). Refer to [Finalizing Pending Stops](#) for how the system will eventually stop the service agreement (and then final bill it). There are no parameters for this type of event.

NOTE:

Cut for non-payment field activities are special. The Expire Service Agreement severance event type also makes any "cut for non-payment" field activities created by earlier severance events available to stop service. Specifically, it changes the linkage type of the field activities from Severance Activity to Stop Activity. You can see a service agreement's service points' field activities and their respective linkage type on [Service Agreement - Service Point](#).

Enter a **Long Description** to fully describe the severance event type.

Setting Up Severance Process Templates

Severance process templates define the severance events that will be executed when a service agreement is severed. Open **Admin > Credit & Collection > Severance Process Template > Add** to define your severance process templates.

Description of Page

Enter a unique **Severance Process Template** and **Description** for the severance process template.

If severance processes of this type should be automatically canceled when the customer pays the collection amount on the severance, turn on **Auto Cancel**. This switch would typically only be turned off for severance processes used to reconnect a cut service because you don't want such a reconnection process to be canceled when a payment is made. Refer to [Designing Your Reconnection Procedures](#) for more information.

In addition to turning on the **Auto Cancel** switch, specify a **Cancel Criteria Algorithm** if your organization allows a severance process to be cancelled regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM.

If the **Cancel Criteria Algorithm** is specified, it is executed when a credit is posted to the service agreement associated with a severance process. This algorithm will indicate if the service agreement no longer has debt that warrants a severance process. Refer to [How Are Severance Processes Cancelled](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

If you wish to perform any special processes after a severance process is canceled, specify a **Post Cancel Algorithm**. This can be used to start a reconnection in case the severance process was canceled too late to stop the disconnection. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

When a service agreement is to be severed due to non-payment, the system creates a severance process and links to it one or more severance events based on the **Event Types** entered here. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event:

Event Sequence controls the order in which the severance event types appear under the severance process template. The sequence number is system-assigned and cannot be changed. If you have to insert a severance event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Severance Event Type Specify the type of severance event to be generated.

Dependent On Other Events Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. For example, you would turn this switch on for the event that initiates the field activity to disconnect service. Why? Because you only want to disconnect service after the preceding event that warned the client of impending disconnection is complete.

Days After Prev Response Specify the number of days after the completion / cancellation of the dependent events on which the severance event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of days after the creation of the severance process that the related severance event will be triggered. Refer to [Severance Event Dependencies and Trigger Date](#) and [Calendar vs Work Days](#) for a description of how the system uses this information to set the trigger date on the respective severance events.

When the **Dependent On Other Events** switch is on, use the grid to define the events on which this event is dependent. If multiple events are specified in the grid, all such events must be completed or cancelled before the event will be triggered.

Sequence is system-assigned and cannot be specified or changed.

Dependent On Sequence Specify the sequence number of the severance event on which the above severance event depends.

FASTPATH:

For more information about severance event types, see [Setting Up Severance Event Types](#). For more information about trigger dates, see [Severance Event Dependencies & Trigger Date](#).

Designing Your Write-Off Procedures

The design of your write-off procedures is relatively straightforward. Simply follow the instructions in the following topics.

Designing Your Write-Off Debt Classes

Multiple write-off debt classes are needed when you have different write-off procedures for different types of service agreements. If all service agreement debt is written-off the same way, then you'll have just one write-off debt class (call it Generic). However, if you're like many organizations, you will have multiple write-off debt classes. The following points will help you understand why:

- If you bill for 3 rd parties, you probably have different write-off debt classes for the 3 rd party service agreements. Why? Because you probably treat 3 rd party uncollectable debt differently from your own debt.
- You will need a separate write-off debt class for service agreements whose debt cannot be written off. Why? Because there is a switch on the write-off debt class control table that controls if service agreements in the write-off debt class are eligible for write-off processing. Given that you will have some service agreements that hold debt that aren't eligible for write-off processing (e.g., service agreements that hold written-off debt and service agreements that overpayments), you will need at least one other write-off debt class.
- If you use the system to calculate charges for your organization's company usage, you'll need another write-off debt class (we refer to it as the "N/A" write-off debt class below). Why? Because all service agreements must have a write-off debt class, even those that will never have debt.

SA's Write-Off Debt Class	Account's Collection Class	Account's Collection Class
Normal W/O		
N/A		

Designing Write-Off Controls

Set up a matrix using the collection classes you designed when you were designing your collection procedures ([Designing Your Collection Procedures](#)).

SA's Write-Off Debt Class	Account's Collection Class Residential	Account's Collection Class Commercial/Industrial
Normal Write Off		
N/A		

Each cell should have a "write-off control" that defines what to do when the system detects finalized debt that hasn't been paid. This is true even of the "N/A" write-off debt class. Why? Because you may want the system to write-down these stopped SAs when they have a small balance. For example, if you have a write-off service agreement that subsequently receives a partial payment that leaves a small amount owing, you probably want the system to generate a write-down adjustment (so that the write-off service agreement will close). We'll initially fill in the matrix for the "N/A" write-off debt class.

SA's Write-Off Debt Class	Account's Collection Class Residential	Account's Collection Class Commercial/Industrial
Normal Write Off		
N/A	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.

NOTE:

If the Write Off Monitor encounters debt associated with a non-defined collection class and write-off debt class, it will issue an error.

For each cell that isn't designated as N/A, you need to answer the following questions:

- Are you allowed to transfer debt to other non-closed service agreements linked to the account? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Are you allowed to write-down small amounts of debt (or small credits)? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Should you refund credit balances with a check? If so, you need to define the algorithm to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- If debt remains after doing the above, how do you write it off (e.g., do you first refer the debt to a collection agency and only write it off after waiting 30 days)?

We'll fill in the above matrix with our assumptions:

SA's Write-Off Debt Class	Account's Collection Class Residential	Account's Collection Class Commercial/Industrial

Normal Write-Off	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for residential debt.</p>	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt / credit is < \$10 and > \$-10, write down the debt using a write-down adjustment.</p> <p>If the debt / credit is <= \$-10, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for commercial debt.</p>
N/A	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.</p>	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.</p>

We can now use the information in the above matrix to design the necessary Write Off Process Templates and Write Off Event Types.

Designing Write Off Process Templates & Write Off Event Types

The following table shows the write-off process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Write Off Process Template	Write Off Event Type	Triggered X Days From Start Of Write Off Process
Residential	Refer to collection agency	0
	Letter notifying customer of referral	0
	Cancel collection agency referral	60
	Write off	60
Non-Cash Deposit Exists	To Do for non-cash deposit redemption	0
	To Do to highlight unpaid SA(s) still exist (and they will be reconsidered for write-off processing)	10
Commercial	Refer to collection agency	0
	Letter notifying customer of referral	0

To Do to check up on collection agency's efforts	30
Cancel collection agency referral	60
Write off	60

If we extract each unique event type from the above table, we end up with the following:

Write Off Event Type	Event Type
Notification of write-off referral	Send letter - Debt referred to a collection agency
Refer to collection agency	Refer to collection agency
Cancel collection agency referral	Cancel collection agency referral
Write off	Write off
To Do for non-cash deposit redemption	Generate To Do - Redeem non-cash deposit
To Do to highlight unpaid SA(s) still exist	Generate To Do - SA(s) linked to a non-cash deposit remain unpaid (and will be reconsidered for write-off processing)
To Do to check up on collection agency's efforts	Generate To Do - Check up on collection agency's efforts

And now you're ready to set up your write-off procedures.

Setting Up Write-Off Procedures

In the previous section, [Designing Your Write-Off Procedures](#), we presented a case study that illustrated a mythical organization's write off procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Write Off Debt Classes

Every SA type has a write-off debt class. This class is one of several fields that control the write off criteria applied to the service agreement's debt. Select **Admin > Credit & Collection > Write Off Debt Class** to define your debt classes.

FASTPATH:

For more information about debt classes, see [Designing Your Write-Off Debt Classes](#).

Panel controls

To modify a write-off debt class, simply move to a field and change its value. To add a new write-off debt class, click + to insert a row, then fill in the information for each field. The following fields display:

Write Off Debt Class Code The unique identifier of the write off debt class.

Eligible for Write Off Indicates if service agreements belonging to this write off debt class are eligible for write-off processing. This should only be turned off if this debt cannot be written off, e.g., write off debt.

Description The description of the write off debt class.

Setting Up Write Off Event Types

Write-off event types control what is done by a given write-off event. Select **Admin > Credit & Collection > Write Off Event Type > Add** to define your write-off event types.

Description of Page

Enter a unique **Write Off Event Type** code and **Description** for the write-off event type.

Select the **Write Off Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Cancel Agency Referral, Generic Algorithm, Refer to Agency, Send Letter, Create To Do Entry, Write Off using Distrib Code, and Write Off using SA Type. The following discussion describes the parameters that must be defined for each type of write-off event.

The Affect Credit Rating/Cash-Only write-off event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Affect Credit Rating By** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Affect Cash-Only Score By** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

FASTPATH:

For more information, refer to [Account - Credit Rating](#).

The Cancel Agency Referral event type will cancel previous collection agency referrals. No parameters are needed for this type of event.

The Generic Algorithm write-off event type causes the algorithm defined in the **Generic Algorithm** to be executed. You use this type of algorithm when the standard types of write off events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type are activated.

The Refer to Agency event type will refer the debt associated with the process' SAs to a collection agency. You must supply the **Agency Selection Algorithm** that is used to determine the collection agency associated with the referral. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the collection agency to which bad debt should be referred.

NOTE:

Letters. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the write off event type. Refer to [Setting Up Letter Templates](#) for more information.

The Send Letter write-off event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following parameters for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Create To Do Entry write-off event type causes a To Do entry to be issued. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-WOEV for the type of To Do entry that's created).

The Write Off using Distrib Code event type causes bad debt to be written off in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. Use this method if, for example, you want to write-off revenue differently than you write-off liabilities. When this type of event is activated, the system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreements. The type of service agreements to which the debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

The Write Off using SA Type event type causes all debt associated with the process' SAs to be transferred to a write-off service agreement linked to the account. Enter the following **Parameters** for this type of event:

- **CIS Division / SA Type** is the type of write-off service agreement to which the debt will be transferred. Note well,
 - The system will reuse an existing service agreement if an active SA of this type is already linked to the account; otherwise the system will create a new service agreement of this type.
 - The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on the write-offable SA Type. Refer to [SA Type - Main Information](#) for more information.
 - The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write off SA type. Refer to [SA Type - Detail](#) for more information.

Enter a **Comment** to fully describe the write-off event type.

Setting Up Write Off Process Templates

Write-off process templates define the write-off events that will be executed when a write-off criteria rule is violated. Select **Admin > Credit & Collection > Write Off Process Template > Add** to define your write-off process templates.

Description of Page

Enter a unique **Write Off Process Template** code and **Description** for the write-off process template.

The rows in the following grid define the events that will be created when a write off process is created using this template. The following fields display:

Event Sequence Controls the order in which the write-off event is executed. The sequence number is system assigned and cannot be changed. If you need to insert a write-off event between two existing events, you must remove the latter events, insert the new event, and then re-enter the removed events.

Write-off Event Type Code Specify the type of write-off event to be generated. The event type's description is displayed adjacent.

Days After Process Creation Specify the number of days after the creation of the write-off process that the related write-off event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective write-off events.

FASTPATH:

For more information about write-off event types, see [Setting Up Write Off Event Types](#). For more information about trigger dates, see [Write-off Event Trigger Date](#).

Setting Up Write Off Control

Write-off controls define how the system handles finalized, unpaid debt belonging to a given collection class and write off debt class.

Write Off Control - Main

Select **Admin > Credit & Collection > Write Off Control > Add** to define basic information about a write-off control. After entering basic information, navigate to the **Criteria** tab to define the type of write-off process to start when given criteria are met.

FASTPATH:

For more information about write-off control, refer to [Designing Write-Off Controls](#).

Panel controls

Enter a **Write Off Control** code and **Description** for the write-off control (WOC).

Enter the **Collection Class** to which the WOC applies.

Enter the **Write Off Debt Class Code** to which the WOC applies.

Enter general **Comments** to further describe the WOC.

Define the **Synch All Algorithm** used by the system to generate adjustments that cause current balance to equal payoff balance on the service agreements to be written off. This type of algorithm is issued before you actually start a write-off process as current balance is meaningless at write-off time (the customer owes you the payoff balance). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that synchronizes current and payoff balances.

Define the **Debt Transfer Algorithm** used by the system when it attempts to transfer the unpaid debt to another active service agreement linked to the stopped SA's account. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that transfers unpaid balances.

Define the **Write Down Algorithm** used by the system when it attempts to write-down small debt and/or credit balances. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that writes down small amounts.

Define the **Credit Refund Algorithm** used by the system when it refunds a credit balance to a customer. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that refunds credit balances.

Write Off Control - Criteria

Select **Admin > Credit & Collection > Write Off Control > Search** and navigate to the **Criteria** page to define the type of write-off process to start when given criteria are met.

FASTPATH:

The following information is not intuitively obvious. Refer to [Designing Write-Off Controls](#) for more information.

Panel controls

The information in the grid defines the write-off process to be executed for debt belonging to the previously defined collection class and write off debt class. The type of write-off process may differ depending on some condition. For example, you may have a different write-off process if the customer has a non-cash deposit. You must have at least one entry in this collection otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **Write Off Criteria Algorithm** that references the WO CRIT DFLT the algorithm type.

The following fields display:

Priority controls the order in which the criteria will be checked by the Write Off Monitor (higher priorities are checked before lower priorities). The first criteria algorithm that is met (i.e., returns a value of *True*) will cause the associated write-off process to be initiated.

NOTE:

The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: [Collection Class Control](#), [Severance Criteria](#), and [Write Off Control](#) .

Write Off Criteria Algorithm The Write Off Monitor checks if the condition defined by the W/O Condition Algorithm applies to the account whose debt is being analyzed. If a condition is met, a write-off process is created using the associated write-off process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
 - On this algorithm, reference an Algorithm Type that determines if a customer's bad debt should be processed using the associated **Write Off Process Template**.
-

IMPORTANT:

You must have at least one entry in this grid otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **W/O Criteria Algorithm** that references the WO CRIT DFLT algorithm type.

Write Off Process Template If the Write Off Monitor determines the condition defined by the w/o condition algorithm applies, a write-off process is created using the associated write-off process template.

Where Used

Write-off controls contain the data that controls the Write Off Monitor. Refer to [How Does The Write-Off Monitor Work?](#) for more information.

Setting Up Collection Agencies

You must set up a collection agency for each such organization to which you refer delinquent debt. To define a collection agency, select **Admin > Credit & Collection > Collection Agency**.

Description of Page

Enter an easily recognizable **Collection Agency** code and **Description** for each collection agency.

A collection agency must be associated with a Person. Choose the **Person ID** of the organization from the prompt.

FASTPATH:

Information about how to set up persons is discussed in [Maintaining Persons](#).

Turn on the **Active** switch if the collection agency is actively receiving referrals.

Specify the **Batch Control** that's used to route new and cancelled referrals to the collection agency. The batch control's description is displayed adjacent.

Where Used

Collection agencies get assigned to collection agency referrals when the collection agency referral background process executes. Refer to [How Do Collection Agency Referrals Work?](#) for more information.

Setting Up Feature Configuration

You must set up a [Feature Configuration](#) if you use the [champion / challenger](#) functionality.

The following describes the various **Option Types** that must be defined:

Champion Template\$Challenger Template\$Percentage(1-100). You need only set up options of this type if your implementation implements [Champion / Challenger](#) functionality. Options of this type are entered in the format A\$B\$nnn where A is the collection process template of the champion template, B is the collection process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The collection monitor uses this option to override the champion collection process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

How To

The contents of this section describe how to set up various credit and collections scenarios.

How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

Some organizations that offer multiple services do not sever all services when the customer falls into arrears. Rather, they nominate a single service agreement to sever in the hopes that the lack of service will cause the customer to remit payment. The following diagram illustrates the control tables values required to implement this type of requirement.

The following important concepts are illustrated above:

- The collection process's last event does NOT sever all services. Rather, it calls an algorithm that selects a single service to sever. A base package algorithm allows you to define the primary service to sever and a secondary service to sever (if the customer does not have the primary service). If you sold electricity and gas, you would probably define the primary service as electricity and the secondary as gas (because electricity is easier to cutoff than gas).
- The severance process that is started for the primary service cuts service. If the customer doesn't remit what is owed, the second severance event calls an algorithm that severs all other service agreements in the debt class.
- Because you are nominating a single service to sever, you must set up a special value in collection class control to force the ADM to ignore all service agreements in a debt class when one of the SAs in the debt class is being severed. Notice that the age / amount in the criteria is so large that it could never be violated.
- In addition, because the entire debt class must no longer be in arrears to stop the collection and severance processes, you must plug-in the appropriate collection process and severance process cancellation criteria on the debt class. Refer to [How Are Collection Processes Cancelled](#) and [How Are Severance Processes Cancelled](#) for more information about how these algorithms are used. Also note, you do not need service agreement cancellation criteria defined on your collection process templates and severance process templates (because cancellation is controlled at the debt class level).

Defining Asset Options

NOTE: The asset management functionality described in this section is available only to cloud implementations using Oracle Utilities Customer Cloud Service or Oracle Utilities Meter Solution Cloud Service.

Asset Activity Types

Understanding Asset Activity Types

Activity types define the main attributes broad range of activities, such as maintenance, repairs, inspections, field work etc. The base package includes an asset activity type business object (W1-SOMActivityType) that should be used when created asset activity types.

Activity types are defined by:

- **Activity Business Object:** The business object used for asset activities of this type
- **Activity Schedule Information:** Default scheduling information for asset activities of this type, including Activation Lead Days, Work Lead Days, and Activity Disposition.
- **Attachments:** One or more attachments associated with asset activities of this type, such as procedures or checklists.
- **Exception Handling:** Details regarding exception handling for asset activities of this type, including default To Do Type, To Do Role, and retry options.
- **Completion Event Types:** One or more completion event types associated with asset activities of this type. See [Understanding Completion Event Types](#) for more information.
- **Object To Create:** The service history type to be created by asset activities of this type. Service history records are created by Create Activity Type's Service History completion events.

Refer to [Defining Asset Activity Types](#) for more information about setting up asset types.

NOTE: Asset activity types are created by the system when [field task types](#) are created in Service Order Management.

Defining Asset Activity Types

You use the **Activity Type** portal to display and maintain asset activity types.

Refer to [Understanding Asset Activity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Activity Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type:** This zone displays basic information about the activity type.
- **Attachments:** This zone attachments associated with the activity type.

Asset Completion Event Types

Understanding Asset Completion Event Types

Asset completion event types are used to define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.

Asset completion event types are referenced on activity types to indicate which completion events should be included as part of the lifecycle of activities of that type. For example, this affects when service history is created for an activity, and the disposition of the assets on an activity as the activity is processed. Asset completion events can be configured as optional or required for activities of different types.

Asset completion event types are defined by:

- **Completion Event Business Object:** The business object used for asset completion events of this type
- **Identifiers:** One or more identifiers that can be used to characterize asset completion events of this type
- **Inbound Communication:** Information used to create asset completion events of this type using information defined within an inbound communication business object, or within its raw message
- **UI Payload Create Data Mover:** XPath statements executed when creating asset completion events of this type online. These statements are used to populate elements within the payload from the completion event business object.

Refer to [Defining Completion Event Types](#) for more information about setting up completion event types.

Defining Asset Completion Event Types

You use the **Completion Event Type** portal to display and maintain asset completion event types.

Refer to [Understanding Asset Completion Event Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Completion Event Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Completion Event Type** : This zone provides information about the selected completion event type, including as inbound communications and attachments.
- **Unlink Activity Types:** This zone enables the removal of an activity type from the completion event type. To remove an activity type select the activity type(s) to remove and click **Remove**. The selected activity types will no longer appear in the **Unlink Activity Types** zone.
- **Link Activity Types:** This zone enables adding an activity type to the completion event type. To link an activity type:
 1. Enter search criteria in the **Activity Type Description** field and click **Search**. The zone will display a list of activity types matching your search criteria.
 2. Select the activity type(s) to add and click **Link**. The selected activity types will now appear in the **Unlink Activity Types** zone.

Asset Inbound Communication Types

Understanding Asset Inbound Communication Types

Asset inbound communication types define the information required for the system to receive messages from external systems. These typically hold value mappings of the inbound communication elements to an xpath element in the completion message.

Asset inbound communication types are defined by:

- **Inbound Communication Business Object:** The business object used for asset inbound communications of this type
- **Exception Handling:** Details regarding exception handling for asset inbound communications of this type, including default To Do Type, To Do Role, and retry options.
- **Message Validation:** Source elements within the inbound communication business object or raw message used for validation of asset inbound communications of this type
- **Communication Data Mapping:** Information used to populate communication business object elements from information within the communication's raw message
- **Attachment Suppression:** Substitution text used in place of large data attachments in the completion event list on the inbound communication. Used when messages received from an external system contain attachment data that are very large.

Refer to [Defining Asset Inbound Communication Types](#) for more information about setting up asset inbound communication types.

Defining Asset Inbound Communication Types

You use the **Communication Type** portal to display and maintain asset inbound communication types.

Refer to [Understanding Asset Inbound Communication Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Inbound Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List:** This zone lists all asset inbound communication type records. Broadcast a record to display the details of the selected record.
- **Communication Type:** This zone provides information about the selected communication type, such as attachment suppression, communication data mapping, message validation and exception handling.

Asset Types

Understanding Asset Types

Asset types define the attributes for assets and components of a certain type including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.

Asset types are defined by:

- **Component Relationship:** A flag that indicates if components can be installed on assets or components of this type
- **Asset Business Object:** The business object used for assets or components based on this asset type
- **Valid Location Types:** A list of location types where assets or components of this type can be located

- **Valid Attached To Asset Types:** A list of valid asset types where components of this type can be attached (applicable to components only)
 - **Valid Service History Types:** A list of valid service history types that can apply for assets or components of this type
- Refer to [Defining Asset Types](#) for more information about setting up asset types.

Asset Classes

Assets are defined by classes, each of which is based on a specific business object, and determines the type of asset: an asset or a component.

The table below lists the asset classes and the business object for each.

Asset Class	Business Object
Asset	W1-AssetType (Operational Device Asset Type)
Component	W1-ComponentType (Operational Device Component Type)

Defining Asset Types

You use the **Asset Type** portal to display and maintain asset types.

Refer to [Understanding Asset Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Type** : This zone provides information about the asset type.
- **Asset Type Statistics:** This zone displays statistics for the asset type.

Service History Questions

Understanding Service History Questions

Service History Questions are used to guide workers through corrective and preventive inspection processes as part of an asset's service history.

Service history questions are associated to a service history type which is then associated to an asset type.

During a corrective or inspection process, workers can be guided through a series of questions assessing the condition of the asset. The answers can be "weighted", which when calculated, gives an overall score as to the condition of the asset. The calculation is generally a sum (answer points * question weight), but can vary depending on the service history type. The total inspection points are then normalized to an overall grade or score. The condition rating and confidence rating are also calculated and the asset is updated with the appropriate values.

A service history question's answers can be defined as check boxes, multiple choice, or free-form text.

Refer to [Defining Service History Questions](#) for more information about defining service history questions.

Defining Service History Questions

You use the **Service History Question** portal to display and maintain Service History questions.

Refer to [Understanding Service History Questions](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Question**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Question:** This zone provides information about the question.
- **Service History List:** This zone displays a list of service history types that reference the question.

Service History Types

Understanding Service History Types

Service history types define the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.

Service history types are defined by the following:

- **Service History Business Object:** The business object used to create service history records of this type.
- **Category:** The category to which service history records of this type belong. The base package includes the following categories:
 - Downtime
 - Failure
 - Inspection
 - Maintenance
 - Repair
- **Subclass:** The specific subclass of the service history type, based on the **Service History Business Object**. Oracle Utilities Customer To Meter supports two subclasses of service history types:
 - Operational Device Service History
 - Questionnaire Service History

Each service history type subclass includes other specific configuration information, outlined below.

Operational Device Service History Types

Operational Device Service history types are also defined by the following:

- **Service Schedules:** One or more template work orders and time intervals that should be used to schedule work order generation for service history records of this type

Questionnaire Service History Types

Questionnaire Service history types are also defined by the following:

- **Follow-up Actions:** One or more actions intended as “follow-up” actions for service histories of the service history type, such as work orders or work order activities, users can configure those follow-up actions on the service history type. Note that if a regulatory compliance requirement is associated with a follow-up action, a compliance type must be specified. For example, a Service History Type of “Grade 2 Gas Leak”, might include a follow-up action of “Recheck” which could be configured with a “30 day” Compliance Type and a follow-up action of “Repair” which could be configured with a “1 year” Compliance Type.
- **Stop Processing Service History Type:** One or more service history types that should stop the processing of **Follow-up Actions**. For example, certain problem that needs follow up actions was reported. Then another service history, which indicates the problem has been fixed or its severity has changed, is recorded. Businesses might want to stop/cancel the follow up actions based on the original problem/severity.
- **Questions:** A list of one or more questions used to guide inspection of an asset. Questions are defined in the **Questions** portal.

Defining Service History Types

You use the **Service History Type** portal to display and maintain service history types.

Refer to [Understanding Service History Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service History Type:** This zone provides information about the service history type.
- **Questionnaire Tree:** This zone displays the service history types' questionnaire, based on the questions defined for the service history type. Applicable for Questionnaire service history types only.
- **Unlink Asset Types:** This zone lists the asset types currently linked to the service history type. To unlink one or more asset types, check the corresponding checkboxes and click **Remove**.
- **Link Asset Types:** This zone is used to search for and link asset types to the service history type. To link new asset types,
 1. Enter search criteria in the **Asset Type Description** field.
 2. Click **Search**.
 3. Select the asset types to link by checking the corresponding checkboxes.
 4. Click **Link**.

Configuration Types

Understanding Configuration Types

Configuration types define the information required for various asset configurations with other assets, components, firmware, and other data.

Configurations are referenced on specifications which are then referenced on assets and components to indicate the best way that these entities can work with the other entities that they are connected to in the field.

Configuration types are defined by the following:

- **Configuration Class:** The class for configurations of this type

- **Configuration Category:** The category of configurations of this type
- **Configuration Business Object:** The business object used for configurations of this type

Configuration Classes

In general configuration classes define the types of connections that are being configured. Each configuration class is based on a specific business object, which is the business object used for configurations of each class and type.

The table below lists the configuration classes and the business object for each.

Configuration Class	Business Object
Single Asset	W1-SingleAssetConfig (Single Asset Configuration)
Asset/Component	W1-AssetCompConfig (Asset/Component Configuration)
Asset to Asset	W1-AssetToAssetCompConfig (Asset to Asset/Component Configuration)
Asset/Component to Asset	W1-AssetCompToAssetConfig (Asset/Component to Asset Configuration)
Asset to Asset/Component	W1-AssetToAssetConfig (Asset to Asset Configuration)
Asset/Component to Asset/Component	W1-AssetCompToAssetCompConfig (Asset/Component to Asset/Component Config)

Defining Configuration Types

You use the **Configuration Type** portal to display and maintain configuration types.

Refer to [Understanding Configuration Types](#) for more information.

You can access the portal by selecting **Admin.**, then **Asset Management**, then **Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Type List:** This zone lists all configuration type records. Broadcast a record to display the details of the selected record.
- **Configuration Type :** This zone provides information about the selected configuration type.

Configurations

Understanding Configurations

Configurations document and manage valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.

Configurations are defined by the following:

- **Configuration Type:** The [configuration type](#) upon which the configuration is based
- **Status:** The current status of the configuration
- **Configuration Detail:** Specific information related to the configuration such as the assets and components involved, the firmware, characteristics, identifiers and other important information

Defining Configurations

You use the **Configuration** portal to display and maintain configurations.

Refer to [Understanding Configurations](#) for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration:** This zone provides information about the selected configuration.
- **Configuration Attachments:** This zone lists any attachments defined for the configuration.

Configuration Reports

Understanding Configuration Reports

Configuration reports provide a summary of any currently installed configurations.

These reports show whether the configuration in an installation is valid or invalid, the identifiers and values being used, and display all of the assets/components and other elements that make up the installed configuration.

Configuration reports are defined by the following:

- **Reporting Mode:** The mode in which the report is run (One Time or Recurring)
- **Status:** The current status of the report (Pending or Submitted)
- **Report Criteria:** Specific information used to establish the filter criteria when generating the report, such as the assets and components involved, the firmware, characteristics, identifiers and other important information.
- **Report Result:** Specific information for each configuration, including the number of configurations, the assets and components involved, and the specifications and firmware versions of each. If the configuration is invalid, the **Configuration** column is blank in the report results. Users can navigate to specific valid configurations to review and edit the setup as needed. In addition, users can generate a work order to correct, reconfigure, or otherwise maintain any of the configurations by clicking **Generate Activity**.

Base Package Configuration Reports

The base package includes a number of configuration reports, each based on one of the support configuration classes (see [Understanding Configuration Types](#)).

The table below lists the configuration reports and the business object for each.

Configuration Report	Business Object
Single Asset Configuration Report	W1-SingleAssetCfgRpt
Asset/Component Configuration Report	W1-AssetCompCfgRpt
Asset to Asset Configuration Report	W1-AssetToAssetCfgRpt
Asset/Component to Asset Configuration Report	W1-AssetCompToAssetCfgRpt
Asset to Asset/Component Configuration Report	W1-AssetToAssetCompCfgRpt

Defining Configuration Reports

You use the **Configuration Report** portal to display and maintain configuration reports.

Refer to [Understanding Configuration Reports](#) for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration Report**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Report:** This zone provides information about the selected configuration report.

Defining Location Options

Asset Location Types

Understanding Asset Location Types

Asset location types define the details of locations of a certain type where assets or components can be installed. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.

Asset location types are defined by the following:

- **Class:** The general class for asset locations of this type, such as commercial or residential, a shop or warehouse, etc.
- **Location Business Object:** The business object used for asset locations of this type
- **Number of Assets Allowed:** A flag that indicates whether or not asset locations of this type can accommodate a single or multiple assets
- **Service Type:** The type of service (electric, water, etc.) that asset locations of this type support
- **Allow Related Work Locations:** A flag that indicates whether asset locations of this type should be allowed to be connected to a work location
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on asset locations of this type. Used primarily for reporting.
- **Valid Communicate-To Location Types:** One or more asset location types to which asset locations of this type can communicate. The **Tree View** tab of any asset or location will display other related assets with a visual indication of their relationship.

NOTE: Asset location types are used to define locations where assets and components are installed. Locations where assets that are out of service are stored and maintained are defined via [Out of Service locations](#) and [Out of Service location types](#).

NOTE: In Oracle Utilities Customer To Meter, asset location types are maintained via [Merged Maintenance](#).

Defining Asset Location Types

You use the **Asset Location Type** portal is used to display and maintain asset location types.

Refer to [Understanding Asset Location Types](#) for more information.

You can access the portal by selecting **Admin, Location**, then **Asset Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Location Type List:** This zone lists all asset location type records. Broadcast a record to display the details of the selected record.
- **Asset Location Type:** This zone provides information about the selected asset location type.

NOTE: In Oracle Utilities Customer To Meter, asset location types are maintained via [Merged Maintenance](#).

Organization Types

Understanding Organization Types

Organization types define the main attributes for organizations of a certain type.

Organization types are defined by the following:

- **Class:** The general class organization. Parent organizations have a class of “Parent”.
- **Organization Business Object:** The business object used for organizations of this type
- **Valid Parent Organization Types:** One or more valid parent organizations that can be referenced on organizations of this type. Used primarily for reporting.

Defining Organization Types

You use the **Organization Type** portal is used to display and maintain organization types.

Refer to [Understanding Organization Types](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization Type List:** This zone lists all organization type records. Broadcast a record to display the details of the selected record.
- **Organization Type:** This zone provides information about the selected organization type.

Organizations

Understanding Organizations

Organizations are used for categorization and reporting for locations.

For example, your reporting may include a hierarchy that groups locations by a structure of parent and child organizations. Organizations are defined by the following:

- **Organization Type:** The organization's type. [Understanding Organization Types](#) for more information.
- **Organization Disposition:** The current status of the organization (Active or Inactive)
- **Parent Organization:** The parent organization, if applicable.
- **Main Contact:** A contact for the organization

Defining Organizations

You use the **Organization** portal to display and maintain organizations.

Refer to [Understanding Organizations](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization:** This zone provides information about the organization.
- **Child Locations / Organizations:** This zone lists any child locations and/or organizations for the current organization.

Out of Service Location Types

Understanding Out of Service Location Types

Out of service location types define attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.

Out of service location types are defined by the following:

- **Class:** The general class (storeroom, meter shop, etc.) of out of service locations of this type
- **Location Business Object:** The business object used for out of service locations of this type
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on out of service locations of this type. Used primarily for reporting.

Defining Out of Service Location Types

You use the **Out of Service Type** portal is used to display and maintain out of service location types.

Refer to [Understanding Out of Service Location Types](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location Type List:** This zone lists all out of service location type records. Broadcast a record to display the details of the selected record.
- **Out of Service Location Type:** This zone provides information about the selected out of service location type.

Out of Service Locations

Understanding Out of Service Locations

Out of service locations are physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as “In Repair” or “Pending Disposition” the asset location is typically moved to an out of service location.

Out of service locations are defined by the following

- **Location Type:** The out of service location’s type. See [Understanding Out of Service Location Types](#) for more information.
- **Location Disposition:** The current status of the out of service location (Active or Inactive)
- **Parent Location/Organization:** The out of service locations’ parent location or organization (if applicable)
- **External ID:** An ID used to identify the out of service location in external systems
- **Address Information:** The physical address of the out of service location
- **Contacts:** The primary contact for the out of service location. See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.
- **Field Information:** Additional information about the physical location, such as GPS coordinates

Defining Out of Service Locations

You use the **Out of Service Location** portal to display and maintain out of service locations.

Refer to [Understanding Out of Service Locations](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal’s **Main** tab page:

- **Out of Service Location:** This zone provides information about the out of service location.
- **Current Activities:** This zone provides a summary of the activities that are currently associated to the location.
- **Asset Summary:** This zone provided statistics about the number of assets, by asset type, that are currently associated with the location.
- **Owned Attachments:** This zone lists attachments owned by the location.
- **Referenced Attachments:** This zone lists attachments related to the location.

NOTE: See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.

Defining Device Options

Command Sets

Understanding Command Sets

Command sets are used to define a group of commands that are not eligible for a particular device. For instance, if Commission or Decommission commands should be considered ineligible for a particular device model, a command set that references the Device Commission and Device Commission business objects could be created and associated with that device model.

Command sets are specified for individual device models via the Manufacturer portal.

Individual devices of a particular model can be configured to override ineligibility if needed.

Configuring Command Sets

This portal is used to display and maintain a Command Set.

Refer to [Understanding Command Sets](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Command Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Command Set List:** This zone lists all Command Set records. Broadcast a record to display the details of the selected record.
- **Command Set:** This zone provides information about the selected Command Set.

Head End Systems

Understanding Head End Systems

Head end systems are systems that collect measurement data and meter events for eventual submission to the application. Many devices can communicate to the application through a single head-end system, but a utility may have numerous head-end systems through which they communicate with devices.

Head end systems utilize processing methods that specify the type of initial measurement data and device events to create for devices (and their related measuring components) based on measuring component type. Head end systems also utilize processing methods that specify how smart meter commands are processed.

Refer to [Understanding Process Methods](#) for more information about processing methods.

Head End Systems Impact Data Import and Export

Head end systems are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each head end system can be associated to an [external system](#) which is used to define the messages that can be sent to that service provider and how each message is sent.

Understanding Processing Methods

Head end systems, external applications, and market participants can have one or more associated processing methods that define the format or means by which it receives or sends data from or to the application, such as bill determinants, interval data, or meter events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and usage transactions. Processing methods can also be used to define the information an external system wishes to subscribe to receive from our application.

At the lowest level processing methods are used to identify an outbound message type, business object, batch control, or message category and number.

Each processing method is comprised of a business object that defines what is being mapped as well as how it should be mapped.

Important Processing Method System Events

The actual logic to determine the appropriate output for a given head end system, external application, or market participant and processing role for a processing method is executed by the following system event:

- **Determine Processing Method(s):** is a business object algorithm system event that takes in a head end system, external application, or market participant, a processing role, and a list of relevant input data aka related object (e.g. a measuring component, device, etc). For the head end system or external application and the input data it will analyze the selection criteria to determine the appropriate output.

How Processing Methods Work

Processing methods perform two basic tasks:

- They define the criteria for selecting the appropriate output. This can be as simple as providing a single object in return without qualification or in more involved situations it could support determining the appropriate return object based on characteristics of the data being processed. This is accomplished through the data structure defined on the processing method business object.
- They evaluate the criteria for selecting the appropriate output given a specific head end system, external application, or market participant. This is accomplished through the Determine Processing Method system event on the processing method business object.

Each processing method business object can be associated to one or more processing roles. This is done by adding the Applicable Processing Role business object option. It is these processing roles that actually create the association between a head end system, external application, or market participant, the processing method, and the functional event that is being executed. For example, when initial measurement data is processed through the IMD Seeder the processing role Initial Measurement Creation is used to identify the processing method "How to Create MC Related Information" which maps a particular measuring component type to the appropriate initial measurement business object to be used for processing.

When system logic requires the results of a processing method the service Determine Service Providers and Methods is used. This service is available to call via Java or from within scripting through the business service of the same name. It can be called in one of two ways:

With a head end system, external application, or market participant: identifies the appropriate output for a single head end system, external application, or market participant being processed for the input processing role and related objects

Without a head end system, external application, or market participant: used to identify subscribing systems. This will provide a list of any head end system, external application, or market participant that has the input processing role and an appropriate output given the related objects.

Processing Methods Available

There are the following processing methods provided by the base package:

Name	Details	Business Object
How to Create OB COMM/Send OB Message	Identifies Message Number/Category, Business Object, Outbound Message Type and allows for an override by a device type.	D1-HowToCreateActivityOBComm
How to Create MC Related Information	Identifies a business object and allows for an override by measuring component type.	D1-HowToCreateMCInformation
How to Process Device Event Related Info	Identifies a business object, outbound message type, and batch control by device event category allowing for an override by device event type.	D1-HowToProcDvcEvtsInformation
How to Process Device Related Information	Identifies a business object and allows for an override by device type.	D1-HowToProcessDeviceInfo
How to Send Activity Related Information	Identifies a batch control and business object by activity type and allows for an override by device type.	D1-HowToSendActInformation
How to Send Activity Related O/B Messages	Identifies an outbound message type, message category, and message number and allows for override by activity type.	D1-HowToSendActivityResponse
How To Create US Related Information	Identifies a business object and allows for override by usage subscription type.	D2-HowToCreateUSInformation
How To Send US Related Information	Identifies a batch control, business object, and outbound message type and allows for override by usage subscription type.	D2-HowToSendUSInformation
How to Process Service Point Related Info	Identifies a business object and allows for override by service point type.	D1-HowToProcSPRelatedInfo
How to Send Field Activity Related Info	Identifies a outbound message type and allows for an override by field task type.	D1-HowToSendFARelatedInfo
How to Send Field Activity Remark Info	Identifies an outbound message type for an activity remark type.	D1-HowToSendActivityRemarkInfo
How to Translate External Value	Identifies a business object and allows for override by identifier.	D1-HowToTranslateExternalValue
How to Request Customer Notification	Identifies a list of outbound message types.	D1-HowToRequestCustomerNotific
How to Process Business Flag Related Info	Identifies an outbound message type and allows for an override by business flag type.	D1-HowToProcessBusinessFlagInf

Understanding SGG Adapter Configuration

This section describes how to use a head end system's SGG Adapter Configuration portal.

You can use the SGG Adapter Configuration portal to view configuration information and access configuration components for an SGG adapter head end system.

Note: This portal displays configuration information for head-end systems that reference an SGG Adapter Configuration Sheet extendable lookup..

To use the configuration information portal for an SGG adapter head end system:

Select **Admin > Device > Head End System**.

In the Head End system List zone, click the Broadcast icon for the head-end system you wish to view.

Click the SGG Adapter Configuration tab to view the configuration information.

The SGG Adapter Configuration portal contains the following zones:

- **SGG Adapter Configuration Tracker:** This zone displays the configuration details of the adapter, as defined by the SGG Adapter Configuration Sheet extendable lookup referenced on the head end system. The configuration details include:

The components required for usage and event processing and command processing. To view more details about the components, you can click the component name to go to the business object for the component. For example, you can click the business object "SSN - Connect or Disconnect" to go to the business object portal for the SSN - Connect or Disconnect business object.

Status messages describing the configuration status of components. The following table lists the status messages that may be displayed and the possible actions you can take:

If the status message is...	You can...
Set up this processing method	Click the processing role to set up the processing method.
This processing method has been configured	Click the processing role to view the configured processing method.
Update your processing method with a communication BO	Click the status message to set up the processing method.
Update your external system / outbound message type with an Message sender	Click the status message to go to the external system.
Update your processing method with an outbound message type	Click the status message to set up the processing method.
Add a value to get started	Click the status message to go to the extendable lookup.
Values Existing: (number)	Click the status message to go to the extendable lookup.
Add a communication type	Click the status message to go to the communication type portal.
Add a device event type	Click the status message to go to the device event type business object for the communication type. This message appears only for Echelon type adapters.
Master Configuration has been added	Click the status message to view the Master Configuration portal.
Add Master Configuration for this adapter	Click the status message to view the Master Configuration portal.

Upload Statistics Aggregators: This zone lists the IMD Upload Statistics Aggregator measuring components associated with the head-end system.

Configuring Head End Systems

This portal is used to display and maintain Head End Systems.

Refer to [Understanding Head-End Systems](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Head End System**.

The following zones may appear as part of the portal's **Main** tab page:

- **Head End System List:** This zone lists all Head End System records. Broadcast a record to display the details of the selected record.
- **Head End System:** This zone provides information about the selected Head End System.
- **Processing Method List:** This zone provides the list of processing methods defined for the Head End System.
- **Translation Methods List:** This zone provides the list of translation methods defined for the Head End System.
- **Inbound BOs Send By Service Provider:** This zone lists inbound Business Objects that are sent by this Head End System. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current Head End System.

Measuring Component Types

Understanding Measuring Component Types

Measuring component types define the most important properties of a measuring component.

Measuring component types define what a measuring component measures (KWH, temperature, etc.), how regularly it measures it, and whether it should be connected to a physical device, or if it's used as a scratchpad measuring component or an aggregator measuring component. Measuring component types also specify how the measuring component's final measurements should be stored, how the measuring component's user-defined values should be calculated, and specific rules governing validation, editing, and estimation (VEE) for measuring components of the type. In addition, measuring component types define display properties and valid attribute values for measuring components belonging to the type.

The following configurable items are available for most measuring component types:

- **Value Identifiers:** These store the values of UOM, TOU, and SQI that identify the measured amounts for measuring components of this type. Value identifiers specify the quantities stored on the measurement records for measuring components of this type. Please refer to the [Measuring Component Type Value Identifiers](#) topic later in this section for more information.
- **Valid VEE Groups:** These define the VEE groups considered valid for measuring components of this type. Each group supplied here will be available to be selected on measuring components of this type and act as an override to the Fallback VEE Groups.
- **Fallback VEE Groups:** These define default VEE groups for a specific VEE Group Role that can be used with all measuring components of this type. This alleviates the need to specify the same VEE groups on multiple measuring components of the same type. Changes made to these groups will automatically apply to all measuring components of this type unless they have specified their own VEE groups for that particular VEE Group Role. Each VEE group is designated a VEE group role that indicates when and how the VEE group is used (for initial load, manual override, estimation, etc.).
- **Eligible Profile Factors (interval only):** These define the profile factors that are considered to be eligible for interval measuring components of this type. One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a profile factor is required.
- **Valid Profile Factors for Conversion from Scalar to Interval (scalar only):** These define the profile factors that are considered to be eligible for scalar measuring components of this type when converting scalar measurements to interval measurements. These profile factors are used to produce a curve of interval data from a scalar value. Without one of these factors defined scalar to interval conversion will use a flat line method (i.e. evenly divide the scalar value across the intervals). One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a conversion profile factor is required.
- **Valid Scratchpad Measuring Component Types:** These define the scratchpad measuring component types considered valid for measuring components of this type.
- **Related Statistics Measuring Component Types:** These define the measuring component types that will be used to store statistical information about the historical usage of measuring components of this type. Please refer to [Configuring Measuring Component Statistics](#) for more information on how this list is used.
- **Display Properties:** Defines how measurement data for measuring components of this type is displayed, including:
 - *Display Configuration:* Details related to how measurements are displayed, including the 360 chart rendering method, number of hours of data to display, the maximum days to search for measurements, the default TOU map used, the TOU by Day Profile factor used, and default measurement condition.
 - *Event Bar Profiles:* The event bar profiles used when displaying measurement data for measuring components of this type. Event bar profiles are defined as values for the 360 View Event Bar Profile extendable lookup.

- *Final Values Overlay Profiles*: The final values overlay profiles used when displaying measurement data for measuring components of this type. Final values overlay profiles are defined as values for the Final Values Overlay Profile extendable lookup.
- *Measurement Conditions Not Shown on Chart*: The measurement conditions that should be omitted from rendering onto 360 Degree charts. Measurements whose conditions match these values will be rendered as gaps. For example, many 360 Degree charts use the condition "No Read - System" to represent the lack of a measurement, by adding this condition to this list it a gap will be rendered instead of a line with a 0 quantity measurement and a condition of "No Read - System".

When creating a measuring component type the following options are available:

Name	Details	Business Object
Interval Channel Type - Physical	Provides the configuration for a physical interval channel (including interval size). This is recommended for measuring components that measure consumptive usage in interval sizes up to 1 hour.	D1-IntervalChannelTypePhysical
Interval Channel Type - Scratchpad	Provides the configuration for a scratchpad interval measuring component.	D1-IntervalChannelTypeScratchp
Interval Channel Type - Physical Subtractive	Provides the configuration for a physical subtractive interval channel. In addition to standard interval configuration (including interval size) it also provides additional subtractive specific configuration (e.g. rollover validation, estimate reevaluation, etc). This is recommended for measuring components that measure subtractive usage in interval sizes up to 1 hour.	D1-IntrvlChanTypPhysSubtractiv
Register Type	Provides the configuration for a physical register that is manually read (e.g. rollover validation). These can be either consumptive or subtractive but are expected to be read infrequently (e.g. once a month).	D1-RegisterTypePhysical
Auto-Read Register Type	Provides the configuration for a physical register that is automatically read. In addition to the standard register configuration (e.g. rollover validation) it also provides details around the schedule of expected readings (e.g. first daily measurement time and expected hours between measurements). These can either be consumptive or subtractive but are expected to be read frequently (e.g. at least once per day). Note: these measuring component types can also be used to model interval data that is received with a large interval size (24 hours and larger).	D1-AutoReadRegisterType
Aggregator Type	Provides the configuration for an aggregation measurement.	D2-AggregatorType

NOTE: For “interval” data with an interval size greater than one hour, use the D1-AutoRegisterReadType measuring component type business object and the D1-RegisterAutoRead measuring component business object. This business object is well suited to daily and sub-daily readings. Using an interval data business object can result in measurement date problems during daylight saving time.

Refer to [Configuring an Out-of-the-box Aggregation](#) for more information about aggregation configuration

Measuring Component Type Value Identifiers

Measuring components are configured to measure specific types of quantities this is defined by the list of value identifiers on the measuring component type. Up to eleven value identifiers can be specified. The primary measured quantity should

be identified using the Value Identifier Type of Measurement. An additional ten derived values can be computed based on the primary measurement, these are identified with the Value Identifier Type of Value 01 through Value 10. Each value identifier is constructed of:

- **Unit of Measure:** The unit of measure for the quantity being recorded. Examples include kilo-watt hours (kWh), kilowatts (kW), therms, cubic feet (CCF), temperature (Fahrenheit or Celsius), etc. Refer to [Understanding Units of Measure](#) for more information.
- **Time of Use:** Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc. Refer to [Understanding Time of Use](#) for more information.
- **Service Quantity Identifiers:** Used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Generally, SQI is only used when multiple measuring components measure the same thing, but in different ways. A meter that measures both generation KWH and consumption KWH could use SQIs to differentiate between the two. Refer to [Understanding Service Quantity Identifiers](#) for more information.
- **Value Derivation Algorithm:** Unlike UOM, TOU, and SQI this is not used in the identification of what is measured but rather is used to calculate a derived value based on the primary measurement. An algorithm from the list should be selected that contains the appropriate logic for calculating the derived value. This is applicable for those value identifiers with a Value Identifier Type of Value 01 through Value 10. More information on how derived values are calculated can be found in the Important Measuring Component Type System Events topic in this chapter. For more functional information about derived values please refer to [About Final Measurements](#).

The combination of UOM, TOU and SQI define what a measuring component measures. TOU and SQI are optional, but UOM must be defined for all value identifiers. For example, consider a meter (as illustrated in the image below) with two measuring components, both measuring the same unit of measure (kWh), but each measuring component measures consumption in different time of use (TOU) periods (peak and off-peak).

Another example might be a meter that records both generated KWH and consumed KWH. This meter would be configured to measure both UOM and SQL.

A measurement is recorded each time a measuring component is read. This means that for a meter with two measuring components that is read once a month, two measurements, one for each measuring component, would be recorded each month.

Important Measuring Component Type System Events

The measuring component type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Calculate Interval Consumption:** receives the interval list and performs any necessary calculations on that interval data to compute consumption. Since interval data is already received as consumption data algorithms for this system event are typically limited to application of the appropriate multipliers. Refer to the algorithm type Calculate Interval Consumption (D1-IN-CNSUMP) as an example.
- **Calculate Scalar Consumption:** receives information about the scalar reading and calculates the consumption as appropriate. Algorithms for this event typically support calculating the consumption using a stop and start reading or backing into a reading using consumption and a start reading. Much like the interval counterpart it will apply the appropriate multipliers. Refer to algorithm type Calculate Scalar Consumption (D1-SC-CNSUMP) as an example.
- **Calculate Subtractive Interval Consumption:** receives the interval list and supporting information (e.g. the start reading for the first interval) and either calculates the consumption by subtracting the interval's reading from the prior interval's reading or calculates the reading by adding the current interval's consumption to the prior interval's reading. Refer to algorithm type Calculate Subtractive Interval Consumption (D1-SIN-CNSUM) as an example.
- **Condition Mapping:** receives the details of a single subtractive interval along with the details for its start reading and computes the applicable final condition and reading condition. This is leveraged solely for subtractive interval measuring component types. Refer to algorithm type Subtractive Interval - Condition Mapping (D1-SIN-CNMAP) as an example.

These system events are typically called from within initial measurement processing during the initial stages of the initial measurement lifecycle (e.g. the Pre VEE status of most initial measurement business objects).

In addition to the measuring component type business object algorithms there is an additional system event provided on measuring component type itself:

- **Value Derivation:** receives details of an initial measurement and an associated final measurement. Using these inputs it can compute a value derived either from the primary measurement or one of the other derived values. Refer to algorithm type Derive a quantity using a formula (D1-DERIVAQTY) as an example.

Important Measuring Component System Events

The measuring component business object that is associated to a given measuring component type supports a special system event that is used in the periodic estimation process:

- **Periodic Estimation:** this system event will scan the measuring component's final measurement history to identify missing measurements and create either a To Do, or an estimation initial measurement, or both. More detail about this system event can be found by visiting the following algorithm types: Refer to algorithm type Create Interval IMD and To Do Based Upon Install History (D1-CIITBIH) and Auto-Read Scalar Periodic Estimation (D1-ARSPE) as an example.

Measuring Component Business Object Options

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below are a list of business object options that are defined on the device business object and their impact on system processing:

- **Estimation Initial Measurement Data BO:** Is used to identify the appropriate estimation IMD to create.
- **Manual Override IMD BO:** Is used to identify the appropriate manual override IMD to create.
- **System IMD BO:** Is used to identify the appropriate system IMD to create.
- **Measuring Component Consumption Function:** identifies a function that can be executed from any compatible measuring component 360 Degree zone. Each measuring component can support 0 to many of these functions.
- **Interval Initial Measurement Function:** identifies a function that can be executed from any compatible initial measurement zone. Each measuring component can support 0 to many of these functions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Configuring Measuring Component Types

This portal is used to display and maintain a Measuring Component.

Refer to [Understanding Measuring Component Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Type:** This zone provides information about the selected Measuring Component Type.

Measuring Component Comparison Types

Understanding Measuring Component Comparison Types

Measuring component comparison types define the details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated. For example, measuring component

comparison types can be used on measuring components that store weather data so that comparisons can be made based on temperature. These are used when performing “proxy day” estimations, allowing the application to search for days that are similar to historical data (for instance, the same date from the previous month or previous year) to use as the basis for estimation.

Measuring component comparison types use the following parameters:

- A specific metric to be calculated to enable data comparisons. The “Calculate Comparison Coefficient - Pearson Correlation Coefficient” algorithm, included with the base package can be used to calculate a coefficient based on the linear correlation between two data sets (specifically between weather data stored on a measuring component and on the comparison object).
- The specific object to be compared. This can be either the same measuring component (to compare against historical data for the same measuring component), or a factor profile (to compare against profile data).
- The date range for the comparison period, including the start of the comparison period (current date, same date last year, or both), the time each day through which the comparison will be calculated, and the number of days prior to and after the start date that will be compared with the comparison object.
- Average Difference Eligibility: An average value either above or below the average for the current date that will be eligible for comparison. For example, assume the current date’s average is 75, and the prior day’s average is 72. If the Average Difference Eligibility is set to 3 then the prior day value of 72 will be eligible for comparison to the current day average of 75.
- The maximum number of resulting calculations that should be stored as measuring component comparable periods.
- A template that defines which days are considered like each day of the week (for example, weekdays are like other weekdays, weekend days are like other weekend days). This template is defined as a record for the “Like Day Eligibility Template” extendable lookup.
- Work calendars used to determine if specific data should be compared to other weekend days or to the same date in prior years, and which dates, if any, should be excluded from historical data used for comparison.

Configuring Measuring Component Comparison Types

Refer to [Understanding Measuring Component Comparison Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component Comparison Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Comparison Type List**: This zone lists all measuring component comparison type records. Broadcast a record to display the details of the selected record.
- **Measuring Component Comparison Type**: This zone displays details for the selected measuring component comparison type.

Device Configuration Types

Understanding Device Configuration Types

Device Configuration types define the measurements a given device can record. It should be noted that the device configuration type itself does not specify this information but rather the device configuration type will identify the valid list of measuring component types that can be referenced associated to a device.

When creating a new device configuration type there are the following options:

Name	Details	Business Object
------	---------	-----------------

Device Configuration Type	This represents configurations for physical meters and communication components. It identifies a list of valid measuring components types.	D1-DeviceConfigurationType
Item Configuration Type	This represents badged items that are installed at a particular service point. Given the nature of items there are no measuring component types associated to this type.	D1-ItemConfigurationType

Refer to [Configuring Consumption Synchronization](#) for more information on how a device configuration type can be set up to synchronize consumption between two related channels of measurement data.

Configuring Device Configuration Types

This portal is used to display and maintain a Device Configuration Type.

Refer to [Understanding Device Configuration Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Configuration Type List:** This zone lists all Device Configuration Type records. Broadcast a record to display the details of the selected record.
- **Device Configuration Type:** This zone provides information about the selected Device Configuration Type.

Device Types

Understanding Device Types

Device types define information about a class of devices, including properties that apply to all devices of a type. Properties defined for a device type can be overridden for an individual device

Specifically, device types provide information about:

- How a device can be configured by defining the valid list of device configuration types
- How a device communicates by defining a fallback head end system and a list of valid head end systems.
- How a device records measurement data through the fallback incoming data shift which plays an important role in daylight savings processing. Refer to [Daylight Savings Time Support](#) for more information.
- The consumption profile of an item: the unit of measure consumed and method of calculation (profile or straight line)
- Whether the device is attached to a service point or meter (used with items and device communication equipment)
- Characteristics common to all devices of this type (defined in the **Device Type Characteristics** zone).

When creating a new device type there are the following options:

Name	Details	Business Object
Smart Meter Device Type	These devices measure consumption for a given service point, support remote commands, and remote collection of measurement and event data. These devices are associated to a head end system.	D1-SmartMeterType
Manual Meter Device Type	These devices measure consumption for a given service point but require a visit to the service point to collect the measurement data. They are not associated to head end systems.	D1-ManualMeterType

Item Device Type	<p>These devices represent various items that consume consumption at a constant rate which are not directly metered. As consumption is calculated rather than measured so there is no need for an association to a head end system. Devices of this type can either be created individually for "badged" items or can be listed directly on a service point for "unbadged items."</p> <p>These devices may also be configured as equipment that can be attached to a service point.</p>	D1-ItemType
Communications Component Device Type	<p>These devices provide remote collection of consumption data measured by a manual meter on which they are installed. These devices are associated to a head end system.</p>	D1-CommunicationCompMeterType
Device Communication Equipment Type	<p>These devices provide remote collection of consumption data measured by a manual meter to which they are attached. Devices of this sort are sometimes referred to as Encoding Receiver/Transmitter (ERT) modules, or communication modules.</p> <p>These devices are associated to a head end system.</p>	D1-DvcCommEquipmentType

Device Business Object Options Drive Functionality

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below is a list of business object options that are defined on the device business object and their impact on system processing:

- **Device Category:** This defines the type of device and correlates to the core device types that are supported (i.e. smart meter, AMR meter, manual meter, item, or communication component). This value is used by smart meter commands, service order management, and other system processes to make processing decisions.
- **Install Event BO:** This identifies the appropriate install event business object to use when this device is being installed at a service point. Refer to [About Install Events](#) for more information about install events.
- **Valid Command Request BO:** This identifies the commands that are valid for any device of this type. This option can be repeated for as many commands as the device supports. Note: the combination of the device and service provider (aka head end) define the true list of available commands by device.
- More detail about these options can be found by visiting a device business object and inspecting the business object options.

Device Type - Service Quantity

For "badged" and "unbadged" items consumption is not directly measured. Instead, for each item type, the average daily consumption amount is provided. The commodity represented by the daily consumption amount is defined by the item type's unit of measure.

The average daily consumption amount can be effective dated over time to support changes in the consumption profile. This is used in conjunction with the item's calculation method to derive the consumed amount per interval.

Refer to [Multiple Time Zone Support](#) for additional information on how device type service quantities are impacted by multiple time zones.

Valid Device Characteristic Types

The **Valid Device Characteristic Types** zone lists the valid characteristic types that may be instantiated on devices of this type. Characteristics of these types are maintained using the **Device Characteristics** zone in the **Device** portal.

Configuring Device Types

This portal is used to display and maintain a Device Type.

Refer to [Understanding Device Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Type List:** This zone lists all Device Type records. Broadcast a record to display the details of the selected record.
- **Device Type:** This zone provides information about the selected Device Type.
- **Device Type Service Quantity:** This zone displays the list of effective dated service quantities supported by the selected Device Type. This applies only to Items.
- **Device Type Characteristics:** This zone lists characteristics common to all devices of this type.
- **Valid Device Characteristic Types:** This zone lists the valid characteristic types that may be instantiated on devices of the device type. To add or edit valid characteristic types, click **Edit**.

Defining Device Installation Options

Service Point Types

Understanding Service Point Types

Service point types define a specific type of point at which service is delivered.

Specifically, service point types define how the application manages many aspects of the service point's behavior. A service point type may have one or more valid device types defined that limit the types of devices that can be installed at service points of this type.

Service point types are defined by the following:

- **Service Point Business Object:** the business object used by service points of this type
- **Service Point Category:** the types of devices that can be installed at service points of this type. Valid values include:
 - **Meter:** Indicates that a single meter can be installed at service points of this type.
 - **Item:** Indicates that a single "badged" item can be installed at service points of this type.
 - **Multi-Item:** Indicates that one or more "unbadged" items can be installed at service points of this type.
- **Divisions:** one or more divisions associated with service points of this type.
- **Valid Device Types:** the device types considered valid for service points of this type.
- **Valid Field Task Types:** the field task types considered valid for service points of this type. The field task types available when creating field activities can be based on the field task types listed here via the **Restrict Field Task Type by Service Point Type** option on the Service Order Management Master Configuration.
- **Usage Snapshot Configuration:** the configuration(s) to be used to take weekly or monthly usage snapshot(s)
- **Unreported Usage Snapshot Configuration:** the configuration(s) to be used to take weekly or monthly unreported usage snapshot(s)

Configuring Service Point Types

You use the Service Point Type portal to view and maintain service point types.

Refer to [Understanding Service Point Types](#) for more information.

You can access the portal by selecting **Admin, Device Installation, Service Point Type**.

NOTE: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service point types as well service point types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Type List:** This zone lists all service point type records. Broadcast a record to display the details of the selected record.
- **Service Point Type:** This zone provides information about the selected service point type.
- **Valid Field Task Types:** This zone lists the field task types considered valid for the selected service point type.
- **Valid Disconnect Location:** This zone lists disconnection locations considered valid for the selected service point type.

Service Point Quantity Types

Understanding Service Point Quantity Types

Service point quantity types define types of quantities that can be stored for a service point. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, service point quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Service quantity types use the following parameters:

- The service type (electric, gas, water, etc.) for service point quantities of this type
- Quantity identifiers related to the current service point quantity type (used to provide shorthand descriptions of the various types of values measured by service point quantities of this type)

Configuring Service Point Quantity Types

Refer to [Understanding Service Point Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Service Point Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Quantity Type List:** This zone lists all service point quantity type records. Broadcast a record to display the details of the selected record.
- **Service Point Quantity Type:** This zone displays details for the selected service point quantity type.

Divisions

Understanding Divisions

Divisions are used to delineate between different operating companies within a large conglomerate of utilities.

Divisions can have one or more characteristics defined.

Divisions can be defined on several other objects and entities in the system, including:

- Service Point
- Service Order Activities (Request Orchestration activities)
- Service Order Field Activities
- Usage Subscription/Usage Subscription Type
- Usage Calculation Group
- Settlement Calculation Group
- Aggregation Group
- Data Source
- Market Product Type
- Market Product Set
- Measurement Data Snapshot Type
- Attribute Data Snapshot Type

Divisions can be associated with individual users on the **User Miscellaneous Information** zone on the [Miscellaneous](#) tab of the **User** portal.

Measurement Cycles

Understanding Measurement Cycles

Measurement cycles define the schedule for manual meter reading of devices at Service Points in that cycle. Measurement cycles can have one or more associated routes used to collect measurements.

Measurement cycles can also be configured to define when to [create usage transactions](#) for Usage Subscriptions associated to Service Points in the cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycles

This portal is used to display and maintain a Measurement Cycle.

Refer to [Understanding Measurement Cycles](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle List:** This zone lists all Measurement Cycle records. Broadcast a record to display the details of the selected record.
- **Measurement Cycle Type:** This zone provides information about the selected Measurement Cycle.
- **Measurement Cycle Route List:** This zone lists the measurement cycle routes related to the measurement cycle.
- **Measurement Cycle Schedule List:** This zone lists the measurement cycle schedules related to the current measurement cycle.

Measurement Cycle and Bill Determinants

The system can be configured to periodically push bill determinants to subscribing systems. In this case, measurement cycles can be configured to define when to create usage transactions for Usage Subscriptions associated to Service Points in the cycle. Even Service Points whose meters are read automatically may reference measurement cycles.

Creating bill determinants (by creating a usage transaction) is performed by an algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object (similar to creating activities as described above).

When the Pending SP/Measurement Cycle Schedule Route records are processed by the D1-PSPSR batch, rather than create a handheld download activity, the algorithm can create a usage transaction (usage transactions are transactions that cause bill determinants to be calculated for the Service Point's Usage Subscription).

If the implementation needs to both manually read the meter and push bill determinants, both algorithms would be plugged in on the SP/Measurement Cycle Schedule Route business object.

Measurement cycle processing is managed by the following three batch processes:

- **Create Pending Measurement Cycle Schedule Routes (D1-CMCS):** This batch process creates Schedule Routes for Measurement Cycle Schedules whose schedule selection date is on or before the batch business date. This process is used if routes have the same schedule each month, quarter, etc. This process simply copies the routes from the Measurement Cycle to the Measurement Cycle Schedule on/after the scheduled selection date.
- **Create Pending SP / Measurement Cycle Schedule Route Records (D1-CSPSR):** This batch process creates a "SP/Measurement Cycle Schedule Route" transaction for every Service Point in the Measurement Cycle Schedule Route that is ready for processing.
- **Process Pending SP / Measurement Cycle Schedule Route Records (D1-PSPSR):** This batch process transitions the Pending "SP/Measurement Cycle Schedule Route" transactions to their Complete state. Custom algorithms can be configured to do any additional necessary work, such as creating a "Meter Read Download" activity. This custom algorithm would be configured as an Enter algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Measurement Cycle Schedules

Understanding Measurement Cycle Schedules

Measurement cycle schedules define the dates on which devices are scheduled to be read for a given measurement cycle and the routes used to collect measurements for the measurement cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycle Schedules

This portal is used to display and maintain a Measurement Cycle Schedule.

Refer to [Understanding Measurement Cycle Schedules](#) and [Understanding Measurement Cycles](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle Schedule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Schedule Query:** This zone allows you to query for Measurement Cycle Schedules based on Measurement Cycle and select the desired record.
- **Measurement Cycle Schedule:** This zone provides information about the selected Measurement Cycle Schedule.

Setting Up Metered Premise Options

This section describes tables that must be set up before you can define premises.

Setting Up Meter Read Instructions

When you set up a premise you may define instructions to be supplied to the individuals who read the meters located at the premise. To define meter read instruction codes, open **Admin > Geographic > Meter Read Instruction**.

Description of Page

Enter a unique **Meter Read InstructionCode** and **Description** for every meter read instruction.

Setting Up Meter Read Warnings

When you set up a premise you may define warnings to be supplied to the individuals who read the meters located at the premise. To define meter read warning codes, open **Admin > Geographic > Meter Read Warning**.

Description of Page

Enter a unique **Meter Read Warning** and a **Description** for every meter read warning.

Configuring Cross Installed Meter Processing

Cross installed meters is the term for situations in which meters are deployed at an incorrect customer service point. Consider the following example: Meter A is supposed to be installed at Service Point A and Meter B is supposed to be installed at Service Point B, but Meter B was mistakenly installed at Service Point A, and Meter A was mistakenly installed at Service Point B. This means that both customers will be billed incorrectly (customer at Service Point A will be billed for usage at Service Point B and vice versa) until the system can be updated to reflect the correct meter installations.

This process can also be used to issue financial adjustments and/or cancel/rebill any bill segments that are impacted by the change in meters, and create customer contacts related to the changes. See [Adjustments](#) and [Cancel / Rebill Incorrect Bill Segments](#) for more information about adjustments and rebilling.

The Cross Installed Meters process provides a tool to re-configure the meters through a correction process. When a user initiates the Cross Installed Meters process, the system will update device installation event details (like status, date and time of installation), device configurations, and measuring components with the correct information.

Cross installed meter processing requires the following administrative data:

- Customer Contact Class and Type (optional)
- Request Type
- Action Method

Each of these is described in detail below.

See [Correcting Cross Installed Meters](#) in the *Business User Guide* for more information about running cross installed meter processing.

Create a Customer Contact Class and Customer Contact Type - Optional

If you want customer contacts created as a result of cross-installed meter processing, you will need to reference a Contact Class and Contact Type. If you want to use a specific contact class and/or contact type, you will need to create these.

See [Setting Up Customer Contact Options](#) for more information about creating contact classes and contact types.

Create a Request Type

Each process flow instance has an associated request record, which is based on a specific request type. You must create a request type based on the "Cross Installed Meter Request Type" business object that will be used for cross installed meter processing.

Use the following procedure to create a request type used with cross installed meter processing

1. Select **Admin, General, Request Type, Add**.
2. Select "Cross Installed Meter Request Type" from the **Request Type Business Object** drop-down list on the **Select Business Object** screen and click **OK**.
3. Enter the following on the **Cross Installed Meter Request Type** screen:
 - **Main:**
 - **Request Type:** A code for your request type
 - **Description:** A description of your request type
 - **Crossed Installed Meter Parameters:**
 - **Swap Meters Service Script:** Cross Installed Meter - Swap Meters (this is the script that performs the change to Install Events)
 - **Insight Type:** Cross Installed Meters - Inline (default)
 - **Field Task Type:** D1-ServiceInvestigation (this defines the Field Task Type for field activities created by clicking the **Investigate** button on the **Swap Meters** panel)
 - **Create Customer Contact:** Indicates if customer contacts should be created as part of the cross installed meter process
 - **Contact Class:** The contact class used for customer contacts created from cross installed meter process flows. Applicable only if **Create Customer Contact** is set to "Yes".
 - **Contact Type:** The contact type used for customer contacts created from cross installed meter process flows. Applicable only if **Create Customer Contact** is set to "Yes".
 - **Bill Correction Parameters:**
 - **Allow Adjustment:** Indicates whether or not to allow adjustments when correcting bill segments

- **Adjustment Type:** Indicates the type of adjustment used when correcting bill segments
- **Allow Rebill:** Indicates whether or not to cancel/rebill when correcting bill segments
- **Allow Estimates:** Indicates whether or not to allow the use of estimated usage when using cancel/rebill to correct bill segments
- **Billing Option:** Indicates the billing option (Use Cut off Date or Use Schedule) used when using cancel/rebill to correct bill segments
- **Cancel Reason:** Cross Installed Meter (this is the Cancel reason used when using cancel/rebill to correct bill segments)

4. Click **Save**.

See [Setting Up Request Types](#) for more information about creating request types.

Create an Action Method

You must also configure an Action Method to associate the base package Cross-Installed Meter Process Flow Type (X1-CROSSEDMETER) with your custom Request Type.

Use the following procedure to create an action method used with cross installed meter processing

1. Select **Admin, System, Action Method, Add**.
2. Select "Cross Installed Meter Action Method" from the **Request Type Business Object** drop-down list on the **Select Business Object** screen and click **OK**.
3. Enter the following on the **Cross Installed Meter Action Method** screen:
 - **Main:**
 - **Action Method:** A code for your action method
 - **Action Method Role:** Cross Installed Meter
 - **Description:** A description of your request type
 - **Default Details:**
 - **Process Flow Type:** Cross Installed Meter (this is provided with the base package)
 - **Request Type:** Cross Installed Meter (the Request Type created above)
 - **To Do Type:** Cross Installed Meter (this is provided with the base package) This defines To Do Type for To Do Entries created by the Create Meter Process Completion Event.
 - **To Do Role:** A To Do Role for To Do Entries created by the Create Meter Process Completion Event.
4. Click **Save**,

See [Defining Action Methods](#) for more information about creating Action Method records.

Setting Up Consumption Estimation Parameters

The system estimates consumption under the following situations:

- At billing time, when "real" consumption cannot be computed due to the lack of a meter read, the system estimates how much the customer used assuming the following conditions are true:
 - The service agreement allows estimation.
 - The rate schedule allows estimation.

- The bill cycle schedule (if one is being used) allows estimation.
- The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption). Note that the base product estimation algorithms may attempt to estimate peak registers.
- The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. But consider what would happen if we estimated a consumptive register, the consumption associated with the next real read will be billed in its entirety.
- When a meter read is added, the system verifies that the resultant consumption is congruous with historical consumption trends (i.e., high / low checks are performed).

This section describes the tables that must be set up to estimate consumption.

Defining General Options

Units of Measure

Understanding Units of Measure

Units of Measure (UOM) identify quantities measured and recorded, such as KWH, KW, cubic feet, degrees Celsius, etc. UOMs are based on a specific service type.

Important Unit of Measure System Events

Unit of Measure supports the following business object algorithm system events:

- **Axis Conversion:** this event receives a list of measurements along with a source UOM and interval size and a target UOM and interval size. It should then perform the necessary actions to convert the source UOM and interval size into the target UOM and interval size. Refer to the algorithm Axis Conversion algorithm (D1-AXIS-CONV) as an example.

Configuring Units of Measure

This portal is used to display and maintain a Unit of Measure.

Refer to [Understanding Units of Measure](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Unit Of Measure**.

The following zones may appear as part of the portal's **Main** tab page...

- **Unit of Measure List:** This zone lists all units of measure. Broadcast a record to display the details of the selected record.
- **Unit of Measure:** This zone provides information about the selected unit of measure.

Service Quantity Identifiers

Understanding Service Quantity Identifiers

Service Quantity Identifiers (SQI) are used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Some examples include: Generated, Consumed, etc.

SQIs can also be used as a stand-alone representation of a service quantity that is not measured (one that is not properly described as a UOM) within a usage service quantity collection (such as a billing determinant).

Configuring Service Quantity Identifiers

This portal is used to display and maintain a Service Quantity Identifier.

Refer to [Understanding Service Quantity Identifiers](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Service Quantity Identifier**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Quantity Identifier List:** This zone lists all Service Quantity Identifiers. Broadcast a record to display the details of the selected record.
- **Service Quantity Identifier:** This zone provides information about the selected Service Quantity Identifier.

Time of Use

Understanding Time of Use

Time of Use (TOU) periods are modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc.

Configuring Time of Use

This portal is used to display and maintain a Time of Use.

Refer to [Understanding Time of Use](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Time Of Use**.

The following zones may appear as part of the portal's **Main** tab page:

- **Time Of Use List:** This zone lists all Time Of Use records. Broadcast a record to display the details of the selected record.
- **Time Of Use:** This zone provides information about the selected Time Of Use.

Service Types

Understanding Service Types

Service Types define specific types of service for which usage can be recorded and captured, such as electric, gas, steam, etc.

Configuring Service Types

This portal is used to display and maintain a Service Type.

Refer to [Understanding Service Types](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Service Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Type List:** This zone lists all Service Type records. Broadcast a record to display the details of the selected record.
- **Service Type:** This zone provides information about the selected Service Type.

Factors

Understanding Factors

Factor are a centrally stored set of values for use in validation rules, bill determinants calculations, and other processes.

A factor can have different values depending upon some definable attribute of a system object, such as customer size associated with a service point. Examples of factors can include minimum and maximum thresholds, loss factors, etc. Classes of factors are defined that can have numeric values (as in the above examples), or values pointing to profile measuring components, or VEE groups.

A factor's values are effective-dated values - either a number, a profile measuring component, a temperature profile measuring component, a VEE group, or some custom-defined value - assigned to a factor and associated to the value of some attribute of a system object. For example, consider a service point that can be classified as residential, commercial, or industrial. The tolerance percentage by which a customer's consumption can exceed last month's consumption can be based on the service point category.

For this example, factor values for a single factor called "tolerance percentage" could be:

- Residential - 20%
- Commercial - 10%
- Industrial - 5%.

Configuring Factors

This portal is used to display and maintain Factors and Factor Values.

Refer to [Understanding Factors](#) for more information.

Prerequisites: You must define factor characteristic source algorithms, factor characteristic types, and factor characteristic values before you can create a factor. Refer to the Oracle Utilities Application Framework online help for more information about algorithms, characteristic types, and characteristic values.

You can access the portal by selecting **Admin**, then **General**, then **Factor**.

The following zones may appear as part of the portal's **Main** tab page:

- **Factor List:** This zone lists all factor records. Broadcast a record to display the details of the selected record.
- **Factor:** This zone provides information about the selected factor.
- **Factor Char Value and Factor Value List:** This zone lists the characteristic values associated to the factor characteristic. For each characteristic value it will display the related factor values. From this zone you can click the **Factor Value** link to see the factor value in more detail on the **Factor Value** portal.

Processing Timetable Types

Understanding Processing Timetable Types

Processing timetable types define types of schedules that can be referenced by different processes and objects in Oracle Utilities applications such as Oracle Utilities Meter Data Management and Oracle Utilities Market Settlements Management. For example, if a process requires requesting data from an external system on a daily basis, a daily processing timetable type could be used to define the details of this schedule.

Processing timetable types are used by standalone data request measuring components to control the schedule by which requests for data are processed (for example, in a settlement process in which zonal load is requested on a daily basis). They are also used in the attribute data snapshot creation process.

The base package includes two processing timetable type business objects used with specific scheduling patterns:

- **Daily Processing Timetable:** Used for daily schedules
- **Defined Dates Processing Schedule:** Used for schedules that should execute on specific dates.

Parameters used to define processing timetable types include:

- **Execution Frequency Class:** Designates the type of processing timetable, Daily or Defined Dates (based on the business object)
- **Scheduling Information:** Details about how the schedule is executed, including:
 - **Period Cut-Off Time:** The time of day that represents the end of a period. In many instances this will be 12:00 AM. However, for something like a "Gas Day" this might be set to 09:00 AM.
 - **Earliest Execution Time:** Used to prevent records from being processed until after this time each day. This time relates to the processing time.
 - **Lag / Lead:** A flag that indicates whether periods in the past (Lag) or future (Lead) should be processed (applies to Daily schedules only)
 - **Lag Days / Lead Days:** The number of days in the past (Lag) or future (Lead) that should be processed (applies to Daily schedules only)
 - **Restrict Processing by Work Calendar:** Used to restrict processing to only the work days configured in the Work Calendar and will exclude any holidays added to the calendar (applies to Daily schedules only)
- **Workflow Information:** Details about how the processing timetable aligns with process workflows, including warning time and target due time
- **Processing Dates:** A list of specific dates on which the process should be executed (used with Defined Dates Processing Schedule only)

Configuring Processing Timetable Types

Refer to [Understanding Processing Timetable Types](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Processing Timetable Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Processing Timetable Type List**: This zone lists all processing timetable type records. Broadcast a record to display the details of the selected record.
- **Processing Timetable Type**: This zone displays details for the selected processing timetable type.

Initial Measurement Data

Configuring the Initial Measurement Algorithms

The behavior of initial measurement data processing can be adjusted by updating parameters in several key algorithms in the lifecycle.

NOTE: This is not a list of all algorithms and algorithm parameters that can be customized in the initial measurement processing lifecycle. Rather, it is a selection of some of the more impactful parameters.

Initial Measurement Data Seeder Algorithms

- Derive Service Provider and Measuring Component (D1-DER-SPRMC):
 - Enabling a standalone measuring component search allows initial measurement data to be processed without a device identifier. This is useful when profile or temperature data is loaded through the IMD Seeder and a match must be made on measuring component identifiers alone.
 - If measuring component identifiers can be repeated across measuring components for the same device then the error for duplicate measuring components being found can be turned off. This is useful for certain head end systems that will have multiple channels with the same channel identifier. When a duplicate is found the search will fall back on other means for identifier the correct measuring component.
- Perform Date/Time Adjustments and Undercount/Overcount Check (D1-DODTTMADJ):
 - Undercount validation can be turned off completely or left enabled. When left enabled the automatic filling of gaps can be turned off separately.
 - The overcount check can be turned off.
 - The automatic adjustment of the individual interval date/times to an interval boundary can be turned on.

NOTE:

If your implementation receives initial measurement data with date/times that do not include an explicit time zone and the devices report date/times in standard time, you may need to add the following configuration:

- Navigate to **Admin > Integration > Message Option**
- In the **XAI compliance** option, ensure that the following text is provided:
`xsd:strict:dstGapInStandardTime`

This will prevent a date/time reported in standard time that falls on the missing hour of the day Daylight Savings Time is entered from being misinterpreted.

Specific Initial Measurement Data Algorithms

- Normalize measurements (overwrite identical existing Measurements) (D1-NORM-IMD):

- When the initial measurement data includes measurements that match exactly with the existing final measurements they can either be overwritten or skipped.
- If logging of changes to final measurements is desired then it must be indicated as such in this algorithm. It is suggested to keep this turned off for high volume initial measurement data such as initial load. See [Configuring Measurement Logging](#) for more details.

NOTE: Refer to [Configuring Consumption Synchronization](#) for additional parameters that can be adjusted on specific initial measurement data algorithms.

Configuring Measurement Logging

There are two components to logging changes to final measurements:

- **Initial Measurement Finalization:** the "normalization" algorithm on a particular initial measurement data business object will determine how final measurements are updated. For performance reasons certain types of initial measurement data (e.g. initial load) are delivered with a final measurement update method that will skip any logging. This can be controlled by parameters on the algorithm that implements the algorithm type Normalize Measurements for Initial Measurement Data (D1-NORM-IMD). Specifically the "Create Measurement Log on Update (Y/N)" parameter should be set to "Y". As mentioned creating these logs has a performance impact and it is not recommended for use on initial load.
- **Measurement Business Object:** there must be an algorithm for the audit system event configured. The base package delivers the algorithm type Add Measurement Log Record (D1-AMSRMTLOG). It is this algorithm that actually records the log entries.

Logging User Updates to Manual Initial Measurements

By default, manual edits made by users of these zones are not logged on the Log tab. Logging of manual edits to manual initial measurements can be enabled by adding a logging algorithm on an appropriate lifecycle state of the manual initial measurement business objects. The Log User Transaction (D1-LOGUSRTRN) base package algorithm can be used for this. This Enter algorithm is designed to be defined on the Initial state of the manual initial measurement business objects, but it can also be defined on any (non-transitory) Interim or Final state as well.

To ensure logging of any or all manual edits made to manual initial measurements, this algorithm should be specified on any state in which users will make manual edits. This will most often be the Pending or VEE Ready states, but could also include the Error, Exception, or Finalized states.

CAUTION: When defining this algorithm, the user should exercise caution and determine if previous algorithms in the sequence within the state contain any form of transitioning logic that may inadvertently cause this algorithm to be bypassed.

Removing Unwanted Initial Measurements

Over time, implementations can accumulate unnecessary non-final initial measurements which effectively become "stuck" in the system. Examples of these types of initial measurements include:

- Erroneously imported duplicate initial measurements
- Initial measurements that failed validation and were not corrected or replaced
- Initial measurements that triggered service issue monitors that remain unresolved

These initial measurements can also have related VEE Exceptions, To Do Entries, and Service Issue Monitors that remain "stuck" as well. This unnecessary data can impact overall system performance and should be reviewed and removed from time to time.

The Remove Unwanted Initial Measurements feature can be used to identify and close or delete these unwanted non-final initial measurements and any related VEE exceptions, To Do Entries and service issue monitors. This process is initiated by creating Request records which specify the parameters used to locate the non-final initial measurements to be removed. The request in turn initiates a batch process which identifies non-final measurements and related VEE Exceptions, To Do Entries, and/or Service Issue Monitors.

This functionality uses the following system objects:

Table listing objects used by this feature.

Object Type	Object Name	Description
Request Type Business Object	Remove IMDs Request Type (D1-RemoveIMDsType)	Used to define types of initial measurements removal requests. The Remove IMDs Request (D1-RemoveIMDsRequest) request business object (see below) is defined as the "Related Transaction BO" for this business object, meaning that requests created for request types based on this business object use the Remove IMDs Request (D1-RemoveIMDsRequest) request business object.
Batch Control	Remove Non-Final IMDs (D1-RENF)	Used to identify non-final measurements and related VEE exceptions, To Do Entries and/or Service Issue Monitors (Service Tasks).
Request Business Object	Remove IMDs Request (D1-RemoveIMDsRequest)	Used to create and process initial measurement removal requests.
Fact Business Object	Remove IMD Object Count (D1-RemoveIMDOjbecCount)	Used to capture details of the initial measurements and related objects to be removed.

Remove Unwanted Initial Measurements Request Types

Requests used to remove initial measurements are based on request types which specify the batch control used to identify and remove the initial measurements.

To create request types used with this feature:

1. Select Menu, **Admin, General, Request Type, Add**.
2. Select "Remove IMDs Request Type" from the **Request Type Business Object** drop-down list, and click **OK**.
3. Enter the following:
 - **Request Type:** A code for the request type
 - **Description:** A description of the request type
 - **Batch Control:** Search for and select the batch control to be used for requests of this type. The default is Remove Non-Final IMDs (D1-RENF), but implementations can create custom versions of this batch control.
4. Click **Save**.

Remove Unwanted Initial Measurements Requests

To create an initial measurement removal request:

1. Select **Menu, Tools, Request, Add**.
2. Select the appropriate request from the **Request Type** drop-down list and click **OK**.
3. Enter the **Submission Parameters** for the request. These include:
 - **Mode:** The mode in which the process will be run. Options include:

- **Preview:** Returns a count of non-final initial measurements and related objects (VEE Exceptions, To Do Entries, and Service Issue Monitors)
- **Close:** Transitions non-final initial measurements to the "Discarded" state and completes and/or closes related objects. Details regarding the data impacted by "Close" requests are captured and displayed in the **Object Log** zone.
- **Delete:** Deletes non-final initial measurements any related objects. Details regarding the data impacted by "Delete" requests are captured and displayed in the **Object Log** zone.
- **Thread Count:** The number of processing threads allocated to the process
- **IMD Business Object:** Used to restrict the initial measurements processed to those of a specific business object
- **IMD Status:** Used to restrict the initial measurements processed to those in a specific non-final state, including Pending, Held, Additional Mapping, Mapping Error, VEE Ready, Defer, Error, VEE Complete, Exception, or Force Complete
- **IMD Create Date/Time From:** Required. The start date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time From** would be "01-01-2023 12:00 AM".
- **IMD Create Date/Time To:** Required. The end date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time To** would be "01-31-2023 12:00 AM".
- **Device Configuration:** Used to restrict the initial measurements processed to those related to a specific device configuration.

4. Click **Save**. The request will then open in the **Request** portal.

5. Click **Submit Batch** to process the request.

Initially requests are created in the "Pending" status. When the request is run (by clicking **Submit Batch**), a batch process based on the batch control defined on the request type is executed.

- If the batch process errors, the request **Status** is set to the "Batch Error".
- If the batch process completes, the request **Status** is set to the "Completed".

Details of the process are captured in the **Submission Information** section, and the **Object Log** zone.

The **Submission Information** section includes:

- **Batch Submission:** Link to the batch job submission for the batch process. Click the link to navigate to the **Batch Job Submission** portal to view details of the batch process.
- **IMD SDE Extract Through Date/Time:** The date and time through which specialized data extracts have been performed for initial measurements impacted by the process.
- **End of Batch Date/Time:** The date and time when the batch process was completed.

The **Object Log** zone contains table with details regarding the initial measurements and related objects processed, including:

- **Object:** The type of object processed (Initial Measurement Data, Service Task, To Do Entry, or VEE Exception)
- **Specialized Data Extract Occurred:** An indicator as to whether or not ("Yes" or "No") occurred for initial measurement data
- **Count:** The number of objects processed.

Example:

Table listing sample results.

Object	Specialized Data Extract Occurred	Count
Initial Measurement Data	No	434
Initial Measurement Data	Yes	134
Service Task		1
To Do Entry		425
VEE Exception		413

Batch Control

The Remove Non-Final IMDs (D1-RENF) batch control identifies and closes or deletes unwanted initial measurements and their related objects. When run, this batch process creates a fact (using the Remove IMD Object Count (D1-RemoveIMDObjectCount) business object) that captures details regarding the batch process and the objects being removed during the process. These details are viewed in the **Object Log** zone in the **Request** portal.

Note that the Request ID is a required parameter for this batch control, meaning that this batch control cannot be run on its own. It can be only run from an initial measurement removal request.

Implementations can create specific versions of this batch control for use when removing specific types of data. For instance, an implementation could create a "Preview" version of this batch control, or a version used only with interval initial measurements.

Implementations can alter the processing of this batch control by creating alternate algorithms for each of the System Events used by this batch process. Refer to [Ad-hoc Processes](#) in the [Plug-in Driven Background Processes](#) section for more information.

Recommendations and Warnings

- We recommend using the **Preview** mode to identify potential initial measurements for removal before processing a request in either the **Close** or **Delete** mode. This allows you to review and verify the data to be removed before closing or deleting it.
- We recommend that access to this feature be limited to system administrators and other power users. Access to this feature can be restricted via the Remove IMDs Request BOAS (D1-RMIMDREQBOAS) application service.

WARNING: If used improperly, this feature can inadvertently remove valid operational data (such as initial measurements in "Pending" status awaiting VEE processing). There is no process for "undoing" the removal of initial measurements and related objects using this feature.

Defining Validation, Editing, and Estimation (VEE) Options

Exception Types

Understanding Exception Types

Exception Types define the groupings of exceptions for an IMD based on their functional similarity. This provides a way to define VEE Exceptions in a distinct enough way to understand the root issue that was generated from the VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Exception Types

This portal is used to display and maintain an Exception Type.

Refer to [Understanding Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Exception Type List:** displays all of the Exception Types so you can choose the one you want to display in more detail
- **Exception Type:** shows the specific configuration for the selected Exception Type

There are two different options to use when creating an Exception Type:

Name	Details	Business Object
VEE Exception	This will create a "normal" VEE Exception that is attached to an IMD for tracking of conditions triggered in the VEE process.	D1-VEEException
VEE Exception - Monitor Service Point	In addition to tracking the failure in the VEE process, this VEE Exception generates a Service Issue Monitor . This allows for cumulative tracking of VEE Exceptions that can be configured to result in a Service Investigative Order (field work) for the Service Point.	D2-VEEExceptionServiceMonitor

VEE Groups

Understanding VEE Groups

VEE groups are collections of VEE Rules that are applied to initial measurement data. During the VEE process, the system executes the VEE Rules defined in each VEE group. The rules within a VEE group are defined in a specific sequence, allowing control over the order in which the rules are executed.

VEE groups can be associated to a specific measuring component, or to a measuring component type (or both). VEE groups associated with a measuring component type are applied to all measuring components of that type, while those associated to a specific measuring component are applied only to that measuring component. VEE groups associated to a measuring component override those assigned to a measuring component type.

VEE groups can also be referenced by the [Execute VEE Group](#) VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Groups

This portal is used to display and maintain a VEE Group.

Refer to [Understanding VEE Groups](#) for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **VEE Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Group:** Defines basic information about VEE group
- **VEE Rules List:** lists the VEE Rules belonging to the group
- **Referencing VEE Rules List:** lists the VEE Rules that reference the group
- **Referencing VEE Group Factors List:** lists the VEE group factors that reference the group
- **Referencing Measuring Component Type List:** lists the measuring component types that reference the group
- **Referencing Measuring Component List:** lists the measuring components that reference the group

VEE Rules

Understanding VEE Rules

VEE Rules are standard and custom Validation and Estimation rules that perform checking and/or manipulation of initial measurement data. VEE Rules are created for a specific VEE group. For example, if you were configuring two VEE groups and both included a specific VEE Rule, you would need to create two instances of the VEE Rule, one for each group.

The specific validation and estimation processing performed on initial measurement data is defined in individual VEE Rules, each performing a specific set of targeted logic. The base product contains many VEE Rules you can use in your implementation, but you can also create your own custom VEE Rules.

Some VEE Rules generate VEE Exceptions if the initial measurement data fails the conditions specified for the rule. Other rules override measurements, changing measurement values as dictated by the rule's parameters. Some rules can both create exceptions and override the measurement as part of a single process. By convention, VEE Rules change the Post-VEE quantities of initial measurement data, but VEE Rules can change anything on an initial measurement.

Every VEE Rule has an effective period. Rules will only be applied if the initial measurement's start date is within the rule's effective period. For example, an Interval Spike Check rule with a Start Date of 11/15/2010 will only be applied if the start date of the initial measurement is on or after 11/15/2010.

This allows you to update the specifics of a rule without removing the previous version of the rule. For example, you might change the tolerance of an Interval Spike Check rule from 1.2 to 1.5 as of a certain date. However, for initial measurement data for the period prior to the change, you would want to use the tolerance for the original version of the rule (1.2) instead of the new tolerance (1.5).

On almost every VEE Rule, the failure of the rule results in a VEE Exception and the [Exception Type](#) for the failure can be configured on the rule. These Exception Types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the initial measurement data to be put into the exception state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the initial measurement data from being finalized. Multiple "issue exceptions" can be created during VEE processing. If at least one issue exists after all rules have been applied, the initial measurement data is transitioned to the exception state
- **Terminate:** Used to report a severe issue that will cause the VEE process to stop and the initial measurement data to be transitioned immediately to the exception state. Only one terminate exception can be issued (as the first one causes VEE processing to stop on an initial measurement data).

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Rules

This portal is used to display and maintain a VEE Rule. Also, a list of the specific out-of-the-box rules is included below the instructions for using the portal.

Refer to [Understanding VEE Rules](#), [Understanding VEE Groups](#), and [Understanding Exception Types](#) for more information. For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

You can access the portal by selecting **Admin**, then **VEE**, then **VEE Rule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Rule:** this zone displays all of the configuration items specific to this instance of a VEE Rule.
- **Eligibility Criteria List:** this zone displays any VEE Rule Eligibility Criteria that have been setup. These eligibility criteria determine conditionally whether the VEE Rule should be executed or not. Use the Add button to create a new eligibility criteria for the rule you're viewing.

Validation VEE Rules

Below is a list of the validation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Consecutive Interval Check	Interval	This validation rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data.
Duplicate IMD Check	Interval or Scalar	This rule allows for a duplicate IMD to be flagged.
Dynamic Comparison Validation	Interval or Scalar	This powerful, flexible validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Then you define formulas (no programming required) for the comparison of current measurements to these statistics.
Ensure IMD Exists for Sibling MCs	Interval or Scalar	This rule validates that an IMD exists for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.
Final Measurement Replacement	Interval or Scalar	This validation rule allows you to define a variety of configuration options to decide if new data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking.
High/Low Check	Interval or Scalar	This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.

Inactive Measurement Check	Interval or Scalar	This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a Usage Subscription.
Interval Size Validation	Interval	This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.
Interval Spike Check	Interval	This rule checks for spikes within an IMD and generates an exception if one is found.
Multiplier Check	Interval or Scalar	This rule validates that the register multiplier supplied with the IMD is equal to the multiplier stored on the measuring component. If not, an exception is created using the register multiplier exception type and severity configured on the rule.
Negative Consumption Check	Interval or Scalar	This rule flags any IMD where the total consumption is negative.
Prolonged Estimation Check	Interval or Scalar	This validation rule creates an alert when a device has been estimated for an extended period of time.
Raise Missing Quantity Exception	Interval	This rule flags any missing interval data.
Sum Check	Interval or Scalar	This rule is used to compare the difference between interval data to scalar data for a period of time, or between a set of TOU scalar reads to a "Sum" scalar reading.
Unit of Measure Check	Interval or Scalar	This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.
Zero Consumption Check	Interval or Scalar	This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid exceptions in that case.

Estimation VEE Rules

Below is a list of the estimation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Interval Adjustment From Scalar	Interval	This rule performs adjustments to interval values based on the values from the associated scalar data on the same device.
Interval Averaging Estimation	Interval	This rule finds historical interval data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.

Interval Create Estimation IMD for Gap	Interval	This estimation rule creates a new Estimation IMD to fill gaps between the interval data received from the Head End. <i>Note: this estimation rule acts differently from the other rules as it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.</i>
Interval Interpolation Estimation	Interval	This rule attempts to interpolate gaps within an IMD using prior and subsequent intervals as starting points for linear interpolation.
Interval Profile Estimation	Interval	This rule estimates any missing interval data for the IMD based on a referenced Profile Factor.
Interval Proxy Day Estimation	Interval	This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement.
Scalar Calculation From Interval	Scalar	This rule performs adjustments to scalar values based on the values from the associated interval data on the same device.
Scalar Estimation	Scalar	This rule finds historical scalar data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.
Scalar Profile Estimation	Scalar	This rule estimates any missing scalar data for the IMD based on a referenced Profile Factor.
Scalar Proration	Scalar	This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries. It will also take into account any related interval data within the same period to exclude from the calculation.
Subtractive Interval Adjustment Rule	Subtractive Interval Adjustment Rule	This rule performs adjustments to qualifying interval consumption values for subtractive interval measuring components based on an adjustment target calculated using a start and stop reading for the period that encapsulates the intervals to adjust.

Decision-Making VEE Rules

There are VEE Rules delivered as part of the base product that help with decision-making when executing VEE (listed below). For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Purpose
Exception Handler	This rule allows for termination of the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.

Execute VEE Group

This rule performs a call to execute a separate VEE Group which includes execution of all VEE Rules within that group.

Successful Termination

This rule allows VEE to be successfully terminated based on a list of exceptions.

VEE Group Matrix (Factor)

This rule provides a way to choose different instances of a VEE Rule using a Factor. This factor leverages characteristics that are defined on Service Point, Device, or Measuring Component.

Validation VEE Rules

Consecutive Interval Check

Overview

This rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data. It can be used to find faulty meters that are reporting consecutive outage codes, zero measurements, or negative values. It can also be used by water utilities to identify leaks based on the interval never reaching zero.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CONSINTRV Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

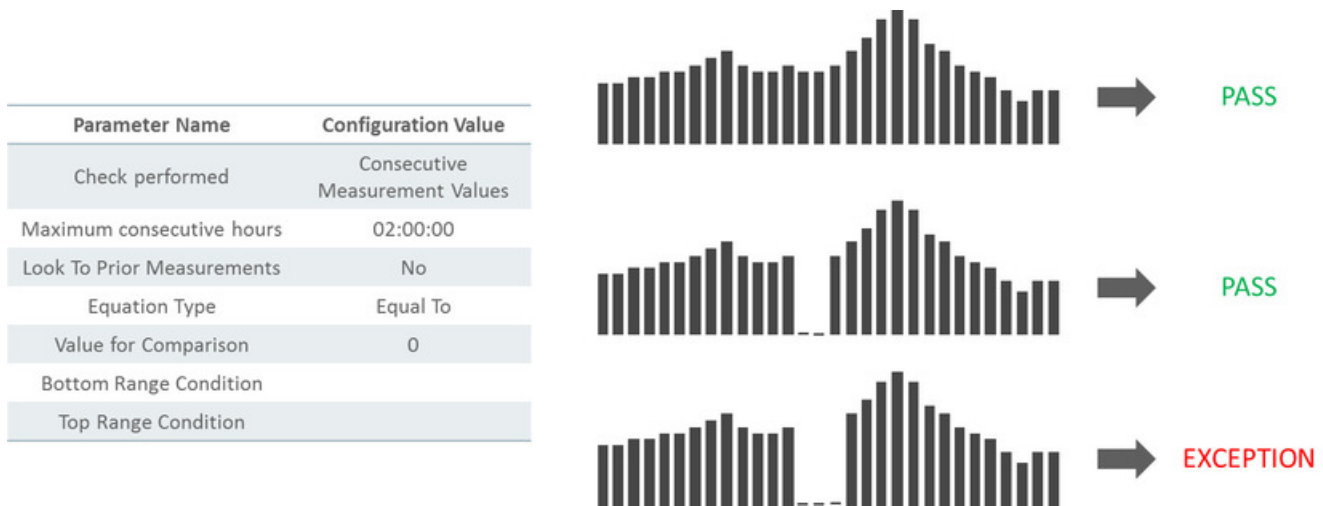

Business Object

D2-ConsecutiveIntervalCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Rule configured to fail for zero values

Scenario 2: Rule configured to fail for negative values

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Less Than
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 3: Rule configured to fail for missing condition codes

Parameter Name	Configuration Value
Check performed	Consecutive Condition Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	
Value for Comparison	
Bottom Range Condition	Missing
Top Range Condition	Missing

KEY

- = Regular data
- = Missing data

Scenario 4: Rule configured to fail for outage condition codes only if its zero

KEY
 ■ = Regular data
 ■ = Outage data

Parameter Name	Configuration Value
Check performed	Both
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	Outage
Top Range Condition	Outage

Scenario 5: Rule configured to fail if a long period of consecutive water values are greater than 0.1

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	20:00:00
Look To Prior Measurements When First Interval Matches Criteria	No
Equation Type	Greater Than
Value for Comparison	0.1
Bottom Range Condition	
Top Range Condition	

Scenario 6: Look back at prior measurements when the first interval matches criteria

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	Yes
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Duplicate IMD Check

If the current Initial Measurement Data (IMD) being validated is determined to be a duplicate of an existing IMD for the same measuring component, this rule will produce a VEE exception of the type and severity configured on the VEE Rule. The algorithm logic looks for duplicate IMDs using the following criteria:

- associated to the same measuring component as the current IMD
- utilizes the same IMD business object as the current IMD (for example, Initial Load Scalar)
- references the same To Date/Time (ends on the same date) as the current IMD
- exists in a "Finalized" state
- the contents of pre-VEE are identical to the pre-VEE of the current IMD

If any IMDs are found that meet all of the above criteria, the current IMD is deemed to be a duplicate.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-DUPIMDCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-DuplicateIMDCheck

Dynamic Comparison Validation

This validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Setting up these [Measuring Component Statistics](#) is a prerequisite to using the rule.

Users can define formulas (no programming required) for the comparison of current measurements to these statistics. This is powerful rule will allow utilities to look for unusual usage patterns. For example:

- Lowest/highest usage ever
- Current usage is more than three standard deviations from the mean
- Detect unexpected zero usage
- Detect negative usage while ruling out known cases
- Abnormal usage
- Voltage threshold monitoring
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-DYNCOMCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-DynCompValidation

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Detect new "high water mark"

Historical Statistics		
Statistics MC Type: MC_STATS_13MONTHS		
Max	15 min	4.320

Dynamic Values	
Variable Name: IMD1	Variable Name: CS1
• Source Type: IMD	• Source Type: Channel Statistics
• Set Function: Max	• MC Type: MC_STATS_13MONTH
	• Value: Max

Equation

$$IMD1 > CS1 * 1.1$$

This equation is comparing the max interval in the new IMD to the max interval from the last 13 months of history from the MC. If greater than 110% of max then fail.

Example 2: High Usage

Historical Statistics		
Statistics MC Type: MC_STATS_LASTMONTH		
Average	15 min	1.630
Standard Deviation	15 min	0.519
Statistics MC Type: MC_STATS_LASTYEAR		
Average	15 min	1.893
Standard Deviation	15 min	0.851

Dynamic Values	
Variable Name: IMD1	Variable Name: CS3
• Source Type: IMD	• Source Type: Channel Statistics
• Set Function: Max	• MC Type: MC_STATS_LASTYEAR
	• Value: Average
Variable Name: CS1	Variable Name: CS4
• Source Type: Channel Statistics	• Source Type: Channel Statistics
• MC Type: MC_STATS_LASTMONTH	• MC Type: MC_STATS_LASTYEAR
• Value: Average	• Value: Standard Deviation
Variable Name: CS2	
• Source Type: Channel Statistics	
• MC Type: MC_STATS_LASTMONTH	
• Value: Standard Deviation	

Equation

$$(IMD1 - CS1) / CS2 > 3$$

$$AND (IMD1 - CS3) / CS4 > 3$$

This equation checks that the standard score of the current max interval is within 3 standard deviations of historical data from last month and last year. If greater than 3 standard deviations, an exception is thrown.

Example 3: Detect unexpected zero usage (method 1)

Historical Statistics		
Statistics MC Type: MC_STATS_LASTMONTH		
Total Count	15 min	2880
Zero Count	15 min	3
Statistics MC Type: MC_STATS_LASTYEAR		
Total Count	15 min	2880
Zero Count	15 min	0

Dynamic Values	
Variable Name: IMD1	Variable Name: CS_T2
• Source Type: IMD	• Source Type: Channel Statistics
• Calc Function: Sum	• MC Type: MC_STATS_LASTYEAR
	• Value: Total Count
Variable Name: CS_T1	Variable Name: CS_Z2
• Source Type: Channel Statistics	• Source Type: Channel Statistics
• MC Type: MC_STATS_LASTMONTH	• MC Type: MC_STATS_LASTYEAR
• Value: Total Count	• Value: Zero Count
Variable Name: CS_Z1	
• Source Type: Channel Statistics	
• MC Type: MC_STATS_LASTMONTH	
• Value: Zero Count	

Equation

$$IMD1 = 0$$

$$AND CS_Z1 / CS_T1 < 0.01$$

$$AND CS_Z2 / CS_T2 < 0.01$$

This equation finds zero intervals in the current IMD that seem to not fit with historical trends for the customer based on prior counts of zero intervals.

Example 4: Detect unexpected zero usage (method 2)

Historical Statistics		
Statistics MC Type: MC_STATS_LASTMONTH		
Min	15 min	0.43
Statistics MC Type: MC_STATS_LASTYEAR		
Min	15 min	0.52

Dynamic Values	
Variable Name: IMD1	Variable Name: CS1
• Source Type: IMD	• Source Type: Channel Statistics
• Calc Function: Min	• MC Type: MC_STATS_LASTMONTH
	• Value: Min
Variable Name: CS2	
• Source Type: Channel Statistics	
• MC Type: MC_STATS_LASTYEAR	
• Value: Min	

Equation

$$IMD1 = 0$$

$$AND CS1 > 0$$

$$AND CS2 > 0$$

This equation finds zero intervals in the current IMD that seem to not fit because the minimum values for the meter historically have never reached zero during comparable periods.

Example 5: Detect negative usage while ruling out known cases

Historical Statistics

Statistics MC Type: MC_STATS_13MONTHS		
Negative Count	15 min	0

Dynamic Values

Variable Name: V1	• Source Type: IMD	• Calc Function: Min
Variable Name: V2	• Source Type: Channel Statistics	• MC Type: MC_STATS_13MONTHS
	• Value: Negative Count	

Equation

$V1 < 0 \text{ AND } V2 = 0$

This equation detects negative usage on the current IMD while the prior 13 months shows no cases of negative usage.

Example 6: Abnormal usage

Historical Statistics

Statistics MC Type: MC_STATS_LASTMONTH		
Average	15 min	1.630
Standard Deviation	15 min	0.519

Statistics MC Type: MC_STATS_LASTYEAR		
Average	15 min	1.893
Standard Deviation	15 min	0.851

Dynamic Values

Variable Name: IMD_STD	• Source Type: IMD	• Calc Function: Standard Deviation	Variable Name: LM_STD	• Source Type: Channel Statistics	• MC Type: MC_STATS_LASTMONTH	• Value: Standard Deviation
Variable Name: IMD_AVG	• Source Type: IMD	• Calc Function: Average	Variable Name: LY_AVG	• Source Type: Channel Statistics	• MC Type: MC_STATS_LASTYEAR	• Value: Average
Variable Name: LM_AVG	• Source Type: Channel Statistics	• MC Type: MC_STATS_LASTMONTH	• Value: Average	Variable Name: LY_STD	• Source Type: Channel Statistics	• MC Type: MC_STATS_LASTYEAR
	• Value: Average			• Value: Standard Deviation		

Equation

$IMD_AVG \leftrightarrow 0$
 $AND\ ABS(IMD_AVG - LM_AVG) < 0.5$
 $AND\ ABS(IMD_AVG - LY_AVG) < 0.5$
 $AND\ ABS(IMD_STD - LM_STD) > 1.5$
 $AND\ ABS(IMD_STD - LY_STD) > 1.5$

This equation determines that the average of the current IMD is close to the historical average but that the standard deviation is far off. This points to abnormal usage.

Example 7: Voltage threshold monitoring

Historical Statistics

None

Dynamic Values

Variable Name: VOLT_MAX	• Source Type: IMD	• Calc Function: Max
Variable Name: VOLT_MIN	• Source Type: IMD	• Calc Function: Min

Equation

$VOLT_MIN < 117$
OR
 $VOLT_MAX > 127$

This equation determines if the voltage data in the current IMD has fallen below or exceeded the bounds that a utility needs to keep customer voltage within. This is usually set to values that catch incorrect voltage before the value drops below the regulatory requirement.

Ensure IMD Exists for Sibling MCs

This rule validates that an IMD exist for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.

A check is also performed that all of the Initial Measurements have the same External Source ID (indicating that they all came from the same usage file).

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ENSIMDMC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-EnsureIMDExistsForSibling

Final Measurement Replacement

This validation rule allows you to define a variety of configuration options to decide if new scalar or interval data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking. One common use for this rule is rejecting trivial measurement changes to prevent very small changes for a bill from being sent to a customer.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-VLMSRCOND Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Replacement of measurements based solely on value difference

KEY	
	= Regular
	= System Estimated
	= No Read – System
	= No Read – Outage
	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 2: Percentage change to replace measurement

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Percentage Change
Value Change Tolerance	
Percentage Change Tolerance	50
Condition Code Prioritization by Groups	

Example 3: Partial replacement of estimated data with regular data based on condition range prioritization

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 4: Partial replacement of regular data with outage data based on condition range prioritization

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 5: Super not replaced by regular (retain a smoothed spike)

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

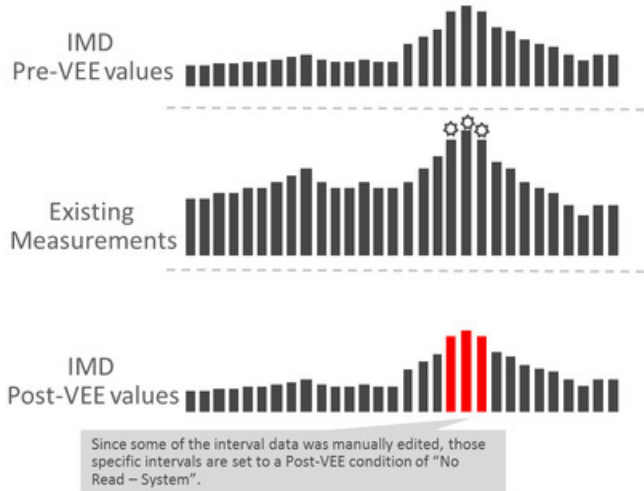

Example 6: Prevent replacement of manually edited data

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super
- = User Edited data

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 7: Allow replacement of manually edited data if the condition group is lower than new data

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super
- = User Edited data

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

High/Low Check

This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.

Numerous configuration options are provided including:

- A Historical Pre-Window and Post-Window that determines the number of days to check before and after the period being examined.

- Percentages to control how much of the historical data can be user edited, estimated, or non-normal data.
 - What type of historical data to look at first
 - What to do when an outage has occurred
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-HILO-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-VEERuleHighLowCheck

Inactive Measurement Check

This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a usage subscription.

- When the 'Check Measurements on Disconnected Device' flag is set to "Yes", the logic will compare the IMD measurements total to the threshold configured. If the total measurements are above the threshold, then logic compares the IMD dates to two things: 1) On/Off Dates related to the Install Event and 2) the Installation and Removal Dates of the Install Event. If the On or Off falls within the dates for an interval IMD, then the logic will only sum intervals that fall during the disconnected periods.
 - When the 'Check for Uninstalled Device' flag is set to "Yes", the logic will check for a valid Install Event based on the IMD dates.
 - When the 'Check for Missing Usage Subscription' flag is set to "Yes", the logic will check for an active Usage Subscription based on the IMD dates.
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INACTVCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-InactiveMeasurementCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Non-zero data during disconnected period

Example 2: Non-zero data after removal date with no new install

Example 3: Data received when device has no Install Event records

Example 4: Data received when not connected to a Usage Subscription record

Interval Size Validation

This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSIZVAL Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSizeValidation

Interval Spike Check

This rule looks for spikes by taking the highest interval and the third-highest interval, and determining the percent difference between the two. If the percent difference is larger than the tolerance configured on the rule, the algorithm logs an exception of the type and severity configured on the rule.

The rule can be executed in one of two modes (as configured on the rule):

- The spike check is performed for every 24-hour chunk of data in the initial measurement data set
- The spike check is performed for the entire initial measurement data set

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSPKCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSpikeCheck

Multiplier Check

This rule validates that the register multiplier supplied with the Initial Measurement is equal to the multiplier stored on the measuring component.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-REGMULCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RegisterMultiplierCheck

Negative Consumption Check

This rule checks if the total consumption of the initial measurement is less than zero. If the rule encounters negative consumption, an exception will be logged if the related Measuring Component Type is not configured to "allow negative consumption", or if the Override MC Type Allow Negative Consumption flag on the rule is set to "Yes".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-NCON-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-NegativeConsumptionCheck

Prolonged Estimation Check

This validation rule can be used on either interval or scalar and will alert you when a device has been estimated for an extended period of time. The IMD must first fall within the condition code range configured on the rule for this to execute. Next the validation finds the 'Most Recent Non-Estimated Read Date Time' from the Measurement Component. If this date plus the 'Days of Estimation Allowable' from the VEE Rule is less than the IMD End Date then a Prolonged Estimation Exception is created.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-PROESTCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProlongedEstimationCheck

Example Scenario

Below is an example scenario that can be achieved based on configuration of this rule.

Raise Missing Quantity Exception

This rule flags any missing interval data while providing a soft parameter on the algorithm to exclude a condition range if desired.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RAIMISQTY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RaiseMissingQuantityExcp

Sum Check

This rule evaluates whether consumption for the current Initial Measurement Data is within a tolerance of the sum of the consumption during the same period for any measuring components related to the current one. If the values are not within the defined tolerance of each other, and exception is logged.

The rule can be used to evaluate consumption totals for an interval measuring component that has a related scalar measuring component with the same UOM to ensure that the total consumption of the interval measuring component is within a tolerance of that of the scalar value. It can also be used to evaluate consumption totals for scalar TOU meters that have a "check" register (for example, three registers that measure ON-PEAK, OFF-PEAK, and SHOULDER, with a fourth check register that measures the total consumption).

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUM-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-SumCheck

Unit of Measure Check

This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-UOMCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UOMCheck

Zero Consumption Check

This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid To Dos by having a different exception type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ZEROCNCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ZeroConsumptionCheck

Estimation VEE Rules

Interval Adjustment From Scalar

This rule adjusts interval Initial Measurement Data based on scalar values using one of two options configured on the VEE Rule. Both options require that a scalar measuring component be related to the current interval measuring component using the Consumption Reference Measuring Component, and that one or more final measurements be present for the related measuring component between the start and end date/times of the current Initial Measurement Data set.

1. Adjust all intervals. In this case, the scalar consumption provides a value that is then used to proportionally adjust all of the intervals in the set. The formula used is $(\text{Scalar Consumption} / \text{Total Initial Measurement Consumption}) * \text{Interval Amount}$. If the total of all of the intervals had been equal to zero originally, the rule adjusts all of the intervals to the same value.
 2. Adjust intervals based on condition. For this option, a range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range. The adjustment is done by applying an adjustment factor to each of the intervals within range.
-

NOTE:

Business Object

D2-IntervalAdjustmentFrmScalar

Interval Averaging Estimation

The algorithm estimates when the current Measuring Component is eligible. Estimation is performed only if all these conditions are satisfied:

- The Measuring Component is interval.

- The Measuring Component is linked to a Service Point or the VEE Rule's Estimate If Not Attached to SP field is set to "Estimate".
- The Percentage of Missing Intervals is less than the VEE Rule's Maximum Percentage Missing Intervals Threshold.

The algorithm will compute the Total Accumulated Consumption and the Total Number of Intervals using a variety of methods including scanning holidays, similar days of the week, or neighboring days. Once a set of valid comparison days are found then these are used as the basis of creating estimated intervals for the current IMD.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTAVGEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAveragingEstimation

Interval Create Estimation IMD for Gap

This rule is very different from other VEE rules in that it does not examine the current initial measurement but rather looks to see if there are any missing measurements prior to the initial measurement being processed (i.e. a gap exists). If so and the scenario meets the configured options it will generate an estimation initial measurement to fill in that gap.

This rule is intended to provide more real-time filling of missing measurements as opposed to running periodic estimation. However, it is still expected that periodic estimation will be used in conjunction with this rule such that any gaps that are not filled in by this rule would eventually be filled in by periodic estimation.

This rule can be configured to perform minimal validation of that gap that is identified and defer to the estimation initial measurement to validate against other initial measurements and final measurements that may overlap the gap. Conversely, it can also be configured to validate the gap and exclude any periods where a final measurement or in progress initial measurement overlaps the gap's duration.

NOTE:

This estimation rule acts differently from the other rules - it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CREESTIMD Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

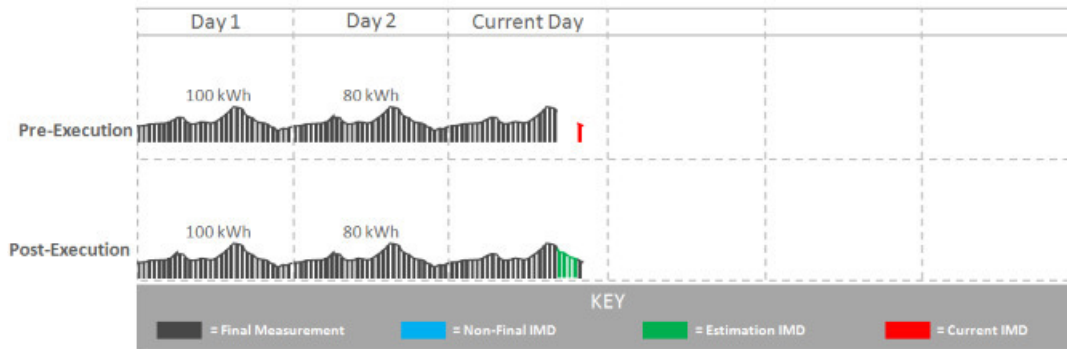

Business Object

D2-CreateEstimationIMDRule

Example Scenarios

The following are sample scenarios that can be achieved based on configuration of this rule.

Example 1: A 4-hour gap exists and the rule is configured to always fill gaps. Maximum hours are set to 4 and the gap fill is set to "always".

Since the maximum hours has not been exceeded and the rule is configured to always fill the gap, a 4-hour estimation IMD is created to fill the gap.

Example 2: A 4-hour gap exists and the rule is configured to always fill gaps. However, the maximum number of hours to fill is 3.

Since the gap is 4 hours long and the maximum hours to gap fill is 3 hours, no estimation has been created. An exception would be created if the rule were configured this way.

Example 3: A non-contiguous gap exists and the rule is configured to "Skip In-Progress IMDs and Final Measurements" with a maximum number of IMDs set to 2.

In this scenario:

- One interval in the 4-hour gap is covered by a final measurement.
- One interval in the 4-hour gap is covered by an in-progress IMD.
- Two estimation IMDs are generated one to fill each hour not covered by a final measurement or in-progress IMD.

Interval Interpolation Estimation

This rule attempts to interpolate gaps in Initial Measurement Data sets using prior and subsequent intervals as starting points for linear interpolation. A configuration parameter determines the maximum number of consecutive intervals within a gap before that gap can no longer be interpolated.

If a given gap lies at the beginning or end of the Initial Measurement Data set, this algorithm seeks out final measurements immediately before or after the set in an attempt to find two reference measurement values for interpolation. In this situation, assuming that the condition of the measurement retrieved lies in NEITHER of the algorithm parameter ranges you have configured (the measurement is neither "missing" nor an "outage"), this measurement value is then used as the basis for interpolation.

In the event that the gap is the entire length of the Initial Measurement Data set (and the VEE Rule is configured such that this is not too large of a gap), the routine attempts to find final measurements as described above.

If a valid measurement can be found for only one side of a given gap, the interpolation logic assigns each interval in the gap the same value - the value of the measurement retrieved. This is referred to as applying a "flat load".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTINTEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalInterpolationEst

Interval Profile Estimation

This rule uses a profile measuring component's interval consumption as a source of values to assign to intervals in the current Initial Measurement Data set that are marked "missing" via the interval's condition. If the interval is marked with a condition indicating "outage", the algorithm skips it.

If a measurement is not available for the profile measuring component on the date/time, the interval is left unchanged.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTPROEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProfileEstimation

Interval Proxy Day Estimation

This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement. [Measuring component comparison periods](#) are used as the main driver for determining similar temperature days.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTPROXY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProxyDayEstimation

Scalar Calculation From Interval

This rule calculates a single consumption amount for a scalar measuring component's Initial Measurement using the total consumption for the same date/time range for a related interval measuring component.

The scalar value replaces any existing value within the Initial Measurement (in the post-VEE list) and updates the condition to the value configured on the VEE Rule. This VEE Rule updates the condition to the value defined in "Condition Value for High Quality Condition" when the measurement condition value for all underlying interval data and the previous scalar measurement (when Evaluate Condition Of Previous Scalar Measurement is configured as "Yes") is greater than or equal to the "Minimum Condition Quality to Override" (If "Minimum Condition Quality to Override" is defined) otherwise it updates the measurement condition of the Initial Measurement Data to the condition defined in "IMD Created Condition Value".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCACALINT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarCalcFromInterval

Scalar Estimation

This rule uses historical data for the same measuring component to derive an estimated value for a scalar Initial Measurement. Depending upon a VEE Rule configuration parameter, the routine uses historical data from a month ago followed by a year ago, or vice-versa. If the data for the first historical period turns out to be usable, the second historical period will not be evaluated. Whether historical data qualifies for use in estimation is configured via the rule parameters in conjunction with the below algorithm parameters.

The rule rejects consumption from a historical period as unusable for estimation if too great a portion of the period is covered by final measurements that are not high-quality. The first pair of parameter values are used when evaluating the acceptable System-Estimated Percentage for historical periods as configured on the VEE Rule. Once an estimated value is calculated, the routine backs into a reading (which involves backing out multipliers and, if the measuring component is subtractive, adding the result to the prior reading).

An interim High/Low can also be configured on this rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCALAREST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarEstimation

Scalar Profile Estimation

This VEE rule arrives at a scalar estimate by looking at final measurements for a profile measuring component covering the same date range as the current Initial Measurement. The profile measuring component to be used as a source of measurement data is defined via a profile factor on the rule. This rule is meant primarily for a configuration in which the profile measuring components are interval, although the profile could be scalar as well.

If a measurement already exists in the current Initial Measurement with a condition that lies within the ranges specified in the pairs of algorithm parameters for "system estimate" and "regular", the routine does not attempt to estimate.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCAPROEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarProfileEstimation

Scalar Proration

This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries.

If the scalar MC does have a related interval MC and 'Minimum Related Measurement Condition' is defined the algorithm will take into consideration any intervals during the proration period that meet a minimum condition quality defined by the 'Minimum Related Measurement Condition' when performing the proration. This is to keep the prorated scalar estimates in sync with any existing interval measurements. To do this the algorithm will augment the total duration and total quantity being prorated by the related interval MC's qualifying measurements. For example, take the following scenario:

- Scalar proration is executing for a scalar IMD for 01/01 12:00 AM - 01/02 12:00 AM (24 hours)
- The subsequent measurement is for 150 kWh and has a measurement date/time of 01/04 12:00 AM (72 hours)
- The related interval MC has measurements on 01/03 12:00 AM to 01/04 12:00 AM totally 100 kWh (24 hours)

Therefore the result of the calculation for the scalar IMD from 01/01 12:00 AM to 01/02 12:00 AM would be 25 kWh. Since the interval measurements covered 24 of the 72 total hours of the 150 kWh that would leave 50 kWh to be split among the remaining 48 hours. Which leaves 25 kWh for 01/01 12:00 AM to 01/02 12:00 AM and 25 kWh for 01/02 12:00 AM to 01/03 12:00 AM.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCLRPRORT Algorithm Type.

Business Object

D2-ScalarProration

Subtractive Interval Adjustment Rule

This rule adjusts qualifying consecutive intervals for a subtractive interval initial measurement (IMD) based on the known consumption between a set of actual readings. The readings can either be leveraged from other intervals within the IMD or from the final measurements when there are no suitable readings within the IMD. The adjustment is done by applying an adjustment factor to each of the qualifying intervals.

The rule supports adjusting multiple sets of qualifying consecutive intervals by calculating a consumption adjustment target and adjustment factor specific to each set of consecutive qualifying intervals.

Intervals are considered to be qualified for adjustment based on condition. A range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUBINADJV Algorithm Type.

Decision-Making VEE Rules

Exception Handler

This rule allows you to terminate the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-EEH Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleExceptionHandler

Execute VEE Group

Many implementations need to execute a group of validations for any data being received. For example, you might want to perform device identifier validations, multiplier checks, and UOM checks on all measuring components. One inefficient way to meet this requirement would be to repeat these three rules in multiple VEE groups. However, this solution becomes hard to maintain if changes to the rules are required (or if new "global rules" are introduced) as each group would have to be updated. Instead of this, you can use the "Execute VEE Group" rule to execute a referenced VEE Group. Using the example

above, you could create a group called "Rules for All MCs" that contains a device identifier validations rule, a multiplier check rule, and a UOM check rule, and then reference the "Rules for All MCs" group in a Execute VEE Group rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-RFG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D1-VEERuleSuccessTermination

VEE Group Matrix (Factor)

Another situation likely to occur in many implementations is where specific rules may need to be applied to measurement data based on specific criteria, such as geography. For example, some geographic territories may have unique VEE Rules in addition to rules that are applied to all geographic territories. The "VEE Group Matrix (Factor)" rule allows for a Factor to determine which VEE Rule gets executed based on defined characteristics.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-FCT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleGroupFactor

Prerequisite Setup

Since the prerequisite setup items for this rule are more involved, the following procedure describes these in detail:

1. Create the Characteristic Type and Values to be used by the factor that will be referenced by the rule.
 2. Create the Characteristic Source Algorithm to be used by the factor that will be referenced by the rule.
 3. Create the VEE Groups to be associated to the characteristic values.
 4. Create the Factor that will be referenced by the rule.
-

5. Create the Factor Values for the factor, each referencing an effective-dated characteristic value/VEE group pairings.
6. Create the rule, referencing the factor

Measuring Component Statistics

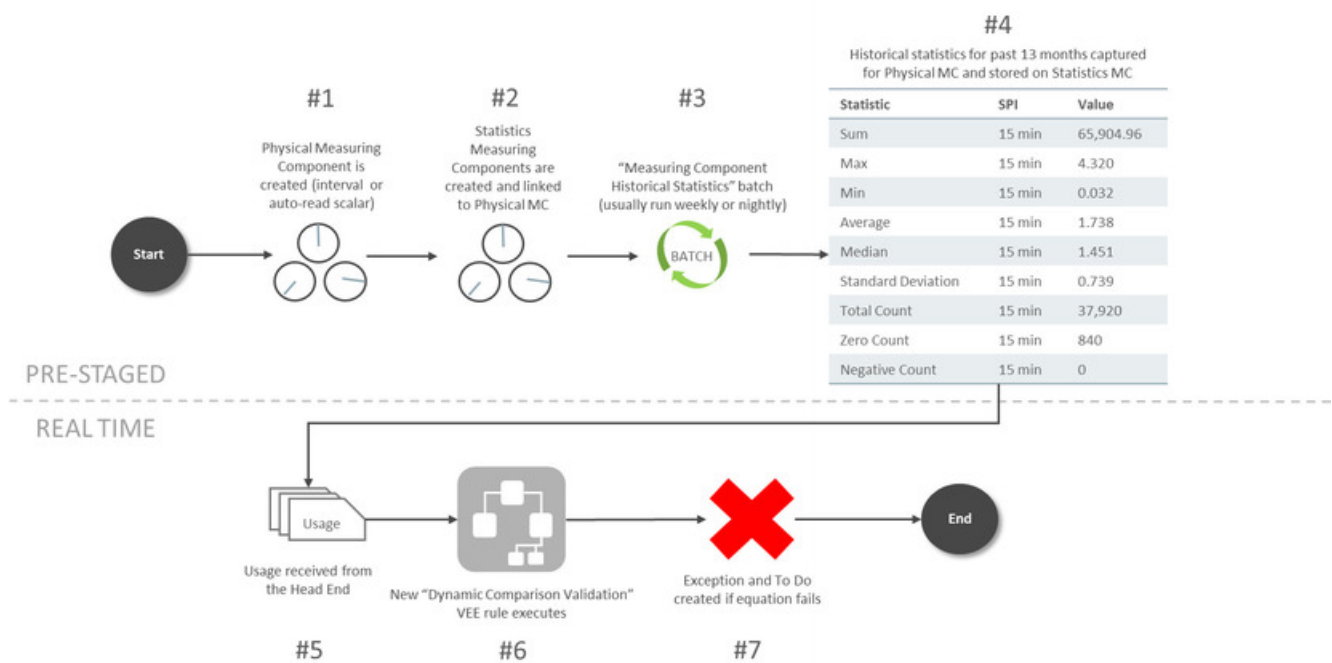

Understanding Measuring Component Statistics

Oracle Utilities Meter Data Management provides a way to stage statistics for Measuring Components in order to speed up VEE processing. These statistics are primarily meant for use in conjunction with the [Dynamic Comparison Validation](#) VEE Rule, but could also be generated for other analytics or reporting.

Some of the potential benefits of using Measuring Component Statistics are:

- Reduce the data volume for VEE queries by up to 1000 times (this is most beneficial when replacing VEE Rules that query historical data such as High/Low)
- Offload heavier processing of historical data to "system downtimes" - potentially nights or weekends

Below is an overview example of how Measuring Component Statistics can be implemented along with the Dynamic Comparison Validation:

The steps for pre-staging Measuring Component Statistics are detailed below:

1. A Physical Measuring Component is created. The algorithm to trigger the creation of Statistics Measuring Components is only set on Interval or Auto-Read Scalar BOs as part of base product.
2. New Statistics Measuring Component are created and linked to the Physical Measuring Component.
3. The Measuring Component Historical Statistics Batch (D1-MCHS) is run based on the schedule you've defined. The suggestion is to run this either nightly or on the weekends during quieter times for overall system processing.
4. A measurement is created for the Statistics Measuring Component that holds historical statistics related to the Physical Meter for a specific period of time (in this example it's set for 13 months).

The steps for how VEE can take advantage of Measuring Component Statistics are detailed below:

1. IMDs are received from the Head End.
2. The [Dynamic Comparison Validation](#) VEE Rule is configured to execute for the meter. This validation uses the historical statistics from the Statistics Measuring Component in order to perform its validation logic.
3. An exception and potentially a To Do is generated based on the failure of the VEE rule.

Storage Impact from Statistics

Much consideration was given to the storage implications when designing Measuring Component Statistics. Below is an outline of the storage impact to customers who choose to calculate and store Channel Statistics. An example impact to a utility with 1 million Physical Meters (each with 4 channels of information) is shown in the far right column:

Area	Additional Data in MDM	Example Impact (assuming utility has 1 million Physical Meters)
Additional MCs <i>Assumption: Statistics are only configured on the primary billing channel MC Type for the majority of your Physical Meters.</i>	1-3 extra MCs per Physical Meter <i>Assumption: customers will only configure Statistics on their primary billing channel MC Type for the majority of their Physical Meters.</i>	1 - 3 million extra MCs <i>This increases the Measuring Component table by an extra 25% to 75% from its size without statistics.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Only Retain Most Recent Record".</i>	1 extra Measurement per Physical Meter	1 - 3 million extra Measurements for the life of MDM <i>This data is a minuscule fraction compared to the overall AMI data footprint.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Retain Historical Records".</i>	1 extra Measurement per Physical Meter per week	1 - 3 million extra Measurements per week (52-156 million per year) <i>This data is 0.2-0.5% of the size of the AMI data collected in that same week.</i>

Configuring Measuring Component Statistics

Measuring Component Types

In order to start generating Measuring Component Statistics, two different configurations must occur for [Measuring Component Types](#):

- New Measuring Component Types must be configured that leverage the **Channel Statistics Type** business object. These should be setup as the periods for which Measuring Component Statistics should be calculated. For example, if you would like to be able to reference both last month, last year, as well as the past 13 months as statistics periods, then 3 different Channel Statistics Types must be setup for this. These could be setup as follows:
 - "Last Month" Channel Statistics Type:
 - Calculation Lag Days = 0
 - Calculation Horizon Days = 30
 - "Same Month Last Year" Channel Statistics Type:
 - Calculation Lag Days = 365
 - Calculation Horizon Days = 395
 - "Prior 13 Months" Channel Statistics Type:

- Calculation Lag Days = 0
- Calculation Horizon Days = 395

NOTE: *it's recommended to set the Statistics Retention Mode to "Only Retain Most Recent Record" on the Channel Statistics Type to reduce the amount of data being stored in Oracle Utilities Meter Data Management.*

- For a Physical Measuring Component Type leveraging either "Interval Channel Type" or "Register - Auto-Read Type", the **Related Statistics Measuring Component Types** section must be filled in with the appropriate types that should be created for the Physical Measuring Component.

VEE Rule

If you have a desire to leverage Measuring Component Statistics for VEE, the [Dynamic Comparison Validation](#) VEE Rule section should be referenced. A number of detailed examples of how to implement this rule are provided in this section as well.

Related Batch Controls

There are a few batches directly involved with Measuring Component Statistics:

- **Measuring Component Historical Statistics (D1-MCHS):** this batch monitors any active Statistics Measuring Components to execute the logic for calculating a new set of historical statistics.
- **Statistics Measuring Component Creation (D1-STMCC):** this batch is used to create Statistics Measuring Components on any Physical Measuring Components that were created prior to configuring this module. This is especially useful for existing customers that want to implement Statistics Measuring Components for all of their devices.

NOTE: Refer to [Understanding Measuring Component Statistics](#) for more information.

Defining Usage Options

This section describes concepts and common tasks related to usage administration.

The Big Picture of Usage Requests

Oracle Utilities Meter Data Management is used by some organizations who use a meter data management (mdm) system to record meter reading information. Since meter reads are not available in Oracle Utilities Customer Care and Billing to calculate consumption during the billing process, usage (or bill determinants) must be requested by Oracle Utilities Customer Care and Billing from the mdm system, Oracle Utilities Meter Data Management.

The following sections describe how the base-package usage request process works.

Requesting Bill Determinants

The term bill determinant request is another way to refer to a usage request. These usage requests are created during the batch billing process, and also when a user generates an online bill segment or performs cancel / rebill. The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request.

Online Billing Usage Requests

- Usage requests created from an online billing request are not held in the initial state. These usage requests are transitioned through their lifecycle resulting in the request being sent to Oracle Utilities Meter Data Management (MDM) and, once a response is received, the bill segment is regenerated.
- The bill segment remains in the Freezable state until the user freezes the bill segment and completes the bill. If the freezable bill segment is regenerated, however, the system cancels the usage request and creates another usage request for the bill segment.
- In addition to the standard MDM usage request elements, the system captures the responsible user id.

Usage Request Lifecycle

The usage request business object (BO) contains the rules that govern the processing of a usage request. The base product provides the BO C1-UsageRequest which serves as a parent BO and contains the following lifecycle:

- All usage requests are created in the initial Pending state. If the usage request was created from the batch billing process, the batch Usage Scheduled Monitor Process must be executed to transition the usage request.
- If there are pending sync requests for the usage request's service agreement, the usage request is held in the Awaiting Data Sync state until the sync is processed.
- Once all pending sync requests related to the usage request have been processed, the usage request transitions to the Send Request state. An enter algorithm on this transitory state is responsible for sending the usage request to Oracle Utilities Meter Data Management (MDM).
- The usage request sits in the Awaiting Bill Determinants state until a response is received from MDM, or a time out is encountered.
- When a response is received from MDM, the usage request is transitioned to either the Bill Determinants Received state, or the Error state. In the case of an error, the following occurs:
 - If the usage request was created from the batch billing process and the billing window is still open, a new usage request will be created the next time billing runs and the process is repeated. If however, the billing window is no longer open, a to do entry is created for manual follow up.
 - If the usage request was created from an online billing process, the user will be notified. The bill segment remains in the error state and the user can either delete the bill segment, or attempt to generate it again. If the bill segment is regenerated, a new usage request is created and the process is repeated.
 - The system transitions usage requests in the Bill Determinants Received state to the Bill Determinants Processed state. An enter algorithm on this final state is responsible for generating the bill segment. If the usage request was created from the batch billing process, the bill segment is frozen and the bill is completed. For online billing usage requests, the user is responsible for freezing the bill segment and completing the bill.

Summary Billed Accounts and Usage Requests

A "summary" account refers to an account with service agreements that cover more than one premise. If these premises are linked to service points that span different measurement cycle routes scheduled for reading on different dates, there's no guarantee that all the account's SAs will be billed at the same time. This is because batch billing for manually read meters is based on the meter's scheduled reading date.

For example, assume a summary account has two SAs each linked to a different premise. One is on route X, scheduled for reading every first of the month and the other is on route Y, scheduled for reading every 20th of the month. Assume that the account's bill cycle is cycle X (which matches the schedule of premise/SP on route X). When billing runs on the first of the month, the service agreements tied to route Y won't have any reads. And because route Y is not scheduled for reading, the system will not estimate the consumption. Instead, it will skip billing the route Y SAs until the next month. This means some SAs are always one billing cycle behind.

Requesting Bill Determinants for Summary Billed Accounts

Usage requests for summary billed accounts are handled as follows:

- On the first night of the billing window usage requests are created for each SA and sent to Oracle Utilities Meter Data Management (MDM). MDM then checks what the next schedule read date is for each service point.
- Assuming Oracle Utilities Meter Data Management owns meter read schedules; when batch billing executes Oracle Utilities Customer Care and Billing (CCB) cannot determine whether a summary account's service agreement should be included on the bill or not.
- If MDM determines that an SA/usage subscription should be skipped from billing, it notifies CCB by including a skip indicator and reason on the usage response, as well as the SA's next scheduled read date. This date is captured as a **MDM Next Scheduled Read Date** characteristic on the SA, and the usage request is cancelled. The system still attempts to complete the bill since this might be the last outstanding usage request for the bill
- When billing next runs, the base *Get bill segment consumption using a usage request* algorithm first checks if the SA should be skipped as follows (Note that this check is also performed in first billing run):
- Get the **MDM Next Scheduled Read Date** characteristic on the SA. If this date is after the bill segment end date, we'll skip the SA from billing

If your implementation would like to wait until the bill cycle window end date before attempting to complete summary account's bills, ensure that the **Complete Bill at End of Bill Cycle** pre-bill completion algorithm is defined on customer class. This is useful if scheduled reads are expected in the bill cycle window, but not necessarily on the window start date.

Corrected Read Notifications

If a read that was used for bill determinant calculations is modified in the mdm system, notification is sent to Oracle Utilities Meter Data Management.. Resulting in the creation of an off cycle bill generator. The system uses the business object defined as the OCBG Corrected Read BO MO option on the Off Cycle Bill Generator maintenance object to create the OCBG.

What happens next depends on the lifecycle that your implementation has configured for the OCBG Corrected Read BO. Here are examples of what might occur:

- Create a To Do entry for manual follow up.
- Find any frozen bill segments that might be affected by the corrected read and perform cancel/rebill.

Configuring The System For Usage Request Integration

Oracle Utilities Customer Care and Billing sends usage requests to Oracle Utilities Meter Data Management (MDM) in the form of an xml message. MDM sends responses back to Oracle Utilities Customer Care and Billing.

The following sections describe at a high level the data setup required to send usage requests to MDM.

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to [Ways To Control The Start Date Of A Bill Segment](#) and [Ways To Control The End Date Of A Bill Segment](#) for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing uses the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

Oracle Utilities Customer Care and Billing lacks knowledge of the type of meter installed at a service point. Thus, both interval processing period as well as scalar processing information is captured on a usage request. Oracle Utilities Meter Data Management (MDM) then uses the appropriate period to calculate bill determinants based on the type of meter installed.

MDM returns the true usage period used to calculate bill determinants on the usage response. This usage period is captured on the bill segment.

The Big Picture of Time of Use Mapping and Pricing

This section provides an overview of the concepts related to setting up your control tables to support time of use mapping and pricing with the rates.

NOTE: Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.

Mapping to Time of Use (TOU) Periods

Many customers choose not to price their interval data using interval prices. Customers may choose for their interval data to be mapped into time of use (TOU) periods. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times). The TOU Map has a TOU Map Type, which defines the interval size between TOU map data rows.

Time of use periods can (and often do) change during the year.

Map #123 (TOU Group 2)	
Effective 1 Jan 2000	
Interval Date/Time	
30/Apr/00 16:30	On Peak/Winter
30/Apr/00 16:45	On Peak/Winter
30/Apr/00 17:00	Off Peak/Winter
30/Apr/00 17:15	Off Peak/Winter

01/May/00 7:45	Off Peak/Summer
02/May/00 8:00	On Peak/Summer
02/May/00 8:15	On Peak/Summer

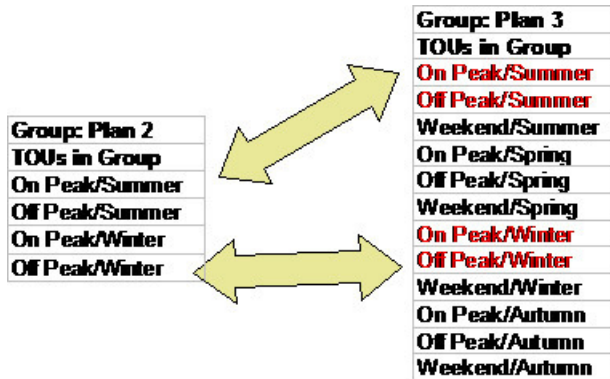

All the possible TOU codes for a given map are grouped together in a TOU group. Refer to [Grouping of TOU Codes for TOU Mapping](#) for more information.

Grouping of TOU Codes for TOU Mapping

This section describes the relationship between TOU Codes and TOU Mapping.

Overview of TOU Codes and TOU Mapping

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times).

TOU Sequence for TOU Mapping and Pricing

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Time of Use (TOU) Mapping and Pricing

The following section describes the logic used by the system to map an interval data curve to TOU periods using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take an interval data curve and will map the interval values to TOU periods based on a TOU Map. The interval data curve is retrieved from either a specific usage request or from the new rate engine buffer populated prior to calling the rate engine.

This type of data manipulation is typically handled using a calculation rule based on the 'math' calculation rule type.

Once the interval data curve values have been mapped to TOU periods, prices can be applied to the time of use period quantities using calculation rules based on the 'service quantity' calculation rule type.

Calculation Rules for TOU Mapping & Pricing

Calculation Rules are used to perform time of use mapping and time of use pricing.

Time of Use Mapping

Time of use mapping will be typically handled using a calculation rule based on the 'math' calculation rule type. Calculation rules of this type can perform many functions. Two examples include:

- Applying a TOU map to an interval data curve to produce service quantities that will be added to the bill segment's SQ collection.
- Applying a TOU map to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the resultant curve.

For further details on the 'math' calculation rule type, refer to [Base Package Math Calculation Rule](#) for more information.

Time of Use Pricing

Time of use pricing will be typically handled using calculation rules based on the 'service quantity' calculation rule type. Calculation rules of this type can perform many functions. For example:

- Add or update a service quantity in the bill segments SQ collection
- Create bill calculations lines that levy charges based on some type of consumption. For example, applying a price to a specific service quantity in the bill segment's SQ collection

For further details on the 'service quantity' calculation rule type, refer to [Base Package Service Quantity Calculation Rule](#) for further information.

NOTE: Calculation rules are implemented using algorithms that contain the logic to be performed. If your implementation requires a new type of calculation rule, you can configure a new calculation rule type and reference the appropriate algorithm on it.

TOU Map Used For Mapping

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule.

Attributes of TOU Maps

TOU map types define attributes shared by TOU maps of a given type. The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting.

Designing Your Time of Use (TOU) Mapping and Pricing Options

This section provides an overview for designing your control tables to support time of use (TOU) mapping and pricing with the new rating engine.

Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules

As you know from the rates chapter, the system can handle mapping of interval data curve values into different time of use periods and pricing these quantities using the 'math' and 'service quantity' calculation rule types respectively. Refer to [Base Package Calculation Rule Descriptions](#) for more information.

The following guidelines provides a high level outline on how you should go about designing a rate schedule that involves time of use mapping and pricing.

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up exactly how the information should appear on the customers' printed bills.
- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. Which time of use map is used to define the time periods?
- In order to perform time of use mapping and pricing, calculation rules need to be designed
 - A calculation rule based on the 'math' calculation rule type may be used to map an interval data curve into time of use periods. This calculation rule must know the TOU map to apply to the interval data curve to map into the relevant time of use periods. The time of use period quantities are populated in the bill segments SQ collection.
 - Calculation rules based on the 'service quantity' calculation rule type may be used to apply prices to each mapped time of use period quantity. These calculation rules each require either a price or regular bill factor for pricing each time of use period quantity. The bill factor may contain the price directly, or may indicate that the price is customer specific and can be found as contract quantities for the service agreement.

Once you have your calculation rules designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Designing Your TOU Codes for TOU Mapping

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. It should be noted that it's possible that will not bill for every time of use period.

Designing Your TOU Groups for TOU Mapping

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are available to be used in a single map. You must also decide if you want to use a sequence number to define the relative order of a TOU code within a TOU group.

When TOU data is created for a TOU map, only TOU periods defined on a specified TOU group can be specified.

Designing Your TOU Map Types for TOU Mapping

Now that you have your TOU groups defined, you can begin defining TOU map types. Recall that the TOU map type defines the attributes that may be shared by TOU maps of the same type.

The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting. Refer to [Designing Your Time Options](#) for more information.

TOU Map Type Interval Size

The interval size of a TOU map must divide evenly into the interval size of the interval data curve that uses the map (because the system joins the date/time of the interval data curve values to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute interval data curve. However, it is not OK to have a 60 minute TOU map used with a 15 minute interval data curve because the join will miss 3 out of 4 interval data curve values.

TOU Map Type Override Template

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support override templates. Refer to [Designing Your TOU Map Templates](#) for TOU Mapping for more information.

- A TOU map's TOU map type defines the default TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the default template.
- An individual TOU map can have override templates. If the TOU map doesn't have an override template, the default template defined on the TOU map type is used to generate the map's TOU data.

Refer to [Creating TOU Map Types](#) for further information.

Designing Your TOU Map Templates for TOU Mapping

In order to help your users to create and maintain data for TOU maps, you may define TOU map templates, which can be used to generate data for a TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates.

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map

- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period. The system periodically generates TOU map data for TOU maps by interpreting the rules defined in the template.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays by specifying the following:

- A Work Calendar that defines when holidays start and end
- Either:
 - A Holiday TOU period for consumption on holiday
 - A Holiday TOU Map Template that defines the TOU codes to use for different times in the year

TOU Map Template Interval Size

TOU map templates can also specify an interval size. This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose interval size is divisible by the template's interval size. For example, a 60 minute template can be used to generate TOU data for TOU maps with an interval size of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every interval size.

Refer to [Creating TOU Map Templates](#) for further information.

Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

This section provides an overview of setting up your control tables to support time of use mapping and pricing with rates.

Creating TOU Map Templates

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates and used for TOU map data generation.

Prerequisites: You must define TOU groups and work calendars before you can create TOU map templates. Refer to the Oracle Utilities Application Framework online help for more information about creating work calendars.

To maintain existing TOU map templates, select **Admin > Usage > TOU Map Template > Search** then use standard actions to edit, duplicate, or delete a TOU map template.

To define a new TOU map template, follow these steps:

1. Select **Admin > Consumption > TOU Map Template > Add**. If your system supports more than one TOU map template business object, you will be prompted to select a business object for this TOU map template.
2. Enter a name and a meaningful description for the TOU map template.
3. Select the TOU group to be used by the TOU map template.
4. Select the default TOU for the TOU map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.

5. Select the work calendar for the TOU map template. Work calendars define the days of the week on which work is performed, and specify holidays.
6. Select the holiday TOU for the TOU map template (from the TOU Group).
7. Select the TOU map template used for holidays (if applicable).
8. Specify the interval size for TOU map data created from the map template. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
9. To specify TOU schedule's date ranges and which TOUs should be used for this TOU map template, click the + or - sign in the TOU Schedule Section and enter or select the following:
 - Start and End Dates for a specific date range
 - Start and End Days of the Week: To add or remove Start and End Days of the Week pairs, click the + or - sign and select the appropriate weekdays
 - Start and End Times: To add or remove Start and End Times within a Start and End Days of the Week pair, click the + or - sign and enter the appropriate times
 - TOU
10. Click **Save**.

Now you can use the TOU map template when creating TOU types.

Creating TOU Map Types

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule. TOU map types define attributes shared by TOU maps of a given type.

Prerequisites: You must define TOU map templates and time zones before you can create TOU map types. Refer to the Oracle Utilities Application Framework online help for more information about creating time zones.

To maintain existing TOU map types, select **Admin > Consumption > TOU Map Type > Search** then use standard actions to edit, duplicate, or delete a TOU map type.

To define a new TOU map type, follow these steps:

1. Select **Admin > Consumption > TOU Map Type > Add**

NOTE: If your system supports more than one TOU map type business object, you will be prompted to elect a business object for this TOU map type.

2. Enter a name and a meaningful description for the TOU map type.
3. Select the business object to use when creating TOU maps of this type
4. Select the time zone for the TOU map type.
5. Specify the interval size for TOU map data created from the map type. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
6. Select the default TOU map template for the TOU map type
7. To add or remove override TOU map templates for this TOU type, click the + or - sign in the Override TOU Map Templates section and select the TOU map template.
8. Click **Save**.

Now you can use the TOU map type when creating TOU maps.

Usage Subscription Types

Understanding Usage Subscription Types

Usage Subscription Types define a collection of properties defining a class of Usage Subscriptions. Usage Subscription types also control valid values for various attributes of Usage Subscriptions.

For a deeper functional understanding, refer to the [About Usage Subscriptions](#) or [About Usage Calculation](#) sections .

Configuring Usage Subscription Types

This portal is used to display and maintain a Usage Subscription Type.

Refer to [Understanding Usage Subscription Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Type List:** displays all of the Usage Subscription Types so you can choose the one you want to display in more detail
- **Usage Subscription Type:** shows the specific configuration for the selected Usage Subscription Type

The Usage Subscription Type defines a number of lists for "valid" objects that can be used in conjunction with the overall usage calculation process:

- Valid Usage Recipients
- Valid Service Point Types
- Valid Usage Calculation Groups
- Valid Dynamic Option Types

Integrating Usage Transactions

Requesting Usage Transactions from External Systems

When Oracle Utilities Meter Data Management is deployed with Oracle Utilities Customer Care and Billing usage transactions can be created via a request from Oracle Utilities Customer Care and Billing.

To invoke a usage transaction request, Oracle Utilities Customer Care and Billing invokes a Usage Transaction Request Inbound service script which invokes the Usage Transaction Seeder (D2-UsgTranSeeder) business object. This business object does the following:

- Determines the usage subscription ID based on an external usage subscription ID
- Determines the appropriate usage transaction business object to create. This uses the "How To Create Usage Subscription Related Information" processing method defined for the "Usage Transaction Creation" processing role on the service provider that represents the external system.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Processing and Sending Usage Transactions to External Systems

When Oracle Utilities Meter Data Management is integrated with a customer information system (such as Oracle Utilities Customer Care and Billing), usage transaction information, including bill determinants and other data can be sent to the customer information system (again, such as Oracle Utilities Customer Care and Billing).

Usage transactions are sent to subscribing systems when they enter the "Sent" state. The "Send Usage" (D2-SEND-USG) Enter algorithm on the Sent state of the base package usage transaction business object (D2-UsageTransaction) determines the method used to send the information, based on the Usage Recipient (service provider) defined on the usage transaction's Usage Subscription. Usage transactions can be sent to service providers via either online real-time processing or periodically via batch processing.

Online Real-Time Processing

To set up the service provider to support online real-time notification of usage transactions, do the following:

- Create one or more Outbound Message Types that reference the outbound message business object to be used to send usage transaction information to the external system. The base package include the following business object for Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).
- Define a Message Sender that will be used to send the message to the external system.
- Add the outbound message type to the service provider's External System and reference the Message sender created above.
- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Online
 - **Processing Method:** How To Send US Related Information
 - **Status:** Active
 - **Default Processing Method:**
 - **Outbound Message Type:** the outbound message type created above
 - **Override Processing Method:** outbound message types for specific usage subscription types if applicable

For a deeper understanding of integrating usage transactions with a customer information or Oracle Utilities Customer Care and Billing, refer to the [Configuring the Bill Determinant Interface](#) in the Interface section.

Batch Processing

If Oracle Utilities Meter Data Management is integrated with a customer information system (such as Oracle Utilities Customer Care and Billing) that requests bill determinants, usage transaction processing should be coordinated with the requesting system's billing process.

Requests from a billing system that have been indicated as "batch requests" (such as those produced by Oracle Utilities Customer Care and Billing batch billing process) accumulate in a "calculation deferred" state to be processed specially by the **Usage Transaction Calculate Defer Monitor** batch control (D2-UTCD).

To set up the service provider to support periodic batch processing of usage transactions, use a periodic monitor batch control. These batch programs should invoke the business objects that will contain the usage transaction information. The base package includes the following business object for this: Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).

Next, setup the following configuration:

- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Batch

- **Processing Method:** How To Send US Related Information
- **Status:** Active
- **Default Processing Method:**
- **Batch Control:** the batch control created above
- **Override Processing Method:** batch controls for specific usage subscription types if applicable

Errors encountered when processing Usage Transactions can be reprocessed with the following batches:

- Reprocessing usage transaction "seeders" in error (D2-UTSED)
- Reprocessing usage transactions in error (D2-UTID)

If unexpected errors occur that leave usage transactions in an unmonitored state, the **Usage Transaction Monitor** batch control (D2-UT), or one based on this batch control with parameter values tailored to any specific requirements, can be used to process those usage transactions.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section.

Generating Usage Transactions in Oracle Utilities Meter Data Management

There may be some cases where Usage Transactions should be generated in Oracle Utilities Meter Data Management rather than requested from an external system. Generation of these usage transactions are scheduled around the time when the meter installed on the service point is read.

Base product delivered a batch program that reads all pending measurement cycle schedule routes with selection date on or before the business date and creates as SP measurement cycle schedule route business object instance that stages the creation of these usage transactions.

For additional details refer to the D1-CSPSR batch control and D1-SPMrmtCycScheduleRoute business object.

Usage Transaction Exception Types

Understanding Usage Transaction Exception Types

Usage Transaction Exception Types define the groupings of exceptions for a Usage Transaction based on their functional similarity. This provides a way to define Usage Transaction Exceptions in a distinct enough way to understand the root issue that was generated from the usage calculation rule.

For a deeper functional understanding of Usage Calculation, refer to the [About Usage Calculation](#) section.

Configuring Usage Transaction Exception Types

This portal is used to display and maintain a Usage Transaction Exception Type.

Refer to [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Transaction Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Transaction Exception Type List:** displays all of the Usage Transaction Exception Types so you can choose the one you want to display in more detail
- **Usage Transaction Exception Type:** shows the specific configuration for the selected Usage Transaction Exception Type

Usage Calculation Groups

Understanding Usage Calculation Groups

Usage calculation groups are collections of usage calculation rules that are used to either calculate bill determinants or validate bill determinants. During the usage transaction process, the system executes the usage calculation rules defined in the usage calculation group referenced on the usage subscription. The rules within a usage calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

Usage calculation groups are associated with specific usage subscriptions and usage subscription types (or both). When assigned to usage subscriptions, usage calculation groups contain the usage calculation rules to be used to calculate usage / bill determinants. Usage calculation groups associated with usage subscription types are those groups considered valid for usage subscriptions of that type.

Usage calculation groups can also specify a list of device donfiguration types that are considered valid. Usage calculation groups should only be associated with usage subscriptions for service points related to device configurations of a valid device configuration type.

Usage calculation groups can also be referenced by the [Execute Usage Calculation Group](#) usage calculation rule.

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section.

Configuring Usage Calculation Groups

This portal is used to display and maintain a usage calculation group.

Refer to [Understanding Usage Calculation Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Group**: Defines basic information about usage calculation group
- **Usage Calculation Rules List**: lists the usage calculation rules belonging to the group
- **Referencing Usage Calculation Rules List**: lists the usage calculation rules that reference the group
- **Referencing Usage Subscription Type List**: lists the usage subscription types that reference the group
- **Referencing Usage Subscriptions List**: lists the usage subscriptions that reference the group

Usage Calculation Rules

Understanding Usage Calculation Rules

Usage calculation rules are standard and custom rules that perform calculations on measurement data to generate bill determinants and other values used by external systems, such as billing systems, customer information systems, etc. Usage calculation rules are created for a specific usage calculation group. For example, if you were configuring two usage calculation groups and both included a specific usage calculation rule, you would need to create two instances of the usage calculation rule, one for each group.

The base package includes rules that calculate common bill determinants including:

- Scalar reads
- Time-of-use consumption (by applying a time-of-use map to an interval channel)
- Interval curves (either real or derived)
- Virtually anything else that can be calculated from the information in the system

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section.

Usage Transaction Exceptions

On almost every usage calculation rule, the failure of the rule results in a usage transaction exception and the [Usage Transaction Exception Type](#) for the failure can be configured on the rule. These usage transaction exception types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the usage transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the usage transaction from being sent. Multiple "issue exceptions" can be created during usage transaction processing. If at least one issue exists after all rules have been applied, the usage transaction is transitioned to a failure state requiring review and approval.
- **Terminate:** Used to report a severe issue that will cause the usage calculation process to stop and the usage transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a Usage Transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full usage period should always be set to Terminate as an Exception Severity.

Rounding Usage Transaction Service Quantities

Several usage calculation rules provide a means for defining the manner in which service quantities are rounded during usage calculations. Service quantity rounding can be defined using the **SQ Rounding Details** which allow configuration of the method by which quantities are rounded (Up, Down, or Nearest) and the number of decimal positions retained after rounding.

Creating Measurement Data Snapshots

Daily Scalar Calculation Rule, Get Interval, Get Item Counts and Consumption, and Get Scalar Details usage calculation rules can be configured to create measurement data snapshots during usage transaction processing. Measurement data snapshots are used by data aggregation in Market Settlements Management.

Measurement data snapshot configuration is done in the **Extract To Measurement Data Snapshots** section, and includes the following options:

- **Measurement Data Snapshot Type:** The measurement data snapshot type for measurement data snapshots created by the usage rule.
- **Usage Transaction ID To Use:** A flag that designates the type of ID to use to identify the usage transaction on the measurement data extract. Options include:
 - **Usage Transaction ID:** The usage transaction's ID
 - **Usage Transaction External ID:** The external ID for the usage transaction. Used when the usage transaction is triggered by external system such as a CIS (or by the billing functionality in Customer To Meter)
- **Extract To Different Usage Subscription:** A flag that designates whether or not the measurement data snapshot should be extracted to a different usage subscription, such as one used by Market Settlements Management. Options include:
 - **No:** The extract will reference the usage subscription for which usage calculations are being processed. This option is used when Meter Data Management and Market Settlements Management are installed in different application environments. In this case, the extract can be exported from Meter Data Management for subsequent import into Market Settlements Management.

- **Yes:** The extract will reference a different usage subscription such as one used by Market Settlements Management. This option is used when Meter Data Management and Market Settlements Management are installed in the same application environment. In this case, the measurement data snapshot is “exported” within the system to the Settlement Item, where it can be used in data aggregation processing. When this option is selected, the **Source Identifier Type** and **Target Identifier Type** fields must be configured to define how the system will determine the correct settlement usage subscription to use.
- **Irregular Data Flag Mapping:** Ranges of condition codes used to flag data as “irregular”. The value of the **Irregular Data Flag** (based on the IRREGULAR_DATA_FLG lookup) is used to flag data that falls with each range configured. A blank **Irregular Flag** value denotes that the condition range is considered to be "Regular".

See [About Measurement Data Snapshots](#) for more information about measurement data snapshot creation and processing.

Configuring Usage Calculation Rules

This portal is used to display and maintain a usage calculation rule.

Refer to [Understanding Usage Calculation Rules](#), [Understanding Usage Calculation Groups](#), and [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Rule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Rule:** Defines the usage calculation rule, including parameters used when executing the rule
- **Eligibility Criteria List:** Lists the eligibility criteria defined for the rule

Pre-Calculation Usage Calculation Rules

The following is a list of the pre-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Alignment and Delay Usage Calculation Rule	Interval or Scalar	This rule can be used to handle two main needs: 1) aligns all measuring components for a Usage Subscription to the same date (whether on the same device or separate devices) 2) delays the usage transaction until the end of the retry window based on the quality of available data and other configured parameters.
Check Existence of Installed Device	Interval or Scalar	This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.

Calculation Usage Calculation Rules

The following is a list of the calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Apply Math (Interval Data)	Interval	<p>This rule is used to perform calculations on interval data and stores the results in the usage transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions).</p> <p>This rule provides aggregated usage for all selected interval measuring components (filter by TOU, SQI & UOM) associated to a usage subscription.</p> <p>This rule can also multiply total usage by a factor using a custom formula.</p>
Coincident Peak and Individual SP Demand	Interval	<p>This rule is used to calculate the coincident peak demand for all of the service points on the usage subscription and the demand values for each service point at the coincident peak. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).</p>
Daily Scalar Usage Calculation Rule	Scalar	<p>This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified usage period. It creates bill determinants by taking the difference between the beginning and ending reading for the bill period.</p> <p>This rule can also be used to provide register readings by measuring component.</p> <p>For consumption values, only the beginning and ending readings are exported</p> <p>This rule supports date breaks (the normal Get Scalar Data rule does not).</p>
Get Interval Data	Interval	<p>This rule is used to get interval quantities from interval measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.</p> <p>This rule retrieves the interval data for measuring components associated to a usage subscription by TOU, SQI and UOM.</p> <p>This rule converts the interval data to another interval length or unit of measure.</p>

Get Item Counts and Consumption	Interval or Scalar	This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption.
Get Scalar Details	Scalar	<p>This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period.</p> <p>This rule creates bill determinants by summing all scalar readings for the bill period. This rule can also be used to provide register readings by measuring component. All readings are exported by this rule.</p> <p>Note: This rule is used for traditional monthly read meters.</p>
Get Subtractive Interval Details	Interval	<p>This rule is used to get interval quantities from subtractive interval measuring components installed on the service points linked to the usage subscription for the specified 'interval' usage period.</p> <p>It also identifies the start and stop readings for each usage period using subtractive interval readings.</p>
Get TOU Mapped Usage	Interval	This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.
Interval Tier Calculation	Interval	<p>This rule calculates the difference between a source and reference vector.</p> <p>This rule loops through each tier that is configured and calculates the imbalance amount associated to that tier level.</p> <p>This rule breaks down that difference into one to many positive or negative tiers, and create a service quantity for each tier calculated.</p>
Profile Accumulation	Interval	This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.
Rolling Demand	Interval	This rule is used to calculate rolling demand for all of the service points on the usage subscription. Rolling demand can be based on a rolling consumption total, rolling consumption average, or coincident peak

demand. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).

Round and Adjust Usage	Interval or Scalar	This rule copies identified source and target Service Quantities and inserts these as Service Quantities that are rounded and adjusted.
Vector and Service Quantity Math	Interval	<p>This rule is designed to facilitate configuration of complex vector calculations. It is based on a series of underlying services with vectors configured as input to the calculations.</p> <p>Typical uses:</p> <p>Perform math using interval data, e.g., take the difference between two curves, find max values, find coincident peaks, multiply a curve by a value, apply TOU maps, etc.</p> <p>Define complex formulas using various interval curves, profile factor values or calculated service quantities (bill determinant values).</p> <p>Support math functions: sin, cos, square root, etc.</p> <p>Store derived curves in memory that can be used in subsequent calculations</p> <p>Please note, this rule is not as efficient as other rules.</p>

Post-Calculation Usage Calculation Rules

Below is a list of the post-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Usage High/Low Rule	Interval or Scalar	This rule compares the Service Quantities of the Usage Transaction to historical values. If the current value is too high or too low compared to historical data then an exception is thrown.
Validate Against Tolerance	Interval or Scalar	This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.
Business Flag Hold	Interval or Scalar	This rule can stop a usage transaction from proceeding when there have been business flags for the applicable service points. The hold can either be indefinite or set to expire

Decision-Making Usage Calculation Rules

There are usage calculation rules delivered as part of the base product that help with decision-making when executing running the usage calculation process. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Purpose
Execute Usage Calculation Group	This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group.
Exception Handler	This rule is used to terminate execution of the usage processor if exception count criteria specified in the rule is met.

Advanced Aside: Using Factors For Variables

A situation common in some implementations involves converting one unit of measure (UOM) to another. However, the conversion factor used in conversions of this can differ based on many different types of criteria, such as the location of the service point or other characteristics. This sort of calculation can be implemented as a usage calculation rule that accumulates consumption for one UOM and converts the consumption to a different UOM by applying a factor to it.

Factors used for this purpose have a Factor Class of "Number," and use some unique rules:

- Number factors reference a characteristic type (with pre-defined values).
- Number factors reference an algorithm that retrieves or derives the value of the characteristic type at runtime.

Factor values for a Number factor are effective-dated pairings of a characteristic value and a corresponding value. Because these pairings are effective-dated, the value returned from the factor can change over time for each characteristic value. At run time, the rule retrieves / derives the characteristic value for the factor's characteristic type and then finds the value associated with the respective characteristic value. Factors can be related to any real or dynamic attribute, so rules of this type are very flexible. For example:

- **Real Attribute:** you could create a rule that retrieves a specific value based on the location of a service point.
- **Dynamic Attribute:** you could create a rule that retrieves a percentage value based on the amount the customer conserved as compared to the same period in the prior year, returning one value if the amount conserved is between 5% and 10%, another value if the amount conserved is between 10% and 20%, and yet a third value if the amount conserved is greater than 20%. The amount conserved is dynamically calculated at execution time and is compared to the characteristic values defined for the factor, and returns the appropriate value. In this example, if the amount conserved was anything less than 5%, no percentage value would be returned.

Pre-Calculation Usage Calculation Rules

Alignment and Delay Usage Calculation Rule

This rule attempts to delay usage calculation until high quality data for calculating bill determinants have become available. It is especially useful for usage subscriptions having multiple sources of usages such as multiple service points or multiple measuring components on the installed meter. The rule ensures that the usage calculated is based on a common date or alignment date, identified for these sources.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ALGNDELAY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-AlignmentandDelay

Check Existence of Installed Device

This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CHKEXTDVC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Get the total KWH for the period

Calculation Type = Single Variable

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
- UOM = KWH
- Set Function = Sum

Scenario 2: Get the higher value between the total KWH or total KVARH

Calculation Type = Math Function

Math Function = Max

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KWH
 - Set Function = Sum
-

Variable Name = V2, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KVARH
 - Set Function = Sum
-

Scenario 3: Total KWH multiplied with a factor value

Calculation Type = Mathematical Expression

Mathematical Expression = V1 * V2

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KWH
 - Set Function = Sum
-

Variable Name = V2, where the following is configured:

- Variable Type = Factor
 - Factor = factor code that holds the multiplier
-
-

Daily Scalar Usage Calculation Rule

This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified 'Interval' usage period. Only automatically read scalar measuring components with value identifier that matches usage calculation rule's UOM/TOU/SQI will be processed.

If configuring this rule with interval and scalar usage calculation rules under a usage calculation group, it should be executed after interval usage calculation rule and before the scalar usage calculation rule.

This rule calculates usage based on the beginning and ending reading values -- ignoring intermediate readings. This rule will not estimate data based on the usage transaction estimate flag. Frequently read scalar devices must use periodic estimation processes.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETFRESCR Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CalFrequentlyReadScalar

Get Interval Data

This rule is used to get interval quantities from interval measuring components installed in the service points linked to the usage subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule are processed. Measurements within the period are stored in the usage transaction's service quantities' interval data list. The SQ entry's quantity is calculated based on the **Calculate Function** defined in the usage calculation rule. This is done for every entry in the usage period list. Each service quantity recorded by this rule is linked to a service point and measuring component.

By supplying the Axis Conversion parameters on the usage calculation rule, this algorithm will convert the identified measuring component's consumption into the supplied UOM and interval size prior to storing the consumption into the service quantity's interval data list.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETINTDAT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetIntervalData

Get Item Counts and Consumption

This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption. Once the item detail entries are created, the rule processes goes through them to create usage period SQs.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETITEMCC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetItemCountsConsumption

Get Scalar Details

This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period. By default all scalar measuring components are processed but if specific UOMs/TOUs/SQIs are defined in the usage calculation rule then only applicable measuring components are processed. Measurements within the period are retrieved. The usage transaction request may indicate whether or not 'Estimate' measurements are allowed.

The measurement details are stored in the usage transaction's scalar details. The usage is also stored in the usage transaction's service quantities unless otherwise specified in the usage calculation rule (using Build Service Quantity indicator).

This rule can be configured to perform measurement quality assessment, which will result in the population of the measurement quality list with the quantities and corresponding conditions of those measurements (regular, estimated, etc.).

Please note: this rule should not be used with readings occurring daily or more frequently as it will retrieve all of the readings to store in the Usage Transaction. The [Daily Scalar usage calculation rule](#) may be a better option for this use case.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETSCALAR Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetScalar

Get Subtractive Interval Details

This rule is used to calculate the usage for a subtractive interval measuring components. This differs from the Get Interval Data usage calculation rule in that it also retrieves a start and stop reading for each usage period it calculates. The start and stop readings are then used to provide entries into the usage scalar details table which are then made available in the usage transaction sent to the billing system for bill presentment.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUBINTADJ Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetSubtractiveInterval

Get TOU Mapped Usage

This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule instance are processed.

Measurements within the period are mapped to time of use quantities based on the TOU map defined on the usage calculation rule. If dynamic options are specified in the referenced TOU map and if there are dynamic option events in effect within the usage period then the TOU map associated with the dynamic option is used for the entire dynamic option event period. This calculation is performed for every usage period requested.

The calculated time of use quantities are stored in the usage transaction's service quantities per Service Point and measuring component.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETTOUUSG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetTOUUsage

Interval Tier Calculation

This rule calculates the difference between a source and reference vector. It then breaks that difference into one to many positive or negative tiers. For each tier calculated it will create a service quantity with the optional ability to create additional service quantities for the total of all positive tiers and the total of all negative tiers. This rule will loop through each tier that is configured and calculate the imbalance amount associated to that tier level.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETINTIER Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalTierCalculation

Profile Accumulation

This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.

The typical application of this rule is for customer self-service rate compare, in which a self-service user has selected a set of usage adjustments to apply to their historical consumption to assess the effect on the amount consumed.

This rule algorithm retrieves the customer's usage (the source UOM) for the usage period using one of two options:

- A channel linked to a Usage Subscription
- A usage transaction service quantity

Then it takes each entry in the usage transaction's profile factor list, finds the profile measuring component for each, retrieves the measurement data for the profile, applies axis conversion to align it to the source UOM and target interval size, and adds it to the source vector. Each profile's data is added progressively to arrive at a final vector. The final vector may then be TOU-mapped, and the vector itself may be preserved or discarded.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-DYNPRFLAC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileAccumulation

Profile Service Quantity

This rule intervalizes scalar service quantity values based on a profile measuring component.

This rule first retrieves scalar service quantities, identified by the rule's UOM/TOU/SQI. If multiple service quantities exist for the service point they will be summarized at the service point level. In the case of a split or broken usage period for a service point, the usage period is merged and the quantities are summarized. Each service quantity is subject to intervalization. The profile measuring component is then derived using the profile factor supplied with either the usage

subscription or service point as characteristic sources. If the profile is not available, an exception will be created using the exception details on the rule.

If a dynamic option type is provided, the events associated with it are retrieved for the usage transaction period. Any intervalized quantities that coincide with the dynamic option events start/end date time are then recorded in a new usage period service quantity of usage type "Correlated SQ".

If no dynamic option type is provided, the intervalized quantities are recorded in a new usage period service quantity of usage type "Profile SQ".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-PRFSVCQTY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileServiceQuantity

Rolling Demand

This rule is used to calculate rolling demand for all of the service points on the usage subscription. Demand is calculated from consumption. In electric service markets, these are typically represented by kilowatts (kW) and kilowatt hours (kWh) respectively, where demand values are calculated by multiplying consumption interval values by the number of intervals per hour. For example, the demand associated with a fifteen (15) minute interval value of 25kWh would be 100kW (25 x 4 intervals per hour).

This rule has two main modes: calculating rolling demand for a usage subscription based on either a rolling consumption total (Total) or rolling consumption average (Average), or calculating the coincident peak among all of the service points on a usage subscription based on either a rolling consumption total (Total - Coincident Peak) or rolling consumption average (Average - Coincident Peak). The coincident peak calculation can be performed on either all readings, or those designated as "on-peak" or "off-peak" via time of use mapping using the Coincident On-Peak or Coincident Off-Peak function, See [Defining Time of Use Mapping Options](#) for more information about time of use mapping.

The number of intervals in the rolling total or rolling average is determined via rule configuration. The **Roll Interval Size** parameter (in the **Calculation Details** section) divided by the **Common Interval Size** parameter (in the **Interval Data Retrieval Parameters** section). For example, if **Roll Interval Size** was 01:00:00 (1 hour) and the **Common Interval Size** was 00:15:00 (15 minutes), the rolling total or average would be based on sets of 4 intervals (1 hour divided by 15 minutes).

Rolled Demand Total

The "Rolled Demand Total" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling consumption total.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	100
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	105
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	105

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak

The "Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak" **Roll Calculate Function** identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling total at the coincident peak.

The data used in the calculation is based on the specific **Roll Calculate Function** selected:

- **Total - Coincident Peak:** Evaluates all measurements matching the configured unit of measure
- **Total - Coincident On Peak:** Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Total - Coincident Off Peak:** Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest total for all of the service points within the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	100
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	105
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represent the demand at the coincident peak:

Date/Time	Coincident Peak Demand
10/27/2022 4:00 PM	100

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average

The "Rolled Demand Average" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling average (calculated from the rolling total).

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Rolling Average:** The rolling average of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 12:00 PM	12	11	23			
10/27/2022 1:00 PM	10	12	22			
10/27/2022 2:00 PM	11	13	24			

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 3:00 PM	13	13	26	95	23.75	23.75
10/27/2022 4:00 PM	14	14	28	100	25	25
10/27/2022 5:00 PM	13	13	26	104	26	26
10/27/2022 6:00 PM	12	13	25	105	26.25	26.25
10/27/2022 7:00 PM	11	12	23	102	25.5	25.5
10/27/2022 8:00 PM	12	13	25	99	24.75	24.75
10/27/2022 9:00 PM	13	14	27	100	25	25
10/27/2022 10:00 PM	12	14	26	101	25.25	25.25
10/27/2022 11:00 PM	12	12	24	102	25.5	25.5

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	26.25

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average - Coincident Peak / Rolled Demand Average - Coincident On Peak / Rolled Demand Average - Coincident Off Peak

The "Average - Coincident Peak / Average - Coincident On-Peak / Average - Coincident Off-Peak" **Calculate Function** identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling average at the coincident peak.

The data used in the calculation is based on the specific **Roll Calculate Function** selected:

- **Rolled Demand Total - Coincident Peak:** Evaluates all measurements matching the configured unit of measure
- **Rolled Demand Total - Coincident On Peak:** Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Rolled Demand Total - Coincident Off Peak:** Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Rolling Average:** The rolling average of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))

- **Demand:** The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 12:00 PM	12	11	23			
10/27/2022 1:00 PM	10	12	22			
10/27/2022 2:00 PM	11	13	24			
10/27/2022 3:00 PM	13	13	26	95	23.75	23.75
10/27/2022 4:00 PM	14	14	28	100	25	25
10/27/2022 5:00 PM	13	13	26	104	26	26
10/27/2022 6:00 PM	12	13	25	105	26.25	26.25
10/27/2022 7:00 PM	11	12	23	102	25.5	25.5
10/27/2022 8:00 PM	12	13	25	99	24.75	24.75
10/27/2022 9:00 PM	13	14	27	100	25	25
10/27/2022 10:00 PM	12	14	26	101	25.25	25.25
10/27/2022 11:00 PM	12	12	24	102	25.5	25.5

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 4:00 PM	25

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Notes and Recommendations

- When using the "Coincident On Peak" or "Coincident Off Peak" **Roll Calculate Function**, you must specify either a TOU map (in the **TOU Map** field) or a TOU map template (in the **On Peak Off Peak Schedule** drop-down list) in the **Calculation Details** section, and specify the appropriate time of use period (On-Peak or Off-Peak, respectively) in the **TOU** field in the **Results** section.
- A recommended practice is to configure a Service Quantity Identifier (SQI) to uniquely identify coincident peak data and specify it in the **SQI** field in the **Results** section.

Note: Additional detail on the logic of this rule can be found in the **Detailed Description** of the D1-CALROLDDEM Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-CalcRollingDemandRule

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Calculate demand for services points based on rolling total

- **Interval Data Retrieval Parameters:**
 - **UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Total
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 2: Calculate demand for services points based on rolling average

- **Interval Data Retrieval Parameters:**
 - **UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Average
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 3: Total - Coincident Peak

- **Interval Data Retrieval Parameters:**
 - **UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Total, Coincident Peak
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:** Coincident Peak

Scenario 4: Average - Coincident On Peak

- **Interval Data Retrieval Parameters:**

- **UOM:** Kilowatt-Hour
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Average, Coincident, On Peak
 - **Roll Interval Size:** 01:00:00
 - **Reference TOU Map by Template:** Yes
 - **On Peak Off Peak Schedule:** <TOU map template>
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:** On Peak
 - **SQI:** Coincident On Peak

Round and Adjust Usage

This rule copies identified source and target Service Quantities and inserts these as period Service Quantities that are rounded and adjusted. This rule captures the source and target Service Quantity identifiers, rounding method, and Service Quantity bucket to hold the adjustment. The usage calculation rule also has an option to validate the difference between the source and target service quantities.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RNDADJUSG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RoundAndAdjustUsage

Vector and Service Quantity Math

This rule is designed to facilitate configuration of complex vector and scalar quantity calculations. It is based on a series of underlying services, including Axis Conversion, Apply Formula (most importantly), and Apply TOU Map. It can be configured to accept as input up to five vectors - where a single vector can represent the combination of all measuring components with linkages to the Usage Subscription with the configured UOM/SQI. It can also accept a list of scalar variables that can be taken in as factor values, usage transaction service quantities, set functions on a vector, or numeric values.

Vectors can be combined using a simple formula expression, or using condition formula expressions. Both interval values and interval conditions can be referenced. The result is interval-by-interval processing of the vector formula. The resulting final vector can be stored, TOU mapped, and/or subjected to a final set function (such as sum or max).

This rule stores service quantities of type "other" - meaning that the service quantities created by this rule do not have linkages to a specific Service Point or measuring component, given the potentially diverse sources of the data taken as input by this rule that lead to the final quantity.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-MATH Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-Math

Post-Calculation Usage Calculation Rules

Usage High/Low Rule

This rule is used to validate the current usage against historical usage - previous year usage or previous usage. It ensures that any increase or decrease of the current usage relative to historical usage is within a tolerance.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-USGHIGLOW Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UsageHighLowRule

Validate Against Tolerance

This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-VALUSGTOL Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ValAgainstTol

Business Flag Hold

This rule can be used to place a hold on a usage transaction until the business flags related to the usage transactions service points can be investigated. The hold can be placed in one of two ways:

- **Calculation Window Based:** holds will remain until either a user manually bypasses the usage exception error or the current date is within a configurable tolerance of the calculation window end (aka the retry until date time).
- **Indefinite:** holds require a user to manually bypass the usage exception that is generated.

Defining which business flags should result in a usage transaction is a matter of identifying which business flag types, priorities, and confidences should be included.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-AUR-IBFH algorithm type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-BusinessFlagHold

Decision-Making Usage Calculation Rules

Execute Usage Calculation Group

This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group. It is especially useful in cases where repeating the same rule over and over would be hard to maintain.

For example, you may want to calculate a straightforward kWh sum for every usage calculation group. Creating a separate CALC_KWH_SUM usage calculation group for this one calculation allows you to isolate the configuration points. Then the CALC_KWH_SUM usage calculation group can be referenced in every other usage calculation group that needs this sort of service quantity.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AUSGR-RFG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-UsageRuleReferredUsageGroup

Exception Handler

This rule evaluates the exception list that was accumulated during the execution of the calculation rules against exception criteria configured on this rule. This used to terminate the execution of usage calculation group processor if there are far too many exceptions hit during the execution.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-UREXPCHAN Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UsageRuleExceptionHandler

Detailed Configuration Examples

Demand Calculation Options Using Interval Data

There are a number of ways to calculate a demand value from interval data when retrieving bill determinants for CIS. A few examples of demand calculations are listed below:

Scenario 1: Use interval data for demand at a common block size: the [Vector and Service Quantity Math](#) usage calculation rule can be used to calculate demand from the interval data. Below is one example of configuration to handle demand calculation based on 30 minute blocks:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	Yes	
Result // SQ Entry Quantity Source	Set Function Against Derived Vector	
Result // Set Function Against Derived Vector	Max	This function pulls the max value based on the configuration in the "Vector Processing" section.

Scenario 2: Use interval data for demand by TOU period: This example is very similar to the last and again leverages the [Vector and Service Quantity Math](#) usage calculation rule. However, instead of calculating a single demand value for the entire period it will calculate a demand value for each TOU period:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.

Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	No	
Result // Apply TOU Map To Derived Vector	Yes	
Result // TOU Map	(your TOU Map)	Select the TOU Map you'd like to apply.
Result // Time Of Use Calculate Function	Max	This function pulls the max value based on the configuration in the "Vector Processing" section and then buckets it based on the selected TOU Map.

Usage Calculation Types

Understanding Usage Calculation Types

Usage calculation types define calculations executed at a customer level where there may be more than one calculation per usage subscription. For example, a customer may have a usage subscription for producing billing determinants but there may be additional calculations that will be executed on a much less frequent basis (annually, quarterly, etc). Usage calculation types provide a way to leverage a single usage subscription to drive multiple different calculations.

Usage calculation types use the following parameters:

- **Request Type:** Used to drive the creation and processing of the usage transactions for all usage subscriptions that are valid for the usage calculation type.

NOTE: Request types for usage calculation types should be based on the Usage Calculation Request Type business object (D2-UsageCalculationReqType)

- **Service Point Quantity Creation:** Details of the quantities created by usage calculations of this type, including service point quantity type, and UOM, TOU, and SQI.
- **Applicable Usage Subscription Types:** A list of usage subscription types for which this usage calculation type is applicable. Each usage subscription type is defined by an effective date range, the usage transaction business object used for the usage calculation, the result UOM/TOU/SQI, and the usage calculation group used to perform the calculations.

Configuring Usage Calculation Types

You use the **Usage Calculation Type** portal to maintain and view usage calculation types.

Refer to [Understanding Usage Calculation Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Type List:** This zone lists all usage calculation type records. Broadcast a record to display the details of the selected record.
- **Usage Calculation Type:** This zone displays details for the selected usage calculation type.

Usage Subscription Quantity Types

Understanding Usage Subscription Quantity Types

Usage subscription quantity types define types of quantities that can be stored for a usage subscription. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, usage subscription quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Usage subscription quantity types use the following parameters:

- **Service Type:** The service type (electric, gas, water, etc.) for service point quantities of this type.
- **Usage Subscription Quantity Business Object:** The business object used for usage subscription quantities of this type.
- **Usage Subscription Quantity Identifiers:** Value identifiers related to the current usage subscription quantity type (used to provide shorthand descriptions of the various types of values measured by usage subscription quantities of this type).

Configuring Usage Subscription Quantity Types

You use the **Usage Subscription Quantity Type** portal to display and maintain usage subscription quantity types.

Refer to [Understanding Usage Subscription Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Quantity Type List:** This zone lists all usage subscription quantity type records. Broadcast a record to display the details of the selected record.
- **Usage Subscription Quantity Type:** This zone displays details for the selected usage subscription quantity type.

Dynamic Option Types

Understanding Dynamic Option Types

Dynamic options specify terms that override how usage is normally calculated, such as a critical peak period that affects the TOU mapping of interval consumption. Dynamic option types store information common to dynamic options of a specific type.

There are two classes of dynamic options:

- **Interval Set:** Used to represent dynamic option types that provide a set of intervals that will be included in a calculation.

- **Usage Event:** Used to represent dynamic option types that provide a specific period of time during which a dynamic option is applicable.

Interval Set dynamic option types also define key information about the interval data they represent, including:

- **Unit of Measure:** Identifies the quantity that Interval Set dynamic options and Interval Set dynamic option events based on this type are measuring.
- **Interval Size:** Defines the size of the intervals for Interval Set dynamic option events of this type, represented as hours:minutes:seconds (HH:MI:SS).

Configuring Dynamic Option Types

This portal is used to display and maintain a Dynamic Option Type.

Refer to [Understanding Dynamic Option Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Dynamic Option Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Dynamic Option Type List:** displays all of the Dynamic Option Types so you can choose the one you want to display in more detail
- **Dynamic Option Type:** shows the specific configuration for the selected Dynamic Option Type

Bill Cycle

Understanding Bill Cycle

Bill cycle identifies window period when a customer is going to be billed and when the bill determinants are going to be calculated.

Configuring Bill Cycle

This portal is used to display and maintain a Bill Cycle.

Refer to [Understanding Bill Cycle](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Bill Cycle**.

The following zones may appear as part of the portal's **Main** tab page:

- **Bill Cycle List:** displays all of the Bill Cycles so you can choose the one you want to display in more detail.
- **Bill Cycle:** shows the specific configuration for the selected Bill Cycle.
- **Bill Cycle List:** lists the bill cycle schedules of the current bill cycle.

Defining Time of Use Mapping Options

Time of Use Groups

Understanding Time of Use Groups

Time of Use (TOU) Groups are groups of TOUs that are associated to TOU templates that limit the TOUs available for use in a TOU schedule. These TOUs will be available as the default, holiday, and schedule TOUs within the template.

Each TOU in the group is given a priority. The priority is important in a few ways:

- The [TOU Overlay](#) 360 Degree zone uses these priorities to decide which TOUs will be rendered as a unique shade and which will fall into a category of "other" when the maximum number of distinct TOUs to graph has been reached.
- These priorities are available for use in customized logic.

Configuring Time of Use Groups

This portal is used to display and maintain a TOU Group.

Refer to [Understanding Time of Use Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Group**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Group List:** This zone lists all TOU Group records. Broadcast a record to display the details of the selected record.
- **TOU Group:** This zone provides information about the selected TOU Group.

Time of Use Map Templates

Understanding Time of Use Map Templates

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period.

The system periodically generates TOU map data for TOU maps by interpreting the rules defined template.

Attributes used to define TOU map templates include the following:

- **TOU Group:** the TOU group used by the map template Default TOU: the default TOU for the map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
- **Work Calendar:** the work calendar used to identify holidays. On each holiday the Holiday TOU will be used. For additional information see [Defining Work Calendar](#) in the Oracle Utilities Application Framework *Administrative User Guide*.
- **Holiday TOU:** the TOU used for holidays (from the TOU Group)
- **Holiday Template:** the TOU map template used for holidays (if applicable)
- **Interval Size:** the size of the intervals for TOU map data created from the map template, represented as hours:minutes:seconds (HH:MI:SS).

- **TOU Schedules:** date ranges (including month, day, and time ranges) and which TOU periods apply to each

Refer to [Understanding Referencing Master Data by Identifiers](#) for information on how admin configuration can reference a TOU map by a TOU template to ease migration of data between environments.

TOU Map Template Interval Size

TOU map templates can also specify an interval size (in seconds-per-interval, or SPI). This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose SPI is divisible by the template's SPI. For example, a 60 minute template can be used to generate TOU data for TOU maps with SPIs of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every SPI.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays in two ways. Both options require that the template references a Work Calendar that identifies each of the holidays throughout the year. In addition they require either:

- A Holiday TOU that will be used for each holiday for the duration of that holiday (e.g. Off Peak)
- A Holiday TOU Map Template that defines the TOUs that should be used for holidays that fall during different seasons within the year (e.g. Off Peak Summer, Off Peak Winter)

Important Time of Use Template System Events

The time of use template supports the following business object algorithm system events:

- **Derive TOU:** receives a date time and determines the TOU code for that date time based on the configuration of the time of use template schedule. See the Derive Time Of Use For Date Time (D2-DERTOU-DT) algorithm type as an example.

Configuring Time of Use Map Templates

This portal is used to display and maintain a TOU Map Templates.

Refer to [Understanding Time of Use Map Templates](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Template**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Template List:** This zone lists all TOU Map Template records. Broadcast a record to display the details of the selected record.
- **TOU Map Template:** This zone provides information about the selected TOU Map Template.

Time of Use Map Types

Understanding Time of Use Map Types

TOU Map Types define important properties of TOU maps of the type, including the interval size and the valid TOU map templates.

Attributes used to define TOU map types include the following:

- **Time Zone:** the time zone to be used when generating the TOU map data. Refer to [Multiple Time Zone Support](#) for more information about how time zones impact TOU map data in multiple time zone environments.
- **Interval Size:** the size of the intervals for TOU map data created from maps of this type, represented as hours:minutes:seconds (HH:MI:SS). The interval size cannot be larger than the interval size defined on the Default TOU Map Template or any of the Override TOU Map Templates.
- **Default TOU Map Template:** the default TOU map template used by maps of this type
- **Override TOU Map Templates:** one or more TOU map templates that can be used as an override on TOU maps of this type.

TOU Map Type Interval Size

The SPI of a TOU map must divide evenly into the SPI of any measuring component that uses the map (because the system joins the date/time of the measurement to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute measuring component. However, it is not OK to have a 60 minute TOU map used with a 15 minute measuring component because the join will miss 3 out of 4 measurements.

However, it is important to note that the TOU mapping process is at its most efficient when the measurement data that is being mapped is of the same interval size as the TOU schedule it is being mapped against. When there are differences in the interval size the process must first convert the measurement data into the appropriate interval size for the TOU Map prior to applying the TOU Map.

This means that for each TOU Map Template you should have sufficient TOU Map Types to cover the various interval sizes that will be supported by your measurement data. For example, if you have measuring components with interval sizes of 15 minutes, 30 minutes, and 60 minutes then for each TOU Map Template there should be TOU Map Types with interval sizes of 15 minutes, 30 minutes, and 60 minutes.

Default and Override TOU Map Templates

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support a fallback/override pattern used in other areas of the system.

- A TOU map's TOU map type defines the default (or "fallback") TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the "fallback" template.
- An individual TOU map can have an override template. If the TOU map doesn't have an override template, the fallback template defined on the TOU map type is used to generate the map's TOU data.

Important Time of Use Map System Events

The TOU Map business object that is associated to a given TOU map type supports a special system event that is used in the generation of TOU map data:

- **Create TOU Map Data:** receives a date range and for that date range it will create the appropriate TOU map data for the TOU map. See the Create TOU Map Data (D2-CRETMD-CT) algorithm type as an example.

Configuring Time of Use Map Types

This portal is used to display and maintain a TOU Map Types.

Refer to [Understanding Time of Use Map Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Type List:** This zone lists all TOU Type records. Broadcast a record to display the details of the selected record.

- **TOU Map Type:** This zone provides information about the selected TOU Map Type.

Defining Premise and Service Point Options

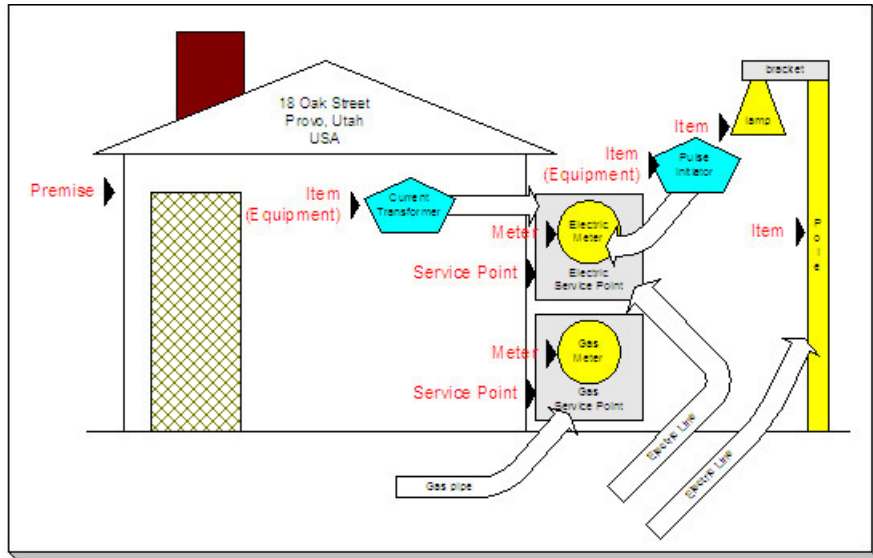

A premise is where a customer consumes the services supplied by your company. Located at a premise are the various devices that consume energy and measure consumption. Before you can define premises and devices, you must set up the control tables defined in this section.

WARNING:

The topics in this section do not describe every table that must exist in order to set up premises and service points. Many premise and service point control tables are described in [Defining Device Options](#), and [Defining Service Order Options](#). The tables described in this section are those that must be set up regardless of the type of service.

An Illustration Of A Premise

The following picture illustrates a premise with 2 service points, 2 meters, and 2 badged items:

The following concepts are illustrated above:

Premise A premise describes a location at which your company supplies some type of service. In addition to the obvious address information, a premise also contains geographic coordinates, meter read instructions, and taxation jurisdiction information.

FASTPATH:

For more information about the control tables that must be set up before you can define a premise see [Setting Up Premise Options](#).

Service Point A service point (SP) is a geographic location at which service(s) are delivered to a premise. The SP record maintains information about the type of service, the measurement cycle (if the service is metered), the field office responsible for maintaining the service, the distribution company that supplies the service, etc.

There are three major categories of service points:

- Those where the rate of consumption and the total amount of consumption is measured (e.g., electricity, gas, water) by a meter. You can think of this type of service point as a "socket" into which a meter can be plugged. Over time, many meters may be plugged into the socket. We refer to these types of service points as metered.
- Those that hold badged items. A badged item is a physical device with a unique identity (e.g., a specific street light, a specific hydrant). You can think of this type of service point as a "socket" into which a badged item can be plugged. Over time, many items may be plugged into the socket. We refer to these types of service points as item-based.
- Those used to hold one or more non-badged items. For example, if your organization doesn't badge street lamps, you can use a single service point to hold an infinite number of lamps. We refer to these types of service points as non-badged.

FASTPATH:

Refer to [Service Points \(SPs\)](#) for more information about non-badged items.

An unlimited number of SPs may exist at a premise. However in reality, the number of SP's is related to the number of services supplied by your company. For example, an electric and gas company will typically have two SPs per premise.

FASTPATH:

For more information about the control tables that must be set up before you can define service points refer to [Setting Up Generic Service Point Options, Defining Device Options](#).

Field activities may be dispatched to all types of service points.

Meter A meter is a physical device used to measure the amount of gas, water, or electricity used by a customer. While most meters measure consumption in a single unit of measure (e.g., gallons, cubic feet, kilowatt-hours), some electric meters are extremely sophisticated and measure several different factors. For example, some electric meters measure how much was used, when it was used, the efficiency of consumption, the maximum amount used, and a few other unusual things.

FASTPATH:

For more information about the control tables that must be set up before you can define a meter, refer to [Defining Device Options](#), and [Setting Up Consumption Estimation Parameters](#).

Item An item that is not consider to be "equipment" is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. Items are related to service points and a service point can have one or more items linked to it.

FASTPATH:

For more information about the control tables that must be set up before you can define an item, refer to [Configuring Device Types](#).

For more information about premises and service points, refer to [Understanding The "V"](#).

Setting Up Premise Options

This section describes tables that must be set up before you can define premises.

Defining Premise Types

Open **Admin > Geographic > Premise Type** to define the premise types used to categorize your premises.

Description of Page

Enter a unique **Premise Type** and a **Description** for every premise type.

Allow CIS Division controls whether premises of this type can use the CIS Division on the premise page. Valid values are Not Allowed, Optional, and Required.

If your implementation requires restricting data by CIS Division, it is recommended that Allow CIS Division be set to Required.

Implementing Address Validation

In order to set up address validation, you must ensure that the following Option Types are defined with their corresponding values on the General System Configuration – Feature Configuration page:

Option Type	Description
Address Validation Script	Indicates the name of the BPA script to invoke when a user clicks on the validate address button. This option is required if the Allow Address Validation option is set to Y. The base product includes sample script C1-ValAddr that uses Oracle Spatial procedures and functions to geocode an address and return its matching quality code.
Allow Address Validation	Indicates whether an integration with address validation software is implemented. If set to Y, the system will render a validate button along with the address fields displayed throughout the application to trigger address validation. Valid values are 'Y' and 'N'. If set to Y, the Address Validation Script to invoke must be specified.

As described in the above table, the base product includes sample script C1-ValAddr uses Oracle Spatial procedures and functions to geocode an address and return a matching quality code. To use this script, ensure that the Oracle Spatial Geocoding (F1-ORAGEOCD) algorithm is plugged in on installation options for the geocoding service system event. A data source containing the geocoding data must also exist on the database.

If your implementation uses something other than Oracle Spatial for address validation, you'll need to create a new address validation BPA script to specify on the General System Configuration feature configuration. For additional information about creating this script, see the steps descriptions for the C1-ValAddr script in the application. The new script should contain the following move step to update the page:

- If the calling page is an old style page, the move from the BPA to the page can be achieved by specifying a move step from a source field to a User Interface Field.
- If the calling page is a display map, the move from the BPA to the page can be achieved by specifying a step to read the Business Object, modify the values as returned by the validation software, and then update the BO.

Setting Up Generic Service Point Options

This section describes tables that must be set up before you can define service points.

Setting Up Service Point Types

Every service point must reference a service point (SP) type. The SP type controls almost all aspects of the service point's behavior (e.g., the type of field activity that may be dispatched to it, the type of service agreement that may be linked to it, the type of device that may be installed at it).

The topics in this section describe the windows used to set up your SP types.

WARNING:

Setting up SP types requires careful analysis of your company's SA types, field activities, and its consumption estimation philosophy. Refer to [Designing SP Types](#) for more information about this design process.

Setting Up Premise & Service Point Postal Defaults

You set up postal defaults if your company is able to default field values onto new premises and service points based on the premise's postal code. The topics in this section describe how to maintain postal defaults.

FASTPATH:

For more information about where these default values are used, refer to [Maintaining Premises](#) and [Maintaining Service Points](#).

Postal Defaults - Main

To define premise postal defaults, open **Admin > Geographic > Postal Code Default > Add**.

Description of Page

Enter the **Country Code** and range of postal codes to which the default values apply using the **From Postal** and **To Postal**.

NOTE:

You may not have postal defaults whose from / to postal codes overlap.

Trend Area is not applicable for Customer to Meter.

Enter the **County** to be defaulted onto new premises located in this postal code range.

Enter the **City** to be defaulted onto new premises located in this postal code range.

Enter the **CIS Division** to be defaulted onto new premises located in this postal code range.

Enter the **State** to be defaulted onto new premises located in this postal code range.

Enter the **Time Zone** to be defaulted onto new premises located in this postal code range.

Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a premise.

FASTPATH:

For more information about characteristics, see [Setting Up Characteristic Types & Their Values](#) and [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

This information is defaulted when a new Premise is added. Characteristics and geographic values are also defaulted when the postal code for a Premise is changed. Refer to [Maintaining Premises](#) for more information.

Postal Defaults - Service Default

To define values to be defaulted for a service point located in a postal range, open **Admin > Geographic > Postal Code Default > Search** and navigate to the **Service Defaults** page.

FASTPATH:

For more information about where these default values are used, refer to [Maintaining Service Points](#).

Description of Page

Use the **Service Defaults** collection to define values to be defaulted on service points located in a given postal code range belonging to a given **Service Type** (note, a service point's Service Type comes from its SP Type).

Stock Location is not applicable for Customer to Meter.

- Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a service point.
- Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Designing SP Types

Every service point must reference an SP type. When you set up an SP type, you define how the system manages many aspects of its service points' behavior.

NOTE:

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SP types. In reality, setting up your SP types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing your SP types is an iterative process. To minimize the number of iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SP types.

SP Type	Service Type
---------	--------------

Service Segmentation

At a minimum, you will have one SP type for every different type of service that exists at your premises. If we assume that your organization sells gas, water, waste water and electricity services, you will need four SP types.

SP Type	Service Type
GAS	Gas service
WATER	Water service

WASTE WATER

Waste water service

ELECTRIC

Electric service

Device Segmentation

For each service, determine if there exist meters, badged items, or non-badged items at the service points. For example, if we assume:

- Electric service has service points with meters, badged lamps, and parking lots.
- Gas and water services just use meters.
- Waste water service doesn't actually have a meter installed at it (it uses the water consumption measured by the water service point's meter)

Then your SP types will be:

SP Type	Service Type	SP Sub Type
GAS - METERED	Gas service	Meter
WATER - METERED	Water service	Meter
WASTE WATER	Waste water service	Unbadged
ELECTRIC - METERED	Electric service	Meter
ELECTRIC - BADGED LAMP	Electric service	Item
ELECTRIC - PARKING LOT	Electric service	Unbadged

SA Type Segmentation

Every SP Type whose service points can be linked to a service agreement has one or more SA types. These define which type of service agreements can pay for the service point's service. If different service points have different valid SA types, you will need to split the SP types accordingly.

The SA Type segmentation of SP Types is the most complicated design decision you'll have to make. Unfortunately, the decision making process is subjective and iterative. The iterations are caused by the fact that the number of SA types is dependent on the number of SP types (and vice versa). We recommend the following to help work your way through this conundrum:

- Design your SA types using the information in [Defining Service Agreement Types](#).
- Return to your SP types and determine if, given the proposed SA types, you can define a list of valid SA types for each SP type. If you find the population of SA types (and their valid rates) could result in invalid rates paying for service at a service point, divide your SA types further.

Defining Bill and Measurement Cycles

This chapter is dedicated to issues related to defining cycles, routes and schedules in the system.

Defining Bill and Measurement Cycles

Every account references a bill cycle. An account's bill cycle controls when it is billed.

Every manually read metered service point references a measurement cycle. A service point's measurement cycle controls when a service point's meter is measured.

The design of your measurement and bill cycles is inextricably linked because you probably want to bill your customers shortly after their meter devices are measured.

In this section, we describe how to design and set up these cycles. In addition, we discuss how to set up bill period schedules. These are used to define the bill segment end date for special types of non-metered service agreements.

NOTE:

Recommendation. We recommend reviewing [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) before setting up this information.

The Big Picture of Bill Cycles, Measurement Cycles, and Bill Periods

The topics in this section provide background information about a variety of bill cycle, measurement cycle, and bill period issues.

Designing Cycles for Metered Services

The topics in this section provide background information about a variety of measurement cycle issues.

A Description of the Cyclical Meter Read Process

Manual meter readers using handheld devices record most meter reading measurements in the field. These meter reads are uploaded into the system for use by Oracle Utilities Meter Data Management.

A service point's installed meter device is measured due to the following data relationships:

- Every metered service point references a schedule route.
- A route references a measurement cycle.
- A measurement cycle has measurement cycle schedules that define when the service points in the cycle are measured.
- Every measurement cycle schedule contains two dates:
 - **Scheduled selection date.** This is the date Meter Data Management could use to select the service points in the cycle for download to your handheld software via custom algorithms to create handheld activities when pending measurement cycle schedules are proposed (refer to [Measurement Cycle and Bill Determinants](#) for more information).
 - **Expected work date.** This is the date the meter is expected to be read.

NOTE:

Overriding a route within a specific schedule. Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for

example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to [Designing Measurement Cycles, Routes, And Schedules](#) for more information.

- On the scheduled selection date, Meter Data Management could create a download file, via custom algorithms, containing information to be sent to your handheld software. This download file should contain information about every register or measuring component on every meter in the routes being downloaded.
 - Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant measurements are uploaded into the system for subsequent use by other processes such as usage transactions for billing.
-

WARNING:

It is very important to create a measurement cycle schedule for every expected read date regardless of whether the cycle's routes are downloaded. Why do you have to do this? Because Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement during usage calculations. If it can't find a reading on or near this date, Oracle Utilities Meter Data Management may estimate consumption. Without a measurement cycle schedule, MDM wouldn't know when to look for readings. So, for example, if you estimate a given cycle's consumption EVERY OTHER MONTH, you must create a measurement cycle schedule for EVERY month. On each month's schedule, you must define if the routes should be downloaded.

FASTPATH:

For more information about the how to control when a cycle is read, refer to [Setting Up Measurement Cycle Schedules](#).

Designing Measurement Cycles, Routes, And Schedules

The topics in this section provide information describing how to design your measurement cycles, routes, and schedules.

- [Designing Measurement Cycles For Meter Reading](#)
- [Designing Schedule Routes For Meter Reading](#)
- [Designing Metered Measurement Cycle Schedules](#)

Designing Measurement Cycles for Meter Reading

The criterion that affects the number of measurement cycles has nothing to do with when meter readers physically read your meter devices. Rather, the frequency that you bill the meter's consumption (real or estimated) is what controls the number of measurement cycles.

So, for example, if you bill every month, but read every OTHER month, you'll have 20 measurement cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 measurement cycles. If you bill quarterly, you'll have 60 measurement cycles. Etc.

NOTE:

Different billing frequencies are possible for different service points. If you have different billing frequencies for your different types of metered service, you'll need a different set of cycles for each billing frequency. For example, if you bill water quarterly and electricity monthly, you'll have 20 bill cycles (one for each bill day during a month), but you'd need 60 quarterly measurement cycles for your water service points, and 20 monthly measurement cycles for your electric service points. This would result in a customer getting billed every month. However, four times a year, their bill would contain a charge for both electricity and water.

[Top of the Page](#)

Designing Service Routes For Meter Reading

The following points describe the relationship between a meter read, a route and a measurement cycle:

- A measurement cycle contains one or more routes.
- A route has one or more service points.
- A service point holds an installed meter device.
- And a device is what is measured.
- Therefore, the number of devices a person can read in a day limits the number of service points in a route.

WARNING:

If your company supplies electric service and uses MV90's, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because usage calculation is dependent on the route's cycle to determine the expected meter read date.

[Top of the Page](#)

Designing Metered Measurement Cycle Schedules

The process of designing your measurement cycle schedules is either easy or complicated. It will be easy if all routes within a cycle are downloaded when the measurement cycle is scheduled for download. It will be complicated if you download a subset of routes within a cycle on any given download date. We'll provide a few examples to help explain why.

If you download all cycles in a route whenever the cycle is downloaded, your measurement cycle schedule will look as follows.

NOTE:

Bill cycles. We've included each measurement cycle's related bill cycle to help you understand when the measurement cycle's consumption will be billed. Bill cycles are discussed in [Bill Cycles](#).

Measurement Cycle	Download Date	Expected Work Date	Which Routes To Download	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	All	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	All	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	All	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	All	4	3-Jun-99 to 7-Jun-99	7-Jun-99

Etc. to 20

Now let's complicate life. If we assume you physically read your routes every other month (but bill monthly using estimated consumption), then you'll need the following measurement cycle schedule.

Measurement Cycle	Download Date	Expected Work Date	Which Routes	Bill Cycle	Bill Window	Estimation Date
1	30-May-99	31-May-99	1, 2, 3 - Download 4, 5, 6 - Estimate	1	31-May-99 to 2-Jun-99	2-Jun-99

2	31-May-99	1-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	2	1-Jun-99 to 3- Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	3	2-Jun-99 to 4- Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	4	3-Jun-99 to 7- Jun-99	7-Jun-99
Etc. to 20						
1	29-Jun-99	30-Jun-99	1, 2, 3 - Estimate 4, 5, 6 - Download	1	30-Jun-99 to 2-Jul-99	2-July-99
2	30-Jun-99	1-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	2	1-July-99 to 3- Jul-99	3-July-99
3	1-July-99	2-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	3	2-July-99 to 4- July-99	4-July-99
4	2-July-99	3-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	4	3-July-99 to 7- July-99	7-July-99
Etc. to 20						

Notice the following:

- You still have 20 measurement cycles even though you only read the meters every other month. Why? Because Oracle Utilities Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement. If it can't find a reading on this date, Meter Data Management estimates consumption. Without a measurement cycle schedule, Meter Data Management wouldn't know when to look for readings.
- Every other month you download half the routes in each cycle and estimate consumption for the other half.
- If you don't download all routes when a measurement cycle is scheduled, you have to indicate how to handle every route in the cycle.

The above design is infinitely flexible. You can use it to handle any number of requirements:

- Estimate consumption every seventh month.
- Bill every month, but only read once a quarter.
- Etc.

Bill Cycles

The topics in this section provide background information about a variety of bill cycle features.

The Cyclical Billing Process & Window Billing

The cyclical bill creation process creates most bills. This process works as follows:

- Every account references a bill cycle. The bill cycle's schedule controls WHEN the system attempts to create bills for the account.
- Every bill cycle has a bill cycle schedule that defines the dates when a cycle's accounts are to be billed. Rather than attempt to create bills on one evening, most bill cycles use a concept of "window billing" where the system attempts to produce bills for accounts over a few nights. The first night (i.e., the day the window opens) should be the earliest day on which meter reads for the account can enter the system. The last night (i.e., the day the window closes) should be the last possible day in which a meter read can enter the system. This concept of window billing allows you to start billing accounts on the earliest possible day and then bill the stragglers over successive evenings. This results in much better cash flow.
- When the bill cycle creation process runs, it looks for bill cycles with open bill windows. It then attempts to create bills for the accounts in each such cycle. If a bill is created, it will send it out that evening. If a bill cannot be created, the system will create a bill in the "error" state with a message that can be analyzed by your billing staff. The next day, your staff can either correct the problem or not. When the bill cycle creation process next runs, it deletes all "error" bills and attempts to recreate them. It continues this throughout the bill window. If bills are in error at the end of the window, they will remain in this state until a user fixes them. If the bills are still in error when the cycle's next window opens, a billing error will be generated.

The following diagram should help clarify the above.

FASTPATH:

For more information about the how to control when bills are produced for a cycle, refer to [Bill Cycle - Bill Cycle Schedule](#).

Designing Your Bill Cycle

The number of bill cycles is determined by the frequency that you bill your customers. So, for example, if you bill every month, you'll have 20 bill cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 bill cycles. If you bill quarterly, you'll have 60 bill cycles. Etc.

Keep in mind the following:

- You may need additional bill cycles if you allow customers to be billed off-cycle. For example, you could create a bill cycle called "Seniors" and link this to every senior citizen. You would set up this bill cycle's schedule to create bills shortly after social security checks are issued.
- You may need other bill cycles for customers with non-metered services (e.g., land leases, one time invoices).

IMPORTANT:

An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) for more information.

The Relationship Between Metered Measurement Cycles and Bill Cycles

As you can deduce, a service point's measurement cycle is related to an account's bill cycle.

The following table is an example of how you would set up the various dates on the various schedules that control meter reading and billing.

Measurement Cycle	Download Date	Expected Work Date	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc.					

Notice the following about this example:

- The bill cycle code is the same as the measurement cycle. This is not necessary, it's just good practice.
- The bill window starts on the first date on which a meter read could be uploaded.
- The bill window ends on the day after the last possible day a read could be uploaded for the bill cycle.
- Oracle Utilities Meter Data Management only estimates consumption on the last day of the bill window.

FASTPATH:

For more information about the bill cycle schedule, refer to [Setting Up Bill Cycles](#).

How Does An Account Get Its Bill Cycle?

Most accounts are created behind-the-scenes when a user uses the "add account" option on [Person - Main Information](#). An account created like this doesn't have a bill cycle. Rather, it sits in limbo awaiting the activation of its first service agreement. When a service agreement is activated, the system populates the account's bill cycle using the following algorithm:

- If an account's bill cycle is protected, the activation of a service agreement will not affect an account's bill cycle. Refer to [Protecting An Account's Bill Cycle](#) for more information.
- If the service agreement being activated is for metered service, the account is given a bill cycle that will generate bills shortly after the service point is read. The route the system follows to get this bill cycle is a bit indirect:
 - A metered service agreement references one or more metered service points.
 - Every metered service point references a measurement cycle (the measurement cycle controls when the meter at the service point is read).
 - Every measurement cycle references a default bill cycle. It is this bill cycle that is populated on the account paying for service at the service point.
- If the service agreement being activated is for metered service and the associated service point is externally managed along with its measurement cycle and bill cycle, an external call is made to obtain the bill cycle from Meter Data Management. This bill cycle is assigned to the service agreement's account.
- If the service agreement being activated is not metered, the system cannot populate the account's bill cycle because there is no measurement cycle from which to default the bill cycle. This means the account's bill cycle will be blank until a user specifies a bill cycle for the account (using the Account page).

NOTE:

A To Do entry highlights accounts without a bill cycle. A To Do entry highlights those accounts that require a user to specify a bill cycle. This entry is generated for accounts without a bill cycle that have active service agreements.

When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. Refer to [What Happens At Finalization Time?](#) for more information.

When a service point's measurement cycle is updated, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the measurement cycle. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options [Feature Configuration](#) is set to Y.

When an externally managed service point's measurement cycle is updated that results to a change in the bill cycle, a change notification is sent by Meter Data Management to trigger an corresponding update of the associated account's bill cycle in Customer Care and Billing. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options [Feature Configuration](#) is set to Y.

Protecting An Account's Bill Cycle

Over time, as a customer moves from premise to premise, their bill cycle is changed behind-the-scenes to be in sync with the latest service point's measurement cycle (as described in the previous section). If you do not want the system to change an account's bill cycle when a metered service agreement is activated, you need to turn on the account's **protect bill cycle** flag. You would do this if a customer liked to be billed at the start of the month regardless of when their device was read.

When the last service agreement for an account is stopped, the protect bill cycle flag is reset. This is to ensure that if the customer returns to start new service again, the bill cycle can be set based on [How Does An Account Get Its Bill Cycle](#).

What Happens If An Account Has Service Agreements Spanning Metered Measurement Cycles?

A single account can have service agreements that are in several measurement cycles. The bill cycle on such an account will default based on the last activated metered service agreement.

It's important to be aware that an account will only have bills created when its bill cycle schedule so indicates. This means that the consumption for some service points could remain unbilled for a few weeks.

Designing Bill Periods

Bill periods are used by non-metered service agreements whose bill end dates need to fall on strict dates. You need only set up this information if you have this type of service agreement.

FASTPATH:

Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.

Every bill period has a calendar that defines when bill segments are created for service agreements that use the bill period. Examples of bill periods include:

- Quarterly Bill - Last Day Of Quarter
- Quarterly Future Bill - Last Day Of Quarter
- Monthly - 15th Day Of Month.
- Monthly Future Bill - Last Day Of Month.

The Quarterly Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
1-Oct-1998	30-Sep-1998
1-Jan-1999	31-Dec-1998
1-Apr-1999	31-Mar-1999
1-Jul-1999	30-Jun-1999
...	

The Quarterly Future Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
15-Dec-1998	31-Mar-1999
15-Mar-1999	30-Jun-1999
...	

The remainder of this section provides examples using the above calendars.

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.

- The service agreement's SA type references the Quarterly Future Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempt to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
18-Dec-1998	18-Dec-1998 thru 31-Mar-1999
15-Mar-1999	1-Apr-1999 thru 30-Jun-1999
...	

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempts to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
1-Jan-1999	18-Dec-1998 thru 31-Dec-1998
1-Apr-1999	1-Jan-1999 thru 31-Mar-1999
...	

FASTPATH:

Refer to [Setting Up Bill Periods](#) for information about how to define this information.

Setting Up Bill Cycles

An account references a bill cycle. The bill cycle defines when the account is billed and when the account's debt is checked to determine if it's overdue. To define a bill cycle and its bill cycle schedule, open **Admin > Billing > Bill Cycle > Add**.

Description of Page

Enter a unique **Bill Cycle** and **Description** for every bill cycle.

If your implementation requires restricting bill cycles to accounts by CIS Division, specify a **CIS Division** on the bill cycle.

Use the **Bill Cycle Schedule** collection to define when bills are produced for the accounts in a given bill cycle. The following fields are required for each instance:

Window Start Date Specify the date on which the system should start trying to create bills for accounts in the cycle.

Window End Date Specify the last day on which the system will create bills for accounts in the cycle. This should be the last possible date on which a meter read could be loaded into Oracle Utilities Meter Data Management for the account.

Accounting Date Specify the financial date associated with the bills' financial transaction. The accounting date defines the financial period(s) to which the bills will be booked in your general ledger.

Estimate Date The date on which Oracle Utilities Meter Data Management may start estimating consumption if a real measurement cannot be found. When specified, this date is typically on or shortly before the window end date.

Freeze and Complete Turn on this switch if the system should freeze and complete any bill that is created without errors. If this switch is turned off, all bills created by the billing process will be left in the unfinished state. You would only turn this switch off if you want to verify an entire bill run prior to freezing it (e.g., if you are introducing a new version of a rate). If you turn this off, you will need to return to this page after verifying a bill run and turn it back on for the customers to

receive bills. When the system next runs, it deletes all unfrozen bills and recreates them as per the instructions on the bill cycle schedule.

The batch bill creation process uses this schedule to define the bill cycles for which it should create bills.

NOTE:

Don't forget. After you set up the bill cycles that correspond with measurement cycles, go to [Setting Up Measurement Cycle Schedules](#) and update the measurement cycles accordingly.

Setting Up Service Cycles And Measurement Cycle Schedules

Refer to [Measurement Cycles](#), [Measurement Cycle and Bill Determinants](#), and [Setting Up Measurement Cycle Schedules](#) sections for more information

Setting Up Measurement Cycle Schedules

FASTPATH:

Refer to [Designing Cycles for Metered Services](#) for more information about measurement cycle. Refer to [The Relationship Between Metered Service Cycles and Bill Cycles](#) for more information about how measurement cycles are linked to bill cycles.

Description of Page

When you want to add a new measurement cycle schedule, you must specify the following information:

Service Cycle Enter the measurement cycle ID of the cycle whose routes will be downloaded.

Scheduled Selection Date Specify the date on which the system is meant to download information about the cycle's meters. This date should be a day or two before the scheduled work date.

Define the date the meters in the route are scheduled to be read using **Scheduled Work Date**. This date is extremely important as billing uses it when it looks for meter reads for service points in this cycle. If billing can't find a reading, consumption will be estimated as of this date (assuming the service agreement allows estimation).

Click **Pre-Generate Routes** if you need to finesse the cycle's routes on this Scheduled Selection Date (e.g., because some of the routes shouldn't be downloaded on a given date because the system is meant to estimate consumption). If you don't click this button, the system will create the routes on the scheduled selection date. It does this by creating a route extract for each downloadable route within the cycle (as defined by the route type). If you click this button, the system shows all routes within the cycle in the grid below. You must then define how the system is supposed to download each route on the scheduled selection date.

Click **Delete Routes** if you have pre-generated the routes and you want to remove them and allow the system to create the routes on the scheduled selection date.

Use the **Service Schedule Routes** to define how individual routes within the cycle should be handled during the download. The following fields are required for each schedule read date:

Service Route The unique ID of the service route. The route's route type is displayed adjacent.

Schedule Type This defines if and how the system is supposed to download the route's meter reads. Valid values are: Cust Read, Download, Estimate. Only those routes defined as Download will have meter reads downloaded. The other values are used to document why the route won't be downloaded.

Schedule Status This defines the download status of the route. Valid values are Pending and Complete. This value is only displayed for routes with a schedule type of Download.

Where Used

This information is used by the meter read download process to determine which meter reads to download.

This information is used by the billing process to determine the date on which it expects to find a read. If it cannot find a read on or around this date, and it's OK to estimate consumption, consumption will be estimated as of the scheduled work date. The system uses the service agreement's rate schedule's frequency to determine the period of time around the scheduled work date in which it looks for a read. Refer to [Defining Frequency Codes](#) for more information.

Setting Up Bill Periods

Some SA types reference a bill period. The bill period defines when the service agreement's bill segments are produced and the respective end date of each bill segment.

FASTPATH:

Refer to [Designing Bill Periods](#) for more information.

To define a bill period and the bill period schedule, open **Admin > Billing > Bill Period > Add**.

Description of Page

Enter a unique **Bill Period** and a **Description** for every bill period.

Use the **Bill Period Schedules** collection when the system should create bill segments for service agreements that use a given bill period. It also defines the end date of each respective bill segment. The following fields are required:

Bill Date Specify the earliest date on which the system is allowed to create a bill segment for service agreements using this bill period.

Bill Seg End Date Specify the end date of the bill segment. For future bills, this will be after the bill date. For retro bills, this will be before the bill date.

This information is used by the bill segment creation process to determine the end date of service agreements that use a bill period.

Defining Statement Cycles

If you have persons set up in the system to receive statements with financial information, you will need to assign them to a statement cycle and define a schedule for the statement cycle.

FASTPATH:

Refer to [The Big Picture of Complex Statements](#) for more information about statements.

The Big Picture Of Statement Cycles

A statement cycle has a similar purpose to that of a bill cycle. It controls when statements will be produced.

The Cyclical Statement Process

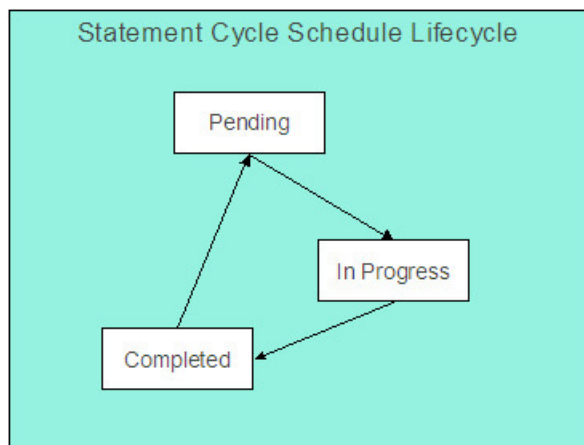

Persons who wish to receive statements will work with you to determine how often these statements should be produced. Some persons may want a monthly statement, some a quarterly and some annually. For each unique schedule that is designed for your various statement persons, you will set up a Statement Cycle and its schedule.

Designing Your Statement Cycles

The number of statement cycles is determined by a combination of the frequency that you will send statements to the statement persons and how many statement cycles you wish to manage within the same frequency.

So, for example, for all the statement persons who wish to receive a monthly statement, will you create only one monthly Statement Cycle so that all monthly statements are produced the same day? Or will you have several monthly statement cycles scheduled throughout the month? The answer will depend on the volume of statements being produced and on how you want to manage the statement production.

Lifecycle of a Statement Cycle Schedule

Pending The statement cycle schedule is added in this state. The Create Statements background process find records in this state to process on the appropriate date.

FASTPATH:

Refer to [Create Statements Background Process](#) for more information.

In Progress Records in this state are currently being processed by the Create Statements background process.

Completed Records in this state have already been processed by the Create Statements background process. If a problem occurs with the Create Statements background process and it needs to be rerun, simply change the status back to pending and rerun the process.

Setting Up Statement Cycles

A Statement Construct references a statement cycle. The statement cycle defines when the statement person will receive statements with financial information related to the accounts and service agreements linked to the statement construct. To define a statement cycle and its statement cycle schedule, open **Admin > Billing > Statement Cycle > Add**.

Description of Page

Enter a unique **Statement Cycle** and **Description** for every statement cycle.

Use the **Statement Cycle Schedule** collection to define when statements are produced for the persons with statement construct records in the given statement cycle. The following fields are required for each instance:

Processing Date Specify the date on which the system should create statements for persons with statement construct records in the cycle.

Status Indicates the status of the cycle schedule. Refer to [Lifecycle of a Statement Cycle Schedule](#) for more information.

The batch statement creation process uses this schedule to determine which statement cycles for it should create statements for the statement construct records. Refer to [Create Statements Background Process](#) for more information.

Defining Service Agreement Type (SA Types)

Every service agreement must reference a SA type. The SA type defines what you sell, how much you sell it for, to whom you sell it, how overdue debt is collected, and how sales will be booked in your general ledger.

NOTE:

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SA types. In reality, setting up your SA types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing SA Types For Service Agreements With Service Points

Designing your SA types is an iterative process. To minimize some iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SA types.

Division/SA Type	Service Type
------------------	--------------

The topics in this section provide guidelines describing how to fill in this table for SA types associated with service agreements that charge for service point-oriented services.

CIS Division Segmentation

A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

If we assume that you are located in a single jurisdiction - say California - we will need a single CIS division for all of our SA types.

CIS Division/SA Type
CA

Service Segmentation

At a minimum, you will have one SA type for every different type of utility service offered by your organization. If we assume you sell electricity, gas, water, wastewater and cable; your SA Types will be as follows:

CIS Division/SA Type	Service Type
CA/G	Gas service
CA/W	Water service
CA/E	Electric service
CA/WW	Waste water service
CA/CABLE	Cable

Receivable Segmentation

Many organizations segregate their receivable balances in the general ledger. For example, the receivable amount associated with gas and water service may be maintained in separate GL accounts.

If your organization does this, you will probably have at least one SA type for each such receivable account because each SA type references a distribution code that typically contains the receivable account.

- The word *probably* is underlined because this is a rule of thumb. There are situations where the number of receivable accounts isn't directly related to the number of SA types. This happens when an organization maintains very detailed receivable accounts in the general ledger and maintaining a one-to-one relationship between SA types and distribution codes would lead to a massive proliferation of SA types (and you don't want this!). If your organization maintains very detailed receivable accounts, please speak to your implementers, they should be able to introduce a small customization to generate the appropriate receivable account rather than extract it from the distribution code.
- The word *typically* is underlined because there are several SA types that don't book to a receivable account when bill segments are generated. For example, company usage and charitable contributions. Refer to [Company Usage Segmentation](#) and [Charitable Contribution Segmentation](#) for examples of SA types that don't book to receivable accounts.

We'll simplify our example and assume your organization has one receivable account for all types of utility service. Given this, we won't need additional SA types to support receivable segmentation:

CIS Division/ SA Type	Service Type	Distribution Code
CA/G	Gas service	A/R-UTIL
CA/W	Water service	A/R-UTIL
CA/E	Electric service	A/R-UTIL
CA/WW	Waste water service	A/R-UTIL
CA/CABLE	Cable service	A/R-UTIL

Revenue Segmentation

Look at your rates and determine which rates can be used by each SA type. The following table shows the sample rates that can be used for each service:

CIS Division/ SA Type	Service Type	Distribution Code	Rates
--------------------------	--------------	-------------------	-------

CA/G	Gas service	A/R-UTIL	GALL-1
CA/W	Water service	A/R-UTIL	WALL-1
CA/E	Electric service	A/R-UTIL	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	CABLE

Now, look at the rates' calculation rule GL Distribution window. You're looking for calculation rules whose GL distribution is affected by revenue class. If there are no revenue classes referenced on the calculation rules, this means that the revenue associated with the rate will be booked to a single GL account regardless of the type of customer. If you see revenue classes, this means that the revenue account associated with the calculation rule(s) differs depending on the SA type's revenue class. If revenue classes are used in the rates, you must create a different SA Type for every revenue class.

Let's assume the following:

- The gas rate (GALL-1) references the RESIDENTIAL, COMMERCIAL and INDUSTRIAL revenue classes in order to differentiate revenue based on the type of customer.
- None of the other rates differentiate revenue based on customer class.

Our SA types will now look as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Notice that we created new SA types for gas in order to specify the respective revenue class. We didn't do this for the other services because it isn't necessary. However, you should feel free to do this if it feels right or if you need it for reporting purposes. For example, if you want to report on all *residential* service agreements, but you differentiate only gas by residential versus commercial, you'll be in trouble.

Rate Segmentation

Every SA Type whose service agreements have their charges calculated with a rate must have one or more rates linked to it. These define which rates can be linked to the SA type's service agreements. If different service agreements have different valid rate combinations, you will need to split the SA types accordingly.

For example, look at the electric rates. If we assume:

- the RES rates can only be used for residential customer,
- the IND rates can only be used for industrial customers,
- the COM rates can only be used for commercial customers,

- the LAMP rates can only be used for lamp customers

Then you might want to set up a new SA type to indicate such. The advantage of doing this is that you get more control over which rates can be used on a given SA type. The disadvantage is that you proliferate SA types. Unfortunately, it's really a question of taste.

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1
CA/LAMP	Electric service	A/R-UTIL	N/A	ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

WARNING:

Don't be too specific in your analysis in respect of rate segmentation because you could end up with a separate SA type for every rate (and you don't want this). We understand this is a very subjective warning, but we recommend that you start out with broad bands of rates that can be used on a SA type and narrow it down if you end up unhappy with the results. For example, you don't have to set up a separate SA type for low-income residential gas customers just because they have a special rate. Rather, you can leave your SA types as they are and treat low-income gas customers as a subset of your residential gas customers. **For more information**, refer to [Setting Up Start Options](#).

NOTE:

Rate override. If a service agreement of this type may be linked to a terms of service record, you must also consider whether or not the [rate schedule could be overridden](#) by a template SA linked to the terms of service record. Refer to [SA Type - Rate](#) for information about the possible values for this field.

Service Point (SP) Type Segmentation

Every SA Type whose service agreements exist to bill for service point-oriented service has one or more SP types. These define which type of service points can be linked to the SA type's service agreements. If different service agreements have different valid SP types, you will need to split the SA types accordingly.

For each service point-oriented SA type, determine if there are any restrictions in respect of the types of service points that can use the SA type's rates. For example, if we assume that only commercial SP types can be used by commercial customers, industrial SP types by industrial customers, residential SP types by residential customers, your SA types will be:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM

CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE

Notice the wastewater SA types reference both water and waste water service points. This is intentional as wastewater service uses the consumption from the water service to calculate some part of the wastewater charge.

Company Usage Segmentation

Up to now, we've discussed SA types associated with service agreements linked to your customers. The system has also been designed to keep track of the expenses associated with your company's use of power. If you want the system to do this, you must create at least one SA type for each service consumed by your organization.

For example, if we assume your organization consumes electric, gas, and water service; your SA types will now be as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES	BD-RATED
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM	BD-RATED
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND	BD-RATED
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED
CA/E-COY	Electric service	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG

CA/G-COY	Gas service	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG
CA/W-COY	Water service	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG

Notice the three company usage SA types do not reference an A/R account as their distribution code. This is because when bill segments are created for these types of service agreements, the system must debit an expense account (or contra-revenue account) rather than a receivable account.

Also notice we introduced a new column - Bill Segment Type. Notice that the customer-oriented SA types use the BD-RATED bill segment type and the company usage SA types use the COMPUSAG bill segment type. Different bill segment types are necessary because company usage SA types use a different algorithm to calculate their bill segment's financial transaction algorithm because they don't affect either payoff or current balance.

FASTPATH:

For more information, refer to [Designing and Defining Bill Segment Types](#).

Debt Class Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you will have to split the SA Type.

FASTPATH:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

If we assume that your residential services are regulated and your commercial and industrial services are deregulated, we won't have to introduce additional SA types.

CIS Division/ SA Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type	Debt Class
CA/G-RES	A/R-UTIL	R - residential	GALL-1	G-RES	BD-RATED	REGU
CA/G-COM	A/R-UTIL	C - commercial	GALL-1	G-COM	BD-RATED	UNRE
CA/G-IND	A/R-UTIL	I - industrial	GALL-1	G-IND	BD-RATED	UNRE
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED	REGU
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED	UNRE
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED	UNRE
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED	REGU
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED	UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED	UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED	REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED	UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED	UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED	UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt

CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the three company usage SA types do not have a debt class. This is because their bill segment type's FT algorithm doesn't cause debt to be created and therefore there is no reason to have a debt class. However, you'll need to create a "dummy" debt class - call it N/A - for these SA types because every SA type must reference a debt class.

Budget Billing Segmentation

Many utilities offer their customers levelized payment plans to smooth out the seasonal bill variations. We call this levelized amount the *budget amount*.

FASTPATH:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Billing - Current Balance versus Payoff Balance](#) for an example of budget billing accounting.

If we assume that you only allow budget billing on the electric and gas residential services, then you'll need to update your CA/G-RES and CA/E-RES SA types:

CIS Division/ SA Type	Dist Code	Rev Class	Rates	SP Type	Bill Seg Type	Debt Class	Recurring Charge Control Info
CA/G-RES	A/R-UTIL	R	GALL-1	G-RES	BD-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/G-COM	A/R-UTIL	C	GALL-1	G-COM	BD-RATED	UNRE	
CA/G-IND	A/R-UTIL	I	GALL-1	G-IND	BD-RATED	UNRE	
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED	REGU	
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED	UNRE	
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED	UNRE	
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:

CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED	UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED	UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED	REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED	UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED	UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED	UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the following:

- We updated the two SA types to allow recurring charge information.
- The Recurring Charge Amount is Optional. Why? Because those customers who aren't on a budget plan won't have a recurring charge amount. Those customers on a budget will have a recurring charge amount.

NOTE:

Turn on Eligible for Budget. Besides indicating that these SA types use recurring charges, you also need to turn on the Eligible for Budget switch on the SA type to indicate that this type of SA participates in budget processing.

Override Budget Eligibility. You may plug in an override budget eligibility algorithm on an SA type that is configured to be Eligible for Budget if certain service agreements of this type are not eligible.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes.

Designing SA Types For SAs Without Service Points

The topics in this section provide guidelines describing how to design the SA types associated with your service agreements that don't have service points.

Overpayment Segmentation

When a customer pays more than they owe, you must decide what to do with the excess money. The following points describe two possibilities:

- You could create a new service agreement to hold the excess (let's call it an overpayment SA). The credit would be transferred from this service agreement to the billable service agreements when the next bill is completed. This means that all billable service agreements have the same opportunity to receive the overpayment when they are billed in the future.
- You could amalgamate the excess payment on one of the existing, billable service agreements. For example, if a customer has both electric and gas service, the excess funds could be kept on either the gas or the electric SA. This would result in the following:

- The service agreements that do NOT receive the overpayment will have debt when they are next billed.
- The service agreement that receives the overpayment could have its future debt offset by the overpayment (meaning that it could have a credit balance until the service agreement's future bill segments offset the overpayment amount).
- The above situation is not desirable unless the customer intentionally overpaid one service agreement. The first method (keeping the overpayment on a separate service agreement) obviates this potential problem. Obviously, if your organization sells a single service (and therefore your customers have a single service agreement) you would choose the second method.

You control which method is used by plugging in the appropriate Overpayment Distribution algorithm on each [Customer Class](#) (i.e., you can choose a different method for different customer classes). If you choose to hold overpayments on a separate SA, then you must set up an SA Type as described in the following table:

CIS Division/ SA Type	Service Type	Distrib. Code	Eligible for Billing	Debt Class	Pay Seg Type	Do Not Overpay	One-time
CA/OVERPAY	Other	A/P - OVER	Not billed	N/A	Normal	No	Yes

Notice the following about the new overpayment SA type:

- It has an interesting distribution code. This is because when a payment segment is created for this type of service agreements, the system must credit a liability (an overpayment is a liability).
- It's important to indicate that the overpayment SA is a one-time service agreement. Why? Because this means that the system will automatically close the SA when it's balance falls to zero (i.e., when all of the overpayment has been used to satisfy future bills).
- A bill segment type is not needed because the system never creates bill segments for such service agreements (they exist only to hold excess credits).
- You may also want to turn on the alert message
- You must plug-in a bill completion algorithm on this SA type. This bill completion algorithm will transfer the credit balance to the account's other service agreements when the bill is completed. Refer to [The Credit Transfer Algorithm](#) for more information about this algorithm.
- You must also reference this overpayment SA type as the parameter value on your overpayment algorithm (this algorithm is plugged in on the desired customer classes). Refer to [Overpayment Algorithm](#) for more information about this algorithm.

NOTE:

If overpayment means charitable contribution. Some organizations sponsor a program that works as follows - if a customer overpays a bill by a given amount (say \$5), this amount is assumed to be a charitable contribution. If you have this requirement, you will create another SA type to hold a customer's charitable contributions. This SA type will look similar to the one described below (see [Charitable Contribution Segmentation](#)) except it is not billable. The funds will be credited to this service agreement by creating a new overpayment algorithm that is similar to the base package Overpayment Algorithm. This new algorithm will be very similar to the existing algorithm. The main difference will be that it will have to check if the overpayment amount is an exact value (say \$5). If so, it will create a payment segment for the charitable contribution SA type; otherwise it will create a payment segment for the overpayment SA.

Write Off Segmentation

When you write off non-collectable debt, you transfer the receivable from a "normal" service agreement onto one or more write-off service agreements. When the debt is transferred to a write-off service agreement, the distribution code on the "normal" service agreement is credited (typically an A/R GL account), and the distribution code on the write-off service agreement is debited.

You will almost always need a write-off service agreement whose distribution code is the write-off expense. However, you probably don't book all of the write-off amount to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you want to book the written off revenue to a write-off expense account and you want to reduce the liabilities (you don't owe the liability if you don't get paid). This means you'll need another SA type for the liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

The following table contains the minimum number of SA Types that you'll need to hold your write-offs.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class	Pay Seg Type	Do Not Overpay
CA/WO-STD	Other	EXP-W/O	Not billed	WO	Normal	Yes
CA/WO-LIA	Other	LIA-General	Not billed	WO	Normal	Yes

Notice the following about the new write-off SA types:

- They have interesting distribution codes. This is because when debt is transferred to these types of service agreements, the system must debit either an expense account (i.e., write-off expense) or a liability account. It's important to note that in [The Ramifications of Write Offs in the General Ledger](#) we explain how this liability account may be overwritten with the liability account that was originally booked.
- Neither needs a bill segment type because the system never creates bill segments for such service agreements (they exist only to hold uncollectable debt)
- Even though the debt is not collectable, it still has a debt class. Why? Because the system shows a customer's debt on many inquiries by debt class and it's important to show write-off debt on these queries.
- The combination of Payment Segment Type and Do Not Overpay are important. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

NOTE:

The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on each write-offable SA type. The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write-off SA type.

An Alternative. If you have a limited number of liability accounts, you may decide to have a separate write-off service agreement for each liability account. Doing this would proliferate the number of service agreements created at write-off time. However, it would simplify the remittance of payment to the taxing authority if the reversed liability is ever paid.

Connection Charge Segmentation

If you levy connection charges, you have two options:

- You can create a SA type that exists purely to handle connect charge debt. After doing this, you'd create a start option for this SA type that causes an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had multiple services (e.g., a combined electric, gas, water utility) that only levies a single connection charge regardless of the number of services started. If you use this approach, make sure to indicate the SA type is non billable.
- You can levy a start adjustment on one of your existing SA types (e.g., CA/E-RES). The easiest way to do this is with a start option. On the start option you'd indicate an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had a single service offering (e.g., an electric-only utility). Refer to [Setting Up Start Options](#) for more information.

In the table below, we show what would be necessary if you want to have a separate service agreement for the connection charge.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class
CA/CONNECT	Other	A/R-UTIL	Not billed	REGU

Notice the following about the new connection charge SA type:

- It has a normal receivable distribution code.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (its charged via an adjustment).
- The debt class is interesting - REGU (for regulated). We are intentionally linking the connection charge debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the connection charge debt the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

Charitable Contribution Segmentation

If your organization accepts charitable contributions made by your customers, you must create a SA type to hold these contributions.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/CHARITY	Other	A/P-CHAR	CHAR	RECUR	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Contrib. Amount

Notice the following about the new charitable contribution SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., charitable contribution payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the charitable contribution is created.
- It uses an interesting bill segment type - RECUR. This bill segment type was set up to create recurring charges that don't automatically stop at some point in time.
- The debt class is interesting - CHAR (for charity). This is done so that past due charitable contribution debt is treated separately from other types of debt.
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

WARNING:

It's important that you assign the charitable contribution SA type with a payment segment type that only affect current balance (as opposed to affecting current AND payoff balance). This is because there is no receivable recognized when the contribution is billed and therefore there is no payoff balance to relieve when it's paid.

Payment Arrangement Segmentation

If your organization allows customers to payoff outstanding debt using payment arrangements (e.g., current bill plus \$X), you will need a new SA type for every debt class that can have a payment arrangement. If we assume you can have payment arrangements for both regulated and unregulated debt, then you'll need at least two more SA types (you may have more SA types if you need to segregate the payment arrangement receivable amount by utility type (or some other type)).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/PA-REGU	Other	A/R-ARRG	REGU	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount
CA/PA-UNRE	Other	A/R-ARRG	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount

Notice the following about the new payment arrangement SA types:

- They have an interesting distribution code. This is because when funds are transferred to these types of service agreements, the system must debit a receivable (i.e., payment arrangement receivable).
- They use an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- Each new SA type references the debt class whose debt it will pay off. We are intentionally linking the payment arrangement debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the arrangement debt as the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use Start Options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Merchandise Segmentation - Installment Billing

If your organization allows customers to purchase merchandise using an installment plan, you must create a SA type for this.

NOTE:

No installments. If the customer must pay for the merchandise in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/MERCH-I	Merch	A/R-MRCH	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new merchandise SA type:

- It has a normal receivable distribution code.
- It uses an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Deposit Segmentation - Installment Billing

If your organization allows customers to pay deposits using an installment plan, you must create an SA type for this.

NOTE:

No installments. If the customer must pay for the deposit in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example. Just make sure the adjustment that's levied to charge for the deposit amount doesn't affect payoff balance (when you bill a deposit, the customer doesn't really owe anything because it's not a true receivable from an accountant's perspective).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/DEP-I	Other	A/P-DEPO	DEP	RECURATB	Amount to bill is Required Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new deposit SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., deposit payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the deposit is created.
- It uses an interesting bill segment type - RECURATB. This bill segment type was set up to create recurring charges that stop when the system has billed the Total Amount to Bill.
- The debt class is interesting - DEP (for deposit). This is done so that past due deposit "debt" is treated separately from other types of debt.
- The recurring charge control information is set up as defined. Note well, the Amount to bill is Required.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

NOTE:

Bill messages on receipt of deposit in full. The base package includes a special FT Freeze algorithm that can be specified on deposit SA Types. It recognizes when a deposit has been paid in full, and creates a bill messages to inform the customer. Refer to algorithm DEP PIF MSG in [Algorithm Types](#) for more information.

Billable Charge Segmentation

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line. You can also use billable charges to "pass through" other bill ready charges generated outside the system, by another application, or by a 3rd party supplier.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each service agreement with unbilled charges. If multiple unbilled charges exist for a given service agreement, only one bill segment will be created and it will contain details about all of the billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.

- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, you must set up at least one SA type to hold your billable charge debt. You may have multiple charges based on billing frequencies, A/R booking, debt monitoring, etc. It's really up to you.

The easiest way to determine how many billable charge SA types you'll need is to define every conceivable billable charge (which you should have done when you designed your [billable charge templates](#)). Then ask yourself if they have the same billing and payment behavior, if so, you'll have one SA type. If not, you'll need one SA type for each combination.

We will assume your billable charges are all used to levy unusual one-off charges that can be collected in the same way, therefore we'll need one SA type.

CIS Division/ SA Type	Service Type	Distrib Code	Debt Class	Bill Seg Type	Billable Charge Templates	Rate
CA/ONETIME	Other	A/R-UTIL	UNRE	BILLCHRG	TREETRIM DAMAGE	None
CA/PASSTHRU	Electricity	A/R-OTHER	UNRE	BILLCHRG	None	None
CA/ADDON	Electricity	A/R-OTHER	EXTERNAL	BILLCHRG	None	TAXES

Notice the following about the new one time SA type:

- It has a normal receivable distribution code.
- Its debt class is unregulated.
- It uses an interesting bill segment type - BILLCHRG. This bill segment type was set up to create bill segments using billable charges.
- It references the valid billable charge templates that can be used on this SA type.

NOTE:

One Time Charge. The ONE TIME example shown above implies this SA type exists to hold one-time charges.

Because of this, you should turn on the One Time Charge switch on the SA type so that service agreement's of this type are automatically closed when final payment is received. You don't have to do this because a customer could have a single billable charge service agreement that is perpetually active for pass through charges (i.e., it doesn't have a stop date). If you do this, the system will create a bill segment for this service agreement whenever it finds an unbilled billable charge linked to the service agreement.

Notice the following about the pass through SA Type:

- It doesn't use the normal distribution code or debt class. This is done so that the debt and receivable can be tracked separately. If these charges were being pass through from another system, you might want to track these financial values separately.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- Templates are not relevant - these charges are not created on-line using templates, but are loaded via the [Billable Charge Upload Staging](#).

Notice the following about the add on charges SA Type:

- This is an example of bill-ready charges (similar to pass through) to which the system adds on other charges, for example, taxes.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.

- It also uses a Rate. In this case, the bill creation algorithm (specified on the bill segment type) will take any billable charge lines and attach them to a bill. In addition, these billable charges will include billable charge service quantities (SQs). These service quantities will also be swept onto the bill segment, and the Rate (TAXES in this example) will be applied. In order for taxes to be calculated, the billable charge SQs must include the total taxable amount - the system is not able to apply the rate on top of the other billable charges. But, it can apply the tax rate to the SQs that are supplied.
- You can also use this technique to bill other rate-ready service quantities, like kWh, CCF, *etc.* This is a way to process rate-ready data for which you have a contract, but you do not know the meter (and therefore, cannot collect real meter reads).
- If the rate has pre-processing calculation groups, these will be applied as well.

FASTPATH:

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Over/Under Cash Drawer Segmentation

In order to balance a tender control that is out-of-balance, your organization must set up an account with a service agreement whose SA type references the over/under expense account. You will probably only have one service agreement that references this SA type, but you still must have it if you remit funds via a cash drawer.

FASTPATH:

For more information about over/under processing, refer to [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/OVR UNDR	Other	EXP-OV/UND	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This is because when a payment segment is applied to this type of service agreement, the system must debit an expense account for under amounts (and credit it for over amounts).
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has over/under payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

Payment Upload Error Segmentation

If the payment upload process detects an invalid account on a payment upload record, it will create a payment for the suspense service agreement defined on the upload process' tender source (see [Setting Up Tender Sources](#)). You should create a special SA type for this service agreement.

FASTPATH:

For more information about the payment upload process, refer to [Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments](#).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/SUSPENSE	Other	EXP-MISC	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This code should probably be a suspense account. All payment segments that are created for this service agreement will eventually be transferred to a "real" service agreement and therefore this GL account's balance should be zero when no payments are in suspense.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has invalid account payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

CIAC Segmentation

If your company bills and refunds Contribution In Aid of Construction (CIAC) contracts, you must create one or more SA types. CIAC contracts are typically used to levy charges associated with line extensions. These types of service agreements are different from other service agreements because the initial amount charged is refunded to the original payee when new properties (or extensions) are added to the extension (or when the new properties are subsequently billed for service).

NOTE:

Billable charges are used for the original CIAC service agreement. CIAC SA types are always Billable Charge SA types because an operator must specify the exact amount to charge the contractor using a billable charge. Refer to [Billable Charge Segmentation](#) for more information.

The following points describe how CIAC processing is implemented in the system:

- When a new line extension is build, you will create a new service agreement that references your CIAC SA type. This service agreement should be linked to a service point associated with the extension. The easiest way to create this service agreement and link it to the service point is by using the Start Account transaction. It's important to remember to define your CIAC SA type as a valid SA type for the SP type used to represent the line extension.
- When a new premise / service point is built that "hangs" off the original extension, the new service point should be linked to the original service point. This can be done by referencing the original service point as the "parent" service point of the new service point using a [foreign key value characteristic](#).
- The system periodically monitors the original CIAC service agreement. The process that performs this monitoring is referenced on the original CIAC service agreement's SA type. The exact processing that takes place during this monitoring is up to your organization's specific business requirement. For example, if you refund 10% of every bill produced for the "downstream" service points to the original contractor, you would have logic in your CIAC monitoring process that looks for recent bill segments produced for the "downstream" service agreements and then creates an adjustment for the master service agreement.

NOTE:

CIAC refunds are idiosyncratic. Because CIAC refund processing is idiosyncratic, we do not supply any CIAC monitoring processes in the base package. This is because the likelihood that they could be used is extremely low because of your organization's unique requirements.

Therefore, if your organization performs CIAC processing, you should create a special SA type.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	CIAC Process	Bill Seg Type
CA/CIAC	Other	A/R - CIAC	UNRE	Refund based on percent of future bills	Billable Charge

Loan Segmentation

If you loan money to customers that is recouped using an amortization schedule, you need to set up an SA type for the loan service agreement.

CIS Division/ SA Type	Service Type	Distrib. Code	Loan A/R Distrib. Code	Debt Class	Bill Seg Type
CA/LOAN	Other	A/R - LOAN	A/R - STLN	UNRE	LOAN

FASTPATH:

Refer to [Setting Up The System To Enable Loans](#) for more information.

Non-Billed Budget Segmentation

If you allow your customers to pay set amounts at specified intervals (e.g. every two weeks), you need to set up SA types for Non-Billed Budget service agreements. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. You may implement two types of Non-Billed Budgets monitored and unmonitored, each type requiring a different SA type. You may also implement different renewal options for Non-Billed Budgets.

CIS Division/ SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/NBB-MON	Other	A/P - OVPY	Monitored	NBB	Optional	Not billed
CA/NBB-UNMON	Other	A/P - OVPY	Unmonitored	N/A	Optional	Not billed

FASTPATH:

For more information about monitored and unmonitored Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#).

Designing SA Type For Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of SA Types. However, many obscure factors could cause the introduction of more SA Types. In this section, we explain these more obscure factors.

WARNING:

We strongly recommend not being too pedantic when considering the factors described in this section. If you can only think of a few strange situations that would necessitate a SA type, think carefully before you introduce it. It's better to be a little less than perfect than end up with large number of obscure SA types.

Cash Distribution Segmentation

Every SA Type has a payment segment type. The payment segment type defines the cash account to which the SA type's payments should be booked. If different service agreements have different cash accounts, you will need to split the SA types accordingly.

Adjustment Profile Segmentation

Every SA Type has one or more adjustment profiles. These profiles define the valid adjustment types that can be booked to the SA type's service agreements. If different service agreements within an SA type have different mixtures of valid adjustment types, you must split the SA types accordingly.

Late Payment Charge Segmentation

An option exists on SA Type that causes the system to generate a late payment charge if payment is not received on time. If you don't levy late payment charges on all service agreements, you will need to determine when you do and design your SA types accordingly.

In addition, if you levy late payment charges, the percentage levied and the algorithm that defines the amount of the outstanding balance subject to the charge is defined on the SA type.

Debt Classification Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you must split the SA Type.

FASTPATH:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

NOTE:

Write Off Debt Class vs. Normal Debt Class. An SA type references both write off debt class and normal debt class. An SA type's write-off debt class controls the write-off rules imposed on service agreements of a given type. An SA type's normal debt class controls the collection rules imposed on service agreements of a given type. Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information about collection rules. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information about write-off rules.

Allow Estimates Segmentation

Every SA Type has a switch that controls whether the system should have Oracle Utilities Meter Data Management estimate consumption if meter reads are missing at billing time. If a given SA Type has different situations when the system should and should not estimate, you will have to split the SA Type.

NOTE:

Override. You can override the value of the SA Type's estimation switch on an individual service agreement. This means that if only a few service agreements don't abide by the SA Type's estimation switch, you can change the switch value of these service agreements.

Severance Criteria Segmentation

Every SA Type has severance criteria. The severance criteria define the severance process used to sever service if the customer doesn't pay. You can have multiple severance processes if different conditions warrant a different process. For example, you may have a different severance process if the customer has life support.

If you have a SA Type that requires different severance conditions other than those currently supported, you can make a programmatic change to introduce the additional conditions OR you can split the SA Type.

FASTPATH:

For more information about severance, refer to [Designing Your Severance Procedures](#).

Deposit Class Segmentation

Every SA Type that exists to hold a cash deposit will reference a deposit class. The deposit class defines the business rules that control various functions including interest calculation and refund criteria. You will need multiple deposit SA Types if any of the deposit class' rules / conditions differ for different types of deposits. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one SA type for residential deposits and another for commercial deposits (where the residential deposit SA type will reference the residential deposit class and the commercial deposit SA type will reference the commercial deposit class).

You will need additional deposit SA types if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one SA type for regulated deposits and another for unregulated deposits.

FASTPATH:

For more information about deposit class, refer to [Designing and Defining Deposit Classes](#).

Sub SA Types

If you operate in a deregulated environment AND if you provide billing services for other service providers, you will need to create SA types to handle the billing of the service providers' charges.

FASTPATH:

Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

Financial Settlement SA Types

If you operate in a deregulated environment, you may have to create financial settlement service agreements for the service providers. As explained in [Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us](#) service providers require a service agreement to hold adjustments used to increase how much you owe the service provider (or how much they owe you).

FASTPATH:

Refer to [Designing SA Types For Service Provider Financial Settlements](#) for more information.

Usage Request SA Types

Oracle Utilities Meter Data Management stores meter reading information and is responsible for calculating bill determinants during billing. The SA types for these customers will require special setup.

FASTPATH:

For more information about usage requests, refer to [The Big Picture Of Usage Requests](#).

Initial Consumption Period Considerations

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different utilities count the first day of a new service agreement differently than others. Because of this, a flag exists on SA Type called **Initial Start Date Option**. This flag controls whether the service agreement's start date is included in the consumption period in a service agreement's first bill segment.

The following table describes the ramifications of the options you can set for this flag.

Flag Value	Consumption Period Calculation	Use This Option When
Add 1 Day Always	The consumption period's start date is calculated by adding 1 day to the service agreement's start date. (The SA start date is never included in the consumption period for the first bill segment.)	You want the initial bill and all subsequent bills to have a consistently calculated consumption period (i.e., the consumption period for the first and all other bills is always one day less than the bill segment's period).
Add 1 Day for Back-to-back	A back-to-back occurs when any service point for this service agreement was previously linked to a different service agreement that	You want to flexibly handle consumption period calculation. If you start customers on the same date as the stop date of the

was stopped on the same date that the new service was started (i.e., there is no gap in the service).

If a back-to-back is detected, the consumption period start date is calculated by adding 1 day to the SA start date.

If no back-to-back is detected, the start date of the consumption period is the SA start date.

previous customer, billing does not include the SA start date in the consumption period. However, if you start a new customer one day (or more) after the stop date of the previous customer, billing includes the first day of the service agreement in the consumption period.

Include First Day	The start date of the consumption period is the service agreement start date. (The SA start date is always included in the consumption period.)	You want to always include the first day AND you will never encounter a back-to-back situation.
-------------------	---	---

The example below shows how the consumption period would be calculated with the various options for a customer who starts service on January 1.

	First Bill Meter Read: Jan 31 Bill Segment Period: Jan 1 to Jan 31	Second Bill Meter Read: Feb 28 Bill Segment Period: Jan 31 to Feb 28	Third Bill Meter Read: Mar 31 Bill Segment Period: Feb 28 to Mar 31
Consumption period using Add 1 Day Always	Jan 2 to Jan 31 (30 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is detected	Jan 2 to Jan 31 (30 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is NOT detected	Jan 1 to Jan 31 (31 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Include First Day	Jan 1 to Jan 31 (31 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)

There may be SA types for which the value of this flag does not affect the consumption period calculation and still other SA types where this flag is never used. For example,

- For billable charge service agreements, the consumption period is equal to the start and end dates on the billable charge and therefore this flag is not applicable.
- A sub SA either inherits the consumption period from the master SA or it uses billable charges. As a result, billing does not use this flag.
- For some service agreements, the charges on the rate are not affected by the consumption period. For example, if you have a customer with a simple meter and a simple usage-based charge, billing calculates the amount of consumption between the start reading and end reading and applies the rate (i.e., the number of days in the consumption period doesn't impact the charges in some rates).
- Some service agreements are not billed, for example, [overpayment service agreements](#). For this type of service agreement and other types of service agreements that are not billed, this flag is not applicable. However, the system does not prevent a value from being entered in these cases to allow for an implementation process to use the flag if needed.

Setting this flag to an appropriate value is significant for certain types of service agreements.

- For services whose rate includes daily charges, the configuration of this flag may impact the first bill segment for the service agreement. For example, if the first bill period is October 1st through October 31st, do you consider consumption period to be 31 days or 30 days? How you want to bill the customer on the first bill determines how you set this flag.

- For service agreements that request usage (or bill determinants) based on interval data, the interval usage recordings typically begin on the first day of service. If you add 1 to the start date, you miss billing for intervals on the first day. In this case, you should set the value to Add 1 Day for Back-to-back.

Processing Sequence Considerations

You may have customers with a complex collection of contracts such that the calculation for one bill segment relies on information calculated by another bill segment for the same account. For example, perhaps you need to process your bill segments as follows:

- Step 1: Calculate bill segments for all the account's "single site" service agreements (i.e., each service agreement related to a single premise)
- Step 2: Calculate the bill segment for additional charges for the "head office" service agreement where the charges are based on the aggregated consumption of all premises from all bill segments (calculated in the first step).

To create the "head office" bill segment for the account, you must control the order in which the system creates the bill segments for each service agreement.

The SA type allows you to indicate a billing processing sequence that controls the order in which the service agreements are processed. The processing sequence is optional and service agreements are processed in ascending order of their SA type's billing processing sequence. As a result, SA Types with a processing sequence of zero are processed first, then 1, then 2, etc.

NOTE:

If you have sub SAs linked to a master SA, the billing processing sequence is used first to order the creation of bill segments for the master SAs. If you populate a processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other. Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

The billing processing sequence also controls the order of service agreements in the following other processes:

- Execution of pre bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the pre bill completion algorithms on its SA type are processed in the order of the algorithm's sequence.
- Execution of bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the completion algorithms on its SA type are processed in the order of the algorithm's sequence.

Designing Prepayment Billing Options

This section provides guidelines describing how to design service agreements that handle smart meter prepaid billing.

When a customer is subject to prepayment, normal cycle-based billing is not used to calculate the bill segments for their service. Rather, a prepay billing (PPB) process creates bill segments frequently (for example, daily) and periodically requests funds to maintain an adequate payoff balance. Bills will only be used to periodically inform the customer of the various financial transactions that have occurred since the last bill was produced.

Implementing prepayment billing requires the configuration of the following objects:

- SA Type
- Adjustment Types
- Bill Segment Type
- Service Task Type

These configuration tasks are described below.

NOTE: For additional information, see the detailed descriptions in the application for the C1-PrepayBillerTaskType and C1-PrepayBillerTask business objects.

SA Type for Prepay Billing

To configure a prepay billing SA Type, create a new SA type with the following attributes:

- Set the Special Role flag to **Bill Determinants Required**. The Prepay Option should be set to **Prepaid Smart Meter**.
- Specify the SA Creation system event with the algorithm CI_CREATEPPB to create the service agreement's prepay biller.
- Specify the Payment Freeze system event with the algorithm STPZ-RMVC to set current amount to zero on a payment.
- If required, specify the Bill Completion system event with an algorithm of the type C1-CREPPBBM to add a bill message that informs an end customer of their prepaid charges for the period. You may need to create an algorithm of this type if it does not exist in your system.
- **Eligible for Budget** should be set to false.
- Reference a new **Prepay Bill Segment Type**, which is described below.

The following adjustment types must also be defined on the prepay SA type:

- **Adjustment Type (Xfer)** specifies the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement
- **Adjustment Type (Current=0)** specifies the type of adjustment used to set the prepaid current balance to zero after debt has been transferred
- **NSF Adjustment Type** specifies the type of adjustment used to levy an NSF charge. The NSF Adjustment Type is described in greater detail below.

The new SA types must be added to the data value mapping between CCB and MDM. This is to enable the synchronization of SAs of this type to MDM. The new CCB SA types can be mapped to existing US types in MDM. For additional information about this configuration, please see the integration documentation.

Adjustment Types for Prepay Billing

- **Funds Request Adjustment Type:** This adjustment type captures the type of adjustment used to request more prepaid funds. This adjustment type is specified on the prepaid biller task type. Specify the following algorithms on this adjustment type:
 - **Adj. Financial Algorithm** should reference the Adjustment FT creation algorithm ADJT-CA (Payoff=0/Current=Adj Amount (No GL)).
 - **Adjustment Freeze Algorithm** should reference an algorithm of the type C1-PPBADJFRZ (Set Prepaid Funds Request FT Details). You may need to create an algorithm of this type if it does not exist in your system.
- **NSF Adjustment Type:** For prepaid customers on autopay, when a user cancels an autopay tender the cancel reason must indicate that an NSF charge should be levied. The system invokes the NSF Charge algorithm specified on the tender's account's customer class which creates the NSF adjustment on the appropriate SA. The charge is levied using the NSF Adjustment Type specified on the SA's SA type. This adjustment type must reference the new adjustment freeze algorithm that will disable automatic payments on the PPB. This algorithm must be based on the algorithm type C1-DISPPBAP (Disable PPB's Automatic Payment). You may need to create an algorithm of this type if it does not exist in your system.

Bill Segment Type Required for Prepay Billing

Configure a new bill segment type for prepaid service agreements. This bill segment type should have the following attributes:

- **Create Algorithm** should be set to C1-BSBS-UR to create bill segment using a usage request.

- **Financial Algorithm** should be set to a new algorithm with algorithm type C1-NEM-GL (Payoff Amt = Bill Amt / Current Amt = 0 (GL affected)). You may need to create an algorithm of this type if it does not exist in your system.
- **Get Consumption Algorithm** should be set to C1-BSGC-USG to get bill segment consumption using a usage request.

Service Task Type for Prepay Billing

Configure a new service task type for prepay billing. This task type should reference the Prepay Biller (PPB) Task Type Business Object (C1-PrepayBillerTaskType). The task type must be specified on the new prepay billing SA creation algorithm. The task type captures the adjustment type used when an adjustment is created to request additional funds from the customer. Ensure that this adjustment type references the adjustment freeze algorithm (C1-PPBADJFRZ) that populates the financial transaction's arrears date.

SA Types And The Financial Design

In this section, we provide an example of how our SA Types map to Bill Segment Types, Payment Segment Types, and Adjustment Profiles. This example is meant to help solidify the power of the financial model, it is not necessarily indicative of how your specific implementation will look.

WARNING:

If you are not comfortable with the topics described in [Defining Financial Transaction Options](#), the following table will not make sense.

Division/SA Type	Distribution Code	Bill Segment Type	Payment Segment Type	Adjustment Profiles
CA/G-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES, BUDGET
CA/G-COM	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/G-IND	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/W-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES

If you operate in a deregulated environment, you will also have additional SA types as described under [Designing Your SA Types And Start Options For Sub SAs](#) and [Designing SA Types For Service Provider Financial Settlements](#) you may have additional SA types.

Setting Up SA Types

In the previous section, Designing SA Types, we presented a case study that illustrated a mythical organization's SA types. In this section, we explain how to use the windows on the SA Type window group to maintain your SA Types.

SA Type - Main Information

Open **Admin > Customer > SA Type > Add** to define core information about your SA Types.

WARNING:

Every SA Type is owned by a CIS Division. This Division controls many values that can be referenced on the SA Type. If you don't understand Divisions and their place in the application, do NOT attempt to set up your SA Types. Rather, refer to [Setting Up CIS Divisions](#) before proceeding.

Description of Page

Enter a unique combination of **CIS Division** and **SA Type** for every service agreement type.

Enter a **Description** for the SA type.

Service Type defines the type of service associated with the SA type. If the SA type has rates, only rates belonging to this service type may be linked to the SA type.

Select the **Distribution Code** and **GL Division** that defines the receivable account for receivable-oriented service agreements. For non-receivable oriented service agreements, this distribution code is typically as follows:

- Charitable contributions. The distribution code is a charity payable account.
- Deposits. The distribution code is a deposit payable account.
- Non-Billed Budgets. The distribution code is an overpayment payable account.

- Company usage. The distribution code is a company usage expense account.
- Write off. The distribution code is a write-off expense account.
- Payment arrangements. The distribution code is a payment arrangement receivable account.

FASTPATH:

For more information about GL accounts, refer to [The Source Of GL Accounts On Financial Transactions](#).

Select the **Revenue Class** associated with the SA Type (and its service agreements). The revenue class may affect the revenue account(s) generated by the service agreement's rate.

FASTPATH:

Refer to [Designing Calculation Groups and Rules](#) for more information about revenue class.

Turn on **Start Options Required** if you want to force a customer service rep to choose a start option when they start service for this SA Type (on the Start Account window). If this switch is off and a rate is required for the SA Type, the system defaults the SA type's default rate on new service agreements. The default rate is defined on the SA Type - Rate page.

FASTPATH:

Refer to [Setting Up Start Options](#) for more information about the pros and cons of requiring start options.

Select the **Pay Segment Type** that defines how payment segments linked to service agreements of this type affect:

- The service agreement's payoff and current balances

FASTPATH:

For more information about payment segment types, refer to [Setting Up Payment Segment Types](#).

When a tender is canceled, a cancellation reason must be supplied. If the cancellation reason indicates a NSF (non sufficient funds) charge should be levied, the system invokes the Levy an NSF Charge algorithm specified on the tender's account's [customer class](#). Because adjustments must be linked to a service agreement, the algorithm must determine the appropriate service agreement to use to levy the adjustment based on business rules. The charge is levied using the **NSF Adjustment Type** of the appropriate service agreement's SA type.

WARNING:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

FASTPATH:

For more information about adjustment types, refer to [Setting Up Adjustment Types](#). For more information about cancellation reasons, refer to [Setting Up Payment Cancellation Reasons](#).

Select the **Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to Distribution Based on Payment Priority and Delinquent Payment Distribution Algorithm for information about payment distribution algorithms that use this field.

NOTE:

The values for this field are customizable using the Lookup table. This field name is PAY_PRIORITY_FLG.

FASTPATH:

For more information about distribution priority, refer to [Distributing A Payment Amongst An Account's Service Agreements](#).

Select the **Delinquent Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to [Delinquent Payment Distribution Algorithm](#) for information about a payment distribution algorithm that uses this field.

NOTE:

The values for this field are customizable using the Lookup table. This field name is DEL_PRIORITY_FLG.

Turn on **Do Not Overpay** if the system is not allowed to distribute an overpayment to this type of service agreement (i.e., the service agreement is not allowed to have a system-created credit balance). This field is available for use by algorithms that distribute overpayments. Refer to [Overpayments Held On Highest Priority Service Agreement](#) for information about an overpayment algorithm that uses this field.

Turn on **Late Payment Charge** if the system should generate a late payment charge for this type of service agreement if payment is not received on time. If this is turned on, you must define the **LPC Calc. Algorithm** used to calculate the late payment charge amount. Refer to [Defining Late Payment Charge Options](#) for more information about late payment charges. Examples of algorithm types used for calculating late payment charges are BILPC-SPRC and BILPC-TOTAL.

Define the **Adjustment Type (Synch Curr)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type. This type of processing happens as follows:

- Most [write-off](#) algorithms that perform financial efforts (e.g., writing off debt), will issue an adjustment of this type if the service agreement's current and payoff balances are not equal.
- If a user stops a customer on a [budget plan](#), the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a user stops a service agreement covered by a [Non-Billed Budget](#), the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a [cancellation of a bill segment](#) occurs after a customer has stopped participating in a budget plan, an adjustment of this type is issued to synchronize the imbalance created when the bill segment's financial transaction is canceled.

Turn on **CIAC SA Type** and specify an appropriate **CIAC Refund Process** if service agreements of this type are used to bill for Contribution In Aid of Construction (CIAC) charges. Refer to [CIAC Segmentation](#) for more information.

SA Type - Detail

Open **Admin > Customer > SA Type > Search** and navigate to the **Detail** page to define additional details about a given SA type.

Description of Page

Turn on **Display As Alert** if Control Central should display an alert if an account has a service agreement of this type that isn't Closed or Canceled. If this switch is on, also enter the **Alert Information** to appear on Control Central. We recommend only using this feature on unusual SA types (e.g., payment arrangements, write-offs) so that a CSR is not presented with an alert for every SA type.

If this SA Type is used for any of the **Special Roles**, defined in the dropdown, indicate which one. Valid values are: Billable Charge, Cash Deposit, Loan, Non-Billed Budget, Payment Arrangement, Write Off, Bill Determinants Required. This information is used on windows with functionality that can only be used by service agreements used for specific roles. For example, the Billable Charge window group can only reference Billable Charge service agreements.

If Special Role is Cash Deposit, you must define the **Deposit Class** of the deposit. You should also define a **Deposit Class** on every SA type to which a given deposit can be distributed.

FASTPATH:

Refer to [What Do Deposit Classes Do?](#) for more information.

If the Special Role is Loan, you must also define the following fields:

- Use the **Interest Bill Factor** to define the bill factor code for the loan interest rate.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the **Loan A/R Distribution Code** to define the distribution code to be used when posting the short-term receivable amount to the general ledger (the normal distribution code is used for the long-term receivable). If the normal distribution code is the same as the **Loan A/R Distribution Code**, the SA type does not differentiate between long- and short-term receivables. If the two distribution codes are different, the SA type differentiates between long- and short-term receivables.

FASTPATH:

Refer to [Defining Loan Options](#) for more information about **Interest Bill Factor**, **Override Interest** and **Loan A/R Distribution Code**.

If the Special Role is Non-Billed Budget , you must also define the following:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to the transfer accumulated credit from the Non-Billed Budget SA to the SAs covered by the Non-Billed Budget when the account is billed or the Non-Billed Budget SA is stopped.
- Use the **Non-Billed Budget Monitoring** to specify whether the Non-Billed Budget is monitored by the account debt monitor.

If the SA type is defined as Eligible for Non-billed Budget, you must also define the following:

- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the service agreement's current balance to zero when a service agreement of this type is linked to an active, monitored Non-Billed Budget.

If the Special Role is Payment Arrangement and you have not enabled Use Alternate PA Creation Logic, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the payment arrangement service agreement.
- Set **Use Alternate PA Creation Logic** if your payment arrangement SA Types share a debt class with other SA Types. When this is set, the current balance on the transfer adjustment on the payment arrangement SA is set to zero instead of using the below adjustment type to set the current balance to zero. When payment arrangements are in their own debt class, the additional credit adjustment offsets the transfer adjustment. This results in an offsetting credit and debit in the payment arrangement debt class and a single credit on the non-payment arrangement debt class. However, when a single debt class is used, the two credits inaccurately impact the way debt age (arrear) is calculated and presented. Using the alternate PA creation logic ensures that debt age is calculated and displayed accurately when a single debt class is used.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the payment arrangement's current balance to zero after funds have been transferred.

If the Special Role is Write Off, you must also define the following adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the uncollectable service agreements to the write off service agreement.

NOTE:

It may be important to your organization to track the original source of debt that is being written off. The system is delivered with three characteristic types: C1-WODST, C1-WOCHT, and C1-WOCHV that can record the distribution code, characteristic type and characteristic value from the FT GL(s) being written off onto the write off adjustment. To

enable this logic, specify these characteristic types as allowable characteristic types on your write off transfer adjustment type.

If the Prepay Option is **Prepaid Smart Meter**, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement.
 - Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the prepaid current balance to zero after debt has been transferred.
-

WARNING:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

The **Stop Option** can be used to automatically stop a service agreement when all other service agreements of an account are stopped. Valid values are: Automatically Stop SA. When all service point related service agreements of an account are stopped then all additional service agreements where the **Stop Option** is set to Automatically Stop SA will also be stopped. This is useful, for example, with charitable contribution service agreements. The charity service agreement should be stopped when all utility related services are stopped.

FASTPATH:

Refer to [The Lifecycle of a Service Agreement](#) for more information on the **Stop Option**.

Turn on **One Time Charge** if this SA type is used for one-time invoices. When a one-time invoice service agreement is created, the system sets the stop date of the SA to be equal to the start date.

Turn on **Sub SA** if this SA type is used to define the business rules for sub service agreements.

FASTPATH:

Refer to [Sub Service Agreements](#) for more information about sub service agreements.

Renewal of SAs of this type may be Optional, Not Allowed or Required depending on your business processes. If renewal is not allowed, the SA expires on the expiration date. Renewal treatment is an important consideration for SAs that require an expiration date, such as [non-billed budget SAs](#).

If renewal is required or optional, specify the **Days Before Expiration for Renewal**. Note that currently this is only used by Non-Billed Budgets to calculate the renewal date based on the expiration date.

If the Special Role is Non-billed Budget, **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

FASTPATH:

Refer to [Credit and Collections and Non-Billed Budgets](#) for more information about monitoring Non-Billed Budgets.

Set **Eligible for Payment Arrangement** to Eligible if this SA type can be included in a payment arrangement.

NOTE: This is automatically set to Ineligible on SA types with a Special Role of Payment Arrangement.

Where Used

The alert information is used by Control Central to alert a CSR when unusual service agreements exist for an account. Refer to [Control Central - Search](#) for more information.

Only SA types designated as being Billable Charge may have billable charges linked to them. Refer to [Maintaining Billable Charges](#) for more information.

Only SA types designated as being Cash Deposit are processed by the various deposit-related background processes (e.g., interest calculation, automatic refund, etc.). Refer to [The Big Picture Of Deposits](#) for more information.

Only SA types designated as Loan are used to define the loan terms for a loan SA. Refer to [Loans](#) for more information.

Only SA types designated as Non-billed Budget may be used to set up Non-Billed Budgets. Refer to [Non-Billed Budgets](#) for more information.

Only SA types designated as being Payment Arrangement may be used on the payment arrangement window group. Refer to [Setting Up Payment Arrangements](#) for more information.

Only SA types designated as being Write Off may be specified as the write off SA type on distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

Only service agreements whose SA type is designated as being Write Off appear on the Write Off SAs query. Refer to [Write Off - Write Off SAs](#) for more information.

SA Type - Billing

Open **Admin > Customer > SA Type > Search** and navigate to the **Billing** page to define how the system manages bill segments for service agreements of a given SA type.

Description of Page

Turn on **Eligible for Billing** if the system should create bill segments for service agreements of this type. This will typically be turned on for all service agreements except for those used to hold write-off amounts or to levy one-off adjustments.

Define the minimum number of days a bill segment (other than the final segment) must span using **Minimum Days for Billing**. This is useful to prevent initial bill segments that span only a few days.

FASTPATH:

For more information about minimum days, refer to [Preventing Short Bill Segments](#).

Select the **Bill Segment Type** that controls both how bill segments for this SA Type will be created and how the related financial transaction affects the general ledger and the customer's debt.

FASTPATH:

For more information about bill segment types, refer to [Setting Up Bill Segment Types](#).

Use **Default Description on Bill** to define the verbiage that should print on the customer's bill.

NOTE:

Rates overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a rate. Why? Because the description that appears on the bill segment is defined on the rate schedule's rate version calculation group.

Billable charges overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a billable charge. Why? Because the description that appears on the bill segment is defined on the billable charge.

Use the **Billing Processing Sequence** if you need to control the order in which service agreements linked to this SA type are processed by billing.

FASTPATH:

Refer to [Processing Sequence Considerations](#) for more information.

Use **Bill Print Priority** to define the order in which the SA type's bill segments should appear on bills (relative to the other SA types that appear on a bill).

NOTE:

The values for this field are customizable using the Lookup table. This field name is BILL_PRT_PRIO_FLG.

Use **Max Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, an operator truly intends to send the bill out, they should regenerate the bill. Refer to [How To Correct A Bill Segment That's In Error](#) for more information.

WARNING:

The value entered in this field will DEFAULT onto service agreements of this type when they are first created. An operator may change the default value on a service agreement in case a specific customer has unusually high bills that continually error out. It's important to be aware that if you change the value of High Bill Amount on an SA type and there already exist service agreements of this type, the existing service agreements will contain the original value (the new value on the SA type will not be propagated on the existing service agreements).

Use **Graph Unit Of Measure** to define the unit of measure of the graphed consumption on the bill (if any).

Turn on **Allow Estimates** if the system should indicate to Oracle Utilities Meter Data Management whether to generate estimated consumption if meter reading(s) cannot be found at billing time. This value is defaulted onto service agreements and can be overridden on an individual service agreement.

Turn on **Characteristic Premise Required** if a characteristic premise must be linked to the service agreement when the service agreement is activated. The characteristic premise is used to define the taxing authorities associated with the service agreement's bill segments. It is also used to identify where the service agreement's service is located on various windows.

FASTPATH:

For more information about how characteristic premise is used, refer to [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the **Initial Start Date Option** to control how billing should calculate the consumption period for the very first bill for service agreements of this type. This field is not applicable for sub SA types or SA types with a special role of Billable Charge. Valid values are Include First Day, Add 1 Day Always and Add 1 Day for Back-to-back. Refer to [Initial Consumption Period Considerations](#) for more information.

Non-metered service agreements may have the end date of their bill segments defined on a user-maintained bill period schedule. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter). If this SA type should be billed like this, select Use Bill Period in the **Use Calendar Billing** field. When this option is used, you must define the **Bill Period** whose schedule defines the bill segment end dates.

FASTPATH:

For more information about bill period schedules, refer to [Designing Bill Periods](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Instead of the Use Bill Period method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16th of some month, the ongoing bill segments will start on roughly the 16th of each month. This option is frequently used to bill for garbage or cable service. If this SA type should be billed like this, select Anniversary Future Billing or Anniversary Past Billing in the **Use Calendar Billing** field. When either option is used, you must define the **Anniversary Bill Frequency**. This frequency defines the amount of time between bill segments.

FASTPATH:

For more information about anniversary billing, refer to [Using The Anniversary Method](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Total Bill Amount indicates whether service agreements of this type can use the total amount to bill field on the service agreement page. Valid values are Not Allowed and Required. Only SA types used to bill for deposits or loans should have this field set to Required.

If Required is selected, you must enter the **Total Amount To Bill Label**. The **Total Amount To Bill Label** defines the label that prefixes the total bill amount on the service agreement page for service agreements of this SA type.

FASTPATH:

For more information about total amount to bill and deposit service agreements, refer to [Total Amount To Bill](#). For more information about total amount to bill and loan service agreements, refer to [Setting Up The System To Enable Loans](#).

Recurring Charge indicates whether service agreements of this type can use the recurring charge field on the service agreement window. Valid values are Not Allowed, Optional and Required. If either Optional or Required are used, you must enter:

- **Recurring Chg Amt Label**. This defines the label that prefixes the recurring charge amount on the service agreement window for service agreements of this SA type.
 - **Recurring Charge Frequency**. This defines the following:
 - Specifies the frequency at which the Recurring Charge Amount specified on service agreements of the SA Type is to be billed.
 - Serves as the basis for proration of the Recurring Charge Amount.
 - Specifies the frequency at which service agreements of the SA Type without a rate and/or meters will be billed.
-

FASTPATH:

For more information about how to use the recurring charge information, refer to [Charitable Contribution Segmentation](#), [Merchandise Segmentation - Installment Billing](#), [Deposit Segmentation - Installment Billing](#), [Payment Arrangement Segmentation](#), [Budget Billing Segmentation](#), [The Terms Of A Loan Are Stored On A Service Agreement](#).

Turn on **Eligible for Budget** if service agreements of this type can participate in budget billing. If this switch is turned on, then you must define the **Adjustment Type (Synch Current)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type when a budget is cancelled. (The Adjustment Type (Synch Current) field is on the main page.)

FASTPATH:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Budget Billing Segmentation](#) and [Designing and Defining Budget Plans](#) for more information.

Set the **Eligible for Non-Billed Budget** flag to Eligible for Non-Billed Budget if you want SAs of this type to be eligible to be covered by a Non-Billed Budget. If this flag is set to Eligible for Non-Billed Budget, you must also define the **Adjustment Type (Current = 0)** field (on [SA Type - Detail](#)).

FASTPATH:

Refer to [Current Amount For SAs Covered By A Non-Billed Budget](#) and [SA Types for SAs Covered by Non-Billed Budgets](#) for more information.

Require Total Amount Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's required total amount switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Require Total Amount Switch:	SA Type Require Total Amount Switch:
	Not allowed	Required
Apply Rate To Usage Request	Metered services. Lamp services. Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	N/A
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	N/A	Deposit installment plans.
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices. Pass through charges	N/A
Loan	N/A	Loans.

Allow Recurring Charge Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's allow recurring charge switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Recurring Charge Switch:	SA Type Recurring Charge Switch:	SA Type Recurring Charge Switch:
	Not allowed	Optional	Required
Apply Rate To Usage Request	Metered services - no budget Lamp services Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	Metered services - budget optional	Metered services - budget required
Recurring Charge With Auto Stop	N/A	Payment arrangements. Merchandise installment plans.	Payment arrangements. Merchandise installment plans.

		Zero-interest loans. SEE NOTE!	Zero-interest loans. SEE NOTE!
Recurring Charge For Amount To Bill	N/A	Deposit installment plans. SEE NOTE!	Deposit installment plans. SEE NOTE!
Recurring Charge	Charitable contributions	N/A	N/A
Billable Charge	One time invoices. Pass through charges	N/A	N/A
Loan	N/A	N/A	Loans.

NOTE:

Most recurring charge SA types require a recurring charge amount on their service agreements. However, the above matrix indicates you can have recurring charge SA types where this value is optional. Why? A special algorithm exists in billing that says if the recurring charge amount is 0 (zero) the system will bill the remaining payoff balance or total amount to bill. This algorithm exists so that you can easily bill the amount in one lump sum (i.e., don't bill it in installments).

Where Used

The billing information is used when the system creates a bill segment for service agreements of this type.

SA Type - Rate

Open **Admin > Customer > SA Type > Search** and navigate to the **Rate** page to define the rates that may be referenced on service agreements of a given type.

Description of Page

Turn on **Rate Required** if the bill segment creation algorithm for the SA type expects a rate schedule to be referenced on service agreements of this type.

FASTPATH:

For more information, refer to [Rates](#).

When a rate changes within a bill segment's consumption period, the period is divided into separate usage periods – one for each active rate schedule during that period. The usage periods and their related consumption (or billable quantities) are then prepared for billing, and the rate schedule calculations are applied to their associated periods.

This feature is possible if the usage subscription type is configured with the base Dynamic Usage Group Determination algorithm, which determines the applicable usage group for each effective rate schedule. This algorithm requires that the CCB rate schedule has usage group extendable look-ups configured for the rate schedule and device configuration type combinations.

A typical use case is when there is a smart meter rollout in the middle of billing period and there are rate schedule changes that coincide with the meter exchange date. The usage group that is tied to the old meter will have rules that calculate scalar consumption, and the usage group that is tied to the new meter will have rules that calculate interval consumption. The end result is that the customer is billed with scalar consumption for the period where old meter was installed, and billed with interval consumption for the period where new meter is installed.

If the Contract Management module is not [turned off](#), which includes [umbrella agreement management](#), indicate the **Rate Source**. Check SA Only indicates that the rate schedule currently in effect for the service agreement should always be

used. Check TOS First, then SA indicates that if the service agreement is linked to a terms of service record, the service agreement's rate could be [overridden by one linked to the terms of service](#) record.

The information in the **Rate Schedules** collection defines the rates that may be referenced on service agreements of this type. The following fields are required for each SA Type:

Rate Schedule Specify the rate schedule; its description is displayed adjacent.

Use As Default Turn on this switch for the rate to be defaulted on new service agreements.

Rate Required versus Bill Segment Algorithm

The following table shows appropriate combinations of the SA type's rate required switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not applicable. Otherwise, we list typical types of service agreements that will use a combination. Be aware that no cross validation exists between the rate required switch and the bill segment creation algorithm when setting up the SA type.

Bill Segment Create Algorithm	SA Type Rate Required Switch:	SA Type Rate Required Switch:
	Not allowed	Rate required on SA
Apply Rate To Usage Request	N/A	Metered services. Lamp services. Misc item services. Company usage.
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	Deposit installment plans.	N/A
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices.	Billable charges that require a rate to add-on extra charges (like taxes) or billable charges where the consumption is interfaced and the system is responsible for calculating the charges.
Loan	Loans.	N/A

Where Used

This information is used to default and validate the rate specified on a service agreement. Refer to [Service Agreement - Rate Info](#) for more information.

SA Type - SP Type

Open **Admin > Customer > SA Type > Search** and navigate to the **SP Type** page to define the service point types that may be referenced on service agreements of a given type.

Description of Page

Turn on **Service Points Required** if at least one service point should be linked to service agreements of this type in order to properly bill the service agreements.

The information in the **SP Types** collection defines the service point (SP) types that may be referenced on this SA type's service agreements. The following fields are required for each SA Type:

SP Type Specify the SP type; its description is displayed adjacent.

FASTPATH:

For more information about SP types, refer to [Designing SP Types](#).

Where Used

This information is used to validate the types of service points linked to a service agreement. Refer to [Service Agreement - SA / SP](#) for more information.

SA Type - Adjustment Profiles

Open **Admin > Customer > SA Type > Search** and navigate to the **Adj Profile** page to define the adjustment profiles that define adjustment types that may be referenced on service agreements of a given type.

Description of Page

Define the **Adjustment Type Profiles** that, in turn, define adjustment types that may be referenced on service agreements of a given type.

FASTPATH:

For more information about adjustment type profiles, refer to [Setting Up Adjustment Type Profiles](#).

Where Used

This information is used to validate the adjustments linked to the service agreement. Refer to [Adjustment - Main Information](#) for more information.

SA Type - C&C

Open **Admin > Customer > SA Type > Search** and navigate to the **C&C** page to maintain attributes that affect how the system severs the service agreement when collection attempts fail.

FASTPATH:

Refer to [Designing Your Severance Procedures](#) for more information.

Description of Page

Select the **Debt Class** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class.

Select the **Write Off Debt ClassCode** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class during write-off processing.

NOTE:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements

differently when you try to collect overdue debt versus when you write-off debt. Refer to [The Big Picture Of Write Off Processing](#) for more information.

The information in the **Severance Criteria** collection defines the SA Type's severance criteria. Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer or premise. For example, you may have a different severance process if the customer has life support equipment.

FASTPATH:

The following information is not intuitively obvious. Refer to [Designing Your Severance Procedures](#) for more information.

The following fields are required for each instance:

Priority The priority controls the order in which the system determines if the severance process should be applied (the first severance process whose algorithm applies is used). Higher priorities are checked before lower priorities.

Severance Criteria Algorithm Select the algorithm to be used to check if the severance process should be initiated for service agreements of this type. If a condition is met, a severance process is created using the associated severance process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
 - On this algorithm, reference an Algorithm Type that determines if the severance of a service agreement should be processed using the associated **Severance Process Template**.
-

IMPORTANT:

You must have at least one entry in this collection otherwise the system will not start a severance process when a service agreement of this type needs to be stopped due to non payment. This entry should have the lowest priority code and should reference a **Severance Criteria Algorithm** that references the SV CRIT DFLT algorithm type.

Severance Process Template Specify the severance process template to use to sever the service agreement; its description is displayed adjacent.

Where Used

The debt class has multiple uses:

- The system summarizes an account's debt by debt class on [Account - Main Information](#) and [Account - Financial Balances](#).
- Debt class is one component that controls how the system analyzes an account's overdue debt (the others are the account's collection class and currency). Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information.
- Write off debt class is one component that control how the system writes off an account's stopped service agreements. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information.

The severance criteria are used when a collection event is activated that indicates that service should be severed.

SA Type - Billable Charge Template

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Template** page to define the billable charge templates that can be used on service agreements of a given type.

NOTE:

Only billable charges have billable charge templates. Only service agreements that are defined as Billable Charges (in the Special Role on the Details window) may use the grid on this window.

Description of Page

The information in the **Billable Charge Template** collection defines the SA Type's permissible billable charge templates. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge. The following fields are required for each template:

Billable Charge Template Specify the billable charge template. Its description is displayed adjacent.

Use As Default Turn on this switch for the template to be defaulted on new billable charges linked to service agreements of this type (if any).

FASTPATH:

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Where Used

This information is used to limit the billable charge templates that can be used for a given SA type.

SA Type - Characteristics

To define characteristics common to all service agreements of a given type, open **Admin > Customer > SA Type > Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define a **Characteristic Type**, **Sequence**, and **Characteristic Value** common to all service agreements of this type.

NOTE:

You can only choose characteristic types defined as permissible on a SA Type record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

SA Type - Algorithms

Open **Admin > Customer > SA Type > Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for service agreements of a given type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
 - Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
-

WARNING:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Bill Completion	Optional	<p>These algorithms are executed whenever a bill is completed for an account that contains a non-canceled service agreement of this type. The following situations necessitate the definition of a completion algorithm on an SA type:</p> <ul style="list-style-type: none"> - As explained under Technical Implementation of A/R Transfer and Technical Implementation of Routing Billable Charges To Service Providers, when a bill is completed, the system needs to set up the data necessary to interface any "master" SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate algorithm on the master SA types. - As explained under Billing For SAs Covered By The Non-Billed Budget, when a bill is completed for accounts that have a Non-Billed Budget SA, the system needs to distribute the Non-Billed Budget's credit balance to the covered SAs. The system will only do this if you specify an appropriate algorithm on the NBB SA types. - As explained under Overpayment Segmentation, when a bill is completed, the system may apply an excess credit from a prior overpayment to an account's service agreements. <p>Note. Algorithms of this type are called for all non- Canceled service agreements, regardless of whether or not they are billed. If your algorithms should only be processed under certain conditions (for example, only process this algorithm for Active service agreements), then it is the responsibility of the algorithm to check the conditions before continuing.</p>
Bill Eligibility	Optional	<p>These algorithms are executed during billing and allow logic to be introduced to check additional criteria to determine if an SA is eligible for billing.</p>

Break NBB SA	Optional	<p>These algorithms are executed when a Non-Billed Budget is manually stopped via the Non-Billed Budget maintenance page.</p> <p>Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.</p>
Break Pay Arrangement	Optional	<p>These algorithms are by executed by severance events when the event is created for payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place when a customer breaks a payment arrangement. Refer to Monitoring Payment Arrangements for more information about breaking payment arrangements.</p>
Budget Eligibility	Optional	<p>These algorithms are executed when determining in a service agreement is eligible for budget. Algorithms of this type are only applicable on SA types that are marked as eligible for budget and may be used to override that setting and indicate that the service agreement is not eligible.</p> <p>For example, maybe service agreements in a certain rate are not eligible. Or perhaps service agreements with a given characteristic value are not eligible.</p>
Cut Process Rule	Optional	<p>These algorithms are executed to create a cut process for service agreements of this type. Refer to The Big Picture Of Cut Processes for more information.</p>
FT Freeze	Optional	<p>These algorithms are executed whenever a financial transaction is frozen that is linked to a service agreement of this type. The following situations necessitate the definition of an FT freeze algorithm:</p> <ul style="list-style-type: none"> - As explained under Technical Implementation of Routing Consumption To Service Providers, when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. - As explained under Technical Implementation of Paying The Service Provider, when a financial transaction (FT) is

frozen that is associated with a sub SA, the system must check if this FT should trigger the "payment" of a service provider. If so, it has to create an adjustment to increase how much we owe the service provider. The system will only do this if you specify an appropriate FT Freeze Algorithm on the sub SA types.

High Bill Amount	Optional	<p>This algorithm type checks for high bill amounts during batch billing. A bill threshold amount can be defined on a service agreement. By default the system compares this threshold amount to the bill segment amount during batch billing. If the bill segment amount exceeds the given threshold value, a bill error is generated. No proration takes place on the threshold amount if the bill segment's consumption period falls outside of the rate frequency's normal period.</p> <p>This algorithm may be used to override the default system behavior. It will prorate the SA's bill threshold amount before comparing it to the batch bill segment amount if the consumption period falls outside of the rate frequency's normal period.</p>
Landlord Reversion	Optional	<p>These algorithms are used to create, update or cancel a service agreement for a landlord when service is started, stopped or updated for a premise that references a landlord agreement.</p> <p>Algorithms of this type are called:</p> <ul style="list-style-type: none"> - When starting a new SA (start initiation) - When stopping an SA (stop initiation) - When canceling a pending start SA - When changing the stop / start dates of back-to-back service agreements
Loan Interest Charge	Optional	<p>These algorithms are executed whenever the interest charge needs to be calculated for a loan, such as when the loan amortization schedule is created and when a bill segment is created for a loan SA. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p>
Loan Periods and Amount	Optional	<p>These algorithms are executed whenever a user clicks the Calculate button on Loan - Main or on the Start SA Confirmation dialog for a loan SA. It calculates either the number of periodic payments or the payment amount (depending on whether the user specifies the number of payments or the payment amount</p>

		as input). This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Loan Schedule	Optional	These algorithms are executed whenever the system needs to create a loan amortization schedule for a loan, such as when you renegotiate the terms of a loan on Loan - Main . This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Override Proration Days	Optional	This algorithm is invoked from rate application, right after base has determined if proration applies. It is used to override base days, normal days and "is within proration window" indicator, which were determined by base logic. Only one algorithm may be plugged-in to this system event. This is available only in the calculation rule based rating engine.
Payment Arrangement	Optional	These algorithms are by executed to handle the creation, breaking and canceling of payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place during the lifecycle of a payment arrangement. Refer to Monitoring Payment Arrangements for more information about payment arrangements. Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.
Payment Freeze	Optional	These algorithms are executed whenever a payment is frozen. The following situations necessitate the definition of such an algorithm: - For a loan SA, such an algorithm is required to create a frozen adjustment that transfers any credit balance resulting from an overpayment to the loan's principal balance. Refer to Defining Loan Options for more information.
Pre-Bill Completion	Optional	These algorithms are executed immediately prior to bill completion when a bill contains a bill segment for a service agreement whose SA type has such an algorithm. The following situations necessitate the definition of such an algorithm: - If you want to delete a bill segment that's in error on the last night of a bill cycle when there are other bill segments that aren't in error, use such an algorithm.

Process NBB Scheduled Payment	Optional	These algorithms are executed by the NBB Scheduled Payment Processing background process whenever a scheduled payment is due. If the Non-Billed Budget SA is unmonitored, this algorithm is not called. This algorithm should be specified on Non-Billed Budget SA types to create the necessary adjustments for the Non-Billed Budget SA.
Proposal SA Acceptance	Optional	These algorithms are executed when a proposal service agreement is accepted. Refer to Enabling The Creation Of A Real Service Agreement for more information.
Proposal SA Bill Segment Generation	Optional	These algorithms are executed to generate simulated bills segments for a proposal service agreement . Refer to Enabling The Generation Of Simulated Bill Segments for more information.
Proposal SA Creation	Optional	These algorithms are executed when a proposal service agreement is created. Refer to Enabling The Automatic Generation Of Billing Scenarios for more information.
SA Activation	Optional	<p>These algorithms are executed when a service agreement status changes from Pending Start to Active. It performs any additional activities that are necessary to activate an SA. The following situations necessitate the definition of such an algorithm:</p> <p>If you want to create a customer contact to indicate that a non-billed budget has been activated, use such an algorithm.</p>
SA Cancel	Optional	<p>These algorithms are executed when a service agreement status changes to Canceled. It performs any additional activities that are necessary to cancel an SA.</p> <p>An example of when you may use this algorithm is that perhaps your business rules dictate that the creation of a payment arrangement should create a credit rating history transaction. When a payment arrangement SA is canceled, the credit rating should be updated with an end date.</p>
SA Creation	Optional	<p>These algorithms are executed when a service agreement is created. The following situations necessitate the definition of such an algorithm on an SA type:</p> <ul style="list-style-type: none"> - If you want to create a To Do entry whenever a new service agreement of a given type is added, specify such an algorithm.

		<p>- If you want to automatically activate SAs of a given type (instead of waiting for the background SA activation process to run), specify such an algorithm.</p> <p>- If you want to create a Workflow Process when a service agreement of a given type is added, specify such an algorithm.</p>
SA Information	Optional	<p>We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "SA information" algorithm on installation options or the system default "SA information" if no such algorithm is defined on installation options.</p>
SA Renewal	Optional	<p>These algorithms are executed by the Service Agreement Renewal background process whenever an SA is due for renewal or when the user clicks the Renew button (for Non-Billed Budgets). It performs any activities that are necessary to renew an SA and returns the new renewal and expiration dates for the SA.</p>
SA Stop	Optional	<p>These algorithms are executed whenever a service agreement's status changes from pending stop to stopped. The following situations necessitate the definition of a SA stop algorithm:</p> <ul style="list-style-type: none"> - For Non-Billed Budgets to distribute any remaining credit balance from the Non-Billed Budget SA to the covered SAs, you must specify such an algorithm. - For service credit memberships that have a refundable membership fee, an SA Stop algorithm attempts to refund the fee if this is the last SA linked to the membership that is being stopped.
SA Stop Initiation	Optional	<p>These algorithms are executed whenever a service agreement's status becomes pending stop. The following situations necessitate the definition of a stop initiation algorithm on an SA type:</p> <ul style="list-style-type: none"> - As explained under Finalizing Pending Stops, service agreements are normally transitioned from pending stop to stopped by a background process (or manually). For Non-Billed Budget SAs to transition to stopped automatically (without waiting for the

background process), you must specify such an algorithm.

When does a SA become pending stop?

Service agreements typically become pending stop when a user initiates a request to stop service on [Start Stop - Main](#). A [severance process](#) with an Expire SA [severance event](#) causes a service agreement to become pending stop (when the event is executed). Additionally, the [Stop Expired Service Agreements](#) background process starts the process to initiate the stop of an SA when the expiration date is on or before the process date.

Start Stop Field Work

Optional

These algorithms are executed to create the field activities necessary to start and stop service. Refer to [Starting Service and Field Activities](#) and to [Stopping Service and Field Activities](#) for a description of when algorithms of this type are called. The following situations necessitate the definition of a start stop fieldwork creation algorithm:

- If a service agreement has field activities created to start and stop service at its service points, its SA type must have an appropriate start stop field work creation algorithm.
-

SA Type - Billable Charge Overrides

The [BCU2 - Create Billable Charge](#) background process is responsible for creating billable charges for each billable charge upload staging record interfaced into the system. This process will override the values of the various switches referenced on a billable charge upload staging line if the respective service agreement's SA type has an override value for the billable charge upload staging line's billable charge line type.

NOTE:

This information is optional. If you don't need to override the values of a [Billable Charge Line Type](#) you don't need to set up this information.

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Upload Override** page to define override values for a given SA Type / Billable Charge Upload Staging Line Type.

Description of Page

Use the **Billable Charge Overrides** collection to define values to be overridden on billable charge lines uploaded from an external system (refer to the description above for the details). The following switches may be overridden for a given **SA Type** and **Billable Charge Line Type**.

- Use the **Show on Bill** switch to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.
 - Use the **Appear in Summary** switch to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.
-

- Use **Memo Only, No GL** switch to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.
- Use **Distribution Code** to define the value to be defaulted into the Distribution Code on billable charge upload lines that reference this line type.

SA Type - Contract Option Type

Open **Admin > Customer > SA Type > Search** and navigate to the **Contract Option Type** page to define the contract option types, which are valid for service agreements of a given type.

NOTE:

This tab may not appear. This tab is suppressed if the interval billing Contract Options module is [turned off](#).

Description of Page

If the SA Type's special role flag is set to Bill Determinants Required, you may define the **Contract Option Types** that are valid for contract options linked to a service agreement of this type.

Where Used

This information is used to validate the contract options linked to the service agreement. Refer to [Service Agreement - Contract Options](#) for more information.

SA Type - NBB Recommendation Rule

Open **Admin > Customer > SA Type > Search** and navigate to the **NBB Rec'n Rule** page to define the recommendation rules that are valid for Non-Billed Budget SAs of this type.

Description of Page

If the SA Type's special role is Non-Billed Budget, you may define the **Recommendation Rules** that are valid on non-billed budget SAs of this type. Check the **Use As Default** box to indicate the default recommendation rule for service agreements of this type.

FASTPATH:

For more information about Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#).

Where Used

The Non-Billed Budget recommendation rules are used to recommend the payment amount and payment schedule for Non-Billed Budget service agreements. Refer to [Maintaining Non-Billed Budgets](#) for more information.

Setting Up Start Options

Start options save users time and prevent data entry errors because they default many values on a service agreement (e.g., the rate schedule, recurring charge amount, contract riders, contract terms, characteristics, terms and conditions, etc. can all be defaulted onto a service agreement from a start option).

A SA type may have zero or more start options.

- A SA type without start options is usually one that has a very limited number of options. For example, if a SA type has a single valid rate and no customer-specific contract values, you don't need to setup a start option (the SA's default rate can default based on the information defined when you setup the SA type).
- A SA type with multiple start options is one where many different permutations are possible. For example, a SA type that can have multiple rates and each rate can have multiple riders is a good candidate for start options (where each start option will default, for example, a specific rate and set of contract riders).

When the [Start/Stop](#) transaction is used to start service AND the service being started uses a SA type with start options, the user is asked to select one of the start options. The service agreement that's created is populated with fields from the start option.

When the [Order](#) transaction is used to start service, the user selects start options, but only indirectly. It works like this:

- A user selects a "package" of services to start service for a customer.
- A "package" contains one or more start options.
- When a user selects a package, the system creates a service agreement for each start option on the package (and defaults the information on each service agreement from the respective start option).

A start option's default values may change over time (i.e., the information on a start option is effective-dated). The start service logic uses the version of the start option that is effective on the day service starts.

Start options can cause a great deal of information to be populated on a service agreement. There are several ways to change this default information:

- A user may override this information using the [Service Agreement](#) transaction.
- If the service agreement is in the pending start state, you can use the [Start/Stop - Pending SAs](#) page to change the service agreement's SA type and/or start option.
- If the service agreement is in active or pending stop states, a button appears on [Service Agreement - Main](#) called **Apply New Start Option**. When pressed, the user is allowed to define a start option and the date its terms become effective on the service agreement. Refer to [Changing A Start Option](#) for the details of this functionality.

The topics in this section describe how to setup start options.

NOTE:

The merge transaction can save setup time. The [Start Options Merge](#) transaction can be used to construct a start option by copying pieces from other start options.

Start Option Considerations - Rate-Oriented SA Types

To understand the following discussion, you should be familiar with the following concepts:

- SA types that use rates have one or more valid rate schedules. Only these rate schedules may be defined on service agreements of a given type.
- One of a SA type's rate schedules may be designated as the "default" rate. The system assigns the "default" rate to new service agreements when a CSR doesn't choose a start option.
- Start options may be used by customer service reps when a service is started for a customer. A start option causes the customer's new service agreement to be populated with a specific rate and contract terms (e.g., contract riders, contract values). The use of start options is not allowed if the service's SA type does not require a start option. The use of start options is required if the service's SA type requires a start option.

Whether or not a SA Type has start options is dependent on the following factors:

- If a SA Type has only one valid rate and the rate doesn't use customer-specific contract terms (e.g., contract riders, contract values), the SA Type does not need any start options. Why? Because the system default's the SA type's default rate on new service agreement when no start option is used at start time.

- If a SA Type has only one valid rate, but under unusual circumstances, it uses customer-specific contract terms, you'll want an option for every situation (both the standard one and the unusual ones).
- If a SA Type has a single rate with a variety of contract terms (which, by definition, are different for each customer), then you'd want a start option for each permissible combination of contract terms. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).
- If a SA type has multiple valid rates and a variety of contract terms (a combination of the previous two points), you'd need a start option for each permissible combination. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).

Start Option Considerations - SA Types That Use Recurring Charges

To understand the following discussion, you should be familiar with the following concepts:

- Many SA types use the recurring charge algorithms to generate the bill segments. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you'd have an SA type called CA/MERCH-I and indicate it uses the recurring charge algorithm.
- When a CSR creates an SA type that uses recurring charge algorithms, they can enter the recurring charge amounts on [Start/Stop Service - Start Confirmation](#) window OR they can specify a start option on this window and let the system populate the recurring charge amount. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you can set up a start option called HP 3PAY with an installment amount of \$300.
- Depending on the type of service being started, you might also need to generate an adjustment when service is started in order to initialize the total debt. For example, when a customer buys a heat pump we'll need an adjustment issued to realize the entire \$900 of revenue.

The following table provides examples of recurring charge SA types with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments
CA/CHARITY	DONATE \$5		5	This causes a charitable contribution to be created with an installment amount of \$5.
CA/CHARITY	DONATE \$10		10	This causes a charitable contribution to be created with an installment amount of \$10.
CA/PA-REGU	PAY \$10 PM		10	This causes a payment arrangement to be created with an installment amount of \$10.
CA/PA-REGU	PAY \$20 PM		20	This causes a payment arrangement to be created with an installment amount of \$20.
CA/PA-UNRE	PAY \$10 PM		10	This causes a payment arrangement to be

				created with an installment amount of \$10.
CA/PA-UNRE	PAY \$20 PM		20	This causes a payment arrangement to be created with an installment amount of \$20.
CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue.
CA/DEP-I	PAY \$40 PM		40	This causes a deposit service agreement to be created with an installment amount of \$40. The CSR would be required to define the total deposit amount to be billed over the life of the service agreement on the secondary SA window on the Start Account window.

Start Option Considerations - Initial Adjustment SA Types

To understand the following discussion, you should be familiar with the following concepts:

- Some SA types depend on an adjustment to book their initial debt. For example, the CA/MERCH-I SA type requires an initial adjustment to book the payoff amount for the entire cost of the merchandise. Another example would be a loan service agreement (refer to [Booking The Principal Amount Using An Adjustment](#) for the details).
- When a CSR starts an SA type that requires an initial adjustment, they can create the adjustment immediately after starting service OR then can specify a start option when they start service and let the system generate the adjustment. You could let the system create the adjustment to book the \$900 associated with the heat pump as shown in the previous section.

The following table provides examples of SA types that use adjustments with several typical start options:

CIS Division/	Start Option	Adjustment Type	Install Amount	Comments

SA Type

CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue.
CA/CONNECT	CONNECT	CONNECT		This causes an adjustment to be issued to realize the connection charge.

Start Option - Main

Open **Admin** > **Customer** > **SA Type Start Option** > **Add** to define a SA type's start options.

Description of Page

Every start option is uniquely identified by the following fields:

CIS Division & SA Type Enter the Division and SA type to which the start option is linked.

Start Option Enter the unique identifier of the option. Pick something easy to recognize as this will be used by CSRs to pick an option when they start service.

Effective Date Enter the earliest effective date. It should be the same as the earliest effective date of the start option's rate (although it doesn't hurt for it to be earlier). The date defaults to the current date. (The status, below, should be Active.)

The remaining fields further describe a start option.

Enter a **Description** for the start option.

Indicate its **Status**. For new start options, the status should be Active. When it's no longer applicable, change it to Inactive.

Enter the primary **Rate Schedule** that should be defaulted onto service agreements created using this option. Refer to [Start Option Considerations For SA Types That Use Rates](#) for more information.

FASTPATH:

For more information about a service agreement's rates, refer to [Service Agreement - Rate Info](#).

Enter the **Adjustment Type** that should be generated, if any, when service is started using this option. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for more information.

Enter the **Recurring Charge Amount** that should be defaulted onto service agreements created using this option. This field is only visible when the SA type allows recurring charges. In addition, the prompt for this field is defined on the SA type

table on the billing window (e.g., it could appear as Payment Amount, Budget Amount, or Installment Amount). Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for more information.

Enter the **Currency Code** in which monetary amounts are denominated.

NOTE:

The currency code defaults from the [installation record](#).

Enter the **Total Amount to Bill** that should be defaulted onto service agreements created using this option. This is useful to initiate either a loan or a deposit. The prompt for this field is defined on the SA type table on the billing window (e.g., it could be Deposit Amount or Loan Amount).

Use **Number of Periods** to default the number of payment periods of service agreements created using this option. This field is only allowed for SA types with special role of Loan. Refer to [The Terms Of A Loan Are Stored On A Service Agreement](#) for more information.

If your SA Type has a special role of Billing Determinants Required, you may enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements that are created using this option. For start day option, you may choose **Current Day** or **Previous Day**.

If your SA Type has a special role of Billable Charge, then you can setup the start option to automatically create a billable charge when a service agreement is created using this start option. For example, you might have a start option that automatically creates a "one-time invoice" service agreement along with a "tree trimming" billable charge. To use this feature you should turn on the **Create Billable Charge** switch and specify the **Billable Charge Template** that will be used to create the billable charge. These fields are only allowed for SA types with special role of Billable Charge.

FASTPATH:

Refer to [Setting Up Billable Charge Templates](#) for more information about templates. Refer to [An Easier Way To Create One Time Charges](#) for an example of how you can setup a campaign with packages that use this type of start option.

NOTE:

The duplicate action in the page actions toolbar enables you to copy another start option. Refer to [Duplicate Button](#) in the system wide standards document for more information.

Start Option - Rate Info

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Rate Info** page to define the start option's default values for contract riders and contract values.

Description of Page

The information in the **Contract Riders** collection defines the contract riders to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Bill Factor The bill factor defines the type of rider. You may only reference bill factors designated as being applicable for contract riders.

Number of Days The number of days the rider should be in effect. This value is used by the system to set the stop date on the service agreement's contract rider. If the rider has no expiration, set this field to 0. Default note: this field will be set to 0 if left blank.

FASTPATH:

For more information about a service agreement's contract riders, refer to [Service Agreement - Contract Riders](#).

The information in the **Contract Values** collection defines the contract values to be defaulted onto service agreements created using this start option. The following fields are required for each event:

Bill Factor The bill factor defines the type of value. You may only reference bill factors designated as allowing values in contract terms.

Number of Days The number of days the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Value The amount of the contract value.

FASTPATH:

For more information about a service agreement's contract values, refer to [Service Agreement - Contract Values](#).

Start Option - Characteristics & Qty

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Characteristics & Qty** page to define the start option's default values for characteristics and contract quantities.

Description of Page

The information in the **Characteristics** collection defines the characteristics to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Characteristic Type This defines the type of characteristic. Note: you may only define characteristics valid on service agreements.

Characteristic Value This defines the characteristic value that will be defaulted.

FASTPATH:

For more information about a service agreement's characteristics, refer to [Service Agreement - Characteristics](#).

The information in the **Contract Quantity** collection defines the contract quantities to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Contract Quantity Type This defines the type of contract quantity.

Contract Quantity The amount of the contract quantity.

FASTPATH:

For more information about a service agreement's contract quantities, refer to [Service Agreement - Contract Quantity](#).

Start Option - Contract Option

NOTE:

This tab may not appear. This tab is suppressed if the interval billing Contract Options module is [turned off](#).

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Contract Option** page to define the start option's contract option default values.

Description of Page

The collection of contract option types will be used to link contract options to a service agreement that will be created with this start option. If the contract option to create for the service agreement will be SA Specific, simply indicate the **Contract**

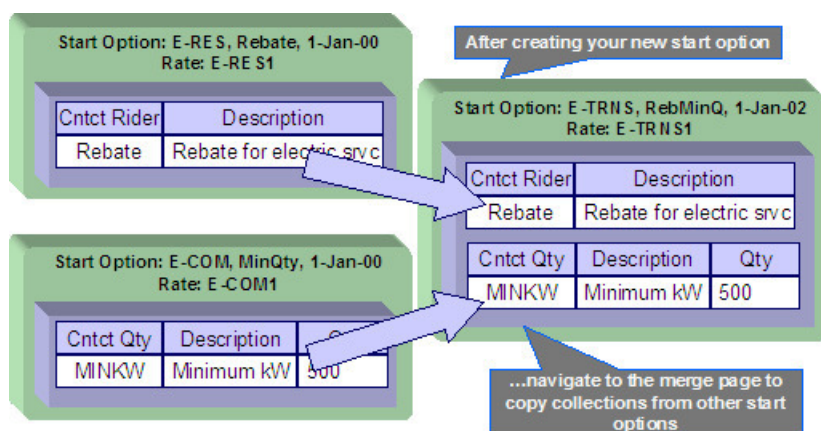

Option Type. This will cause a new contract option to be created with this contract option type and the new contract option will be linked to the new SA at start time. If the contract option to create for the service agreement will be Shared, indicate the contract option type and the **Contract Option ID**. This will cause the specified contract option to be linked to the new SA at start time.

Start Option Merge

Use this page to modify an existing start option by copying information from other start options. This page may be used to copy records from the contract rider, contract value, contract quantity, characteristic, contract option and TOU contract value collections from one or more existing start options to another.

NOTE:

The target start option must exist prior to using this page. If you are creating a new start option, you must first go to the [Start Option](#) page to add the new start option and then navigate to the merge page to copy collection information.

NOTE:

Duplicate versus Merge. The [Start Option](#) page has [Duplication](#) capability. You would duplicate a start option if you want to a) create a new start option AND b) populate it with all the information from an existing start option. You would use the start option merge page if you want to build a start option using pieces of one or more start options.

Start Option Merge - Main

Open **Admin > Customer > SA Type Start Option Merge**.

Description of Page

Select the **Original Start Option**, which is the target for merging the start option collection information.

Select the **Merge From Start Option**, which is your template start option to copy the collections from.

NOTE:

You may only copy information from one Merge From start option at a time. If you wish to copy information from more than one start option, select the first Merge From start option, copy the desired records, Save, then select the next Merge From start option.

The left portion of the page will display any existing records in the collections for the original start option. The right portion of the page will display the existing records in the collections for the Merge From start option.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From start option to the Original start option. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **Contract Riders** collection initially displays existing contract riders linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **Number of Days** for each contract rider is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Values** collection initially displays existing contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor**, **Number of Days** and **Value** for each contract value is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The topics, which follow, describe how to perform common maintenance tasks:

Removing A Row From A Grid

If you wish to remove a record linked to the Original start option, click the "-" button to the left of the record.

Adding A New Row To A Start Option

You may move any of the records from the Merge From start option to the original start option by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing An Uncommitted Row From A Start Option

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Start Option Merge - Characteristics and Quantities

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Characteristics and Quantities** page to copy rows in the characteristic and contract quantity collections.

Description of Page

The left portion of the **Characteristics** collection initially displays existing characteristics linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Characteristic Type** and **Characteristic Value** for each characteristic are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Quantity** collection initially displays existing contract quantities linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Quantity Type** and **Contract Quantity** for each contract quantity are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Contract Option

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Contract Option** page to copy rows in the contract options collection.

NOTE:

This tab may not appear. This tab is suppressed if the interval billing Contract Options module is [turned off](#).

Description of Page

The left portion of the **Contract Option** collection initially displays existing contract option information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Option Type**, **Contract Option ID** and **Description** of the contract option for each contract option row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Terms and Conditions

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Terms and Conditions** page to copy terms and conditions (T&Cs).

Description of Page

The left side of the **Terms and Conditions** grid initially displays the T&Cs linked to the original start option. On the right side, the T&Cs linked to the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for a description of how to perform common maintenance tasks for the grids displayed on this page.

Defining SA Relationship Options

We use the term "SA Relationship" to describe functionality that supports the following situations:

- When companies other than your own provide a service to your customers AND you have some type of interaction with these companies. For example, in a deregulated market, customers deal with both distribution and energy supply companies. These companies typically exchange a great deal of information about their joint customers.
- When multiple rates are associated with a service (where each rate corresponds with a sub-category of service). For example, most water companies charge for both water and wastewater service using separate rates for each. While it is possible to set up water and wastewater as separate service agreements, the SA relationship functionality allows you to set up a single "master" service agreement (for the water service) and associate with it a "sub" service agreement (for the wastewater service).

- When a party representing a group of customers negotiates a contract that is applied over and above those of the individual service agreements. For example, the head office of a national chain may negotiate for additional discounts that should be calculated together or individually. The SA relationship functionality may be used to track the covered service agreements and to calculate and transfer discounts to the head office's service agreement. Refer to the special discounts section.

WARNING:

Setting up the SA relationship control tables is as challenging as your organization's business rules. If you don't have requirements similar to those described above, you don't have to set up anything. If you have these types of requirements, your setup process will be taxing as you must design and set up control tables that manage the financial and consumption interactions that take place between you, your customers, and the various service providers.

The topics in this section describe tables that control your SA relationship functionality.

The Big Picture of SA Relationships and Service Providers

You must set up service providers if companies other than your own provide a service to your customers AND you have some type of interaction with these companies. You will have one service provider for each such company. For example, if you are a distribution company in a deregulated market, you will have a service provider for each company that provides any of the following services:

- Energy (commonly referred to as Energy Supply Companies, Energy Service Providers, Retailers, and Suppliers)
- Meter service (commonly referred to as Meter Service Providers and Meter Agents)
- Meter reading (commonly referred to as Meter Data Management Agencies and Meter Reading Service Providers)
- Billing (commonly referred to as Billing Agents)

The topics in this section provide background information about service providers.

Persons and Service Providers

A great deal of information about your service providers is defined using a person. For example, a service provider's name, address, phone numbers, electronic ID's, etc. are all defined on the person object.

In addition, every service provider must have a service provider object created for it. The service provider object contains information about a provider's relationships with the customer and your organization, for example:

- Do you calculate bills for the service provider? If so, do you have their rates or do they interface their charges to you? Refer to [Billing Relationships](#) for more information.
- Do you send the customers' consumption to the service provider? Do they send it to you? Refer to [Consumption Relationships](#) for more information.
- How are financial settlements between your organization and the service provider implemented (do you pay them when you get paid?, do you purchase the receivable for them?, etc.). Refer to [Service Providers Have Service Agreements Too](#) for more information.
- Etc.

FASTPATH:

Refer to [Designing Your SA Relationship Types and Service Providers](#) for more information.

NOTE:

In some situations, you will need to set up a service provider for your own company. Refer to [When Your Company Is A Service Provider](#) for the details.

Service Providers Are Linked To Service Agreements

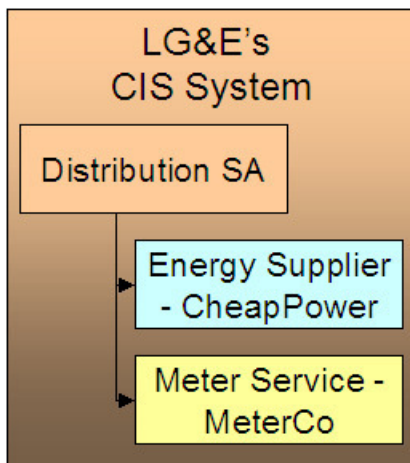

The following diagram illustrates a customer's bill for electric service in a deregulated market. Notice that there are separate sections for energy, distribution and meter service.

NOTE:

Consolidated billing. The following is an example of a bill that consolidates charges from many service providers. Rather than receive a consolidated bill, it is possible for the customer to receive 3 separate bills, one from each service provider (we refer to this as Dual billing).

Customer's Electric Bill	
Energy Supply - Cheap Power	\$12
Distribution - LG&E	\$9
Meter Service - MeterCo	\$2

If we were to look at this customer's service agreement in the distribution company's CIS system, we'd find a service agreement for distribution charges, and linked to it would be information about the meter service and energy service providers:

If we look at this customer's service agreement in the energy supply company's CIS system, we'd find a service agreement for energy charges, and linked to it would be information about the distribution and meter service providers:

And finally, if we look at this customer's service agreement in the meter service company's CIS system, we'd find a service agreement for meter service charges, and linked to it would be information about the distribution and energy providers:

NOTE:

Bottom line. A customer's service providers keep track of the customer and each other in their respective CIS systems. A customer will have a service agreement (or the equivalent) in each service provider's CIS system. A customer's service agreement defines the service providers who supply each type of service.

FASTPATH:

Because information about customers and their services needs to be kept up-to-date in many different CIS systems, there is a need for automated communications between service providers. Refer to [Service Providers Have To Communicate About Customers](#) for more information.

Service Providers May Change Over Time

A customer typically has a choice of service providers. Over time, their choice may change. The system keeps track of a customer's service providers throughout time so that it can accurately cancel / rebill historical bills. This means that the service provider relationship is *effective-dated*.

The following diagram illustrates how a distribution company's system keeps track of a customer's service providers (notice the customer changed energy suppliers):

How To Set Up SA Relationships On A Customer's Service Agreement

There are three ways to set up a customer's service providers:

- **Manually.** An operator can manually change a service agreement's SA relationships. The manual method is NOT recommended as changing service providers typically involves many events (e.g., you have to notify the current service provider that they will be dropped).
- **Use Default Service Providers.** The system will default a service provider on a required SA relationship when a service agreement is activated. Refer to [Defaulting Relationship Types And Defaulting Service Providers](#) for more information.

When Your Company Is A Service Provider

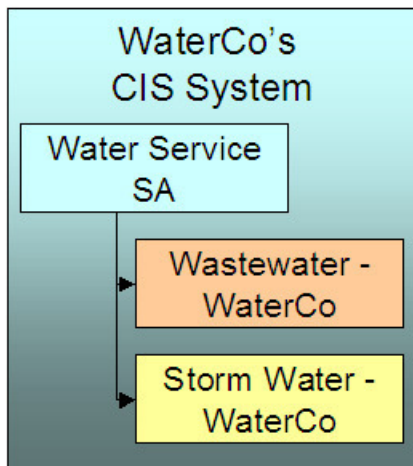

Besides setting up service providers for other companies that provide services to your customer, you may have to set up a service provider for your own company. You have to do this when:

- **Your organization can supply one of the services.** Refer to the illustration in [Service Providers Are Linked To Service Agreements](#). If you are LG&E and you supply energy in addition to distribution, you would need to set up a service provider for your own organization. Why? Because whenever you have a subcategory of service (e.g., energy supply), you must indicate the service provider who provides this service; even when it's you.
- **You decide to break up a service into subcategories** (and have a separate service agreement for each category). For example, a water company may choose to break up service charges into water, wastewater and storm water (they may do this because there are different rates for each category of service). The following is an example of the segregated charges associated with this water company's service charges.

Customer's Water Bill	
Water Service - WaterCo	\$15
Wastewater - WaterCo	\$6
Storm Water - WaterCo	\$5

This water company system may benefit by creating a single service (for water) and indicating there are subcategories of service (for wastewater and storm water). Whenever you have a subcategory of service, you must indicate the service provider who provides this service. And, in this example, the water company would be the sole service provider for each subcategory of service.

Customer's Water Bill	
Water Service - WaterCo	\$15
Wastewater - WaterCo	\$6
Storm Water - WaterCo	\$5

NOTE:

Refer to [We Bill For Them - Rate Ready Bill Segments Are Special](#) for restrictions in respect of using subcategories of service.

Service Providers Have To Communicate About Customers

The providers of service typically have to communicate with each other in respect of the customer's service. The following diagram illustrates the major interfaces of information between your system and your service providers.

Depending on where your organization fits in the service provider hierarchy, you may:

- Bill for other service providers (or they may bill for you). Refer to [Billing Relationships](#) for more information about billing communications.
- Send the customer's consumption to service providers (or they may send it to you). Refer to [Consumption Relationships](#) for more information about consumption communications.
- Apprise service providers of the changes to the customers' service (or they may apprise you). Refer to [How Do You Communicate With Service Providers?](#) for more information about communications between service providers.

Relationships Between Service Providers

Service providers may arrange contractual relationships with other service providers to provide additional services, e.g., an energy service provider may work with a specific meter data management agency to gather and report interval meter read data.
