Use **Campaign** to define the campaign to which this package belongs.

Use **Description** and **Long Description** to describe the package.

Status defines the state of the package. Refer to [Lifecycle of a Package](#) for information about the valid values and the state transition rules.

The tree at the bottom of the page summarizes the information that appears on the remaining tabs. You can click on a hyperlink to transfer you to the appropriate tab with the relevant information displayed.

Package - SAs To Create

This information on this page controls the type of service agreement(s) / service point(s) that are created if this package is selected on an order.

FASTPATH:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Sales & Marketing, Package** and navigate to the **SAs To Create** tab.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

WARNING:

This following information is not intuitive; we strongly recommend that you follow the guidelines under [Designing Campaigns and Packages](#) before attempting to enter this information.

The **SAs To Create** scroll contains one row for every service agreement that will be created if this package is selected on an order. The following fields are used:

- **CIS Division** and **SA Type** define the [type of service agreement](#) to be created.
- **Start Option** controls how the system will populate the new service agreement with default values. Refer to [start options](#) for more information.
- **SP Type** defines the type of service point that will be created / reused. Refer to [Designing SP Types](#) for more information.
- **Start Method Algorithm** controls how the system creates the new service agreement and service point. Refer to [Determine The Method Used To Create Service Agreements](#) for more information.
- **Create Proposal SA** controls if the new service agreement is a real or a proposal SA. This switch only appears if the quotation Contract Management module is not [turned off](#). Refer to [Proposal Service Agreements Must Exist](#) for more information.

Package - Questions & Misc Fields

It is possible to design a campaign so that the user is prompted for additional information when a package is selected on an order. This page is used to define how the package overrides the questions and miscellaneous fields defined on the [campaign](#).

FASTPATH:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Questions & Misc Fields** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Campaign contains a concatenation of basic information about the campaign.

WARNING:

The following information is not intuitive; we strongly recommend that you follow the guidelines under [Designing Campaigns and Packages](#) before attempting to enter this information.

The grid contains one row for every [Questions & Misc Field](#) defined on the **Campaign**. You need only modify this information if this package behaves differently than the campaign (e.g., a field is required on the package, but optional on the campaign). To override a field on this package, turn on the **Override** switch and change the appropriate fields. There are several restrictions in respect of what can be overridden as described below:

- If a question / miscellaneous field is Required on the campaign, no fields may be overridden on the package.
 - If a question / miscellaneous field is Optional on the campaign, you may override all field values. However, if the package has been used on a Completed order, you may not change its **Applicability** to be Required.
 - If a question / miscellaneous field is designated as only applicable on package on the campaign, you should designate its applicability as Required, Optional or Not Used On This Package. If the field is either Required or Optional on this package, you may also override the other field values. Please note that if the package has been used on a Completed order, you may not change its **Applicability** to be Required.
-

FASTPATH:

Please refer to the Description of Page that appears under [Campaign - Questions & Misc Fields](#) for a description of the fields on the page.

Package - Eligibility

This page is used to define the conditions under which a package can be selected on an order.

FASTPATH:

Refer to [The Big Picture Of Package Eligibility](#) and [Determine Package Eligibility Rules](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Eligibility** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

WARNING:

The following information is not intuitive; we strongly recommend that you follow the guidelines under [The Big Picture Of Package Eligibility](#) and [Determine Package Eligibility Rules](#) before attempting to enter this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sequence** to control the relative order in which the group is executed when the system determines if the package can be selected on an order (smaller numbers are executed before larger numbers).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of True.
 - Choose Eligible if this package can be selected on the order.
 - Choose Ineligible if this package cannot be selected on the order.
 - Choose Check Next Group if the next criteria group should be checked.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of False.
 - Choose Eligible if this package can be selected on the order.
 - Choose Ineligible if this package cannot be selected on the order.
 - Choose Check Next Group if the next criteria group should be checked.

The grid that follows contains the package's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being True or False. For example, you might have a row that indicates the customer is eligible for the package if their customer class is residential. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to [Defining Logical Criteria](#) for several examples of how this information can be used.

- Use **Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
 - Choose Field if you want to compare a response to a question / miscellaneous field to a given value. Push the adjacent search button to select the field.
 - Choose Algorithm if you want to compare anything other than a response to a question / miscellaneous field. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
- Use **Criteria Comparison** to define the method of comparison:
 - Choose Algorithm if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data.
 - Choose any other option if you want to compare the **Criteria Field Type** using a logical operator. The following options are available:
- Use >, <, =, >=, <=, <> (not equal) to compare the **Criteria Field Type** using standard logical operators. Enter the comparison value in the adjacent field.
- Use In to compare the **Criteria Field Type** to a list of values. Each value is separated by a comma. For example, if a field value must equal 1, 3 or 9, you would enter a comparison value of 1,3,9.
- Use Between to compare the **Criteria Field Type** to a range of values. For example, if a field value must be between 1 and 9, you would enter a comparison value of 1,9. Note, the comparison is inclusive of the low and high values.

- The next three fields control whether the related logical criteria cause the eligibility group to be considered True or False:
 - Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.

Package - Instructions

This page is used to define special instructions that should be presented to the user when they select this package. This information appears on the [Order - Package Confirmation](#) page.

FASTPATH:

Refer to [Determine If Additional Instructions Are Needed](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Instructions** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

The grid contains a row for each instruction to be presented to the user when they select a package. The following fields are used:

- Use **Sort Sequence** to control the relative order of the instruction.
- Use **Display Icon** to control the icon that prefixes the instruction. Refer to [Display Icons](#) for more information.
- Use **Description** to define the text of the instruction.

The Big Picture of Program Management

The program management functionality satisfies many diverse requirements. For example, you can use this functionality to:

- Market your products and/or services to customers and measure the success of your efforts.
- Encourage customers to enroll in various sales and marketing initiatives. For example, you can use program management to organize a campaign to encourage customers to participate in a conservation program, or to sign up for special contract options.
- Set up marketing surveys and record your customer's responses.
- Assign representatives to accounts.
- And more...

The topics in this section provide more information about the program management functionality.

The Big Picture of Initiatives, Leads, and Representatives

Three objects are at the heart of the program management functionality: **Initiatives**, **Leads**, and **Representatives**.

- An **initiative** defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.
- A **lead** is an instance of an initiative for targeted customers.
- There are two types of Representatives:
 - A **Sales Representative** is a user or group of users who can be assigned to follow up or manage leads. This representative is also responsible to sell or encourage the customer to participate in a program.
 - A **Third Party Representative** is a third party (typically external) who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection, and installation work)

The topics in this section provide background information about these objects.

The Big Picture of Initiatives

An initiative defines a structured campaign designed to encourage customers to participate in a program. An initiative can:

- Target a market segment by specifying criteria that must be satisfied before leads are generated for customers.
- Ensure that customers are still eligible to participate in a program at sign up or enrollment time.
- Define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in the program.
- Define whether the lead is related to other objects (such as, the premise) in addition to the account.
- Contain sub-initiatives. Together, an initiative and its subsidiary initiatives form an initiative hierarchy. This supports reporting purposes and the analysis of the success of different market segments and marketing efforts.

Refer to [Maintaining Initiatives](#) for more information.

About Initiative Hierarchies

Initiatives form an initiative hierarchy when one initiative is configured as a sub-initiative to a parent initiative. An initiative hierarchy can be used when a program is targeted at several market segments, or when different market segments each require a unique marketing effort to be executed. Initiative hierarchies can be up to five levels deep.

The following is a general example of a multi-level initiative hierarchy:

- Level 1 could be a “strategy” initiative.
- Level 2 could contain multiple campaigns. Each campaign can have a different way of marketing the strategy.
- Level 3 could define multiple marketing efforts. Each effort can have a different method for marketing the campaign.
- Level 4 could contain market segments that are the targets of a marketing effort.

NOTE: The terms used above are just for the example. Your implementation would define the actual terms used for the levels in an initiative hierarchy.

A **parent initiative** may be set up for reporting purposes, in which case you could choose to configure the initiative so that no leads are generated for it. For example, a “strategy” may not have eligibility criteria or lead event type profile defined against it. It may simply have sub-initiatives to define segments, and those segments could be the initiatives for which leads

are generated. Reporting is able to be performed at the multiple levels in order to summarize the effectiveness of the sub-initiatives.

The Components of an Initiative

The topics in this section provide information about the components of an initiative.

About Initiative Eligibility Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program. It can also confirm that the customer is still eligible to participate in a program at sign up or enrollment time. An initiative may have zero, one, or many eligibility criteria. Each customer is subjected to these criteria to determine whether they will have a lead generated for them for the initiative and/or whether they are still eligible to sign up or enroll into a program.

Designing these criteria can be easy or time-consuming; it all depends on the complexity of your business rules. The base product provides a number of initiative eligibility criteria types. Most of them perform comparisons based on a specific field; for example, one of the criteria types checks whether an account has submitted a rebate claim for a specific conservation program. Some types of eligibility criteria could simply check whether or not a specific condition is true. For instance, a base-supplied eligibility criteria business object checks that there is no active credit and collection process for the account.

Other types of eligibility criteria perform comparisons with scalar values (such as, a number of days, number of kwh) or with derived values (such as, attributes of an account). The base product provides a Freeform Criteria business object that can be used for these purposes. This business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered with this business object. Your implementations can add to these algorithm types as needed.

Your implementation can decide to use specific criteria business objects (base-supplied and/or implementation-specific), extend the base-supplied Freeform Criteria business object, or a mixture of both. Refer to [Designing Initiative Eligibility Criteria](#) for more details.

To set up an eligibility criterion, you must define the following:

- When the eligibility criterion should be executed - also called criteria execution point
- The field to be compared
- The comparison method

For the **criteria execution point**, the options include:

- Prior to a lead being generated for a customer
- Prior to the customer being signed up or enrolled into a program
- Both of the above

For the **field to be compared**, you can execute an algorithm to:

- Retrieve a field value or values from someplace else in the system (such as, the customer class or types of services associated with the customer)
- Derive a value based on some data from someplace else in the system (such as, the number of days since the last lead was created for the customer)

For the **comparison method**, you select the operator to perform the comparison on the field to be compared. The result from the algorithm will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the customer is eligible
- Indicate that the customer is not eligible

- Check the next condition
- Issue an error (this option is only available for Insufficient Data)

Refer to [Defining Eligibility Criteria for an Initiative](#) for more information about setting up eligibility criteria on an initiative.

About Related Object Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program (see [About Initiative Eligibility Criteria](#) for more information). An initiative may also be targeted at a specific entity (or related object) for that customer; for example, assume a customer has two properties in two different states - one in State A and one in State B. The customer may only be invited to participate, or be eligible, for a program for their specific property located in State A. In this situation, each eligible customer may then be subjected to Related Object Criteria following the execution of Initiative Eligibility Criteria to determine which of their properties are eligible to participate in a program (meaning, have one lead generated just for the account if one of their properties meets the criteria or a lead generated for each of the customer's eligible properties).

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes the object nomination algorithm after executing initiative eligibility criteria. The base-supplied Initiative parent business object (C1-Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account's active and pending start service agreement's service points. The algorithm applies the related object criteria (configured on the initiative) to each premise and if the premise is deemed eligible, it is returned as a related object for the lead.

Designing related object criteria can be easy or time-consuming. It all depends on the complexity of your business rules. The base product provides examples of related object criteria that looks for one or more premises to associate with a lead. One example checks for premises with a specific service point type. Another looks for a premise using its geographic value. For additional ways to find premises to link to a lead, implementations can either add specific related object criteria business objects (similar to the base samples) or extend the base-supplied Freeform Premise Criteria business object. The Freeform Premise Criteria business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered with this business object. Your implementation can add to these algorithm types as needed. Refer to [Designing Related Object Criteria](#) for more details.

When you set up a related object criterion, you must define two things:

- The field to be compared.
- The comparison method.

For the **field to be compared**, you can execute an algorithm to retrieve a field value or values from someplace else in the system; for example, retrieve a premise's service point types for which the customer has service.

For the **comparison method**, select the operator to perform the comparison on the field to be compared. The result from the comparison will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the related object is eligible
- Indicate that the related object is not eligible
- Check the next condition
- Issue an error

Refer to [Defining Related Object Criteria for an Initiative](#) for more information.

Examples of Initiative Criteria

The following is an example of how to set up initiative criteria.

Initiative: Smart Rate Program For Residential Customers

The program targets summertime pricing for residential customers. Customers are required to reduce energy use between 2 PM and 7 PM for no more than 15 summer days, which are referred to as smart days. A higher rate is charged during this time period. A discounted rate is applied for all other times during the season.

Initiative Eligibility Criteria

To be eligible for this initiative, the account must be a residential account with an average daily usage that is more than 10 kWh, not currently on a smart rate program, and is on either the ERES1 or ERES2 rate schedule. The account must also not have any active credit and collection process.

Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data	Criteria Execution Point
10	Residential customers	Retrieve Customer Class (Define an algorithm instance for base algorithm type C1-ICGETACEL, Retrieve account attribute)	=	R	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)
20	Average daily usage > 10 kWh	Retrieve average daily kWh usage (Define an algorithm for base algorithm type C1-ICGETAVSQ, Retrieve average service quantity)	>	10	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)
30	Not on a smart rate program	Retrieve all contract options (Use base algorithm C1-ICGETCOPT)	=	295076574659 (Contract option for smart day events)	Not Eligible	Check next condition	Not Eligible	Both (lead generation and enrollment)
40	Account is current	Check if Account Is Current (Use base	=	true	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)

Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data	Criteria Execution Point
		algorithm C1-ICCHKACCU)						
50	Active service on eligible rate	Retrieve all active rates (Use base algorithm C1-GETACTVRT)	IN	ERES1, ERES2	Eligible	Not Eligible	Not Eligible	Both (lead generation and enrollment)

Related Object Criteria

If the account is eligible, the premise(s) associated with the account's active and pending start service agreement's service points of type E-RES will be linked to the lead as related object(s).

Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data
10	Premises with E-RES (electric residential) service points	Retrieve Premise SP Types (Base algorithm C1-ICPRMSPTY)	=	E-RES	Eligible	Not Eligible	Not Eligible

About the Lead Event Type Profile

Each initiative can define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in a program. Each event or action is defined by a Lead Event Type. For example, one event could be that a letter or an email is sent to a customer. The collection and sequencing of lead event types defined on an initiative is referred to as the Lead Event Type Profile.

Refer to [Creating Initiatives](#) and [Maintaining Initiatives](#) for more information on setting up and maintaining the Lead Event Type Profile on an initiative.

About the Initiative Log

Every initiative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When an initiative is created.
- When an initiative's status changes (e.g. transitions to the active, accumulate statistics, inactive states).
- When lead related background processes are submitted for execution.
- When users want to manually add log entries as desired.

The Lifecycle of an Initiative

The following diagram shows the possible lifecycle of an Initiative:

Pending state: An initiative starts out in a pending state.

Active state: An initiative is transitioned manually by a user to the active state. Leads can only be generated for an initiative in an active state.

Accumulate Statistics state: A user or the system may transition an active initiative to a periodically transitioning accumulate statistics state. During this state, statistics for the initiative are accumulated prior to returning back to the active state.

Inactive state: An initiative may be transitioned manually by a user to the inactive state when they want to deactivate the initiative either temporarily or permanently. A user can manually place the initiative back to the active state from the inactive state.

Refer to [Maintaining Initiatives](#) for more information.

Initiative Information Can Be Overridden

“Initiative info” is the concatenated string of information that summarizes an initiative throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the initiative
- Start date and end date (if available) of the initiative

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Initiative's maintenance object.

The Big Picture of Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program.

Refer to [Maintaining Leads](#) for more information about working with Leads.

How Leads Are Created

Leads are created as follows:

- The system can generate a lead, or leads, for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative.
- Users can manually create a lead at their discretion.

Refer to section [Creating Leads from an Initiative](#) and [Manually Creating a Lead](#) for more information.

The Components of a Lead

A lead has two components: A **Lead Event** and a **Lead Log**.

Lead Event

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

Refer to [The Big Picture of Lead Events](#) for more information.

Lead Log

Every lead has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a lead is created
- When a lead's status changes (e.g. transitions to the active, successful or discarded state)
- When a lead event executes
- Users can manually add log entries as desired.

The Lifecycle of a Lead

The following diagram shows the possible lifecycle of a Lead:

Pending state: Leads can be created in either the **Pending** or **Active** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Active state: Leads can be created in either the **Pending** or **Active** state. When a lead is created or transitioned to the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

Discarded state: An unsuccessful lead transitions to the **Discarded** state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, the lead remains in the active state until a user manually discards it.

Refer to [Maintaining Leads](#) for more information.

Advanced Analysis of Leads

Leads can be sent to an external system (such as Oracle DataRaker) for advanced analysis prior to activating the lead.

The base product provides Advanced Analysis System Lead (C1-AdvancedAnalysisLead) business object for this purpose. Its lifecycle includes steps to send the lead to the external system and activate/discard the lead based on the result of analysis..

Additional configuration is needed in Program Management master configuration to enable external analysis/validation. See master configuration embedded help for more details.

The Lifecycle of a Lead with Advanced Analysis

The following describes the states of a Lead that is sent to an external system for advanced analysis prior to activation..

(Refer to the C1-AdvancedAnalysisLead business object to view the lifecycle diagram.)

Pending state: Leads can be created in either the **Pending** or **Ready for Extract** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Ready for Extract state: At this state, leads are ready to be sent to the external system for analysis. A monitor batch process is defined on this state, to ensure that leads in this state are transitioned only when the batch process runs.

Waiting for Analysis state: When a lead is transitioned to this state, an outbound message containing lead information is sent to the external system.

Error state: The lead is transitioned to this state if the system is unable to send the outbound message. Retry logic on this state will attempt to resend the lead to the external system. Leads in this state can also be **Discarded** if needed.

Active state: When a lead completes external analysis, the External Validation and External Activation Priority flags on the lead are updated. An inbound web service sends back the lead and transitions the lead into the **Active** state. An enter algorithm evaluates the External Activation Priority flag. If the lead is marked as being a priority for activation (based on settings in master configuration), the lead stays in the **Active** state. Otherwise, the lead is **Discarded**.

When a lead is in the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

An enter algorithm on this state sends an outbound message, to notify the external system about lead success.

Discarded state: Leads that are evaluated as non-priority for activation are transitioned to this state. Unsuccessful leads also transition to this state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, unsuccessful leads remain in the **Active** state until a user manually discards it.

Refer to [Maintaining Leads](#) for more information.

Lead Information Can Be Overridden

“Lead info” is the concatenated string of information that summarizes a lead throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the lead
- Creation date/time of the lead.

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead's maintenance object.

Leads Are Highlighted As Alerts

If you plug-in the appropriate alert algorithm (C1-OPENLDALR) on the Installation record, alert(s) will be shown for open leads associated with the person, account and premise in context. A separate alert is shown for each unique Lead that is in a non-final state. Each alert message shows the Lead's info string.

How and When Are Leads Activated

Leads are activated as follows:

- The system can generate a lead for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative. The leads can be created in either a Pending or Active state. These leads can then be activated by a background process when required by the user.
- Users can manually activate a lead at their discretion.

Refer to section [Creating Leads from an Initiative](#) and [Maintaining a Lead](#) for more information.

How are Leads Completed

The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.

- If an active lead is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative, to perform one or more tasks, the lead is determined to be successful if the Notify Third Party lead event is completed.

Users can also manually transition a lead to the Successful state at their discretion. Refer to [Maintaining a Lead](#) for more information about working with Leads.

How Are Leads Discarded

When leads are sent to an external system for analysis prior to lead activation, a possible result of the analysis is that the lead is flagged as non-priority for activation. When this occurs, the lead is discarded.

Unsuccessful leads transition to the Discarded state after a certain amount of time has passed, as defined on the initiative. The initiative's lead event type profile can include an event that automatically discards a lead after a designated number of days. If the initiative does not specify this auto-discard event, the lead remains in the active state until a user manually discards it.

Some types of lead events can also trigger a lead to be discarded when specific conditions are met; for example, a lead that is assigned to a third party representative can be automatically discarded when the third party representative finds that the account is ineligible for the initiative. Refer to [The Lifecycle of a Third Party Representative](#) for more details.

In addition, automatic lead discards capture a lead discard reason. Lead event types that support auto-discard define their respective default lead discard reasons. Refer to [Setting Up Lead Event Types](#) and [Maintaining a Lead](#) for more information

Sign Up Options Can Be Overridden

The lead's Sign Up special action button performs the following:

- Displays a Sign Up UI map (if one exists) to capture additional inputs for sign up processing.
- Executes a Sign Up service script to process the sign up.
- Displays a confirmation map if the sign up is successful.

The Sign Up UI map and Sign Up service script can be overridden via options on the initiative's business object. Refer to [Overriding Initiative Sign Up Options](#) for more details.

The Big Picture of Lead Events

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

You define the number and type of events to be initially inherited by a lead by configuring the Lead Event Type Profile on an initiative. Refer to [About the Lead Event Type Profile](#) for more information.

A lead event can include one or more steps. The lead event type defines a list of step types, if applicable.

The topics in this section provide additional information about lead events.

How are Lead Events Created

If a lead is created in a Pending state, there are no lead events associated with the lead. It is only when leads are created in or transitioned to the Active state, that lead events are created for the lead. The initial number of events and when the events shall occur are inherited from the lead's initiative.

Some types of events can also get created as a result of special actions on the lead. For instance, when a lead process requires a third party representative to perform one or more tasks after signup, the Sign Up action on the Lead portal automatically creates the Notify Third Party lead event.

The Components of a Lead Event

A lead event can have one or more steps. The lead event's business object defines whether or not steps are applicable to that type of event. The corresponding lead event type defines the valid step types. For an example, refer to the Third Party Lead Event (C1-ThirdPartyLeadEvt) and Send Notification to Third Party Lead Event Type (C1-LETypeNotifyThirdParty) business objects provided in base.

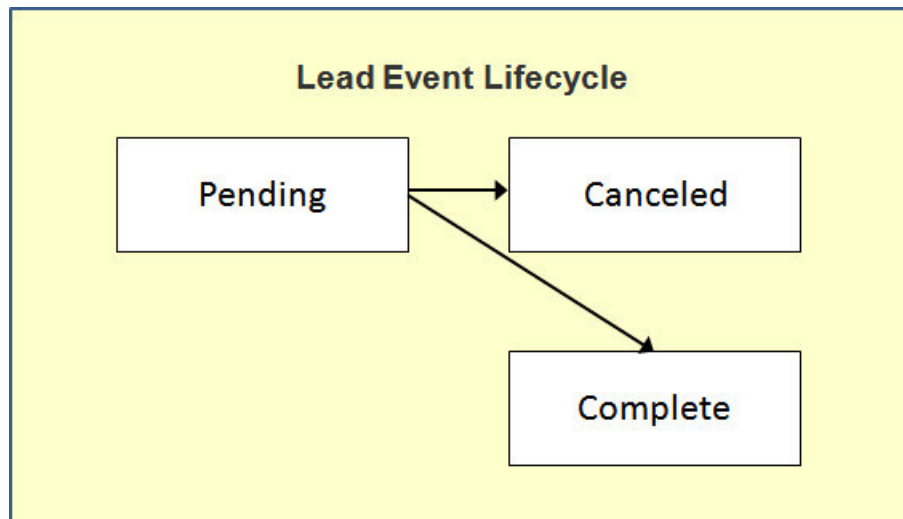

Lead Event Log

Every lead event has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a lead event is created.
- When a lead event's status changes (e.g. transitions to the completed or cancelled state).
- Details of the content sent (if applicable).
- Users can manually add log entries as desired.

The Lifecycle of a Lead Event

The following diagram shows the possible lifecycle of a Lead Event business object:

Pending state: Lead events are initially created in the Pending state. A lead event can take a number of paths after it is created; it all depends on how you've configured the system.

Complete state: A lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. A user may complete a pending event at their discretion.

Cancelled state: A pending event will be cancelled automatically by the system when a lead is canceled. A user may cancel a pending event at their discretion.

Refer to [Maintaining Lead Events](#) for more information.

The Lifecycle of a Third Party Lead Event

The following diagram shows the possible lifecycle of a Third Party Lead Event business object:

Pending state: Third party lead events are initially created in the Pending state. A third party lead event can take a number of paths after it is created; it all depends on how you've configured the system.

In Progress state: A third party lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. The lead event is set to In Progress and the lead event is sent to the third party representative.

Complete state: A third party lead event may be completed based on updates received from the third party. In most cases, the third party lead event is completed when all the event steps are complete. In addition, a user may complete an In Progress event at their discretion.

Cancelled state: A Pending or In Progress third party lead event will be cancelled automatically by the system when the lead is canceled. A user may cancel a Pending or In Progress event at their discretion.

Refer to [Maintaining Third Party Lead Events](#) for more information.

Lead Event Information Can Be Overridden

"Lead Event info" is the concatenated string of information that summarizes a lead event throughout the system. The base-package logic constructs this string by concatenating the following information:

- Lead event type description
- Status of the lead event
- Trigger date of the lead event

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead Event's maintenance object.

Third Party Lead Event Step Information Can Be Overridden

The **Initiative Leads** zone on the **Third Party Representative** portal shows an event step information string for **Last Complete Step** and **Next Pending Step**. A base-package service script constructs this string by concatenating the following information:

- Step type description
- Intended Work Date/Time
- Completion Date/Time

You can override this by specifying an **Override Step Information Script** on the Program Management Master Configuration.

See [Program Management Master Configuration](#) for more details.

How and When Lead Events Are Activated

A lead event contains the date it should be activated; this is referred to as its trigger date. On this date, the Lead Event Periodic Monitor Process (a background process (C1-LDEVT)) invokes the algorithm associated with a lead event's event type. The algorithm, in turn, will decide on the state in which to leave the lead event.

If a user can't wait for the Lead Event Periodic Monitor Process real-time, they can click a button on Lead Event – Main to activate / trigger an event online in real-time. Refer to [Maintaining Lead Events](#) for more information.

You control how a lead event's trigger date is populated by configuring the Lead Event Type profile in an initiative. You indicate the number of days the lead event should be activated after the creation of the lead. Refer to [Maintaining Initiatives](#) for more information.

Activating Events Should Add a Log Entry

As described previously, a lead and lead event have a log holding a history of meaningful events in their lives. Most algorithms associated with a lead event's event type will add an entry to both the lead and lead event logs.

These log entries are more than just an audit trail as they also reference the objects that are created during execution. For example, if an algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

How Lead Events Are Cancelled

A pending lead event will be cancelled automatically by the system when the lead is canceled.

A user may cancel a pending lead event at their discretion. Refer to [Maintaining Lead Events](#) for more information.

A third party representative can also initiate the cancellation of a lead event. Refer to [The Lifecycle of a Third Party Lead Event](#) for more details.

The Big Picture of Sales Representatives

A sales representative is a group or individual who can be assigned to follow up and manage leads.

Individual sales representatives can be members of one or more groups, and they can be an internal user or an external party.

Groups can be used to control which sales representatives are allocated to the leads for an initiative. For example, you can set up a group whose sales representatives are responsible for industrial customers. Initiatives that target industrial

customers can then be configured so that this group is specified as the only one whose sales representatives can be assigned the initiative's leads.

Because many reports will aggregate information for all sales representatives in a group, you may choose to set up a sales representative group just for reporting purposes.

The topics in this section provide additional information about Sales Representatives.

The Lifecycle of a Sales Representative

The following diagram shows the possible lifecycle of a Sales Representative:

Active state: A Sales Representative starts out in an active state.

Inactive state: A Sales Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Sales Representative either temporarily or permanently. A user can manually place the Sales Representative back to the active state from the inactive state.

Refer to [Maintaining Sales Representatives](#) for more information.

Sales Representative Log

Every Sales Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Sales Representative is created
- When a Sales Representative's status changes (e.g. transitions to the inactive state)
- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.

The Big Picture of Third Party Representatives

A third party representative is similar to a sales representative except that they are typically not internal employees and they have a different set of responsibilities.

Lead-related tasks may be outsourced to a third party representative who is better equipped to perform the work. These tasks may include pre-installation visits, energy audits, equipment installation, and equipment recycling. An initiative's lead event type profile defines whether or not lead-related work is sent to a third party representative.

Work is typically sent to a third party representative when a customer signs up for an initiative. The base product provides an online Sign Up action on active leads. This action creates a Third Party Lead Event that triggers the third party notification.

The third party representative is also responsible for providing updates to the system about the assigned leads. These updates can include event status updates, updates to important date/time information (e.g., completion date/time) and comments. This feedback enables users of the system to monitor the progress of leads and provide any necessary customer service.

Refer to the [The Lifecycle of a Third Party Lead Event](#) for more details on third party lead events.

The topics in this section provide additional information about Third Party Representatives.

The Lifecycle of a Third Party Representative

The following diagram shows the possible lifecycle of a Third Party Representative:

Active state: A Third Party Representative starts out in an active state.

Inactive state: A Third Party Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Third Party Representative either temporarily or permanently. A user can manually place the Third Party Representative back to the active state from the inactive state.

Refer to [Maintaining Third Party Representatives](#) for more information.

Third Party Representative Log

Every Third Party Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Third Party Representative is created.

- When a Third Party Representative's status changes (e.g. transitions to the inactive state).
- Users can manually add log entries as desired.

Maintaining Initiatives

An initiative defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.

Refer to [The Big Picture of Initiatives](#) for more information about initiatives.

Initiative Portal

You use the Initiative portal to maintain initiatives.

The **Main** page contains the following zones:

- **Initiative:** Displays the basic information about the initiative.
- **Initiative Eligibility Criteria Overview:** Displays initiative eligibility criteria associated with the initiative.
- **Related Object Criteria Overview:** Displays criteria for finding one or more related objects (such as, a premise) to link to a lead.
- **Initiative Hierarchy:** Displays the entire hierarchy of initiatives that the selected initiative is a part of.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Processing:** Allows you to submit the lead generation or lead disposition batch process.

The **Statistics** page contains the following

- **Lead Summary by Representative:** Displays the summary of leads for the initiative hierarchy, grouped by representatives.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Outcome Graph:** Displays the number of leads linked to the initiative hierarchy that entered the final state within the last 24 months.
- **Lead Statistics:** Displays statistics for the leads associated with the initiative.
- **Lead Monthly Statistics:** Displays statistics for the leads associated with the initiative on a monthly basis.
- **Unassigned Leads:** Displays leads that are not yet assigned to a sales representative and are not in a final state. (**Note:** Leads can be assigned to a sales representative in bulk.)

How To Perform Common Initiative Functions

The topics in this section describe how to perform common initiative functions from the Initiative portal.

Creating Initiatives

Use this procedure to create a new Initiative.

1. Select **Menu > Sales & Marketing > Initiative > Add.**
2. Select the business object that will define the initiative and click **OK.**
3. Enter the initiative's name, (short) description, detailed description, start date, and end date.
4. Specify if the initiative is a master or a subsidiary initiative.

- a) If the initiative is a **Subsidiary Initiative**, search for and select the initiative that is the parent to this initiative.
- 5. Specify whether the master initiative will participate in demand-side analytics processing through Contract Option Participation Analysis.
- 6. Specify whether or not leads can be generated for the initiative.
 - a) If leads can be generated, complete the options regarding communication channel and related object creation.
- 7. In the Third Party Notification section, specify the Lead Event Type to use to notify a third party. This lead event type is used when creating a third party notification lead event, if applicable, when a customer signs up or enrolls into a program.
- 8. In the Lead Reassignment Notification section, indicate how the system should respond if a lead is reassigned to another sales representative.
- 9. In the Statistics Notification section, specify how often, in hours, the statistics for the initiative should be updated.

A background process accumulates the statistics for an initiative when enough time has elapsed since the statistics were last updated. A user may also manually initiate the process to update the statistics for an initiative.
- 10. If this initiative will have leads, add lead event types in the Lead Event Type Profile section to define the events or actions that will occur during the lifetime of the lead to encourage the customer to participate in the initiative. To add lead event types in the Lead Event Type Profile section:
 - a) Assign an **Event Sequence** to each list entry.
 - b) Search for and select a **Lead Event Type** to indicate the type of lead event to generate for each list entry (for example send customer an email or create a customer contact).
 - c) Specify the number of **Days After Lead Creation** that the related lead event will be triggered.
- 11. Click **Save**.

Maintaining an Initiative

The topics in this section describe procedures for maintaining an initiative:

Allowable Record Actions on an Initiative

Use this procedure to maintain an initiative using standard record actions.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to edit the main attributes of an initiative. When you click **Save**, the system updates the record.
 - **Duplicate** – Click the **Duplicate** button to create a duplicate of the initiative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record.
 - **Activate** – Click the **Activate** button to transition a pending or inactive initiative to the active state.
 - **Deactivate** – Click to **Deactivate** button to transition an active initiative to an inactive state.

- **Refresh Statistics** - Click the **Refresh Statistics** button to manually initiate the accumulation of the statistics for the initiative.
- **Delete** – Click the **Delete** button and click **OK** to delete the initiative from the database. Before you delete an initiative, the system verifies that the initiative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete an initiative, the system ensures the initiative has not been referenced on a lead, etc.

Defining Eligibility Criteria for an Initiative

Use this procedure to define eligibility criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define eligibility criteria for the initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative that you want to maintain. *(The selected initiative opens in the Initiative portal.)*
5. To define eligibility criteria for the initiative, click the **Add** link in the Initiative Eligibility Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.

The base package provides a number of initiative eligibility criteria business objects. Each business object defines its valid comparison algorithm(s), operator(s), and value(s). Refer to the maintenance maps of these business objects for details. For more information about eligibility criteria types, refer to [About Initiative Eligibility Criteria](#).

7. Enter a sequence number, description, detailed description, and criteria execution point for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm**, **Comparison Operator** and **Comparison Value**.
9. Complete the Comparison Results section. Specify the action for each possible comparison outcome - meaning, **If True**, **If False**, and **If Insufficient Data**.

Refer to the embedded help on the maintenance map for more details on these fields.

Refer to the embedded help on the maintenance map for more details on these fields.

10. Click **Save**.

Repeat steps 5 to 10 to add additional criterion for the initiative.

Defining Related Object Criteria for an Initiative

Use this procedure to define related object criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define related object criteria for the initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.

4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To define related object criteria for the initiative, click the **Add** link in the Related Object Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.

The base package provides a number of related object criteria types that attempt to link an account's premise(s) to the lead. Each initiative criteria business object defines its valid comparison algorithm(s), operators and value(s). Refer to the maintenance maps of these business objects for details. For more information on eligibility criteria types, refer to [About Related Object Criteria](#).

7. Enter a sequence number, description, and detailed description for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm**, **Comparison Operator**, and **Comparison Value**.
Refer to the embedded help on the maintenance map for more details on these fields.
9. Complete the Comparison Results section. Specify the action to take for each possible outcome of the comparison - meaning, **If True**, **If False**, and **If Insufficient Data**
Refer to the embedded help on the maintenance map for more details on these fields.
10. Click **Save**.

Repeat steps 5 to 10 to add additional criterion for the initiative.

Viewing Initiative Hierarchy

The Initiative Hierarchy zone on the Initiatives portal displays the hierarchy the selected initiative is a part of. By clicking on any initiative in the hierarchy, you will be navigated to the selected initiative.

Creating Leads from an Initiative

The topics in this section describe how to create leads from an Initiative.

Bulk Creation of Leads

Use this procedure to create leads in bulk.

1. Select **Menu > Sales & Marketing > Initiative > Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. To create leads for the initiative, click **Lead Generation** on the Lead Generation and Disposition zone. This zone is displayed for initiatives in the active state, can have leads and allows a batch job to be submitted for the creation of leads.
 - Select the **Lead Status** to leave the created leads in. Valid values are Pending or Active. Creating leads in a pending state allows a user to confirm the lead population prior to activating these leads
 - Specify the **Number of Leads to Generate**. This may be used to create a sample set of leads to test the initiative's eligibility criteria.

- Specify the **Email Address**. You may optionally specify an email address if you want to be informed when the batch job completes

6. Click **OK**.

Uploading Leads

NOTE: This functionality is to be used on small volume uploads.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To upload Leads for an initiative, click the **Lead Upload** link in the Initiative Leads zone title bar. This displays the Lead Upload page, which you can use to upload a CSV file containing account IDs for which leads will be generated.
6. Click **Submit**.

Managing Leads from an Initiative

The procedures in this section describe how to manage leads from an initiative.

Viewing Initiative Leads

The Initiative Leads zone is displayed on both the Main page and the Statistics page.

By default, the Initiative Leads zone is populated with all leads for the initiative (or initiative hierarchy group) for all sales representatives.

On the Statistics page, you can limit the set of leads using the Lead Summary by Representative zone. See [Viewing Lead Summary by Representative](#) for details.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event**. You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event**. You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Activating, Deleting, and Discarding Leads for an Initiative in Bulk

Use the following procedure to activate, delete or discard leads for an initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.

4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. Scroll, as needed, to the Lead Processing zone.
6. To activate, delete or discard leads for the initiative, click **Lead Disposition**. This allows a batch job to be submitted for the activation, deletion or discarding of leads.
 - Select the **Pending Lead Disposition** to indicate the action to take on pending leads. The possible actions are: Activate (pending leads), Delete (in case of erroneous generation), Ignore.
 - Select the **Active Lead Disposition** to indicate to action to take on active leads. The possible actions Ignore and Discard.
 - Select the **Discard Reason** to be used for any active leads that get discarded. The values are maintained on the Status Reason control table.
 - Specify the **Email Address**. You may optionally specify an email address if you want to be informed when the batch job completes
7. Click **OK**.

Viewing Initiative Statistics

The Statistics page displays statistical information about the leads of the current initiative in context. It shows the following:

- Lead counts by sales representative and status
- List of leads
- Graph of completed and discarded leads over a period of time
- Graph of leads by status
- Graph of active leads per sales representative
- Graph of open, completed and discarded leads over a period of time
- Graph of the top discard reasons over a period of time

The following sections describe these zones. You can also refer to each zone's embedded help for more details.

Viewing Lead Summary by Representative

The Lead Summary by Representative zone displays a summary of leads for the initiative (or initiative hierarchy group) by individual representative. If the Initiative is configured not have a sales representative, the zone will group those leads under 'Leads without Representative'.

To limit the summary of leads by sales representative:

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Lead Summary by Representative zone.
6. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.

7. If **Include Inactive Leads** is set to No, leads for the initiative (or initiative hierarchy group) regardless of status are included.

The following is displayed in the result set:

- A summary line for the individual sales representative shows the total Lead Count.
- A breakdown is included beneath each sales representative summary line that shows a subtotal Lead Count by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Graphs and Statistics for an Initiative

The following zones display statistics for the initiative's leads.

NOTE: The system periodically refreshes the statistics for an initiative when the time specified on an initiative has lapsed. A user may also manually initiate the refreshing of statistics if required.

Lead Outcome Graph

This Lead Outcome Graph zone shows the number of Leads linked to the initiative (or initiative group hierarchy) that entered the final state in the last 24 months starting from the most recent completed Lead.

The date shown on the X-axis will be the first day of the month. Note that the information displayed here is based on the most recent completed Lead as of the time the Initiative Statistics is accumulated.

Lead Statistics

The Lead Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chart shows the number of leads for each state in the lead's lifecycle as of the initiative's Statistics Date/Time. Each state can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.
- **Active Leads by Representative:** The chart shows the top five individual sales representatives for the initiative (i.e. sales representatives with the largest number of active leads assigned to them as of the Statistics Date/Time). The top five sales representative can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.

Lead Monthly Statistics

The Lead Monthly Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chronological graph highlights the number of open, completed and discarded leads over time for the initiative in context. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013. Each State can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.
- **Active Leads by Representative:** The chronological graph highlights the top 4 discard reasons over time for the initiative in context. Statistics for all other discard reasons are accumulated in a catch-all bucket. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013. Each Discard Reason can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.

Displaying and Assigning Unassigned Leads

Use the following procedure to review and assign, as appropriate, non-final and unassigned leads that are associated to the initiative in context.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Unassigned Leads Zone.
6. Enter a Start Date and End Date range that encompasses the desired period.
7. Click **Refresh** to view unassigned leads that were created within the period specified.
8. (optional) Assign one or more leads from the result set:
 - a) Select the unassigned leads from the results set.
 - b) Enter the sales representative that will be assigned the leads.
 - c) Press **Assign to Sales Rep**.
 - d) Select the Sales Representative from the dropdown menu and click **OK**.

Maintaining Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program

The topics in this section describe the common functions associated with leads.

My Leads

You can use the My Lead menu item to maintain leads.

- If your User ID is linked to a Sales Representative, you are navigated to the Sales Representative portal with the user in context.
- If your User ID is not linked to a Sales Representative, you are navigated to the Leads Query portal.

Lead Portal

You use the Leads portal to maintain leads. This portal contains the following zones:

- **Lead:** Displays the basic information about the lead.
- **Lead Events:** Displays the events associated with the lead in chronological order.
- **Related Leads:** Displays the leads that are related to the current lead's related objects (e.g. account).
- **Attachments:** Displays uploaded documents that are related to the lead.
- **Notes:** Displays all notes for the lead and its lead events.

- **Third Party Event:** if a third party lead event exists, this zone displays the lead event's information, including the event steps

How To Perform Common Lead Functions

The topics in this section describe how to perform common lead maintenance functions from the Lead portal.

Manually Creating a Lead

Use this procedure to manually create a new lead.

1. Select **Menu > Sales & Marketing > Lead > Add.**
2. Select the lead's Initiative and click **OK.**
The Account Lead page displays so that you can complete the lead.
Enter the following information as required by the Initiative:
3. Search for and select the **sales representative** for the lead.
4. Indicate how the customer requested information about the initiative in the **response channel.**
5. Indicate if the customer has **signed up** for the initiative.
6. Search for and select the **account** that will be associated to the lead.
7. Search for and select the **premise** that will be associated to the lead.
8. Click **Save.**

NOTE: Leads can also be created through the Initiative context menus and Account context menus.

Maintaining a Lead

1. Select **Menu > Sales & Marketing > Lead > Search.**
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh.**
4. In the search results list (not applicable if Lead ID is specified in the search criteria), click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.

NOTE: You may also navigate to the Lead portal by clicking on the appropriate lead from various portals and zones. Examples include:

- Dashboard Portal: Alerts zone
 - Initiative Portal: Initiative Leads zone
 - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events
-

5. Click the appropriate record action button:

Buttons that appear when the lead is Pending:

- **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead. When you click **Save**, the system updates the record.

- **Delete** – Click the **Delete** button and click **OK** to delete a pending lead from the database. Before you delete a lead, the system verifies that the lead is not referenced anywhere in the system. If it is, you cannot delete it.
- **Activate** – Click the Activate button to transition a pending lead to the active state. When a lead is activated, lead events for the lead are created to encourage the customers to participate in the initiative.

Buttons that appear when the lead is Active:

- **Edit** – *see the description above.*
 - **Discard** – Select the **Discard** button to inactivate an active lead. Select a **Status Reason** indicating why the lead is being inactivated and click **Save**. The values are maintained on the Status Reason control table
 - **Complete** – Click the **Complete** button to indicate that an active lead has been successful.
 - **Sign Up** – Click the **Sign Up** button to initiate a script that is defined on the Initiative’s business object. The base package script **C1-IntvSignU** reevaluates the customer to determine if they are still eligible to participate in a program, indicates the customer has signed up or enrolled on the lead and creates a third party lead event (if applicable) to notify the relevant third party of the actions to be performed. The Response Channel on the lead is also updated for analytical purposes
6. Click the **Add Notes** button, in the Notes zone, to capture additional information for the lead.
 7. The **Third Party Event Zone** displays third party lead event (if any) details along with the steps involved in the lead event

Adding New Lead Events to a Lead

1. Select **Menu > Sales & Marketing > Lead > Search**.
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.
5. To add a lead event to the lead, click the **Add Lead Event** link in the Lead Events zone title bar.
6. Search for and select the appropriate lead event type.
7. Specify the Trigger Date of when the lead event is to be executed.
8. Specify the Communication Channel to indicate what form the event will be sent.
9. Click **Save**.

Repeat steps 5 to 9 for add additional lead events.

Adding Lead Notes

1. Select **Menu > Sales & Marketing > Lead > Search**.
2. Enter your search criteria in the Lead Query zone.
The C1-owned base package search options include:
 - Name and address
 - Related object
 - Representative and initiative

- Lead ID
3. Click **Refresh**.
 4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.
 5. Scroll, as necessary, to view the Notes zone.
 6. Click the **Add Notes** link in the zone's title bar.
 7. Enter the desired information in the **Add Notes for Lead** pop-up window and click **Save**.

Maintaining Lead Events

A lead event is an event or action in a lead to take place to encourage a customer to participate in a program. A lead may contain many lead events.

The Lead Event portal is used to maintain lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.
- **Notes:** Displays user-defined comments about this lead event

To maintain a lead event:

1. Select **Menu > Sales & Marketing > Lead Event > Search**.
2. Enter your search criteria in the Lead Event Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

NOTE: You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:

- Initiative Portal: Initiative Leads zone
 - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events
-

5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
 - **Complete** – Click the **Complete** button to indicate a pending lead event is completed.
 - **Cancel** - Select the **Cancel** button to cancel a pending lead event.
6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Third Party Lead Events

A third party lead event represents an action within a lead to either encourage a customer to participate in a program, or perform an on-site service. A lead may contain one or more third party lead events.

The Lead Event portal is used to maintain third party lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.

- **Notes:** Displays user-defined comments about this lead event

To maintain a third party lead event:

1. Select **Menu > Sales & Marketing > Lead Event**.

2. Enter your search criteria in the Lead Event Query zone.

The C1-owned base package search options include:

- Name and address
- Related object
- Initiative and representative
- Lead and lead event

3. Click **Refresh**.

4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

NOTE: You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:

- Initiative Portal: Initiative Leads zone
 - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events
-

5. Click the appropriate record action button:

- **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
- **In Progress** – Click the **In Progress** button to initiate the notification process and have the third party lead event sent to the representative.
- **Cancel** - Select the **Cancel** button to cancel a pending lead event.

6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Sales Representatives

A Sales Representative is a user or group of users who can be assigned to follow up on leads and responsible for selling the initiatives product or service to the customer.

The topics in this section describe the common functions associated with Sales Representatives.

Sales Representatives Portal

You use the Sales Representative portal to maintain sales representatives. This portal contains the following zones:

- **Sales Representative:** Defines the basic information about the representative.
- **Initiative Lead Summary:** Lists initiatives and information about leads for each initiative for the representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
 - **Initiative Leads:** Displays leads for the initiative and representative.
 - **Initiative Lead Event Summary:** Displays lead event statistics for the initiative lead and representative.
 - **Initiative Lead Events:** Displays lead events for the initiative lead and representative.

- **Group’s Representatives:** This zone is displayed for a representative group and lists the individual representatives who are members of the group.
- **Representative’s Groups:** This zone is displayed for an individual representative and lists the representative groups of which this representative is a member.

How To Perform Common Sales Representative Functions

The topics in this section describe how to perform common sales representative functions from the Sales Representative portal.

Creating Sales Representatives

Use this procedure to create a new sales representative.

1. Select **Menu > Sales & Marketing > Sales Representative > Add.**
2. Select the sales representative type that will define the representative and click **OK.**
3. Enter the appropriate information for the representative:
 - For a Group Sales Representative:
 - Specify the Sales Representative name and description.
 - Search for and select Individual Sales Representative who will be a member of the group.
 - For an Individual Sales Representative:
 - Specify the Sales Representative name and description.
 - Search for and select User for the individual sales representative.
 - Search for and select Group Sales Representative that the individual sales representative will be a member of.
4. Click **Save.**

Maintaining Sales Representatives

1. Select **Menu > Sales & Marketing > Sales Representative > Search.**
2. Enter your search criteria in the Sales Representative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the sales representative you want to maintain. The selected sales representative opens in the Sales Representative portal.

NOTE: You may also navigate to the Sales Representative portal by clicking on the appropriate Sales Representative from various portals and zones. Examples include:

- Initiative Portal: The Initiative Zone or the Lead Summary By Representative.
- Lead Portal: Lead zone

5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a sales representative. When you click **Save**, the system updates the record

- **Duplicate** – Click the **Duplicate** button to create a duplicate of the sales representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record
 - **Deactivate** – Click the **Deactivate** button to transition an active sales representative to an inactive state
 - **Delete** – Click the **Delete** button and click **OK** to delete the sales representative from the database. Before you delete a sales representative, the system verifies that the sales representative is not referenced anywhere in the system. If this is the case, you cannot delete the representative. For example, if you attempt to delete a sales representative, the system ensures the sales representative is not referenced on a lead, etc.
6. For an individual sales representative, you can add the sales representative to another group by clicking the **Add Rep to Another Group** link in the Representative's Group zones title bar. Select a group sales representative and click **Save**. You can remove the representative from a group (or groups) by selecting the group(s) and clicking the **Remove Rep from Group(s)** button.
 7. For a representative group, you can add a representative to the group by clicking the **Add Rep To This Group** link in the Group's Representatives zone's title bar. Search for and select the individual sales representative to add to the group and click **Save**. You can remove representatives from a group by selecting the representatives and clicking the **Remove Rep(s) from Group** button.

Displaying Leads and Lead Event Information for a Sales Representative

From the Initiative Lead Summary zone on the Sales Representative portal, you can broadcast a representative, initiative, date range and lead state (if available) to other zones on the portal.

Displaying Leads Associated Information for a Sales Representative

The Initiative Lead Summary zone on the Sales Representative portal displays the leads that have been assigned to the sales representative. If the representative is a group, leads are summarized for all individuals in the group.

To limit the summary of leads for the sales representative:

1. Select **Menu > Sales & Marketing > Sales Representative > Search**.
2. Enter your search criteria in the Sales Representative Query zone.
3. Click Refresh.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized. Otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh**.

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the individual or group rep.
- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Sales Representative Initiatives Leads Zone

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Leads zone on the Sales Representative portal is populated with relevant lead information for the selected item. If the sales representative is a group, leads for all individuals in the group are shown.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event**. You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event**. You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the rep assigned to each lead.

For information about using this zone to reassign leads to another representative, see [Reassigning Leads for a Sales Representative](#).

Initiatives Lead Event Type Summary

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Lead Event Type Summary zone is displayed. If the representative is a group, lead events are accumulated for all individuals in the group. The summary spans the 14 day period on/after the Start Date which defaults to current date if blank. If you want to specify the start date, click Refresh to update the zone.

The following is displayed in the result set:

- The **Event Count** shows the total number of events for a specific Event Type on each day within the 14 day period. You can click on the broadcast icon to see a list of events for the **Event Date** and **Event Type** on the Initiative Lead Events zone.
- The **Event Status** bar provides a breakdown of the total event count by status. Each color segment shown represents a different event status for pending, completed and canceled events. Colors used are defined on the program management master configuration.
 - Hover the mouse pointer over a segment of the bar to see the respective count and status represented by the segment.
 - Click on a segment of the bar to broadcast the event date, event type and event status. Broadcasting from the event status bar instead of the broadcast icon will limit the Initiative Lead Events zone to a particular status.

Initiatives Lead Events Summary

By clicking on one of the broadcast items in the Initiative Lead Event Type Summary zone, the Initiative Lead Events zone is populated. This zone displays lead events for the initiative, representative, lead event type (if available) and status (if available). If the representative is a group, events for all individuals in the group are shown. Only lead events with a trigger date on or after the **Start Date** are displayed.

The following is displayed in the result set:

- **Event Date** and **Lead Event** information is shown for each event. You can navigate to a specific lead event by clicking on a lead event.
- **Lead** shows the lead information for the initiative's lead. You can navigate to the lead by clicking on a lead.

- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking customer information for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Reassigning Leads for a Sales Representative

To reassign leads from one sales representative to another sales representative:

1. On the Initiatives Leads zone, select the leads that you want to reassign and click **Reassign Rep.**
2. Select the Sales Representative to reassign the selected lead to and click **Save.**

Maintaining Third Party Representatives

A Third Party Representative is someone who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection or an installation. Refer to [The Big Picture of Third Party Representatives](#) for more information

The topics in this section describe the common functions associated with Third Party Representatives.

Third Party Representatives Portal

The Third Party Representative portal is used to maintain third party representatives. This portal contains the following zones:

- **Third Party Representative:** Defines the basic information about the third party representative.
- **Initiative Lead Summary:** Displays a summary of initiatives that have leads assigned for the third party representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
 - **Initiative Leads:** Displays leads for the broadcasted initiative and third party representative.
 - **Unassigned Leads:** Displays unassigned leads for the broadcasted initiative that are not yet assigned to a third party representative.

How To Perform Common Third Party Representative Functions

The topics in this section describe how to perform common representative functions from the Third Party Representative portal.

Creating Third Party Representatives

Use this procedure to create a new third party representative.

NOTE: Before adding the third party representative, they must be added as a Person without an account in the system. For more information about this process, see [How To Add A New Customer From Control Central](#).

1. Select **Menu > Sales & Marketing > Third Party Representative > Add.**
2. Enter the appropriate information for the representative:
 - Specify the Third Party Representative name and description.
 - Search for and select the Person record for the third party representative.
 - Select the External System that will be used to communicate to the third party representative.

3. Click **Save**.

Maintaining Third Party Representatives

1. Select **Menu > Sales & Marketing > Third Party Representative**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the third party representative you want to maintain. The selected third party representative opens in the Third Party Representative portal.
5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a third party representative. When you click **Save**, the system updates the record
 - **Duplicate** – Click the **Duplicate** button to create a duplicate of the third party representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record
 - **Deactivate** – Click the **Deactivate** button to transition an active third party representative to an inactive state
 - **Delete** – Click the **Delete** button and click **OK** to delete the third party representative from the database. Before you delete a third party representative, the system verifies that the third party representative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete a third party representative, the system ensures the third party representative is not referenced on a lead, etc.

Displaying Leads Associated Information for a Third Party Representative

The Initiative Lead Summary zone on the Third Party Representative portal displays the leads that have been assigned to the Third Party representative.

To limit the summary of leads for the sales representative:

1. Select **Menu > Sales & Marketing > Third Party Representative > Search**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized; otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh**.

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the third party representative.
- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the third party representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

The Initiative Leads zone on the Third Party Representative portal displays the leads that have been assigned to the third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Completed Step**. You can navigate to the lead event by clicking on the event/step information.
- For active third party lead events, the **Next Pending Step**. You can navigate to the lead event by clicking on the event/step information.
- The **Sales Representative** shows the representative assigned to the lead.

The Unassigned Leads zone on the Third Party Representative portal displays active leads that are not yet assigned to a third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Sales Representative** shows the representative assigned to the lead.
- You can assign leads to the third party representative using the **Assign to Third Party** button.

See [Displaying and Assigning Leads to a Third Party Representative](#) for more information.

Displaying and Assigning Leads to a Third Party Representative

Use the following procedure to view leads that are not assigned to a third party representative, and assign one or more of those leads to the third party representative in context.

1. Select **Menu > Sales & Marketing > Third Party Representative > Search**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the third party representative you want to view. The selected third party representative opens in the Third Party Representative portal.
5. The **Initiative Lead Summary** zone shows the initiatives that have leads assigned to the third party representative in context. Click the broadcast button on an initiative to view its unassigned leads.
6. Scroll down to view the **Unassigned Leads** zone. This zone will display if there are active leads (for the broadcast initiative) that are not yet assigned to a third party representative.
7. To assign one or more leads to the third party representative in context:
 - a) Select the unassigned lead(s) from the results set.
 - b) Press **Assign to Third Party**.
 - c) Click **OK**.

Rates

When you set up a customer in the system, you create a service agreement for every service that the customer uses. The most important information specified on a service agreement is the rate. The rate controls:

- How the service's charges are calculated.
- How the charges are described on the customer's bills.
- How the general ledger is affected by the charges.

It's important to understand that while *most* service agreements are associated to a rate, you may have service agreements that don't use a rate to calculate their charges; for example, you may have [billable charge](#) service agreements to bill a customer for charges that have been calculated in an external system. Whether or not a service agreement uses a rate and the list of rates that can be specified on a service agreement are controlled by the service agreement's [SA Type](#).

In addition to calculating charges for service, your implementation can also use rates to calculate [adjustments](#).

FASTPATH:

Refer to [How Rates Affect The Information On A Bill](#) for how billing uses the information in a rate to calculate a bill segment. Refer to [Calculated Adjustments](#) for how to use a rate to calculate an adjustment.

NOTE:

Do not equate a rate in your legacy system with a rate in this system. You may find that the system's flexibility will result in fewer rates than you have today. For example, your current rate structure may have three rates for service because there are different prices based on the customer's geographic area. In this system, however, you can set up a single rate and vary the price based on where the customer lives.

This chapter describes the structure and process to configure rates.

NOTE:

If you're using Oracle Utilities Rate Cloud Service, refer to the [Oracle Utilities Rate Cloud Service](#) chapter in the *Business User Guide*, and the [Defining Oracle Utilities Rate Cloud Service Options](#) chapter in the *Administrative User Guide* for information about how the rate functionality works in the context of that cloud service.

Rate schedules created using the new rate engine are referred to as **Calculation Rule-Based Rates** or, simply, **Rates**; and those created using the original rate engine are referred to as **Component-Based Rates**. This chapter focuses on Calculation Rule-Based Rates, unless stated otherwise.

CAUTION:

Component-Based Rates, or classic rates, is not the recommended approach for new implementations. Component-Based Rates is intended for upgrading customers who currently use this rate structure and have not converted to Calculation Rule-Based Rates.

Calculation Rule-Based Rates

Calculation Rule-Based Rates (Rates) offer a flexible and reusable structure to calculate charges, centralize configuration, and reduce your development effort and time.

This chapter describes the structure and process to configure Rates.

All Calculation Rule-Based Rates Share a Common Structure

The basic components used to calculate charges are **Calculation Rules**. Each calculation rule is configured to perform a specific type of calculation, such as calculating tax charges, the number of days in a billing period, or the amount of consumption used by a customer in a billing period.

Calculation rules are organized into **Calculation Groups**, which are logical collections of calculation rules that can be referenced by rate schedules. Calculation rules and groups are commonly "generic" and can be applied to multiple rates.

Furthermore, calculation groups can be nested within other calculation rules. When the parent rule is processed, it executes all the rules that are nested in its referenced group. This strategy allows a single rule to execute any number of nested rules. Nesting also allows common calculations to be encapsulated into a set of calculation rules that can be included in multiple rates.

Calculation groups are defined for a rate schedule in one of three ways:

- **Pre-Processing Calculation Groups** perform initial calculations in preparation for the rate version calculation group.
- **Rate Version Calculation Groups** are effective-dated calculation groups that perform the main calculations of the rate schedule.
- **Post-Processing Calculation Groups** perform calculations after rate version calculation groups are executed.

See [About Calculation Groups](#) for more information.

At the highest level, every rate has a single rate schedule that contains basic information that shouldn't change over time; such as, the billing frequency, currency, and the rate's proration strategy. This information combined with the calculations groups, and other high-level configuration, comprise the Rate Schedule

Control Tables That Must Be Set Up Before Creating a Rate Schedule

This section describes tables that must be set up before you can add a rate schedule.

Master Configuration

The **Rate Engine Configuration** master configuration can be used to define the behavior of the Rate Schedule portals used when creating rate schedules.

To edit this master configuration, select **Admin > Master Configuration**, and click the edit icon for the **Rate Engine Configuration**.

The **Rate Engine Implementation** dropdown list defines which rate engine(s) will be used by your organization.

- **Calculation-Rule Based** indicates that your implementation uses calculation rule-based rates, which require the configuration of rate schedules with calculation groups and calculation rules.
- **Component-Based** indicates that your implementation uses component-based rates, which require the configuration of rate versions with rate components, and rate schedules with SQ and register rules.
- **Both** indicates that your implementation uses both rate engines. If this applies to you, then the system will use this option to ease navigation as follows:
 - Select **Menu > Rates > Rate Schedule > Add** to launch the page to add a new rate schedule. *(A hyperlink is included to take the user to the component-based rate schedule maintenance page, if necessary.)*
 - Select **Menu > Rates > Rate Schedule > Search** to launch the **Rate Schedule Query** portal.
 - The query results attempt to highlight component-based rates by appending **“(Component-Based)”** to the rate schedule's description.
 - Once a rate schedule is selected from the result set, the system navigates the user to either the calculation rule-based **Rate Schedule portal** or the component-based **Rate Schedule page**.

The **External Communication** section is used when the rate engine needs to communicate with an external system. For example, service quantities are needed to test a rate on the **Rate Check** portal. These service quantities may be entered on the portal, retrieved from an existing bill segment, or (in the case of a service agreement that requires bill determinants) request service quantities from Oracle Utilities Meter Data Management.

- **Request Type** identifies the various data requests that can be made to an external system. Request types are defined in the RATE_EXT_REQ_TYPE_FLG lookup field. To introduce additional request types, add appropriate lookup values to this lookup field for each request type you wish to support.

The base package includes the following business objects to be defined on the outbound message types created for such requests:

- **Rate Check Usage:** C1-UsageRequestOutMsg (used to request bill determinants from MDM on the rate check portal)
- **External System** and **Outbound Message Type** are used when creating the outbound message for the data request.

Defining Frequency Codes

When you create a rate schedule, you must enter a code defining the frequency in which the prices are expressed, e.g., monthly, quarterly, biannual, etc. To set up frequency codes, open **Admin > Rates > Frequency**.

Description of Page

Enter a unique **Frequency ID** and **Description** for each frequency.

Before entering the remaining fields, you must analyze the "proration provisions" in your rates. For example, consider a rate used to calculate charges for a "month's worth of service". Assume this rate's charges will not be prorated when the customer's service period is anywhere between 27 and 33 days. This rate requires a frequency that indicates:

- **12 Periods / Year** (because it's a monthly rate).
- **MinimumDays Offset** equal to 3.
- **MaximumDays Offset** equal to 3.

When the system creates a bill using a rate with this frequency, it compares the number of days of consumption on the bill to the minimum and maximum number of days inferred by the rate's frequency. In the example above, the minimum number of days would be 27 (365 days / 12 period per year - 3 offset for minimum days). The maximum number of days would be 33 (365 days / 12 periods per year + 3 offset for maximum days). Therefore, if a bill's consumption period is less than 27 days or more than 33 days, the bill's charges are prorated.

NOTE:

Overriding the system's standard proration logic. If the standard proration logic does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation. For example, we have encountered companies who treat a year as having 360 days rather than 365 days. Such a company would need to develop an override proration algorithm and plug it on the [Installation](#) record.

Where Used

Every Rate Schedule must have a frequency. Refer to [Defining Rate Schedules](#) for more information.

Setting Up Bill Factors

This section describes bill factors and how they are used to levy the many charges referenced in a rate.

WARNING:

Most bill factors exist to support calculations performed by calculation rules. This means that you must design your calculation rules before you can design your bill factors. We strongly recommend that you design "on paper" how each rate's calculation rules look before attempting to set up bill factors.

An Overview of Bill Factors

The primary reason that calculation rules exist is to define how much to charge for the services sold by your company. When you create calculation rules, you have four ways to indicate how much to charge:

- Specify the value directly in the calculation rule.
- Define that the value is defined in a *bill factor*.
- Define that the value is calculated by a *for calculation purposes only* calculation rule.
- Tell the calculation rule to call an algorithm to get the price.

The remainder of this section describes the bill factor approach. The other methods are discussed in [Case Study: Three Simple Rates](#).

Bill factors are used to pass a value to a calculation rule; such as specifying a tax rate. To further illustrate this, you could specify the current tax rate, say 6%, directly in every rate's calculation rules OR you could indicate every rate should levy the current state tax rate and have the system look up the applicable rate when it calculates bills. The latter approach involves using a bill factor to indicate that the amount to charge should be retrieved from someplace other than the calculation rule when a bill is calculated.

You can use bill factors to define any of the following types of charges:

- A flat amount. This would typically be used to define service charges, minimum charges, and asset charges.
- An amount for a given unit of measure. This would typically be used to define the price for measured consumption (such as, the price per therm).
- A percentage. This would typically be used for tax rates and discount percents.

As a rule of thumb, you would use a bill factor (rather than specify the value in the calculation rule) when any of the following situations exist:

- The same charge exists in many rates. For example, if there are three rates that all contain the same service charge, it would make sense to use a bill factor to levy this charge rather than specify the same value on three calculation rules.
- The amount being charged is dependent upon some physical characteristic of the customer's equipment. For example, if the price differs depending on whether the customer owns the transformer, you would use a bill factor to specify the price.
- The amount being charged is dictated by some external organization and therefore can change independently from the rate. For example, tax percentages and use fees are set by taxing authorities and can be changed at any time (and you don't want to change the rate when these charges change).
- The amount being charged varies depending on WHERE the customer lives. If you have a rate where the price per gallon differs depending on where the customer lives, you should use a bill factor to levy this type of charge.
- A charge (or discount) is only levied for a subset of customers for defined periods of time. For example, if you have a discount that is only given to customers who have had service for more than two years, you would use a bill factor to specify the discount percent.
- The price differs per customer. For example, you may have a rate for large gas customers where the price per therm is different for every customer. In this situation, you would use a bill factor to specify the price.
- The price differs based on the number of weeks of consumption. This typically occurs in a deregulated environment when the price charge is based on the weighted average spot market price in effect during the bill period.

WARNING:

As you can deduce, bill factors are extremely flexible. While the flexibility makes for a very powerful rate engine, it also presents you a dizzying array of options. We have discovered that to take advantage of the flexibility, you need to gain

an overall understanding of the pricing and taxation provisions in ALL of your rates. Only then can you make logical and pragmatic decisions in respect of the number and type of bill factors.

The Structure of a Bill Factor

All bill factors share a common structure as illustrated below:

The above example shows a standard bill factor, which is made up of the following tables:

- **Bill Factor.** A **bill factor** contains descriptive information and attributes that control how the bill factor may be used in the system.
- **Bill Factor Characteristic.** All bill factors have the capability of having different values depending on some characteristic of the premise or service point. For example, a bill factor used to levy a state tax would have a different tax rate depending on the state in which the customer resides. A **bill factor characteristic** must exist for every state with a tax (states without a tax will not be linked to the state tax bill factor). At billing time, if the system cannot find a bill factor characteristic that corresponds with the customer's state of residence, the charge will be skipped.
- **Bill Factor Value.** Each bill factor characteristic may have many **bill factor values** over time. To continue with our state tax example, each state with a tax can have different tax rates over time. There are different ways in which a bill factor's values may be defined:
 - For bill factors whose values are applicable to many customers where only one value is effective on a given date (such as, a city tax) the values are defined using bill factor values. Refer to [Defining Bill Factor Values](#) for more information.
 - For bill factors whose value differs per customer, the value is defined in the customer's service agreement. Refer to [Service Agreement - Contract Value](#) for more information about bill factors in contract terms.
 - For bill factors whose values are applicable to many customers where more than one value is effective on a given date (such as, an interval price or a weighted average price) the values are defined on an interval value set. Refer to [Defining Interval Values](#) for more information about interval value sets.

An Illustration of a Bill Factor and Its Characteristics

The following picture illustrates how a bill factor and its characteristics are used to retrieve the relevant state tax at billing time:

The following points describe the illustration:

- At billing time, the billing engine sends a request to a rate to calculate the charges for a customer's consumption.
- The rate calculates charges without bill factors until it encounters the calculation rule that levies state tax. This calculation rule references a bill factor. This means the rate must get the tax rate(s) in effect during the billing period from this bill factor.
- The state tax bill factor contains an attribute defining that the premise's taxing state characteristic controls the bill factor value. The bill factor therefore extracts the taxing state from the premise.

NOTE:

Deriving characteristic values. Rather than have the system extract the characteristic value from an entity, you can setup the system to derive the characteristic value when the rate is calculated. For example, if all of your customers are located in a single state, you may not want to maintain the taxing state on every premise. To do this, you could setup the rate to "hard code" a taxing state of say Hawaii. This is an advanced topic, but it may prove useful for your implementation. Refer to [Deriving / Passing In Characteristic Values](#) for the details.

- The premise returns the taxing state and the bill factor extracts the tax rate(s) in effect during the bill period and returns them to the rate.
- The rate applies the tax percents and returns the charges to billing.

NOTE:

Some bill factors don't need a characteristic. There are bill factors whose value does not differ based on a characteristic. For example, if your organization offers employee discounts, the discount percent is probably the same

for all employees and therefore this bill factor doesn't need a characteristic to select the bill factor value at billing time. However, because of the relational design of the system, every bill factor value must reference both a bill factor and a characteristic value. Therefore, if you have bill factors whose value is not related to a characteristic, you must specify a characteristic type on the bill factor with a characteristic value that is exactly the same as the characteristic type.

FASTPATH:

For more information about setting up characteristics, see [Setting Up Characteristic Types and Their Values](#) .

Deriving/Passing In Characteristic Values

In [An Illustration of a Bill Factor and Its Characteristics](#), we described how the system retrieves a characteristic value from a premise when a bill factor is encountered that uses a premise characteristic. This is a very common technique and is easy to understand. However, there are situations when an entity in Oracle Utilities Customer Care and Billing doesn't contain the appropriate characteristic value and therefore other techniques must be used. These techniques may not apply to your implementation, but they're worth understanding to help you form an intuitive understanding of rate application:

- There are implementations that only use the Oracle Utilities Customer Care and Billing rate engine. These implementations do not setup accounts, premises, etc. Rather, they simply setup their rate schedules, calculation rules, and bill factors. The rate engine is called from another application. This means the rate engine can't retrieve characteristic values from within Oracle Utilities Customer Care and Billing (because there are no objects where the characteristic values are defined). In this situation, the application that calls the rate engine must supply the characteristic types and values to be used when a bill factor requires this type of information.
- Assume you have a charge that is based on the account's customer class and the service agreement's revenue class. The characteristic value for this type of charge is not extractable through a single entity. Rather, the system must construct the characteristic value in real-time by concatenating information from the account and service agreement that is being billed. In this situation, you can use pre-processing calculation group to derive this characteristic type and value. This calculation group would create a characteristic type and value in real time by concatenating the account's customer class and the service agreement's revenue class. This characteristic type and value only exists in memory while the rate application executes.

When you setup a bill factor to use a characteristic whose value is derived or passed in, you need to define its characteristic source as Characteristics Collection. This source tells the system to extract the characteristic value from memory rather than extracting it from an object within the system.

NOTE:

The plug-in spots on a calculation rule have access to the Characteristics Collection. You might find this useful if you have a calculation rule that needs to calculate characteristic values for subsequent calculation rules.

Defining Bill Factors

You create a bill factor for every type of charge whose value is not specified directly in a calculation rule.

It is recommended to use two windows to set up a bill factor. On the first, you define general information describing how the bill factor is used in the system. On the second, you define all the characteristic values for the bill factor.

Defining General Bill Factor Information

Begin to define a bill factor by selecting **Menu > Rates > Bill Factor > Add**.

Description of Page

Enter a unique **Bill Factor** code and a **Description** for the bill factor.

Use **Bill Factor Type** to indicate if this bill factor uses Regular, Interval (i.e., real-time), or Time of Use values.

- **Regular.** Indicates that this bill factor's values are specified on [Bill Factor Value - Main](#) or on [Service Agreement - Contract Values](#).
- **Interval.** Indicates that this bill factor's values are specified on [Defining Interval Values](#)
- **Time of Use.** Indicates that this bill factor's values are specified on [Bill Factor TOU Values](#) or on [SA Interval Billing Info - TOU Contract Values](#) (**Note:** This option is only applicable to Component-Based Rates).

Enter a **Currency Code** to define the bill factor's denomination, or currency. This field is disabled if the bill factor is referenced on a calculation rule.

NOTE:

Bill factors referenced on a calculation rules must be denominated in the same currency as is the rate.

Select the **Value Type** to define the kind of value maintained by this bill factor. The Value Type options are:

- **Charge.** The value maintained in this bill factor is a fixed amount (e.g., a flat charge).
- **Percentage.** The value maintained in this bill factor is a percentage.
- **Unit Rate.** The value maintained in the bill factor is a price per service quantity.

This field is disabled if the bill factor is already referenced on a calculation rule or if the bill factor already has values

Turn on **Error If No Value** if the system should create a billing error when a bill factor value doesn't exist for the characteristic value linked to the customer. To clarify, understand that there are different types of bill factors:

- Those that should have a value for every customer whose rate references the bill factor. A bill factor used to levy the relevant state tax is a good example (assuming every state has a tax). For this type of bill factor, if the system cannot find a bill factor value for the taxing state, it must generate a billing error because data is missing from the system. You would turn on **Error if No Value** for this type of bill factor.
- Those that only have a value when the customer has a characteristic value that levies a charge. A bill factor used to levy the relevant city tax is a good example (because not all cities levy taxes). For this type of bill factor, if the system cannot find a bill factor value for the city in which the customer lives, the calculation rule will be skipped and no billing error will be generated. You would turn off **Error if No Value** for this type of bill factor

Bill factors used to levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for the tax exemption will have their tax obligation reduced (or nullified) at billing time. For bill factors that are eligible for tax exemptions, turn on **Tax Exemption**. If a service agreement is fully or partially exempt for the taxes defined by a given bill factor, the bill factor and the exemption information for the customer must be indicated on the Service Agreement page. This field will be disabled if the bill factor is referenced as being tax exempt in a service agreement.

FASTPATH:

For more information about how to make a customer tax exempt, refer to [Service Agreement - Tax Exemptions](#).

Some types of bill factors do not have the same value for all customers. Rather, their value may be unique for every customer or it may be unique for some customers and common for others. For example, you may have rates where the price per kilowatt-hour is defined for every customer using the rate. You may have other rates where certain customers have their own price per kilowatt-hour defined and other customers who use the value defined on the bill factor. For any type of bill factor where a customer may have their own unique price, turn on **Value In Contract Term**. For any service agreement that has a unique value for a given bill factor, the bill factor and the service agreement's value must be indicated on the [Service Agreement](#) page. When applying the rate for a bill factor of this type, the system will first check for the existence of

a contract value for the service agreement and if one is not found, it will use the value on the bill factor. This field will be disabled if a contract term referencing this bill factor exists.

NOTE:

The **Error if No Value** switch also affects what happens if there is no contract term for the bill factor. If the error switch is on, a billing error will be generated. If the error switch is off, no billing error will be generated and the calculation rule will be skipped.

FASTPATH:

For more information about how to specify a bill factor value in a customer's contract, refer to [Service Agreement - Rate Info](#).

Contract riders are used when the charge associated with the bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first 3 months of service, then a contract rider would be used. Turn on **Contract Rider Applicability** if the bill factor's applicability is contingent on the existence of a contract rider. This field will be gray if a contract rider referencing this bill factor exists on a service agreement.

FASTPATH:

For more information about how to establish a contract rider for a customer, refer to [Service Agreement - Contract Riders](#).

The proration information tells the system how to handle changes to bill factor values and their optional contract riders that may occur during a customer's bill period. Turn on **Allow Proration** if changes to the bill factor's value and/or contract riders should be prorated. If the **Bill Factor Type** is not specified as Interval and if changes should **not** be prorated, indicate the **Rate Selection Date Algorithm** to use when the system retrieves bill factor values or determines if contract riders are applicable.

If you have sub service agreements, turn on **Use Sub SA Contract** terms if billing should access contract riders, values, tax exemptions from the sub SA rather than the master. If this switch is off, the system will use the master SA's riders, contract value, and tax exemptions when it creates bills for a sub service agreement. Refer to [Sub Service Agreements](#) for more information.

If the Contract Management module is not **turned off**, which includes [umbrella agreement management](#), and you have checked either Tax Exemption, Value in Contract Term or Contract Rider Availability, indicate the **Terms of Service Usage**. Valid values are Check SA Only, Check TOS Only and Check TOS First, then SA. Refer to [Overriding Rate Terms](#) for details about how to set this value based on your business needs.

Bill Factor Tree

The right half of this page is dedicated to a tree that shows the bill factors characteristics and their respective values (for Regular bill factors) or interval value Sets (for Interval bill factors). You can use this tree to both view high level information about these objects and to transfer to the respective page in which an object is maintained by using the available Go To buttons.

Where Used

Many types of Rate Components may use a Bill Factor to define the price being charged. Refer to [Designing Calculation Groups and Rules](#) for more information.

The BILPC-TOTAL algorithm type that is used to levy late payment charges references the bill factor that defines the late payment charge percent. Refer to [SA Type - Main](#) for more information about this algorithm.

A Service Agreement references Bill Factors as follows:

- When a service agreement's Apply To calculation rule references tax exemptable bill factors AND the customer is tax exempt, the service agreement will define the bill factors from which the customer is exempt. Refer to [Service Agreement - Tax Exemptions](#) for more information.

- When a service agreement's rate references bill factors whose prices are customer-specific (i.e., specified on a contract term), the service agreement will contain prices for these bill factors. Refer to [Service Agreement - Contract Values](#) for more information.
- When a service agreement's rate references bill factors that are contingent on contract riders, the service agreement will define the rider period (if any) for these bill factors. Refer to [Service Agreement - Contract Riders](#) for more information.

Setting Up Bill Factor Characteristics

After defining general information about a bill factor, open **Menu > Rates > Bill Factor > Search** and navigate to the **Bill Factor Characteristics** page to define characteristic values where applicable. For example, a bill factor used to levy the applicable city tax would require the definition of every city that levies a tax.

NOTE:

If all values for a bill factor are specified in contract terms, you do not need to set up Bill Factor Characteristics.

Description of Page

Enter a **Characteristic Type** to indicate the type of characteristic that controls how the bill factor's value is defined. This field will be disabled if Bill Factor Characteristics are specified in the following grid.

The **Characteristic Source** defines where the system retrieves the characteristic value at billing time. The Characteristic Source options are:

Account	The characteristic type's value will be retrieved from the service agreement's account.
Characteristic Collection	Refer to Deriving / Passing In Characteristic Values for an explanation of this value.
Main Person	The characteristic type's value will be retrieved from the main person linked to the service agreement's account.
N/A	The characteristic type's value is the same for all customers using the rate. If this option is used, you must still choose a Characteristic Type. This Characteristic Type should have a single Characteristic Value. The ID of the characteristic value must be identical to the ID of the characteristic type.
Premise	The characteristic type's value will be retrieved from the service agreement's characteristic premise.
SA	The characteristic type's value will be retrieved from the service agreement.
SP	The characteristic type's value will be retrieved from the customer's service point. If multiple service points are linked to the service agreement, one will be chosen at random.

FASTPATH:

For more information about characteristics, see [Setting Up Characteristic Types and Their Values](#) and [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the add and remove buttons to define the **Characteristic Values** that are relevant for the bill factor's Characteristic Type. For example, if the bill factor is used to levy a city tax, you would define the city's that have a city tax in the above collection.

Use the **Minutes Per Interval** if your Bill Factor is of type Interval. This defines, for each characteristic value, the number of minutes expected between each record of interval data.

Use the **External ID** if the values for this characteristic are interfaced to the system from an external source and you want to record an identifier for the source.

NOTE:

If the bill factor's value is the same for all customers, you still must link a "dummy" characteristic value to the bill factor. In other words, you'll have to create a characteristic type called "n/a" and define for it a characteristic value of "n/a". Then, on the bill factor, you reference the "n/a" characteristic type and on the above window, you indicate a characteristic value of "n/a".

Defining Bill Factor Values

After the bill factor and its characteristic values are defined, you define the price / percent and GL distribution associated with each bill factor characteristic. The topics in this section describe the pages used to set up this information.

Bill Factor Value - Main

After the bill factor and its characteristic values are defined, select **Menu > Rates > Bill Factor Value** to define the price / percent applicable to each bill factor characteristic.

IMPORTANT:

You do not set up Bill Factor Values for bill factors whose values are specified in an interval value data set or if all the values are customer specific and are defined as contract terms. Refer to [Defining Interval Values](#) for more information about interval value sets. Refer to [Service Agreement - Contract Value](#) for more information about bill factors in contract terms.

Description of Page

Enter the **Effective Date** and respective **Value** for the bill factor and characteristic value. The first date should be the earliest date on which the bill factor's charges are effective. Subsequent effective dates and values are required whenever the value changes.

NOTE:

Default note. A **Value** of 0, zero, will be defaulted.

Bill Factor Value - GL Distribution

Select **Menu > Rates > Bill Factor Value** and navigate to the **GL Distribution** page to define the GL account affected by the bill factor characteristic.

Description of Page

If the bill factor characteristic's charges are booked to a different GL account depending on the characteristic value, specify the appropriate **DistributionCode** for each **Revenue Class**.

IMPORTANT:

Specifying distribution codes on a bill factor is optional. You would only do this if the GL distribution code differs based on the characteristic value (such as, the city tax payable GL account differs depending on the city). If you do not enter the above information, the distribution code will be used.

The GL distribution code on the bill factor's value will not be used in the following cases:

- Value derived solely on contract value or contract value in combination with contract rider and/or tax exemption, where characteristic value is no longer used to determine the bill factor value.
 - Value derived in calculate service quantity and math calculation rules where multiple bill factors may be configured in the rule resulting to multiple values contributing to the calculation of the line amount.
-

Rate Schedule Execution

When a rate schedule is executed, the system executes the calculation rules contained in the calculation groups defined for the rate schedule as follows:

1. First, the system executes the calculation rules defined within Pre-Processing Calculation Groups.

- The rate engine may a bill segment calculation header for pre-processing calculations, if bill calculation lines are to be created.
- Calculation groups are executed in order according to the Sequence defined on the rate schedule.
- Calculation rules within each group are executed according to the Sequence configured within the group.

2. Next, the system executes the calculation rules within the Rate Version Calculation Groups. The system uses the Effective Date on each calculation group to determine which group(s) to execute. If more than one version of a calculation group is in effect during the billing period, the system may prorate the calculations, based on the configuration of the rate schedule.

- The rate engine creates a separate bill segment calculation header for each rate version calculation group.
- Calculation rules within each group are executed according to the Sequence configured within the group.

3. Finally, the system executes the calculation rules defined within Post-Processing Calculation Groups.

- The rate engine creates a separate bill segment calculation header for post-processing calculations.
- Calculation groups are executed in order according to the Sequence defined on the rate schedule.
- Calculation rules within each group are executed according to the Sequence configured within the group.

Additional Information.

- After every rate version calculation group is processed, the rate application returns the calculation details to the process that called it. This point is important as it means that rate application executes in memory (i.e., it does NOT insert the calculation details on the database, rather, it returns them to whatever process called rate application). Because rate application executes in memory, it can be used to perform billing calculations in many parts of the system. For example:
- Both online and batch billing use rate application to calculate the charges that are eventually saved on the bill's bill segments.
- The [Rate Check](#) transaction calls rate application when you want to check a rate real-time. When you use this transaction, you enter the consumption that's passed into rate application and then rate application shows you the calculation details that result.
- Plug-ins exist that call rate application to estimate bill segments when adequate billing history doesn't exist. For example, the BUDCALC-PH budget recommendation algorithm calls rate application to calculate a budget amount for a customer without adequate history. Another example is the DEPRECOM-MBT deposit recommendation algorithm. This plug-in calls rate application to calculate a recommended deposit amount for a customer without adequate history.

Understanding Calculation Groups and Rules

This section provides descriptions of calculation groups and calculation rules, and describes how to identify components of rates that can be defined using calculation rules and groups.

About Calculation Groups and Rules

This section includes descriptions of calculation groups and calculation rules.

About Calculation Groups

Calculation groups are collections of calculation rules that are applied to calculate quantities for billing and billing charges for service agreements.

As noted previously, calculation groups are associated with specific rate schedules in one of three ways:

- **Pre-Processing Calculation Groups:** These are generally used to derive service quantities or measure measured quantities. The following illustrate some use cases of when a pre-processing calculation group might be needed:
 - When a rate contains prices for things that aren't measured directly by the customers' meters. For example, if the rate calculates a charge based on a service agreement's contracted quantity.
 - When a meter measures something in a unit of measure that has to be converted into a different unit of measure before it can be rated. For example, a meter measures gas in cubic feet, but the rate contains prices in therms. During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header is added if Pre-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header. Before invoking the rate's Pre-Processing Calculation Groups, the rate engine processor builds the initial service quantity (SQ) collection based on the item collection and final values in the read collection.
- **Rate Version Calculation Groups:** These are the calculation groups used create a bill segment for the service agreement. Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, must be executed only in a rate version calculation group. When the system creates a bill segment for a service agreement, it checks if multiple Rate Version Calculation Groups are in effect during the bill period. If so, it uses the rate's **Allow RV Proration** and **RV Selection Date** values to determine if it should prorate the various Rate Version Calculation Groups, or if it should pick one of the Rate Version Calculation Groups effective during the bill period. Rate Version Calculation Groups are executed after the rate's pre-processing calculation groups.
 - **Effective Date:** defines the date on which each rate version calculation group becomes effective.
 - **Description on Bill:** Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to [How To Use Description on Bill](#) in the [Defining Calculation Rules](#) chapter for a discussion of the various substitution variables.
- **Post-Processing Calculation Groups:** These are similar to Pre-Processing Calculation Groups, except that these are executed after the Rate Version Calculation Groups. The intended types of functionality include applying taxes on calculated charges, or deriving more complex GL distribution. Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, are not designed to be executed in post and pre-processing calculation groups. During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header is added if Post-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header.

Calculation groups can also be referenced by "Execute Calculation Group" calculation rules. See "Execute Calculation Group Rules - Nesting Calculation Rules" in [About Calculation Rules](#) for more information.

About Calculation Rules

Calculation rules are standard and custom rules that perform calculations used when calculating quantities for billing and billing charges for a customer's service agreements.

Calculation rules are created for a specific calculation group. For example, if you were configuring two calculation groups and both included a specific calculation rule, you would need to create two instances of the calculation rule, one for each group.

Attributes used to define calculation rules typically include the following:

- **Basic Information:** Basic information about the calculation rule, including its name and description, the calculation group to which the rule belongs, the sequence of the rule within the group, the description that appears on the bill, and other information. This information is standard for most calculation rules.
- **Parameters:** The parameters used by the rule. Parameters are specific to each rule. See [Base Package Calculation Rule Descriptions](#) for details about the calculation rules included with the base package.

Execute Calculation Group Rules - Nesting Calculation Rules

Execute Calculation Group rules are used to define business logic to allow reference to a separated specified calculation group. This allows rules that are used frequently to be bunched under a single calculation group, which can be referenced / called by other rules as needed. For example, if a set of standard rules should be applied to all rate schedules, this set of rules can be configured as part of a calculation group, which is referenced by a single calculation rule of this type. Execute Calculation Group rules use the following options:

- **Referred Calculation Group:** defines the calculation group referenced by the rule.
- **Characteristics:** defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calculation lines.

NOTE: There is a limit of 99 calculation groups that can be called from a calculation group defined directly on a rate schedule or via related child calculation groups when using Execute Calculation Group calculation rules.

Eligibility Criteria

Calculation rule eligibility criteria are user-definable conditions that could cause a given calculation rule to be applied or skipped. This can involve the evaluation of some attribute of the service agreement, or service point, or something else entirely.

A calculation rule can have multiple eligibility criteria for determining if the rule should be applied or skipped, based on a user-defined sequence. Each eligibility criteria uses the following settings:

- **Criteria Comparison:** defines the specific comparison for the criteria, based on the following:
 - **Criteria Field Type:** the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
 - **Comparison Operator:** the operator used in the comparison
 - **Comparison Value:** a user-specified value to which the retrieved value is compared (using the comparison operator)
- **Comparison Results:** defines how the rule should behave, based on the results of the comparison defined under Criteria Comparison:
 - **If True:** the action to take if the comparison is true
 - **If False:** the action to take if the comparison is false

- **If Insufficient Data:** the action to take if there is insufficient data to perform the comparison

Calculation Line Category Types

Calculation line category types are used to establish connections between calculation rules. Calculation rules can specify a member category and value to which they belong. When this same category and value are referenced as a "Target Category" by other rules (the rule is applied to the results of rate version calculation rules (defined in the same rate schedule) that belong to the category and value.

For example, calculation rules whose results are subject to taxes might belong to the "Subject to Tax" (TAXABLE) category and "County Tax" value. Apply To calculation rules defined for the same rate schedule with a target category of "Subject to Tax" and "County Tax" values are applied to "Subject to Tax" member rules.

Calculation Line Category Types are defined by the following:

- **Calculation Line Category Type:** The unique identifier of a calculation line category type definition
- **Description:** The description of the calculation line category type.
- **Category Values:** The valid category values for the calculation line category type.

Base Package Calculation Rules

Oracle Utilities Customer Care and Billing includes the following base package calculation rule types that can be used when creating calculation rules:

- **Apply To:** Used to create bill lines that levy charges based on amounts calculated on other bill lines.
- **Calculate Final Reading Values:** Used to determine the final values for readings based on user-defined UOM/TOU/SQI.
- **Calculate Service Quantity:** Used to derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection.
- **Copy Service Quantity From Master Bill Segment:** Used to copy all the entries from the master bill segment SQ collection to the sub bill segment SQ collection.
- **Execute Calculation Group:** Used to call and pass parameters to another calculation group.
- **Flat Charge:** Used to create bill lines that levy service charges and fees that aren't based on how much the customer uses.
- **Item Type:** Used to create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.
- **Math:** Used to derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities
- **Maximum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount.
- **Minimum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount.
- **Service Quantity:** Used to create bill lines that levy charges based on some type of consumption.
- **Simple Summary:** Used to create a "subtotal" on the bill, by summarizing bill lines produced by other calculation rules in the same calculation group.
- **Stepped Service Quantity:** Used to create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are \$0.43 per kWh, anything in excess of 50 kWh is charged at \$0.71 per kWh)
- **Summary:** Used to create a "subtotal" on the bill. It exists purely for reporting and informational purposes.

See [Base Package Calculation Rule Descriptions](#) for details about each of these calculation rules.

Designing Calculation Groups and Rules

Before starting to design calculation groups and rules for your rates, please review the concepts outlines in the **Designing Rate Components** section in the [Rates](#) chapter. That section provides a good background for understanding how to break down rates into component pieces that can be modeled by calculation groups and rules.

This section provides guidelines for how to design and plan the calculation groups and rules you will need for your rates, and provides a simple case study of how to define the calculation rules and groups you might use for a set of rates for a small municipal electric company.

Analyzing Your Rates and Identifying Calculation Rules and Groups

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Best Practices

When designing calculation groups and rules, the following general rules apply:

- **Pre-Processing Calculation Groups.** Perform any initial processing or conversions that should occur before the rate version calculation group. This can include:
 - Calculating the number of days in a billing period (Calculate Service Quantity)
 - Calculating service quantities that are not measured (demand, kVa, etc.) (Calculate Final Reading Values, Calculate Service Quantity, Math)
 - Validating that consumption is within tolerances set by the rate (residential limits, etc.) (Calculate Service Quantity, with eligibility criteria)
- Calculations processed by calculation rules should be performed by **Rate Version Calculation Groups.** This includes most charge calculations, including:
 - Charges based on service quantities (Service Quantity, Stepped Service Quantity)
 - Customer charges (Flat Charge)
 - Minimum/maximum charges (Minimum Charge, Maximum Charge)
 - Discounts (Apply To)
 - Taxes (Apply To)
 - Summaries (Summary, Simple Summary)
- Additional processing should be performed by **Post-Processing Calculation Groups.** This can include:
 - Allocating consumption/revenue (energy revenue vs. demand revenue) (Service Quantity)

Example Configurations

Let's look at a couple of different possible configurations for a simple electric rate that includes the following:

- Customer Charge
- Service Charge (price per kWh)

- Minimum Charge
- Discount

This rate could be set up in the following ways:

- A single Rate Version calculation group that contains a calculation rule for each of the above
- A set of Rate Version calculation groups as follows:
 - A calculation group for "flat" charges, such as the Customer Charge
 - A calculation group for consumption-based charges (including the Service Charge and Minimum Charge).
 - A calculation group for discounts or other charges applied to the total of other charges (which would include the Discount)

There are no hard and fast rules concerning how calculation rules should be grouped. How this is done should be based on the specific needs of the implementation but it's a good idea to look for ways to keep your configuration simple for maintenance and upkeep purposes. This includes changes to existing rates as well as adding/removing rates over time.

Reusing Calculation Rules

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Identifying Calculation Rules that can be Shared/Reused

As you analyze the bill lines used by your rates, you should look for bill lines that utilize similar or identical variables or calculations. These calculations are candidates for reuse. For example, if all of your residential rates offer a discount for early payment, you would want to create a single rule to calculate that discount, and then use it each of the rates to which it applies.

How to Reuse Calculation Rules

There are two approaches that can be used to reuse calculation rules.

- **Encapsulating Rules in a Calculation Group**

This approach involves grouping rules that can be applied to more than one rate into a single calculation group. You would use this approach when you identify charges and other components in your rates that apply to multiple rates, but that can be grouped together. Taxes for multiple types of jurisdictions (for example, State, County, and City) would be suitable for this approach.

To use this approach, you simply create a calculation group that contains the rules to be applied to more than one rate. For the tax example, you might create the following group and rules:

Calculation Group: Taxes, which includes:

Calculation Rule: State Tax (Apply To)

Calculation Rule: County Tax (Apply To)

Calculation Rule: City Tax (Apply To)

This "Taxes" calculation group can be included as a Rate Version Calculation Group in each of the rates to which the taxes apply. This calculation group could also be referenced by an "Execute Calculation Group" rule, as outlined below.

- **Using "Execute Calculation Group" Rules**

This approach involves creating a calculation group that contains one or more rules, which is then referenced by another "Execute Calculation Group" rule. This approach can be used when you identify a charge or calculation that could be applicable within one or more calculation groups. For example, if multiple rates involve calculating peak demand (or some other quantity that is not measured by your customers' meters), you could create a "Calculate Demand" rule and include it in a group that is then referenced by an "Execute Calculation Group" rule.

To use this approach, you create a calculation group that contains the calculation rules to be used within multiple calculation groups. You then create an "Execute Calculation Group" rule that references the group. Last, you include this "Execute Calculation Group" rule in the calculation groups to which it applies. For the calculate demand example, you might create the following:

Calculation Rule: Calculate Demand (Execute Calculation Group), which references:

Calculation Group: Calculate Demand, which includes:

Calculation Rule: Calculate Demand (Calculate Service Quantity)

The "Calculate Demand" Execute Calculation Group rule can be included in any calculation group used to calculate service quantities that includes calculating peak demand.

"Execute Calculation Group" rules can be used with any calculation group. To return the taxes example from above, if you wanted to include your "Taxes" calculation group within other groups, you could use the following:

Calculation Rule: Taxes (Execute Calculation Group), which references:

Calculation Group: Taxes, which includes:

Calculation Rule: State Tax (Apply To)

Calculation Rule: County Tax (Apply To)

Calculation Rule: City Tax (Apply To)

See "Execute Calculation Group Rules - Nesting Calculation Rules" in [About Calculation Rules](#) for more information about Execute Calculation Group rules.

Leveraging Eligibility Criteria to Dynamically Apply Calculation Rules

Another tool to consider when creating your calculation groups and rules is Eligibility Criteria. Eligibility criteria allow you to define rules that determine the conditions under which a calculation rule is applied or not.

For example, if you need to calculate demand for one or more of your rates, you might create separate calculation rules to calculate demand based on interval values of different units of measure (kWh vs kVarh for instance). You could create rules for each and include them in a single "Calculate Demand" calculation group, but assign eligibility criteria to each such that they are only executed when processing for the specified unit of measure.

See Eligibility Criteria in [About Calculation Rules](#) for more information about eligibility criteria and how they can be used with calculation rules. In addition, refer to **The Big Picture of Rate Component Eligibility Rules** in the [Rates](#) chapter for additional background on eligibility criteria.

Case Study: Three Sample Rates

Let's look at a sample set of rates, and how they might be implemented. We'll also look at which components of these rates can be shared.

Rates

The following rates are electric rates offered by a small municipal electric company.

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
Cost of Service	Stepped charges, as follows:	Stepped charges, as follows:	1. Customer Charge:\$52.00

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
	<p>\$3.08 for the first 10 kWh or less, plus</p> <p>19.23 cents per kWh for the next 40 kWh, plus</p> <p>15.44 cents per kWh for the next 150 kWh, plus</p> <p>14.93 cents per kWh for the next 300 kWh, plus</p> <p>14.71 cents per kWh for all kWh in excess of 500 kWh</p>	<p>\$2.95 for the first 10 kWh or less, plus</p> <p>19.23 cents per kWh for the next 40 kWh, plus</p> <p>18.85 cents per kWh for the next 50 kWh, plus</p> <p>16.86 cents per kWh for the next 400 kWh, plus</p> <p>15.45 cents per kWh for the next 3,000 kWh, plus</p> <p>14.87 cents per kWh for all kWh in excess of 3,500 kWh.</p>	<p>2. Demand: \$11.44 per KW</p> <p>3. Energy: \$11.28 cents per KWH</p> <p>Billing Demand</p> <p>The Billing Demand for any month shall be the greater of the following:</p> <ol style="list-style-type: none"> 1. The maximum 15 minute measured demand during the month as measured in kilowatts, or 2. 70% of the maximum 15 minute measured demand as so determined during the preceding 11 months.
Discount	<p>Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date.</p> <p>For qualifying elderly residents, an additional 10% discount is allowed on the basic rate if paid on or before the discount expiration date and no arrears exist on their accounts.</p>	Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date.	Discount of 10% exclusive of purchased power and fuel adjustment charge paid on or before the discount expiration date.
Purchased Power and Fuel Adjustment	<p>An upward or downward adjustment applied to all kWh sold, based on the total cost of purchased power and fuel compared to the portion of that cost contained in the base rate (11.615 cents/kWh).</p> <p>The purchase power and fuel adjustment shall be rounded to the sixth decimal place and shall be applied to all kilowatt-hours sold in the following month.</p>	See Domestic Rate A	See Domestic Rate A
Misc.	N/A	N/A	Minimum Bill The Customer Charge
Taxes	State, County, and City Taxes	State, County, and City Taxes	State, County, and City Taxes

Calculation Rules

Now let's look at these same rates in terms of how we might implement them using calculation rules. The table below lists the type of calculation rule used for each item on the rate.

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
Cost of Service	Stepped Charges:	Stepped Charges:	Customer Charge: <ul style="list-style-type: none"> • Flat Charge calculation rule

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
	<ul style="list-style-type: none"> Stepped Service Quantity calculation rule Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less) 	<ul style="list-style-type: none"> Stepped Service Quantity calculation rule Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less) 	Demand: <ul style="list-style-type: none"> Service Quantity calculation rule Math calculation rule (to calculate demand from interval values)* Energy: <ul style="list-style-type: none"> Service Quantity calculation rule *Could be included in either a Pre-Processing or Rate Version Calculation Group
Discount	Discount: <ul style="list-style-type: none"> Apply To calculation rule Elderly Discount: <ul style="list-style-type: none"> Apply To calculation rule 	Discount: <ul style="list-style-type: none"> Apply To calculation rule 	Discount: <ul style="list-style-type: none"> Apply To calculation rule
Purchased Power and Fuel Adjustment	PPF Adjustment: <ul style="list-style-type: none"> Service Quantity calculation rule Note: The PPF adjustment rate would be defined as a Bill Factor, updated monthly based on the prior month's total cost.	PPF Adjustment: <ul style="list-style-type: none"> Service Quantity calculation rule 	PPF Adjustment: <ul style="list-style-type: none"> Service Quantity calculation rule
Misc.	N/A	N/A	Minimum Bill: <ul style="list-style-type: none"> Minimum Charge calculation rule
Taxes	State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax) 	State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax) 	State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax)

Shared Components

Now, let's look at the components of these rates that can be shared.

Discounts: Rates A and B both use the same discount, so we could create a single "AB Discount" calculation rule that could be used with both rates. Note: Either this could be in its own calculation group that is listed among the Rate Version Calculation Groups for each rate, or the group could be referenced by an "Execute Calculation Group" rule which in turn would be included in one of the other Rate Version Calculation Groups used in each rate.

Purchased Power and Fuel Adjustment: Rates A, B, and C all use the same adjustment for purchased power and fuel, so we could create a single "PPF Adjustment" calculation rule that could be used with all three rates. Again, this calculation rule could be in its own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

Taxes: Rates A, B, and C are all subject to the same taxes, so we could create calculation rules for each type of tax (State, County, and City) in a single group that could be used with all three rates. Again, these calculation rules could be in their

own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

The Big Picture of Calculation Rule Eligibility Rules

You can use eligibility rules to define the criteria when a calculation rule should be applied (or skipped); for example,

- You may have a calculation rule that generates an employee discount. This calculation rule may have eligibility criteria that requires the person to have a given characteristic type and value (this assumes you use a person characteristic to identify employees) before the calculation rule is applied.
- You may have a calculation rule that applies a surcharge if the customer uses 25% more than they used in the same period in prior year.

NOTE:

Eligibility rules are optional. If you add eligibility rules to a calculation rule, the calculation rule will be skipped or applied per the instructions in the rules. If you don't add eligibility rules to a calculation rule, however, the calculation rule will be executed – this is because calculation rules are eligible by default

The topics in this section describe eligibility rules.

A Rate Component is Eligible by Default

If you don't want to setup eligibility rules, you don't have to. If you don't specify eligibility rules on a calculation rule, it's eligible and will be processed by rate application.

Defining Logical Eligibility Criteria

When you setup an eligibility criterion, you must define three things:

- The field to be compared
- The comparison method
- The comparison results

Criteria Comparison

You have the following choices in respect of identifying the **Criteria Field Type**:

- **Algorithm.** You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present an example later in this section to illustrate the power of this approach.
- **Bill Factor.** You can retrieve a bill factor value to use as a field value in the comparison.
- **Calc Line.** You can retrieve a calculation line amount to use as a field value. The value is derived by summing calculation lines defined as members of a target category.
- **Characteristic.** You can retrieve a characteristic value linked to any of the following:
 - The service agreement being billed
 - The service agreement's account
 - The main person linked to the service agreement's account

- The characteristic premise linked to the service agreement
- One of the service points linked to the service agreement
- In addition, you can retrieve a characteristic value from the Characteristic Collection where values are derived while the rate is being calculated (characteristic values can be created by calculation rules)
- **Contract Quantity.** You can retrieve a contract quantity for the service agreement.
- **Service Quantity.** You can retrieve the value of a given service quantity from the SQ collection based on a specified UOM / TOU / SQL.
- **Historical Quantity.** You can derive a value based on the service agreement's historical bill segment service quantities for the specified UOM / TOU / SQL.

You have the following choices in respect of identifying the **Comparison Method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value

Comparison Results

Once you have this information and have applied your comparison, you must define what action should be taken. You must specify what to do if the results are True, False, or Insufficient Data.

- **If True or False.** You have the option to apply the rule or not, or check the next condition.
- **If Insufficient Data.** You have the option apply the rule or not, check the next condition, or generate an error.

See [Examples of Calculation Rule Eligibility Rules](#) for illustrations of these rules.

Examples of Calculation Rule Eligibility Rules

The topics in this section provide examples about how to setup calculation rule eligibility rules.

A Calculation Rule with a Service Quantity Comparison

Imagine a calculation rule that is only eligible if the customer is a low-income customer and has used more than 1,000 kWh. This calculation rule would need the following eligibility rules:

- Customer is a low income customer
- The customer has used more than 1,000 kWh during the bill period

These rules will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Main person characteristic: Characteristic type = Low income indicator	= YES	Check next condition	Do Not Apply Rule	Do Not Apply Rule
20	SQ value: UOM = KWH	>= 1,000	Apply Rule	Do Not Apply Rule	Error

The criteria are similar - they retrieve a value and compare it to something:

The first criterion is fairly simple:

- **Field to Compare.** We indicate that the value of the Low Income Indicator characteristic is kept on the main person linked to the account should be retrieved. We assumed that this characteristic type has values of YES and NO.
- **Comparison Method and Results.** We indicate that if the person has a characteristic value of YES, then we should check the next condition; otherwise, we indicate if the eligibility rule is false or there is insufficient data, the calculation rule is skipped.

The second criterion works similarly:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KWH that should be retrieved.
- **Comparison Method and Results.** We simply compare the value to 1,000. If the SQ is greater than or equal to 1000, the eligibility rule is True and the calculation rule is applied. If the SQ is less than 1000, the eligibility rule is false and the calculation rule is skipped. If there is insufficient data, there is an error generated.

A Calculation Rule with a Characteristic Lookup and Consumption Comparison

Imagine a calculation rule that is eligible for customers who have signed up for a consumption reduction program and have low consumption. This would require the following criteria:

- Check that the customer has signed up for the reduction program.
- Check to see that the customer's consumption is lower than the threshold.

These rules will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Check if the customer has signed up for the reduction program	= Y	Check next condition	Do Not Apply Rule	Do Not Apply Rule
20	Check if consumption is less than the threshold	< = 100 Kilowatt	Apply Rule	Do Not Apply Rule	Do Not Apply Rule

The criteria are similar - they retrieve a value and compare it to something:

The first criterion works as follows:

- **Field to Compare.** We indicate the value of the reduction program characteristic type (CI_CLMSM) is found on the service agreement. We assumed that this characteristic type has values of Y and N.
- **Comparison Method and Results.** Comparison Method and Results. We indicate that if the service agreement has a characteristic value of Y, then we should check the next condition. If the condition is false or insufficient data, the calculation rule is skipped.

The second criterion works as follows:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KW that should be retrieved.
- **Comparison Method and Results.** We indicate that we want to compare the service quantity to the threshold (100 kW). If the service agreement's bill segment has a service quantity that is less than or equal to 100 kW, it is True and the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

A Calculation Rule with a Discount for Being on Autopay

Imagine a calculation rule that is only eligible if the current customer has signed up for Autopay. This calculation rule would need the following eligibility rule:

- Customer has Autopay

This rule will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: check if customer has Autopay	= Y	Apply Rule	Do Not Apply Rule	Do Not Apply Rule

The criterion calls an algorithm that performs a logical comparison.

The criterion works as follows:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the account associated with the bill segment is on Autopay. If an autopay setup exists, then it returns a value of Y. If not, however, it returns N
- **Comparison Method and Results.** We simply compare the value returned by the algorithm to Y and indicate the appropriate response. If the condition is true, the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

NOTE:

Refer to CI_CHK_APAY for more information about this algorithm.

Working with Calculation Groups and Rules

This section outlines how users work with calculation groups and calculation rules.

Defining Calculation Groups

Use this procedure to define calculation groups.

- Select **Menu > Rates > Calculation Group > Add.**
- Enter a **Name** for the calculation group.
- Enter a short **Description** and **Detailed Description** for the group.
- Click **Save.**

NOTE: You can also add a calculation group directly from the Rate Schedule portal. The **Add Calculation Group** action on the Pre-Processing Calculation Groups, Rate Version Calculation Groups and Post-Processing Calculation Groups sections allows you to create the calculation group and link the new group to the Rate Schedule.

To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See [Defining Calculation Rules](#) for more information about creating calculation rules.

You can now create calculation rules for this group.

See [About Calculation Groups](#) for more information about calculation groups.

Searching and Maintaining Calculation Groups

Use this procedure to search for and view a calculation group.

- Select **Menu > Rates > Calculation Group > Search.**
- Enter your search criteria.

You can search by **Calculation Group** name or **Description**.

- Click **Refresh**.
- In the search results list, click the **Description** link for the calculation group you want to view or edit. The selected calculation group is displayed in the **Calculation Group** portal. You use this portal to maintain calculation groups. This portal includes the following zones:
 - **Calculation Group**: Defines basic information about calculation group
 - **Calculation Rules List**: lists the calculation rules belonging to the group. Eligibility criteria referenced by a calculation rule are listed indented beneath each rule. If a calculation rule in turn references a calculation group, the calculation group executed by the rule is displayed.
 - **Referencing Rates Schedules List**: lists the rates schedules that reference the group
 - **Referencing Calculation Rules List**: lists the calculation rules that reference the group

Use this procedure to maintain a calculation group:

- Select **Menu > Rates > Calculation Group > Search** to navigate to the Calculation Group Query portal.
- Search for and select the appropriate calculation group.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See [Defining Calculation Rules](#) for more information about creating calculation rules.
- To update the sequence values for all calculation rules in the group, click the **Resequence All Rules** link in the **Calculation Rules List** zone title bar.
 - Edit the sequence values for all rules by specifying new **Start Sequence** and **Increment By** values.
 - Click **OK** to update the calculation rules with new sequence numbers.
- To Edit or Delete a specific calculation rule in the group, select the **Edit** or **Delete** icon in the Calculation Rules List zone as appropriate.
- To Delete one or more of the calculation rules in the group:
 - Select one or more of the calculation rules you want to delete.
 - Click **Delete Calc Rules**.
 - Click **OK** to delete the selected calculation rules
- To update the bill print details for one or more of the calculation rules in the group:
 - Select one or more of the calculation rules for which you want to change the bill print details.
 - Click **Update Bill Print**.
 - Edit the bill print details for the selected calculation rules.
 - Click **Save** to update the selected calculation rules with the new bill print details.
- To change the sequence values for one or more of the calculation rules in the group:
 - Select one or more of the calculation rules for which you want to change the sequence values.
 - Click **Resequence Rules**.
 - Edit the sequence values for all the selected calculation rules.
 - Click **Save** to update the selected calculation rules with the new sequence values.

See [About Calculation Groups](#) for more information about calculation groups.

Defining Calculation Line Category Types

Use this procedure to define calculation line category types.

- Select **Menu > Rates > Calculation Line Category Type > Add.**
- Enter a **Category Type** name for the category type.
- Enter a short **Description** and **Detailed Description** for the category type.
- Define the **Category Value** and **Description** for each value for the category type.
- Click **Save.**

You can now reference this category and its values as either the Member Category or Target Category on calculation rules.

See "Calculation Line Category Types" in [About Calculation Rules](#) for more information about calculation line category types.

Maintaining Calculation Line Category Types

Use this procedure to search for and maintain calculation line category types.

- Select **Menu > Rates > Calculation Line Category Type > Search.**
The **Calculation Line Category Type List** zone displays the calculation line category types defined in the system.
- Click the broadcast icon for the calculation line category type you wish to view and/or edit.
The selected calculation line category type is displayed in the **Calculation Line Category Type** zone.
- Click **Edit, Delete,** or **Duplicate** as appropriate.

See "Calculation Line Category Types" in [About Calculation Rules](#) for more information about calculation line category types.

Defining Calculation Rules

Use this procedure to define calculation rules.

- Select **Menu > Rates > Calculation Rule > Add.**
- Select the **Calculation Group** to which the rule will belong.
- Select the **Calculation Rule BO** for the calculation rule.
Refer to [Base Package Calculation Rule Descriptions](#) for detailed descriptions of the available calculation rules and their associated business objects.
- Enter name for the **Calculation Rule.**
- Enter the **Sequence** for the rule. This designates the order in which the rule will be executed within its parent calculation group.
- Enter a short **Description** and **Detailed Description** for the rule.
- Enter or select other parameters for the rule as appropriate.
Refer to [Base Package Calculation Rule Descriptions](#) for detailed descriptions of the available calculation rules and the parameters used by each.
- Click **Save.**

See [About Calculation Rules](#) for more information about calculation rules.

How to Use Description on Bill

Enter the verbiage to appear on the bill segment in the **Description On Bill**. Turn on **Print** if the verbiage should appear on the printed bill.

NOTE:

Suppressing calculation details on the printed bill. Only calculation rules that are used to calculate intermediate values are typically suppressed on a bill. For these types of calculation rules, we recommend using **Description on Bill** to show users how the line was calculated, but select No from the **Print** dropdown menu. This way, users will see the calculation details on the [Bill Segment - Calc Lines](#) window, but the customer won't see it on their bill.

Many lines that appear on a bill do not contain static verbiage. Rather, the printed lines contain information from the calculation process. For example, the bill line for state tax would typically contain the tax percent.

You control exactly what is substituted in the bill line by entering one or more of the following substitution variables in the **Description on Bill** field:

NOTE: If none of the following substitution characters satisfy your need, there is a plug-in option on the calculation rule business object that allows customer modified variables. Algorithms can be attached to the business object as a Build Line Description system event.

Substitution Character	What It Does
%A	<p>Replaces the substitution character with the amount of the bill line. Please be aware of the following:</p> <ul style="list-style-type: none">• If the calculation rule isn't designated as being "for calculation purposes only" (FCPO), all trailing zeroes up to the decimal position of the rate's currency will be removed. If the calculation rule is designated as being "for calculation purposes only" (FCPO), the number of decimal places as defined in the calculation rule's precision will be shown.• All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place.• The Symbol on the Currency control table will prefix the value.• The position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process).
%B	<p>Replaces the substitution character with the begin/start date covered by the bill calculation line.</p> <p>If the charge is proratable, %B may be used in conjunction with %E to display the period covered by the bill calculation line.</p>
%C	<p>Replaces the substitution character with the number of items being billed. Leading zeroes are suppressed.</p>
%D	<p>Replaces the substitution character with message 10101 from message category 11109. This message is maintained in the standard message table.</p>

We recommend this message be set to "(prorated for %1 of %2 days)" where %1 will be substituted with the number of days of prorated consumption charged on the bill line and %2 will be the "normal" days associated with the rate's prices. This message will only be substituted when the calculation rule is prorated. Note, neither %1 nor %2 are required.

Either this character OR %F should be used when you desire to substitute the price / percent into the bill line.

If the charge is proratable, %D should be used in conjunction with %R to print an appropriate message when the charges are prorated.

%E

Replaces the substitution character with the end date covered by the bill calculation line.

If the charge is proratable, %E may be used in conjunction with %B to display the period covered by the bill calculation line.

%F

Replaces the substitution character with message 10102 from message category 11109. This message is maintained in the standard message table.

We recommend this message be set to "(prorated by %1)" where %1 will be substituted with the factor used to prorate the charge. This message will only be substituted when the calculation rule is prorated. Note, %1 is not required.

If the charge is proratable, %F should be used in conjunction with %I to print an appropriate message when the charges are prorated.

%H

Replaces the substitution character with the high value defined on the calculation rule used to calculate the specific stepped charge on the bill line.

%I

Replaces the substitution character with the value specified in the calculation rule / bill factor.

If the value is a percent,

- all leading and trailing zeroes will be suppressed,
- and a "%" will be suffixed to the resultant value.

If the value is not a percent,

- all trailing zeroes up to the decimal position of the rate's currency will be removed,
- and all leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place,
- and note that the position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process).

Either this character OR %R should be used when you desire to substitute the price / percent into the bill line. Using %I will cause the value as specified in the calculation rule to be substituted regardless of whether the charges are prorated.

If the charge is proratable, %I should be used in conjunction with %F to print an appropriate message when the charges are prorated.

%L	Replaces the substitution character with the low value defined on the calculation rule used to calculate the specific stepped charge on the bill line.
%M	Replaces the substitution character with the item type defined on the calculation rule used to calculate the specific item type charge on the bill line. This is only applicable to calculation rule-based rates.
%O	Replaces the substitution character with the description of the time-of-use (TOU) code being billed on this line
%Q	Replaces the substitution character with the service quantity being billed. Leading zeroes are suppressed. The decimal places shown are specified in a field on the Unit Of Measure control table. If you wish to suppress trailing zeroes after the decimal, you must set up the Allow Consumption Zero Suppression In Bill Description option type on the Financial Transaction Options Feature Configuration .
%R	Replaces the substitution character with the value specified in the calculation rule / bill factor. Either this character OR %I should be used when you desire to substitute the price / percent into the bill line. Using %R causes the prorated price / percent to be printed in the bill line (%I causes the price / percent as specified in the rate to be printed during proration situations). If the charge is proratable, %R should be used in conjunction with %D to print an appropriate message when the charges are prorated.
%S	Replaces the substitution character with the summed amount. All trailing zeroes up to the decimal position of the rate's currency will be removed. All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place. The Symbol on the Currency control table will prefix the value. If the value is negative, a "-" will prefix the value. This character should only be used with Minimum, Apply To, and Summary calculation rules.
%T	Replaces the substitution character with message 10103 from message category 11109. This message is maintained in the standard message table. We recommend this message be set to "(%1% exempt)" where %1 will be substituted with the tax exemption percent as specified in the service agreement. This message will only be substituted when the calculation rule's bill factor is eligible for tax exemptions AND the customer is exempt from the tax. Note, %1 is not required.
%V	Replaces the substitution character with the "C1-ADDSC" characteristic ad hoc value retrieved by the calculation rule used to calculate the charge on the bill line.
Lines that don't print	If the bill line is not printed (as defined by the Print option), message 10104 from message category 4 will be appended to the bill line. This message is maintained in the standard message table. We recommend this message be "NOT SEEN BY CUSTOMER!" This message appears in the bill line that appears in the billing windows but does not appear on the customer's bill.

The following are examples of the content of common **Description on Bills** along with how the line would look on the customer's bill:

Description on Bill On Calculation Rule	How It Looks On A Bill
%C lamp pole(s) at %I per pole %F	1,234 lamp pole(s) at \$5.00 per pole (prorated by .3333)
%C lamp pole(s) at %R per pole %D	1,234 lamp pole(s) at \$1.50 per pole (prorated for 10 of 30 days)
First %Q kWh at %I per kWh %F	First 100.32 kWh at \$0.12349 per kWh (prorated by .3333)
First %Q kWh at %R per kWh %D	First 100.32 kWh at \$0.12349 per kWh (prorated for 10 of 30 days)
%Q kWh at %I per kWh	100.32 kWh at \$0.12349 per kWh
State sales tax %R %T	State sales tax 6.25% (50% exempt)
Minimum charge of %I %F	Minimum charge of \$10.00 (prorated by .3333)
Subtotal of %S	Subtotal of \$1,123.23
Charges for %O: %Q kW at %I per kW	Charges for Off Peak Winter: 234.43 kW at \$0.05 per kW

The prorated references will only appear if the calculation rule's charges are prorated due to a short or long bill period.

Searching and Maintaining Calculation Rules

Use this procedure to search for and maintain calculation rules.

- Select **Menu > Rates > Calculation Rule > Search**.
- Enter your search criteria.
Available query options include **Calculation Rule** and **Calculation Rule BO**.
 - When searching by **Calculation Rule**, you can search by **Calculation Group**, **Calculation Rule** name, or **Description**.
 - When searching by **Calculation Rule BO**, you can search by **Business Object**, or **Description**.
- Click **Refresh**.
- In the search results list, click the **Description** link for the calculation rule you want to view or edit. To navigate to the rule's calculation group, click the **Calculation Group** link.
The selected calculation rule is displayed in the **Calculation Rule** portal. You use this portal to maintain calculation rules. This portal includes the following zones:
 - **Calculation Rule**: Defines basic information about calculation rule
 - **Eligibility Criteria List**: Lists optional eligibility criteria for the current calculation rule. Eligibility criteria are used to determine whether a calculation rule should be applied (or skipped) during rate processing.

Use this procedure to maintain a calculation rule:

- Select **Menu > Rates > Calculation Rule > Search** to navigate to the Calculation Rule Query portal.
- Search for and select the appropriate calculation rule.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To define eligibility criteria for the rule, click the **Add** link in the **Eligibility Criteria List** zone title bar. See "Eligibility Criteria" in [About Calculation Rules](#) for more information.

See [About Calculation Rules](#) for more information about calculation rules.

Defining Calculation Rule Eligibility Criteria

Use this procedure to define eligibility criteria for a calculation rule.

Prerequisites: You must create a calculation rule before you can define eligibility criteria.

- Click the **Add** link in the **Eligibility Criteria List** zone title bar.
- Enter a **Sequence** number, **Description**, and **Detailed Description** for the criteria.
- Complete the **Criteria Comparison** section as follows:
 - **Criteria Field:** the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
 - **Comparison Operator:** the operator used in the comparison
 - **Value:** a user-specified value to which the retrieved value is compared (using the comparison operator)
- Complete the **Comparison Results** section as follows:
 - **If True:** the action to take if the comparison is true
 - **If False:** the action to take if the comparison is false
 - **If Insufficient Data:** the action to take if there is insufficient data to perform the comparison
- Click **Save**.

See [The Big Picture of Calculation Rule Eligibility Rules](#) for more information.

Creating Rate Schedules

This section outlines how users work with rate schedules.

Defining Rate Schedules

Use this procedure to define rate schedules.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu > Rates > Rate Schedule > Add**.
The Rate Schedule maintenance screen opens. To navigate to the Component-Based Rate Schedule page, click **Switch to Component-Based**.
- Enter a code for the **Rate Schedule**.
- Enter a short **Description** for the rate schedule.
- Select the **Service Type** (Electric Service, Gas Service, etc.) for the rate schedule.
- Select the **Frequency** (monthly, quarterly, etc.) for the rate schedule
- Select the **Currency Code** used with the rate schedule.
- Select whether or not the rate schedule will **Allow Estimates** when performing calculations.
- Select whether or not the rate schedule will **Allow RV Proration** when performing calculations.
- Select the **RV Proration Date**, used if the rate schedule does NOT allow RV proration. Valid options include Accounting Date, Bill End Date, and Bill Start Date.

- Define the **Pre-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each pre-processing calculation group, specify:

- **Sequence:** The sequence in which the group is executed when the pre-processing groups are processed.
- **Description:** A description of the calculation group
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define the **Rate Version Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each rate version calculation group, specify:

- **Effective Date:** The date on which each rate version calculation group becomes effective
- **Description on Bill:** Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to [How To Use Description on Bill](#) for a discussion of the various substitution variables.
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define the **Post-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each post-processing calculation group, specify:

- **Sequence:** The sequence in which the group is executed when the post-processing groups are processed.
- **Description:** A description of the calculation group
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define one more recommended **Meter Configuration Types** for meters linked to service agreements (by way of their service points) for the rate schedule.
- Define one or more **Bill Messages** that should appear on bills that use the rate schedule. For each message, specify
 - **Bill Message:** The message that should appear on the bill.
 - The **Start Date** and **End Date** when the bill message should appear on the bill. Leave **End Date** blank if the message should appear indefinitely,
- Click **Save**.

This rate schedule can now be referenced on service agreements.

Searching and Maintaining Rate Schedules

Use this procedure to search for and view a rate schedule.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu > Rates > Rate Schedule > Search**.
- Enter your search criteria.
You can search by **Rate Schedule, Description, or Rate Engine** (Calculation Rule-Based or Component-Based).
- Click **Search**.
- In the search results list, click the **Description** link for the rate schedule you want to view or edit.

NOTE: Component-based rate schedules will be highlighted by having "(Component-Based)" appended to their listing in the search results.

- The selected rate schedule is displayed in the (Calculation Rule-Based) **Rate Schedule** portal. You use this portal to maintain rate schedule. This portal includes the following zones:
 - **Rate Schedule:** Defines basic information about the rate schedule.
 - **Rate Schedule Tree:** Displays the hierarchy of Calculation Groups and Calculation Rules for the Rate Schedule. Only the most recent rate version calculation group is initially displayed. In this zone you can:
 - Click a calculation group or calculation rule link to go to the Calculation Group or Calculation Rule portal for the associated calculation group or calculation rule.
 - Click the Broadcast icon for a calculation rule to open the Cross Reference Rule zone. This zone displays the rate schedule's calculation rules that are members of the broadcast calculation rule's target category.
 - Click the **Show All Rate Versions** button to display all rate versions for the rate schedule. This will also display the **Show Effective Rate Version** button, which you can use to display the information for the most recent rate version.

Use this procedure to maintain a rate schedule:

- Select **Menu > Rates > Rate Schedule > Search** to navigate to the Rate Schedule Query portal.
- Search for and select the appropriate rate schedule.
 - The selected rate schedule is displayed in the (new) **Rate Schedule** portal.
 - Click **Edit, Delete, or Duplicate** as appropriate.

NOTE:

If you select a component-based rate schedule, the selected rate schedule is displayed in the (component-based) **Rate Schedule** page.

Base Package Calculation Rule Descriptions

This section provides detailed descriptions of each of the base package calculation rules provided with Oracle Utilities Customer Care and Billing. The descriptions of the calculation rules below contain the following information

- **Rule Name:** The name of the rule
- **Base Package Calculation Rule Business Object:** The base package business object used by the rule
- **Apply Calculation Rule Algorithm Type / Algorithm:** The base package algorithm type and algorithm specified in the "Apply Calc Rule" system event for the rule
- **Rule Parameters:** Parameters used to define the rule (if applicable). Does not include common parameters used by all rules (see Common Parameters).

- **Example:** One or more example configurations of the rule. Note that all examples use default values for all Apply Calculation Rule Algorithm Parameters.

Common Parameters

All calculation rules use the following common parameters:

- **Calculation Group:** The calculation group to which the rule belongs
- **Calculation Rule:** The user-defined name given to the calculation rule
- **Sequence:** The relative position of the calculation rule in respect of the other rules in the calculation group. This controls the order in which the system performs the calculation.
- **Description:** A short description of the rule. This is used as the Information String for the rule in the user interface.
- **Detailed Description:** A detailed description of the rule.

In addition, several of the base package calculation rules also use the following parameters:

- **Description On Bill:** The text that appears on the bill line generated for this calculation rule. Variables can be used to dynamically generate text (such as, price and quantity) when billing calculates the charges. Refer to [How To Use Description on Bill](#) for more information about available substitution variables.
- **Print (Yes or No):** A flag that specifies if the bill line created by this calculation rule should appear on the customer's bill. All bill lines are shown on Bill Segment - Calculation Details. However, only those lines marked as Print are presented to the customer.
- **Print If Zero (Yes or No):** A flag that specifies if a bill line should be printed if the bill line's value is zero.
- **Rounding Type:** This flag specifies if the calculated value should be rounded Down, Up, or Nearest. Used with Precision to control how the system rounds the rule's calculated value.
- **Precision:** This field defaults to a value consistent with the decimal positions defined on the rate schedule's currency code. Used with Rounding Type to control how the system rounds the rule's calculated value.
- **FCPO (For Calculation Purposes Only):** A flag that indicates if this calculation rule exists purely to calculate a value used by another calculation rule. When set to Yes, the system does not include the calculated amount in the bill total. The following are required when FCPO is set to Yes:
 - **Create Bill Line:** Determines if a bill line should be created for the rule (if there is no need to show the results to the customer or a user, there is no need to create a bill line).
 - **FCPO Retention Rule:** If a bill line created, this defines if the FCPO amount should be set to zero on the bill line or whether the bill line's amount should be set equal to the FCPO amount.
- **Override Proration:** A flag that specifies if an override proration algorithm should be used. This is used in situations when the standard proration logic does not satisfy your requirements. In this case, you may plug in an override proration algorithm to calculate the proration factors required by your implementation. This algorithm can be specified on the calculation rule business object or on the parent calculation rule business object if the override proration applies to all rates.
- **Seasonal (Yes or No):** A flag that specifies if charges associated with the calculation rule are only levied during a specific season. If set to "Yes", the following must be specified:
 - **Season Start:** Defines the start of the season for the calculation rule.
 - **Season End:** Defines the end of the season for the calculation rule.
 - **Seasonal Prorate Method:** Defines how the system should prorate a seasonal charge when a bill segment's period is not entirely within the seasonal period. The following options are available:
 - **Accounting Date, Consumption End Date and Consumption Start Date** options will not prorate the charge calculated by the calculation rule. Rather, it will only calculate the charge if the accounting date associated with the

bill segment is within the seasonal period, or if the consumption period's end date is within the seasonal period, or if the consumption period's start date is within the seasonal period respectively.

- **Prorate** will prorate the calculation rule charge based on number of days in the season that is included in the bill period.
- The **Prorate Seasonal SQ** option is only pertinent if you have:
 - Seasonal service quantity (SQ) charges, AND
 - Meters that measure seasonal consumption on separate registers, AND
 - You have a bill that crosses seasonal boundaries, AND
 - You have multiple rate version calculation groups effective across the bill period.

If the Prorate Seasonal SQ option is used, the system will prorate the charge calculated by a SQ calculation rule based on the number of days in the season that is included in the rate version calculation group's period.

- **GL Distribution:** If the charge calculated by the calculation rule impacts the general ledger, you must define the distribution code used to construct the GL account.
 - **Distribution Code Source:** Specifies the type of GL distribution to use for this calculation rule. If the calculation rule's charges should be booked to a single GL account regardless of the service agreement's SA Type's revenue class, select the **Specific Distribution Code** source and enter a **Distribution Code**.
If the calculation rule's charges are booked to a different GL account depending on the service agreement's revenue class, select the **Revenue Class** source and insert the appropriate **Revenue Class** and **Distribution Code** for each that uses the rate.
- **Cross Reference:** Defines the calculation line categories that the resultant calculation details belong to. For example, for a rate that calculates city and state taxes on consumption and demand based charges, the following categories could be used to calculate these taxes:
 - A calculation line category type called "Taxable" with a category value for City Tax and another for State Tax.
 - Each of the rate's calculation rules used for consumption and demand based charges should define the Member Category(s) that it belongs to ("Taxable - City Tax" and "Taxable - State Tax"). In other words, these rules would be defined as a member of the city tax and state tax categories.
 - The Apply To rules used to calculate city tax and state tax should define the respective Target Category(s) ("Taxable - City Tax" and "Taxable - State Tax") that they are applied to.
There are two types of cross-reference categories:
 - **Target Category:** Specifies the category that the calculation rule targets. Used with Apply To, Maximum Charge, and Minimum Charge calculation rules.
 - **Member Category:** Specifies the category to which the calculation rule belongs.
- **Characteristics:** Defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calc lines. You can indicate that "C1-ADDSC" characteristic ad hoc value of a bill line should be substituted into the bill line's description by using the %V substitution variable in the calculation rule's **Description On Bill** field.

Calculation Rule Validation

All calculation rules are validated when created to ensure they contain proper data needed to perform their calculations. The algorithms used to perform these validations are performed by the algorithms specified in the "Validation" system event on the calculation rule's business object.

Calculation Rules

This section provides descriptions for the base package calculation rules.

Apply To

Apply To calculation rules create bill lines that levy charges based on amounts calculated on other bill lines. Apply To calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges to which "Apply To" rules will be applied must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

- **Rule Name:** Apply To
- **Base Package Calculation Rule Business Object:** C1-ApplyTo
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-APPLYTO
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines if the price is a Charge, Percentage or Unit Rate.
 - **Value Source:** specifies the source of the price. Depending on the value source selected, either a Bill Factor, Value, or Value Algorithm is required.
 - **Example:** The following calculation rule applies a county tax other calculation rules that belong the "Taxable - County Tax" category.
Calculation Group: Taxes
Calculation Rule: CNTYTAX
Sequence: 530
Description: County Tax
Description On Bill: County sales tax %R %T
Print: Yes
Print if Zero: No
Rounding Type: Nearest
Precision: 0.01
FCPO: No
Override Proration: No
Calculation Details:
 - **Error If No Value:** No
 - **Seasonal:** No
 - **Value Type:** Percentage
 - **Value Source:** Bill Factor
 - **Bill Factor:** County Tax
GL Distribution:

- **Distribution Source Code:** Specific Distribution Code
- **Distribution Code:** Payable - County Tax
Cross Reference:
- **Target Category (Category Type / Value):** Taxable / County Tax
- **Member Category (Category Type/Value):** Summary Item / Summary Line

Calculate Final Reading Values

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQI.

- **Rule Name:** Calculate Final Reading Values
- **Base Package Calculation Rule Business Object:** C1-CalculateFinalValue
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CALCFNVL
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The unit of measure for the measured quantity.
 - **Time of Use:** The time of use for the measured quantity.
 - **Service Quantity Identifier:** The service quantity identifier for the measured quantity.
 - **Retain Measured SQ:** indicates whether to save the accumulated measured quantity entry in the SQ collection. If this value is set to No, it means the value will be removed from the SQ collection. Before any pre-processing rule is executed, the rate engine will place the sum / max value of the read details into the SQ collection. For example, if the read details contain entries for measured CCF, there will be an entry in the SQ collection for the total CCF from all read details. This might be what is needed, but it may be extraneous if a rule converts the measured quantity into therms. In this situation, the SQ collection only needs therms and the CCF entry can be removed.
 - **Formula:** Defines the formula used to calculate the final read quantity. Bill Factors (or scalar variables) to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Measured Quantity is referenced as MQ in the formula. Mathematical operations supported include addition, subtraction, multiplication and division. For example: $(MQ * V1)$ would be the formula to convert CCF to THERM.
 - **Scalar Variables:** Defines the scalar variables or Bill Factors to be used in the calculation. When referenced in the formula, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Note that only regular bill factors may be used in the formula. Interval and Time of Use bill factors are not supported.
 - **Sequence:** Designates the number of the variable (V1, V2, etc.)
 - **Bill Factor:** The Bill Factor used for the variable.
 - **Result:** Defines the type of data (**Unit of Measure, Time of Use, and/or Service Quantity Identifier**) to be used for the final quantity calculated by the rule.
 - **Processing:** The following processing takes place:
 - The rule will process each read detail whose initial UOM matches the measured quantity UOM.
 - It substitutes the reference to MQ in the formula with each read's measured quantity and then calls the formula service passing the defined bill factors as variables 1 to n. The read's end date is passed as the effective date.
 - It then populates each read's final value with the results of the formula and it populates the final UOM / TOU / SQI with the values defined on the rule.

- It populates the SQ collection with the results (this will either add a new value if the Final UOM / TOU / SQI is not present in the SQ collection, OR it will update the existing SQ quantity with the sum or max of the calculated value depending on the Final UOM's measure's peak value). Note, the initial and final values of such an SQ will be the calculated value.
- It then removes the measured UOM / TOU / SQI from the SQ collection if the rule has been configured as such.
- **Example:** This calculation rule converts CCF (as recorded on the meter) to therms for billing purposes.

Calculation Group: CCF to Therm Conversion (Calculate SQ - SQ and BF)

Calculation Rule: CCF2TH

Sequence: 10

Description: Convert CCF to TH

Calculation Details:

- **Unit of Measure:** 100 cubic feet of gas
- **Retain Measured SQ:** Yes
- **Formula:** $MQ * V1 * V2$
Scalar Variables (Sequence / Bill Factor):
- 1 / Pressure adjustment zone
- 2 / Take point for therm conv.fac
- **Result:**
- **Unit of Measure:** Thermal units

Calculate Service Quantity

Calculate Service Quantity calculation rules derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection. Calculate Service Quantity calculation rules are generally used to either manipulate measured consumption, or to derive quantities that are not measured by a meter.

- **Rule Name:** Calculate Service Quantity
- **Base Package Calculation Rule Business Object:** C1-CalculateServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CALC-SQ
- **Rule Parameters:**
 - **Scalar Variable 1 (Scalar Variable 2, Scalar Variable 3, ... Scalar Variable 5):** Defines one of the scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.).
 - **Type:** Defines the type of variable and can be one of the following:
 - **Algorithm:** an algorithm is responsible for retrieving the scalar variable value, e.g. calculate number of days in the bill period.
 - **Bill Factor:** the value for a specified bill factor that is in effect for the period.
 - **Calculated Line:** the value is derived by summing previously calculated lines defined as members of a target category.
 - **Characteristic Value:** the value is derived by summing characteristic values of a given characteristic type.
 - **Contract Quantity:** the value for a given contract quantity type specified on a service agreement.
 - **Historical Service Quantity:** the value is derived based on the SA's historical bill segment service quantities for the specified UOM / TOU / SQI. The Aggregate Function defines the calculation to perform on the set of

historical service quantities retrieved to derive a single value. Average, Maximum, Minimum and Sum are supported.

- **Service Quantity:** service quantities from the bill period's SQ collection, based on a specified UOM / TOU / SQL. This type of variable allows this rule to make use of values calculated by other rules.
- **Previous Quantity:** the value is derived from the SA's most recent frozen bill segment service quantities for the specified UOM / TOU / SQL.
- **Missing Value Action:** Defines what should take place if the system is unable to retrieve or derive a value for a particular scalar variable. Valid options are as follows:
 - Select **Error** to create an exception
 - Select **Skip** to exit the rule and process the next rule
 - Select **Use Default Value** if the scalar variable should be set to the default value specified
- **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Calculation Rule Processing:** Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
 - **Fail Action:** Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
 - **Calculation Rule Output:** Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
 - **Retain SQ:** Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of **No** should be used for SQ entries that do not have to be retained for audit or analytic purposes.
 - **Formula Source:** Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
 - **Formula:** Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: $(V1*V2)/2$.
 - **Conditional Formula:** this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
 - **Operand 1:** the first operand in the condition. Can reference an expression with one or more scalar variables (designated as Vn), e.g. $[V1+V2]$ or $[(V1/V2)*V3]$.
 - **Operator:** the operator used to compare Operand 1 with Operand 2.
 - **Operand 2:** the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
 - **True Action:** indicates how to proceed if the comparison between the operands is true. Can be one of the following:
 - **Apply True Formula:** indicates that the True Formula be executed.
 - **Check Next Condition:** indicates that the next condition should be checked.
 - **True Formula:** the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as Vn), or a constant.
 - **False Action:** indicates how to proceed if the comparison between the operands is false. Can be one of the following:

Apply False Formula: indicates that the False Formula be executed.

- **Check Next Condition:** indicates that the next condition should be checked.
- **False Formula:** the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IVn, where n is the number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as Vn).
- **Result:** Define the **Unit of Measure**, **Time of Use** and/or **Service Quantity Identifier** to be used if this calculation rule inserts or updates a service quantity in the bill period's SQ collection.
- **Example:** This calculation rule calculates total kWh from On Peak and Off Peak service quantities.

Calculation Group: Calculate KWH

Calculation Rule: TOTKWH

Sequence: 10

Description: Total amount of KWH (On Peak + Off Peak)

Scalar Variable 1:

- **Type:** Service Quantity
- **Missing Value Action:** Error
- **Unit of Measure:** Kilowatt hour
- **Time of Use:** On Peak
- **SQ To Use:** Billable

Scalar Variable 2:

- **Type:** Service Quantity
- **Missing Value Action:** Error
- **Unit of Measure:** Kilowatt hour
- **Time of Use:** Off Peak
- **SQ To Use:** Billable

Calculation Details:

- **Calculation Rule Processing:** Always
- **Fail Action:** Error
- **Calculation Rule Output:** Service Quantity
- **Retain SQ:** No
- **Formula Source:** Simple Formula
- **Formula:** V1 + V2

Result:

- **Unit of Measure:** Kilowatt hour

Copy Service Quantity from Master Bill Segment

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQ.

- **Rule Name:** Copy Service Quantity From Master Bill Segment
- **Base Package Calculation Rule Business Object:** C1-CopySQFromMasterBillSegment
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CPY-MB-SQ

- **Rule Parameters:**
 - **Characteristics:** Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
 - **Characteristic Type:** Defines the characteristic type that is to be associated to the calculation rule.

NOTE:

Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

- **Characteristic Value:** Defines the parameter value that will be associated to the characteristic type.

Execute Calc Group

Execute Calc Group calculation rules call another calculation group, and pass characteristics and their values to the referenced calculation group.

- **Rule Name:** Execute Calculation Group
- **Base Package Calculation Rule Business Object:** C1-CalcRuleReferredCalcGroup
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-ACALR-RFG
- **Rule Parameters:**
 - **Referenced Calculation Group:** Defines the calculation group that's being called.
 - **Calculation Group:** Defines the calculation group that's being called.
 - **Characteristics:** Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
 - **Characteristic Type:** Defines the characteristic type that is to be passed to the referenced calculation group.

NOTE:

Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

- **Characteristic Value:** Defines the parameter value that will be associated to the characteristic type.

Flat Charge

Flat Charge calculation rules create bill lines that levy service charges and fees that aren't based on how much the customer uses. For example a flat charge calculation rule may be used to apply a monthly service charge of \$10 to a customer's bill.

- **Rule Name:** Flat Charge
- **Base Package Calculation Rule Business Object:** C1-FlatCharge
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-FLAT-CHRG
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the rule. For Flat Charge rules, this should be set to **Charge**.

- **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
- **Example:** This calculation rule levies a customer charge.
Calculation Group: Customer Charge
Calculation Rule: CSTCHG
Sequence: 20
Description: Customer Charge
Description On Bill: Customer Charge
Print: Yes
Print if Zero: No
Rounding Type: Nearest
Precision: 0.01
FCPO: No
Override Proration: No
Calculation Details:
 - **Seasonal:** No
 - **Value Type:** Charge
 - **Value Source:** Value
 - **Value:** 5**GL Distribution:**
 - **Distribution Source Code:** Specific Distribution Code
 - **Distribution Code:** Revenue - Energy**Cross Reference:**
 - **Member Category (Category Type / Value):** Subject to tax / City taxable

Item Type

Item Type calculation rules create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.

- **Rule Name:** Item Type
- **Base Package Calculation Rule Business Object:** C1-ItemType
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-ITEMTYPE
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Seasonal:** See [Common Parameters](#).
 - **Item Type:** Defines the types of items to which charges are applied. When defining more than one item type on a single calculation rule, you can indicate that the item type of a bill line should be substituted into the bill line's description by using the %M substitution variable in the calculation rule's **Description On Bill** field.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the item type specified on the calculation rule was not supplied at billing time.
 - **Value Type:** Defines the type of charge. Valid options include Charge, Percentage, or Unit Rate.

- **Value Source:** Defines the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Value/Bill Factor/Algorithm:** The specific Value, Bill Factor, or Algorithm that serves as the source of the price used to calculate the charge.
- **Example:** This calculation rule calculates charges for light poles.
Calculation Group: Lamp Charges
Calculation Rule: POLE CHARGE
Sequence: 10
Description: Pole Charge
Description On Bill: %C lamp poles at %R per pole %D %I
Print: Yes
Print if Zero: No
Rounding Type: Nearest
Precision: 0.01
FCPO: No
Override Proration: No
Calculation Details:
- **Seasonal:** No
 - **Items:**
 - **Item Type:** Pole(s)
 - **Error If No Value:** No
 - **Value Type:** Unit Rate

Math

Math calculation rules derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities.

- **Rule Name:** Math
- **Base Package Calculation Rule Business Object:** C1-Math
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MATH
- **Rule Parameters:**
 - **Vector 1 (Vector 2, Vector 3, ..., Vector 5):** Defines one of the vectors (Vector 1, 2, 3, ..., 5) to be used in the calculation. When used in formulas, interval values for vectors are designated as IV1, IV2, IV3, ..., IV5.

- **Vector Type:** Defines the type of vector. Valid options include **Interval Bill Factor** and **Interval Service Quantity**.
- **Bill Factor:** Defines the Interval Bill Factor from which interval values are derived for the vector.
- **Unit of Measure/Time of Use/Service Quantity Identifier:** The UOM/TOU/SQI used to retrieve interval values from either the usage request service quantity entries given a usage request ID and usage period, or from the rate engine buffer populated prior to calling rate application.
- **Missing Interval Data Action:** Defines the action to take (**Error** or **Skip**) if interval data is missing for the expected period
- **Scalars:** Defines scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n is the number of the variable (based on the sequence in which they are defined in the list).
 - **Scalar Type:** Defines the type of variable. Can be one of the following:
 - **Bill Factor:** The value for a specified bill factor that is in effect for the billing period.
 - **Set Function:** The result of applying a function to a set of interval measurement values (defined as a vector).
 - **Service Quantity:** Service quantities from the current SQ list, based on a specified UOM, TOU, or SQI. This type of variable allows this rule to make use of values calculated by other rules.
 - **Bill Factor:** Defines the bill factor used to retrieve the variable value (applicable only if Scalar Type is Bill Factor)
 - **Unit of Measure:** Defines the UOM for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **Time of Use:** Defines the TOU for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **Service Quantity Identifier:** Defines the SQI for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **SQ to Use:** Every service quantity supplied to a rate has two quantities; the quantity initially measured, and the quantity that should be priced by the rate. Most of the time these two amounts will be the same, unless another rule has executed and caused the billable quantity to change. Each rule needs to know if it should use the **Initial** or **Billable** quantity.
 - **Set Function:** Defines the function used to calculate a scalar value from a set of interval values (defined as a vector). This is applicable only if Scalar Type is Set Function). Can be one of the following:
 - **Average:** calculates the average of the vector's interval measurement values.
 - **Count:** returns the number of interval measurements.
 - **Max:** returns the maximum value from the vector's interval measurement values.
 - **Min:** returns the minimum value from the vector's interval measurement values.
 - **Total:** calculates the total of the vector's interval measurement values.
 - **Vector:** the vector to be used for this variable (applicable only if Scalar Type is Set Function). Can be one of the following:
 - **FV** (Final Vector Interval Value): the vector containing the results of the formula defined in the Calculation Details section.
 - **IV1** (Vector 1 Interval Value): the vector defined as Vector 1.
 - **IV2** (Vector 2 Interval Value): the vector defined as Vector 2.
 - **IV3** (Vector 3 Interval Value): the vector defined as Vector 3.
 - **IV4** (Vector 4 Interval Value): the vector defined as Vector 4.
 - **IV5** (Vector 5 Interval Value): the vector defined as Vector 5.

- **Missing Value Action:** Defines the action to take (**Error**, **Skip**, or **Use Default Value**) if data is missing for the scalar variable for the expected period
- **Default Value:** The default value to use if data is missing for the scalar variable. Applicable only if Missing Value Action is Use Default Value.
- **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Calculation Rule Processing:** Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
 - **Fail Action:** Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
 - **Calculation Rule Output:** Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
 - **Retain SQ:** Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of **No** should be used for SQ entries that do not have to be retained for audit or analytic purposes.
 - **Formula Source:** Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
 - **Formula:** Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as V_n , where n matches the number assigned to the variable (i.e. V_1 = Scalar Variable 1, V_2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: $(V_1 * V_2) / 2$.
 - **Conditional Formula:** this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
 - **Operand 1:** the first operand in the condition. Can reference an expression with one or more scalar variables (designated as V_n), e.g. $[V_1 + V_2]$ or $[(V_1 / V_2) * V_3]$.
 - **Operator:** the operator used to compare Operand 1 with Operand 2.
 - **Operand 2:** the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
 - **True Action:** indicates how to proceed if the comparison between the operands is true. Can be one of the following:
 - Apply True Formula:** indicates that the True Formula be executed.
 - Check Next Condition:** indicates that the next condition should be checked.
 - **True Formula:** the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as V_n), or a constant.
 - **False Action:** indicates how to proceed if the comparison between the operands is false. Can be one of the following:
 - Apply False Formula:** indicates that the False Formula be executed.
 - Check Next Condition:** indicates that the next condition should be checked.
 - **False Formula:** the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IV_n , where n is the number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as V_n).
- **Result:** Defines how service quantities are inserted into the SQ list. Math calculation rules can insert one or more entries into the SQ list.

- **Result Source:** Defines the method to use to calculate for the service quantity. Can be one of the following:
 - **Set Function Against Derived Vector:** Applies a function to the derived interval values. The function to be applied is specified in the Set Function field.
 - **Scalar Formula Result:** Applies a user-defined formula. The formula is specified in the Scalar Formula field.
- **Set Function:** the function to apply to the derived interval values (applicable only if Result Source is set to Set Function Against Derived Vector). Can be one of the following:
 - **Average:** Calculates the average of the derived interval measurement values.
 - **Count:** Returns the number of derived interval measurements.
 - **Max:** Returns the maximum value from the derived interval measurement values.
 - **Min:** Returns the minimum value from the derived interval measurement values.
 - **Total:** Calculates the total of the derived interval measurement values.
- **Scalar Formula:** the formula to apply (applicable only if Result Source is set to Scalar Formula). Variables used in this formula must be defined in the Scalars section. When referenced in formulas, scalar variables are designated as Vn (where n is the number of the variable).
- **Unit of Measure:** the UOM to be used when inserting service quantity entries
- **Time of Use:** the TOU to be used when inserting service quantity entries
- **Service Quantity Identifier:** the SQI to be used when inserting service quantity entries
- **Apply TOU Map:** Indicates if a TOU map should be applied to the derived interval values. If TOU periods and values are returned as a result of TOU mapping, then service quantity entries are inserted.
- **TOU Map:** Defines the TOU Map to apply to the derived interval values (applicable only if Apply TOU Map is set to Yes).
- **TOU Mapping Function:** Defines the function to apply to the derived interval values when calculating for the time of use values (applicable only if Apply TOU Map is set to Yes). Can be one of the following:
 - **Max:** Returns the maximum value from the derived interval values for each TOU period.
 - **Sum:** Returns the sum of the derived interval values for each TOU period.
- **Processing:**

Math rules derive interval values based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate billing quantities. Examples include the following:

 - Derive an interval data curve (vector) given a formula. For example, derive a power factor curve given a formula using kWh and kVarh curves.
 - Apply TOU mapping to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the result.
 - Perform mathematical operations on SQ entries. For example, get total kWh consumption by adding "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" where "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" were calculated by a previous calculation rule.

Each interval data curve is defined as a vector parameter (the rule can define up to 5 vectors). Mathematical operations defined by the "Vector Processing" parameters can be performed between vectors (e.g. IV1 * IV2) and between vectors and scalar variables (e.g. IV1 * V1).
- **Example:** This calculation rule calculates prices for interval usage by multiplying an interval service quantity times an interval price bill factor.

Maximum Charge

Maximum Charge calculation rules are used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount. Maximum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the maximum is levied on must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a maximum discount of \$ -2.00 and previous calculation rules have calculated a discount of \$ -3.00. You want a calculation rule to create a bill line for \$1.00 to reduce the discount. A maximum charge calculation rule will not work in this case because -3 is considered less than -2. For this business scenario you should use a Minimum Charge calculation rule.

Note: Maximum Charge calculation rules are rare. You tend to only see them in deregulated markets where customers have agreed to pay the market rate but want a cap on the maximum they'll pay each bill period.

- **Rule Name:** Maximum Charge

- **Base Package Calculation Rule Business Object:** C1-Maximum
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MAXIMUM
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the maximum value for the rule. For Maximum Charge rules, this should be set to **Charge**.
 - **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Example:** This calculation rule sets a maximum charge for area lighting.

Calculation Group: Customer-Owned Street & Highway Lighting

Minimum Charge

Minimum Charge calculation rules create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount. Minimum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the minimum is levied on must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a minimum discount of \$ -2.00 and previous calculation rules have calculated a discount of \$ -1.00. You want a calculation rule to create a bill line for \$ -1.00 to apply a further discount. A minimum charge calculation rule will not work in this case because -1 is considered more than -2. For this business scenario you should use a maximum charge calculation rule.

- **Rule Name:** Minimum Charge
- **Base Package Calculation Rule Business Object:** C1-Minimum
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MINIMUM
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the minimum value for the rule. For Minimum Charge rules, this should be set to **Charge**.
 - **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Example:** This calculation rule defines a minimum charge for use with residential electric rates.
Calculation Group: Electric Residential

Service Quantity

Service Quantity calculation rules create bill lines that levy charges based on some type of consumption.

Frequently the amount consumed is measured by a meter's registers and sometimes it's calculated using Pre-Processing calculation and sometimes it's derived based on the type of item (such as, lamps). Regardless of how the amount consumed is calculated, the charge for the consumption amount is levied using this type of calculation rule.

- **Rule Name:** Service Quantity
- **Base Package Calculation Rule Business Object:** C1-ServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-SQ
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The UOM used as the service quantity that the price is applied to.
 - **Time of Use:** The TOU used as the service quantity that the price is applied to.
 - **Service Quantity Identifier:** The SQI used as the service quantity that the price is applied to.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
 - **Measures Peak:** Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
 - **GL Statistical Qty:** A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of price to be used in the rule's calculations. Valid options include Charge, Percentage, or Unit Rate.
 - **Value Source:** Defines the source of the price used in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.

- **Example:** This calculation rule calculates charges based a customer's KWH consumption.

Calculation Group: Electric Residential Charges

Calculation Rule: KWHCHRG

Simple Summary

Simple Summary calculation rules create a "subtotal" on the bill by summarizing bill lines produced by other calculation rules in the same calculation group.

- **Rule Name:** Simple Summary
- **Base Package Calculation Rule Business Object:** C1-SimpleSummary
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-SIMP-SUMM
- **Rule Parameters:**
 - **Referenced Calculation Rules:** Defines the calculation rules that should be included in the summary. Note that any calculation rules listed here must belong to the same calculation group as the Summary rule.
- **Example:** This calculation rule creates a summary of TOU-based charges (based on rules within the same calculation group as this rule).

Calculation Group: Commercial TOU Electric Charges

Calculation Rule: KWHTOT

Sequence: 40

Description: Consumption Subtotal

Description On Bill: Consumption Subtotal

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01

Referenced Calculation Rules:

- Off Peak - kWh
- On Peak - kWh
- Shoulder Peak - kWh

Cross Reference:

- **Member Category (Category Type / Value):** Taxable / State Tax

Stepped Service Quantity

Stepped Service Quantity calculation rules create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are \$0.43 per kWh, anything in excess of 50 kWh is charged at \$0.71 per kWh)

- **Rule Name:** Stepped Service Quantity
- **Base Package Calculation Rule Business Object:** C1-SteppedSQ
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-STPD-SQ
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The UOM used as the service quantity that the price is applied to.
 - **Time of Use:** The TOU used as the service quantity that the price is applied to.
 - **Service Quantity Identifier:** The SQI used as the service quantity that the price is applied to.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
 - **Measures Peak:** Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
 - **GL Statistical Qty:** A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
 - **Create Step Summary:** Stepped service quantity calculation rules may be configured with either a single step or multiple steps. The Create Step Summary flag is used to produce a summary bill segment calculation line if the calculation rule has multiple steps. Valid options include:
 - **Summarize Step Lines, Print:** Creates a stepped charge summary bill line that will appear on the customer's bill.
 - **Summarize Step Lines, Do Not Print:** Creates a stepped charge summary bill line that will be shown on Bill Segment - Calculation Details, but not appear on the customer's bill.
 - **Step Calculation Details:**
 - **Seasonal:** See [Common Parameters](#).
 - **Step Multiplier Algorithm:** Specifies the algorithm that will be used calculate the step boundaries. Used only if step boundaries are dynamic and are calculated based on something that's only known at billing time.
 - **Values:** Defines the values associated with each of the ranges (steps) of consumption used by the rule. For example, if the charge is applicable to the first 300 kilowatt-hours, you would enter Low Value 0 and High Value 300. When multiple tiers exist, the high value of the first tier is the low value of the second tier (and so on). To extend our example, the second tier would have a low value of 300; the high value may be left blank (the system assumes a blank high value means "to infinity").

- **Low Value:** Defines the low value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999,999.9999).
You can indicate that the low value of a bill line should be substituted into the bill line's description by using the %L substitution variable in the calculation rule's **Description On Bill** field.
 - **High Value:** Defines the high value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999,999.9999).
You can indicate that the high value of a bill line should be substituted into the bill line's description by using the %H substitution variable in the calculation rule's **Description On Bill** field.
 - **Value Type:** Defines the type of price to be applied to the consumption range in the rule's calculations. Valid options include Charge, or Unit Rate.
 - **Value Source:** Defines the source of the price to be applied to the consumption range in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Value/Bill Factor/Algorithm:** Specifies the Bill Factor, Value, or Algorithm used when calculating charges for the consumption range.
- **Example:** This calculation rule calculates charges for electric service based on stepped charges for kWh consumption during the Fall
Calculation Group: Electric Residential - Stepped
Calculation Rule: KWHSTFL
Sequence: 10

Summary

Summary calculation rules create a "subtotal" on the bill. It exists purely for reporting and informational purposes. Summary calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges should be included in the summary must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

- **Rule Name:** Summary
- **Base Package Calculation Rule Business Object:** C1-Summary
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-SUMMARY
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
- **Example:** This calculation rule creates a consumption summary on the bill based on other calculation rules included in the rate that belong to the "Revenue / Consumption Charge" category.

Rate Check

This section describes the features and functionality of Rate Check.

About Rate Check

The **Rate Check** feature allows you to test your rate schedules under different scenarios. For example, you can test your rates for an existing account using previous bill segments, or by providing user-specified bill period and service quantities.

Performing a Rate Check

NOTE: The Rate Check portal works with both calculation rule-based and component-based rate schedules.

Use this procedure to perform a rate check.

- Select **Menu > Rates > Rate Check**.
- Select the **Rate Schedule** for the rate check.
- Select the **Service Agreement** for the rate check.
- Select the **Bill Segment** for the rate check (if you wish to base the rate check on an existing bill segment).
- Enter the **Start Date**, **End Date**, and **Accounting Date** for the rate check.
- Select the **Revenue Class** for the rate check.
- If you are basing the rate check on user-specified **Service Quantities**, enter the following for each as applicable:
 - **UOM:** The unit of measure applicable for the rate check (based on the specified rate schedule)
 - **TOU:** The time of use applicable for the rate check (based on the specified rate schedule)
 - **SQL:** The service quantity identifier applicable for the rate check (based on the specified rate schedule)
 - **Measured Quantity:** The amount of the service quantity specified.
- **Service Point ID:** The service point which recorded the service quantities, if applicable
Note: If you specified a Service Agreement and Bill Segment, this section is populated based on the selected data, but can be manually overwritten.
- Specify characteristic types and values for any **Characteristics** are applicable to the rate check. Characteristic types and values are used to apply appropriate bill factor values during rate processing.
- If you are using a calculation rule-based rate schedule, specify if the system **Should Trace** the process. This produces logs that outline the calculation groups and rules used by the rate schedule.
- Execute the rate check:
 - If you wish to execute the rate check using a specified bill segment or service quantities, click **Check Rate**.
 - If you wish to execute the rate check using billing determinants retrieved from an external system (such as Oracle Utilities Meter Data Management), select the appropriate function from the **Select Function** dropdown list.

Viewing the Results of a Rate Check

The outcome of the rate check process is displayed on the **Results** tab. This tab contains the following zones:

- **Main:** Displays results of the rate check, including:
 - **Rate Schedule:** The rate schedule used in the rate check
 - **Revenue Class:** The revenue class used for the rate check.
 - **Bill Period:** The start and end dates for the bill period used by the rate check.
 - **Consumption Period:** The start and dates for the consumption period used by the rate check.
 - **Accounting Date:** The Accounting Date used by the rate check.
 - **Calculated Amount:** The calculated total for the rate check
- **Calculation Lines:** Displays the bill calculation headers and lines for the rate schedule.
- **Read Details:** Displays meter read details for the consumption used in the rate calculation.
- **SQ Details:** Displays a list of service quantities used in the rate calculation.
- **Characteristics:** Displays characteristics referenced by the rate calculation (if applicable).
- **Trace Log:** Displays logs that outline the calculation groups and rules used by the rate schedule. This zone is populated only if using a calculation rule-based rate schedule, and if the Should Trace dropdown list is set to "No".

Effective Dates and Price Proration

This section describes how proration applies to different types of calculation rules. Proration implies assessing charges proportionately.

The term "proration" describes two different issues:

- Prorating a charge whose value changes during a bill period. For example, if a tax rate changes during a bill period and you've indicated that such changes should be prorated, the system prorates the tax change (e.g., 20 days at 5% and 10 days at 6%).
- Prorating charges when the time period being billed is not in sync with the time period in which the charges were defined in the rate. For example, if a rate contains a flat monthly charge and the bill period spans two months, the flat charge must be prorated.

This is a complicated topic as it's possible for many proration issues to exist on a single bill. For example, on a single bill:

- The rate structure can change several times during the bill period (i.e., multiple rate versions are effective).
- The taxing authority changes the tax rate.
- The customer's tax exemption changes.
- The customer-specific price can change.
- etc.

Types of Proration

The following section describes the types of proration performed by applying a rate.

FASTPATH:

For more information on how prorated charges are presented on the printed bill, refer to [How To Use Description On Bill](#).

Consumption Period Proration

A rate schedule specifies its frequency. Bill segments generated using a rate are expected to have a consumption period that corresponds to this frequency. When a bill segment's consumption period falls outside of the rate frequency's normal period, proratable service quantities may be adjusted to match the normal period for calculation. The service quantities are then re-adjusted based on calculation period proration.

FASTPATH:

Refer to [Service Quantity Proration](#) for more information about these calculations.

Calculation Period Proration

There can be multiple versions of a given rate over time. Each version has an effective date. When the system detects that a rate schedule has multiple versions of a rate in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the rate schedule's proration parameters.

If multiple rate versions are effective during the consumption period and the rate schedule is configured to prorate the rate versions, a given bill segment will contain a set of bill calculation lines for each rate version. You should consider quite carefully how to handle this situation on your printed bills as rate version proration can confuse a customer.

FASTPATH:

Refer to [Defining Calculation Rules](#) for more information.

Bill Factor Proration

A rate contains calculation rules. The primary reason a calculation rule exists is to define how much to charge for the services sold by your company. When you create calculation rules, you have two ways to indicate how much to charge:

- You can specify the value directly in a calculation rule.
- You can have the calculation rule use a bill factor that contains the value.

Bill factors are effective-dated (meaning, their values may change over time). When the system detects that a calculation rule's bill factor has multiple values in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

FASTPATH:

Refer to [Defining Bill Factors](#) and [Bill Factor Value Proration](#) for more information.

Tax Exemption Proration

Bill factors that levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for tax exemptions will have their tax obligation reduced (or nullified) at billing time.

Whether or not a customer is tax exempt (and the percent exempt) is defined on the service agreement's tax exemption page. A customer's tax exemptability is effective-dated (it may change over time). If a customer's tax exemptability changes during a bill period, the system may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

Contract Value Proration

Some types of bill factors do not have the same value for all customers. For example, you may have rates where the price per kilowatt-hour can be different for every customer using the rate.

For bill factors whose value is customer-specific, the value is defined on the service agreement's contract value page. The contract value is effective-dated (it may change over time). If a customer's contract value changes during a bill period, the system may or may not prorate the changes. You control exactly how the system handles this situation using the bill factor's proration parameters.

Contract Rider Proration

Contract riders are used when the charge associated with a bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first three months of service, then a contract rider would be used.

A customer's contract rider applicability period is defined on the service agreement's contract rider page. A rider's applicability may change during a customer's bill period. You control exactly what the system does when a rider's applicability changes during a bill period using the bill factor's proration parameters.

A Service Agreement's Rate Changes Are Not Prorated

A service agreement's rate is effective-dated (it may change over time). When the system calculates a service agreement's bill segment when multiple rates are effective during the bill period, it will use a single rate from the service agreement's rate history. The system chooses the rate as per the service agreement's SA type's rate selection date.

FASTPATH:

Refer to [SA Type - Rate](#) for more information.

Proration Factors

The purpose of calculation rules is to generate bill calculation lines. When rate application builds bill calculation lines, it may also prorate the charges.

There are multiple types of proration performed by rate application. Service quantities, step boundaries, rate values, and bill factor values may all be prorated as part of applying a rate.

We need to establish some terms in order to understand the calculations.

Normal Days

As mentioned previously, the rate schedule references a frequency that specifies the number of times per year that service agreements referencing the rate are expected to bill. The following formula dictates a rate frequency's normal days: $365 \text{ days} / \text{number of periods per year}$.

Example:

- For a monthly frequency (12 periods per year), $365 / 12 = 30$ days.
- For a quarterly frequency (4 periods per year), $365 / 4 = 91$ days.

FASTPATH:

Refer to [Defining Frequency Codes](#) for more information.

Consumption Period Factor

Before applying a rate, the bill segment's consumption period is determined. The ratio of normal days to consumption period days is the consumption period factor.

The system uses the Minimum and Maximum Days Offset on the rate's [Frequency](#) to determine whether or not the calculation rule should be prorated due to a short or long consumption period.

If the number of days in the consumption period is within the tolerance of days determined by the specified on the rate's frequency, the consumption period factor is 1 (not applicable).

Example:

If the consumption period spans 60 days and the rate's normal days equals 30 days then the consumption period factor is:

- $30 \text{ days} / 60 \text{ days} = 0.5$

If the consumption period spans 31 days and the rate's normal days equals 30 days and the maximum offset is 3 days, the consumption period factor is 1 (not applicable) because the consumption period days falls within the tolerance specified on the frequency.

FASTPATH:

For more information on how a bill segment's consumption period is determined, refer to [How the System Requests How Much Was Consumed](#). For more information on specifying minimum and maximum offset days on frequency, refer to [Defining Frequency Codes](#).

Calculation Period Factor

The calculation period is the date range where a rate version is effective during the consumption period. For each rate version that is effective during the consumption period, a bill segment calculation period is created. A set of bill calculation lines is created for each calculation period.

A calculation period factor is determined for each calculation period. The calculation period factor is the ratio of calculation period days to normal days. If the consumption period factor is 1 (not applicable), then the calculation period factor is the ratio of calculation period days to consumption period days.

Example:

If the consumption period covers April 1 to April 30 and there was a new effective rate version as of April 21, there are two calculation periods.

- Calculation period April 1 to April 20, calculation period factor = $20 \text{ days} / 30 \text{ days} = 0.6666667$.
- Calculation period April 21 to April 30, calculation period factor = $10 \text{ days} / 30 \text{ days} = 0.3333333$.

BF Value Period Factor

The bill factor value period is the date range where a proratable bill factor value is effective during the calculation period.

When a bill factor value changes during the calculation period, the results is that multiple bill calculation lines are generated for the same calculation rule.

The ratio of the number of days within the calculation period that a distinct value is effective to the number of days in the calculation period determines the BF value period factor. When the bill factor is set up not to prorate, the BF value period factor is 1 (not applicable).

Example:

If the state tax rate changes from 6% to 6.5% on April 16 and the calculation period is April 1 to April 30, there are two bill factor value periods.

- Bill factor value period April 1 to April 15, BF value period factor = 15 days / 30 days = 0.5.
- Bill factor value period April 16 to April 30, BF value period factor = 15 days / 30 days = 0.5.

FASTPATH:

Refer to [Defining Bill Factors](#) for more information on specifying whether the bill factor allows proration.

Overriding Proration Factors

If the system logic for determining proration factors does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation.

- For Calculation Rule-Based Rates, the override proration algorithm is specified in the calculation rule's business object.
- For Component-Based Rates, the overriding proration algorithm is specified in the [Installation](#) record.

The system is delivered with an algorithm type that sets the proration factors to 1 (not applicable) when a predefined characteristic is specified on a calculation rule. Refer to OVPF-NOPROR for more information.

Service Quantity Proration

When a bill calculation line is generated for a service quantity type calculation rule, the applicable service quantity is multiplied by the consumption period factor. That product is then multiplied by the calculation period factor to determine the prorated service quantity for the bill calculation line.

Example:

Customer's electricity bill segment's consumption period is from April 1 through May 15. A new rate version for the rate schedule is effective as of April 16. 100 kWh is consumed.

Assuming a monthly frequency, if the consumption period spans 45 days and the first calculation period spans 15 days, and the applicable service quantity is 100 kWh; then:

- Consumption period factor = 30 normal days / 45 days = 0.6666667.
- Calculation period factor = 15 days / 30 normal days = 0.5.
- Prorated service quantity = 100 kWh x 0.6666667 x 0.5 = 33 kWh.

The next calculation period extends to the end of the consumption period (30 days):

- Consumption period factor does not change = 0.6666667.
- Calculation period factor = 30 days / 30 days = 1.0.
- Prorated service quantity = 100 kWh x 0.6666667 x 1.0 = 67 kWh.

Measures Peak

If the calculation rule specifies that the service quantity measures peak, then service quantity proration is not performed. Although service quantities are not prorated if a calculation rule measures peak, calculation rule values (like price per kW) are prorated.

FASTPATH:

Refer to [Calculation Rule Value Proration](#) for more information.

Step Proration

If a calculation rule's charges are based on stepped pricing then the step boundaries are also prorated (as long as the calculation rule is not marked as measures peak). Step boundaries are multiplied by the calculation period factor to determine the adjusted steps boundaries.

Example:

Assuming a monthly frequency, if the calculation rule's step boundaries are 100 kWh to 300 kWh, and the calculation period is 45 days; the step boundaries are prorated as:

- $45 \text{ days} / 30 \text{ days} \times 100 \text{ kWh} = 150 \text{ kWh}$.
- $45 \text{ days} / 30 \text{ days} \times 300 \text{ kWh} = 450 \text{ kWh}$.

Step Multipliers

If the calculation rule specifies that the steps be multiplied by the result value of another calculation rule, step proration is not performed. It is assumed that the result value from the referenced calculation rule has already been prorated, as the referenced step calculation rule is subject to [Calculation Rule Value Proration](#).

Calculation Rule Value Proration

Except for summary type calculation rules (which are not prorated at all), a value is specified on the calculation rule. The value may be a unit rate, percentage or charge. The value may be specified directly on the calculation rule, derived from a bill factor, derived from another calculation rule, or calculated by an algorithm.

Regardless of where the calculation rule value comes from, it will be multiplied by the calculation period factor when determining the charge on a bill calculation line. Exceptions to this rule are:

- Unit rate values where the calculation rule's measures peak attribute is not checked.
- Percentage values.
- Calculation rule values derived from another calculation rule.

Even though the calculation rule values are not prorated for unit rate and percentage value types, if these rate values change during the calculation period due to a bill factor value change, bill factor value proration still applies.

Values derived from another calculation rule are not subject to rate value proration, as calculation rule value proration was already performed on the referenced calculation rule. Again, if the bill factor value changed on the referenced calculation rule, bill factor value proration still applies.

Example:

A calculation rule charges \$2.00 per kW. The rate schedule's normal days equals 30, and the calculation period spans 15 days. The peak kW service quantity is 50 kW.

- The calculation period factor is 0.5 (15 days / 30 days).
- Calculation rule value proration yields $\$2.00 \times 0.5 = \1.00 per kW.

FASTPATH:

For more information on bill factor value proration, refer to [Bill Factor Value Proration](#).

Bill Factor Value Proration

Bill factor value proration behaves the same way any time a bill factor value changes within a calculation period. This could be due to a change in a tax rate, a contract rider becoming effective, a tax exemption expiring, etc.

Multiple bill calculation lines are generated for a given calculation rule when a prorable bill factor value changes during the calculation period.

Example:

If the state tax rate changes from 6% to 6.5% on April 16, and the calculation period is April 1 to April 30.

- The first BF value factor period April 1 to April 15, so BF value period factor is 0.5.
- The value used in the first bill calculation line for state tax is $6\% \times 0.5 = 3\%$.
- The second bill factor value period is April 16 to April 30, so the BF value period factor is 0.5.
- The value used in the second bill calculation line for state tax is $6.5\% \times 0.5 = 3.25\%$.

Example of Generating Prorated Bill Calculation Lines

Let's say that 1200 kWh was consumed from March 17 to April 30. The peak kW for the consumption period is 20 kW.

A monthly rate schedule E-COM1 exists with two rate versions.

Rate version effective prior to April 1 has the following components:

- \$0.05 per kWh.
- \$1.00 per kW.

Rate version effective as of April 1 has the following calculation rules:

- \$0.04 per kWh; as of April 16, \$0.07 per kWh (new effective bill factor value).
- \$1.50 per kW; as of April 16, \$1.25 per kW (new effective bill factor value).

Calculation Period March 17 to March 31

The consumption period spans 45 days, so the consumption period factor is $30 \text{ normal days} / 45 \text{ days} = 0.6666667$.

This calculation period spans 15 days, so the calculation period factor is 0.5.

Service quantity proration for the first calculation period yields:

- $1200 \text{ kWh} \times 0.6666667 \text{ (consumption period factor)} \times 0.5 \text{ (calculation period factor)} = 400 \text{ kWh}$.

- $20 \text{ kW} \times 1$ (not applicable) = 20 kW.

Calculation rule value proration for the first calculation period yields:

- $\$0.05 \times 1$ (not applicable) = \$.05 per kWh.
- $\$1.00 \times 0.5$ (calculation period factor) = \$0.50 per kW.

First Set of Bill Calculation Lines

Bill calculation line 1: $400 \text{ kWh} \times \$0.05 = \20.00 .

Bill calculation line 2: $20 \text{ kW} \times \$0.50 = \10.00 .

Calculation Period April 1 to April 30

This calculation period spans 30 days, so the calculation period factor is 1.

Service quantity proration for the calculation period yields:

- $1200 \text{ kWh} \times 0.6666667$ (consumption period factor) $\times 1$ (calculation period factor) = 800 kWh.
- $20 \text{ kW} \times 1$ (not applicable) = 20 kW.

Calculation rule value proration for the first calculation period yields:

- $\$0.04 \times 1$ (not applicable) $\times 0.5$ (BF value period factor) = \$0.02 per kWh.
- $\$0.07 \times 1$ (not applicable) $\times 0.5$ (BF value period factor) = \$0.035 per kWh.
- $\$1.50 \times 1$ (calculation period factor) $\times 0.5$ (BF value period factor) = \$0.75 per kW.
- $\$1.25 \times 1$ (calculation period factor) $\times 0.5$ (BF value period factor) = \$0.625 per kW.

Second Set of Bill Calculation Lines

Bill calculation line 1: $800 \text{ kWh} \times \$0.02 \text{ per kWh} = \16.00 .

Bill calculation line 2: $800 \text{ kWh} \times \$0.035 \text{ per kWh} = \26.00 .

Bill calculation line 3: $20 \text{ kW} \times \$0.75 \text{ per kW} = \15.00 .

Bill calculation line 4: $20 \text{ kW} \times \$0.625 \text{ per kW} = \12.50 .

Seasonal Proration

Seasonal proration adds another layer of complexity. If calculation rules are specified to prorate seasonally, the seasonal period specified on a given seasonal calculation rule dictates how a calculation rule's value or associated service quantity is prorated.

There are two proration methods, Prorate and Prorate Seasonal SQ, which may be specified on seasonal calculation rules. Both of these proration methods behave the same way with respect to calculation rule value proration. If a given seasonal calculation rule is eligible for [Calculation Rule Value Proration](#), the ratio of days in the season that are applicable during the calculation period to the days in the calculation period determines the seasonal factor. When it comes to service quantity proration, the two proration methods are different. If a given seasonal calculation rule is eligible for [Service Quantity Proration](#), it prorates the service quantities as follows:

- Prorate. A seasonal factor is calculated as the ratio of days in the season that are applicable during the calculation period to the days in the calculation period. This ratio is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.
- Prorate seasonal SQ. In this case, it is assumed that either the meter measures seasonal consumption on separate registers or the consumption has been split into separate service quantities by other means (like an SQ rule). To determine a prorated seasonal service quantity, the seasonal proration factor is calculated as for a Prorate seasonal calculation rule. The seasonal factor is then multiplied by another ratio of total consumption period days to days in the season that are

applicable for the total consumption period. This modified seasonal factor is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.

NOTE:

Prorate seasonal SQ. Specify this option only if you can determine the seasonal consumption as an independent service quantity for use by rate application. Because the service quantities themselves dictate the applicability of the calculation rule, a given service quantity need not appear in rate versions effective outside the season (i.e. a rate version effective on October 1 may not include calculation rules that charge for kWh/summer).

Override Seasonal Proration. If the seasonal functionality provided with the system does not work for your organization, you may override the logic using the Override Seasonal Proration plug-in spot on the [installation](#) record. For example, perhaps the seasonal period is determined dynamically based on the scheduled meter read date of the bill cycle.

Example (Prorate):

Let's say that 600 kWh and 50 kW are the billable service quantities for a consumption period from April 1 to April 30. Prorate seasonal calculation rules are defined on a monthly rate that charge \$0.05 per kWh and \$0.75 per kW from January 1 to April 15. Prorate seasonal calculation rules are defined on the same rate version that charge \$0.06 per kWh and \$0.80 per kW between April 16 and December 31. Assume only one rate version is effective for the consumption period.

- The consumption period factor is 1 (not applicable).
- The calculation period factor is 1.0.
- The seasonal factor for the kWh calculation rule whose season is effective from January 1 to April 15 is 0.5 (15 season days in calculation period / 30 days in the calculation period).
- The resulting bill calculation line uses service quantity proration:
 - $600 \text{ kWh} \times 0.5 \text{ (seasonal factor)} \times \$0.05 = \$15.00.$
- The seasonal factor for the kW calculation rule whose season is effective from January 1 to April 15 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
 - $50 \text{ kW} \times \$0.75 \times 0.5 \text{ (seasonal factor)} = \$18.75.$
- The seasonal factor for the kWh calculation rule whose season is effective from April 16 to December 31 is 0.5.
- The resulting bill calculation line uses service quantity proration:
 - $600 \text{ kWh} \times 0.5 \text{ (seasonal factor)} \times \$0.06 = \$18.00.$
- The seasonal factor for the kW calculation rule whose season is effective from April 16 to December 31 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
 - $50 \text{ kW} \times \$0.80 \times 0.5 \text{ (seasonal factor)} = \$20.00.$

Example (Prorate seasonal SQ):

Let's say that a given meter measures winter consumption separate from summer consumption. The meter itself measures kWh/summer on a register between June 21 and September 18, and measure kWh/winter on another register at other times of the year.

We are generating a bill segment with a consumption period from September 2 to October 30. A monthly rate schedule has two rate versions effective during the consumption period. The latest rate version is effective on October 1.

Each of the rate version calculation groups have Prorate seasonal SQ seasonal calculation rules defined. The first rate version's calculation rules charge \$0.06 per kWh/summer and \$0.05 per kWh/winter. The second rate version calculation group has a single calculation rule that charges \$0.05 per kWh/winter.

Assume that the billable service quantities are 800 kWh/summer and 1600 kWh/winter.

First set of bill calculation lines (September 2 to September 30):

- The consumption period factor is 30 normal days / 60 consumption days = 0.5.
- The calculation period factor is 30 calculation days / 30 normal days = 1.0.
- calculation rule 1 (\$0.06 per kWh/summer):
- The seasonal factor 17 seasonal days / 30 calculation days = 0.5666667.
- The modified seasonal factor is 0.5666667 x 60 consumption days / 17 seasonal days = 2.0.
- The resulting bill calculation line:
- 800 kWh/summer x 0.5 (consumption period factor) x 2.0 (modified seasonal factor) x \$0.06 = \$48.00.
- calculation rule 2 (\$0.05 per kWh/winter):
- The seasonal factor is 12 seasonal days / 30 calculation days = 0.4.
- The modified seasonal factor is 0.4 x 60 consumption days / 42 seasonal days = 0.571428.
- The resulting bill calculation line:
- 1600 kWh/winter x 0.5 (consumption period factor) x 0.571428 (modified seasonal factor) x \$0.05 = \$22.86.

Second set of bill calculation lines (October 1 to October 30):

- The consumption period factor is 30 normal days / 60 consumption days = 0.5.
- The calculation period factor is 30 calculation days / 30 normal days = 1.0.
- Calculation rule 1 (\$0.05 per kWh/winter):
- The seasonal factor 30 seasonal days / 30 calculation days = 1.0.
- The modified seasonal factor is 1.0 x 60 consumption days / 42 seasonal days = 1.428571.
- The resulting bill calculation line:
- 1600 kWh/winter x 0.5 (consumption period factor) x 1.428571 (modified seasonal factor) x \$0.05 = \$57.14.

FASTPATH:

For more information on specifying seasonal proration options, refer to [Defining Calculation Rules](#).

Price Changes and Interval Quantities

All of the above sections described situations where the service quantities will be prorated due to changes in the price during the billing period. The above sections assume that the bill contains a simple metering scenario, where reads will not exist on the date of the price break.

However, consider an interval billing example. There are two basic pricing scenarios for interval quantities:

- Interval prices are applied to interval quantities. In this case, proration is not applicable because the prices are changing at small intervals and the appropriate usage rules in Oracle Utilities Meter Data Management understand how to apply the prices to the interval quantities.
- Time of use prices. In this case, interval quantities are being mapped to time of use codes. Oracle Utilities Meter Data Management can compare interval quantities to a time of use map to create billing determinants for Oracle Utilities Customer Care and Billing. These will result in new entries in the bill segment's SQ collection when received by Oracle Utilities Customer Care and Billing. Calculation rules are then apply the appropriate price(s) for each SQ. In the time of use pricing scenario, it is possible for the prices to change during the usage or billing period. When usage requests are created by Oracle Utilities Customer Care and Billing, they will contain rate version date breaks to indicate to Oracle Utilities Meter Data Management to calculate the usage for each rate version period. Proration should not be necessary when the rate is applied for each usage (rate version) period. However, if prices are configured as bill factors and there

are changes in bill factor values within the usage period, then proration may occur as the date breaks when bill factor values change are not included in the usage request from Oracle Utilities Customer Care and Billing.

Setting Up Estimated Consumption for Items

Some types of physical devices (such as, items) use power but a meter does NOT measure the power consumed. The most common example is a street light. If this situation exists for your company AND if the amount charged for the lamp varies based on the amount of estimated power used, then you will have to maintain estimated DAILY consumption for each type of item. The system uses this information at billing time to estimate how much power was used by the customer's items and then prices the estimated consumption as per the terms in the service quantity calculation rule.

Select **Admin > Rates > Item Type SQ Estimate** to define estimated consumption.

Description of Page

Select the **Item Type** using the search.

Enter the estimated daily consumption in the **Daily Service Quantity**. Each Service Quantity has an **Effective Date** so that changes in the estimated quantities may be recorded over time.

NOTE:

The unit of measure of the daily service quantity is displayed adjacent to the item type description. This value is defined on the item type table. Refer to [Device Types](#) for more information.

Where Used

This information is used when the system calculates a bill segment for a service agreement that references service points with items. If the items reference item types for which the system should estimate consumption, the system extracts the daily consumption amount from this table.

Setting Up Degree Days (and Average Temperatures)

Many organizations print degree-day and/or average temperature information on their customers' bills. Select **Admin > Billing > Degree Days > Search** to define these values for a given trend area.

Description of Page

The easiest way to define degree days is to select a **Trend Area** and **Month In Year** and tab out of the field. The system generates one row in the **Degree Days** collection for each day of the month. After the days exist in the collection, you should define the following for each day:

Degree Day This is a unit of measure used to express the extent to which temperatures vary from a specific reference temperature on a given date.

Maximum Temperature This is the maximum temperature on a given date.

Minimum Temperature This is the minimum temperature on a given date.

Average Temperature This is the average temperature on a given date.

Where Used

This information may be used by your bill print routines.

United Kingdom VAT and CCL

The topics in this section provide information about value added tax (VAT) and climate change levy (CCL) charges that are specific to non-domestic customers in the United Kingdom market.

NOTE:

Applicable for UK market. This section is only relevant for the United Kingdom market. Other markets may disregard this section.

UK VAT Overview

Two rates of VAT, referred to as standard rate VAT and reduced rate VAT, are applicable to energy related charges in the UK. Domestic (i.e., residential) customers always pay VAT at the reduced rate. Non-domestic customers on the other hand normally pay standard rate VAT. However, part or all of the energy related charges for a non-domestic customer might be subject to reduced rate VAT. De minimis and VAT declarations affect the percentage of the energy related charges that is subject to each VAT rate:

- If average daily usage at a premise for a given service type does not exceed a certain threshold (the de minimis limit), all energy related charges at that premise / service type are taxed at the reduced rate.
- Some non-domestic customers, such as those with a mixed-use premise, may be eligible to pay reduced rate VAT on part or all of their energy related charges. Customers may file a VAT declaration specifying the percentage of their energy related charges that are eligible for reduced rate VAT - refer to [Maintaining Declarations](#) for more information. If the declared percentage exceeds a given threshold, the declared percentage is deemed to be 100% and the customer pays VAT at the reduced rate on all energy related charges at that premise. VAT declarations are non-transferable and must be filed for each account, premise, and service type combination.

In addition to the potential for different rates of VAT to be applicable on a bill, UK tax regulations require that excess credits are considered a prepayment of energy related charges together with VAT. Refer to [Excess Credits and UK VAT](#) for more information.

The system comes supplied with various algorithms types that can be used to perform the VAT calculations.

UK CCL Overview

The climate change levy (CCL) is based on the amount of energy used that is subject to standard rate VAT. Similarly to VAT declarations, customers may file for exemption from CCL. A CCL declaration specifies the percentage of the CCL charges that the customer is exempt from - refer to [Maintaining Declarations](#) for more information. CCL declarations are non-transferable and must be filed for each account, premise, and service type combination.

CCL charges themselves are subject to standard rate VAT.

UK VAT and CCL Bill Examples

The following examples show how a bill for a non-domestic customer is affected by de minimis, VAT declarations, and CCL declarations. In the examples, standard rate VAT of 17.5%, reduced rate VAT of 5%, a VAT declaration threshold of 60%, and a CCL charge of 0.43p per unit of energy are used.

Example 1 - Normal Account

This example shows the bill for a normal non-domestic account with no declarations and consumption above the de minimis limit. Standard rate VAT is applied to all energy related charges (the standing charge and the per unit charge) and to the CCL charge.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 2,000 units @ 0.43p	8.60
VAT @ 17.5% on 218.60	38.25
Total	256.85

Example 2 - Account with Consumption Under the De Minimis Limit

In this example, consumption does not exceed the de minimis limit and therefore reduced rate VAT is applied to all the energy related charges. There is no climate change levy because only units subject to standard rate VAT are subject to CCL.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
VAT @ 5% on £210.00	10.05
Total	220.05

Example 3 - Account with VAT Declaration

This example is for a non-domestic account with a VAT declaration of 20%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 1,600 units @ 0.43p	6.88
VAT @ 17.5% on £174.88	30.60
VAT @ 5% on £42.00	2.10
Total	249.58

Example 4 - Account with VAT Declaration and CCL Declaration

This example is for a non-domestic account with a VAT declaration of 20% and a CCL declaration of 10%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. The customer gets a credit (CCL relief) for 10% of the CCL charges as a result of the CCL declaration. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge less the CCL reliefs are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 1,600 units @ 0.43p	6.88
CCL relief	<0.68>
VAT @ 17.5% on £174.20	30.48
VAT @ 5% on £42.00	2.10
Total	248.78

Billing and UK VAT

The following sections describe how VAT rules are implemented when a bill is produced.

Application of De Minimis

The de minimis rule specifies that all energy related charges at a premise be subject to reduced rate VAT if the total usage at a premise does not exceed a certain threshold. To determine if de minimis applies, the total billed consumption for a premise must therefore be known. However, energy usage at a premise may be measured with several meters and billed by multiple service agreements. To ensure that the final billed consumption for the premise is used to determine if de minimis applies, all service agreements for an account of a given service type at a given premise should be billed together and de minimis should be checked after the bill segments have been generated. In addition, all bill segments on one bill for consumption at a given premise must be for the same bill period.

NOTE:

Bill segments from different periods may not appear on the same bill. If a bill segment is canceled, all bill segments associated with consumption at a given premise for the same service type must be canceled and re-billed together. You cannot re-bill the bill segment on a bill for a different period.

An **Apply De Minimis Rule** Customer Class – Pre Bill Completion algorithm type CPBC-DMCH is supplied with the base package that checks for de minimis at bill completion time. The base bill completion algorithm type checks that for any service agreement that was billed, bill segments for all the account's service agreements with the same service type and characteristic premise exist on the bill. It then calculates the total consumption for the premise and determines if de minimis applies. If de minimis applies, it sets a bill characteristic whose value is the premise ID to indicate that de minimis applies and regenerates the bill segment. Refer to the **Apply De Minimis Rule** algorithm type CPBC-DMCH for more information on how this type of algorithm operates.

For calculation rule-based rates, the **Apply VAT to Cross-Referenced Charges** calculation rule business object (C1-**ApplyVatToCrossRefCharge**) calculates standard and reduced rate VAT and applies the de minimis rule if the bill characteristic for de minimis is found. Refer to [Calculation of VAT](#) for more information. Note that during the initial generation of each bill segment, the characteristic will not exist and standard rate VAT will be applied. This means that if you look at a bill before it is complete, VAT may not be accurately reflected.

NOTE:

Batch billing cannot regenerate re-billed bill segments. If you cancel and rebill a bill segment, you should complete the bill on-line so that the re-billed bill segments can be regenerated if de minimis applies.

Calculation of VAT

To calculate VAT, the percentages of energy related charges subject to standard rate VAT and reduced rate VAT must be determined. As these percentages vary from customer to customer and even from one bill to the next for the same customer, their calculation must take place at billing time and is handled by the following:

For calculation rule-based rates, the **Apply VAT to Cross Referenced Charges** business object (**C1–ApplyVatToCrossRefCharge**) is provided to calculate the percentages of energy related charges subject to standard rate and reduced rate VAT, taking into account de minimis and any VAT declaration that is in effect for the service type, account, and premise. The percentages can then be applied to the appropriate charges that are cross-referenced.

Calculation of CCL

CCL is a charge per unit of energy subject to standard rate VAT. It is therefore dependent on the same percentage of energy related charges subject to standard rate VAT determined during the calculation of VAT.

For calculation rule-based rates, a **Calculate Climate Levy and Relief Charges** calculation rule business object (**C1–ApplyCCLCharges**) is provided to calculate CCL charges and CCL relief, taking into account any CCL declarations that are in effect for the service type, account, and premise.

Excess Credits and UK VAT

When a financial transaction that results in a credit balance for a service agreement is frozen, the amount of the excess credit must be accounted for as a prepayment of energy related charges and VAT. VAT is calculated at the reduced rate for domestic customers and at the standard rate for non-domestic customers. When the excess credit is used, the VAT liability is reversed.

A **Create Excess Credit GL Details** Customer Class FT freeze algorithm type CFTZ-VAT-GL is provided to create additional GL detail entries for unbilled revenue and VAT liability when the freezing of an FT results in a credit balance or a change to a service agreement's credit balance.

Excess Credit GL Accounting Example

The following example shows the additional GL details that are created when a service agreement's balance changes and the starting or ending balance is a credit. For this example, a single VAT rate of 10% is used simply to illustrate the principle.

The service agreement has a zero starting balance. Note the following:

- When the first payment is received, the overpayment results in a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.
- When the second bill segment is created, the credit balance is reduced and additional GL entries are created to back out the unbilled GL entries, up to the amount of the credit balance.
- When the bill segment is canceled, the service agreement again has a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.

Event	Normal GL Accounting	Additional GL Accounting	SA Balance
Bill segment for £110 created	A/R 110		110
	Revenue <100>		
	VAT <10>		
Payment of £330 is received	Cash 330	A/R 220	<220>
	A/R <330>	Unbilled Energy <200>	
		Unbilled VAT <20>	
Bill segment for £275 created	A/R 275	A/R <220>	55
	Revenue <250>	Unbilled Energy 200	
	VAT <25>	Unbilled VAT 20	
Payment of £55 is received	Cash 55		0
	A/R <55>		
Bill segment for £275 is canceled	A/R <275>	A/R 275	<275>
	Revenue 250	Unbilled Energy <250>	
	VAT 25	Unbilled VAT <25>	

Setting Up The System For UK VAT and CCL

The following sections provide an overview of how to configure the system to apply UK VAT and CCL charges for non-domestic customers.

Bill Segment Freeze Installation Option

Select Freeze at Bill Completion as the bill segment freeze option. The system determines if de minimis applies at bill completion time and has to regenerate the bill segments as necessary.

Customer Class

Create a separate customer classes for non-domestic customers.

Service Agreements

You must configure the system so that each service agreement that must be checked for de minimis is only linked to service points at a single premise. The service agreement must reference that premise as its characteristic premise. Refer to [Application of De Minimis](#) for more information.

Bill Factors for UK VAT and CCL

- Standard Rate VAT

- Reduced Rate VAT
- VAT Declaration Percentage Threshold. Set up a separate bill factor for each service type as the thresholds differ based on service type.
- De Minimis Average Daily Amount Threshold. Set up a separate bill factor for each service type as the de minimis amounts differ based on service type.
- Climate Change Levy (CCL) Per Unit Price. Set up a separate bill factor for each service type as the CCL per unit prices differ based on service type.

Characteristic Type for De Minimis Amounts

Set up a characteristic type to use for the bill characteristic that indicates when de minimis applies. Define the type of characteristic value as a Foreign Key Value and specify a foreign key reference that points to the premise table. Specify this characteristic type as parameters to the algorithms that apply the de minimis rule and that apply VAT.

You need to define a characteristic type for every service type that is subject to the de minimis rule, as the de minimis limit may apply for one service type but not another on the same bill.

NOTE: A **De Minimis Premise** Characteristic Type is provided that may be used for a specific service type. For additional service types, additional characteristic types will need to be defined.

Distribution Code

Define the following distribution codes:

- Unbilled Prepaid Energy Related Charges
- Unbilled Prepaid VAT

These distribution codes are required as parameters to the algorithms to create the GL details for excess credit.

UOM / TOU / SQI

If using calculation rule-based rates, the calculation rule that calculates CCL requires the consumption that is subject to standard rate VAT as a service quantity.

Define the UOM / TOU / SQI used to store these service quantities.

Service Quantities

If using calculation rules-based rates, the algorithm that checks if the de minimis applies, requires a service quantity containing the total consumption. Unless you have registers that measure the total consumption independent of time of use or interval, you will need to set up a pre-processing calculation group with a calculation rule to aggregate the usage into one service quantity.

Algorithms for UK VAT and CCL

Add the following [algorithms](#):

- Apply De Minimis Rule. Define an algorithm for each service type for which de minimis should be checked. Plug the algorithm(s) in on the customer class for the Pre Bill Completion system event. Refer to the CPBC-DMCH algorithm type for more information about the base package algorithm.
- Create Excess Credit GL Details. Plug this algorithm in on the customer class for the FT Freeze system event. Refer to the CFTZ-VAT-GL algorithm type for more information about the base package algorithm.
- Highlight Effective Declarations for Account and Premise. Plug this algorithm in on the installation option for the Control Central Alert system event. Refer to the CCAL-DECL algorithm type for more information about the base package algorithm.

Calculation Rules to Charge VAT and CCL

Four additional calculation rules are required to charge for VAT and CCL on non-domestic rates:

- Calculate standard rate VAT
 - Calculation Rule Type= Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Standard Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate reduced rate VAT
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Reduced Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
 - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges
 - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
- VAT on CCL
 - Calculation Rule Type = Apply To
 - Value type = Percentage
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.

- Cross-reference the calculation line category for the total CCL and CCL Relief related charges

Setting up the calculation rules as above produces separate lines for VAT on energy related charges and on CCL (i.e., lines will be created for standard rate VAT on energy related charges, reduced rate VAT on energy related charges, and standard rate VAT on CCL charges).

You can set up rates to calculate standard rate VAT on energy related charges and CCL together as follows:

- Calculate standard rate VAT charges
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - FCPO = Yes
 - VAT Calculation Type = Standard Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Value Source = Value
 - Value = 100
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
 - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges
 - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
- Calculate standard rate VAT
 - Calculation Rule Type = Apply To
 - Value type = Percentage
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Cross-reference the calculation line category for the total CCL and CCL Relief related charges
- Calculate reduced rate VAT:
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Reduced Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT

Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts a quote, one or more real service agreements are created.

FASTPATH:

Refer to [Defining Quotation Options](#) for how to setup the system to enable quotation functionality.

NOTE:

Separate module. Please note that the quoting functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The topics in this section describe the quotation functionality.

The Big Picture Of Quotations

The topics in this section provide background information about a variety of quotation features and functions.

WARNING:

If you are not familiar with the concepts described under [Sales and Marketing](#), [Billing](#), [Rates](#) the quotation functionality will be difficult to understand.

Basic Quotation Concepts

The section describes basic quotation concepts.

A Quote Shows How Bill Segments Might Look

A quote shows how a customer's bill segments will look if a given set of pricing terms is applied to a given amount of consumption. The following example illustrates how a quote might look that provides a customer with two different options for their electric service. If the customer elects either option, a new service agreement would be created.

Quote Account: 1231231123 - ABC Supply

Quote Detail 1		Quote Detail 2	
SA Type: Electric	Rate: EQ-10	SA Type: Electric	Rate: AA-34
72 Market Street San Fran., CA		72 Market Street San Fran., CA	
Period: 1-Jan-00 - 31-Jan-00		Period: 1-Jan-00 - 31-Jan-00	
Descript.	Amount	Descript.	Amount
Usage < Cap	\$500	Hedge	\$400
Usage > Cap	\$100	> Hedge	\$201
Period: 1-Feb-00 - 28-Feb-00		Period: 1-Feb-00 - 28-Feb-00	
Descript.	Amount	Descript.	Amount
Usage < Cap	\$525	Hedge	\$625
Usage > Cap	\$111	> Hedge	\$1

Please note the following about a quote:

- A quote is related to an account.
- A quote can contain many quote details. A quote detail shows how bill segments will look if a given set of pricing terms (e.g., rates, riders, contract quantities, contract options, etc.) is applied to a given amount of consumption.
- A quote detail may contain many simulated bill segments. For example, a quote detail could show the customer what their monthly bills would be if a given set of pricing terms were used over the course of several months (where each month has different consumption levels and different prices).
- A quote may contain multiple quote details for the same service. For example, a quote can contain four different pricing options for the same service (where each option is shown using a separate quote detail). The customer can then compare them and choose the optimum option.
- A quote may contain quote details for multiple premises and multiple services at each premise. For example, a quote can contain quote details for electric and gas service at multiple premises.

Proposal Service Agreements Must Exist

You cannot create a quote unless its account has at least one proposal service agreement (SA). A proposal SA contains the pricing terms, legal terms, and template consumption used to generate the simulated bill segments that appear on a quote. It might be helpful to view a proposal SA as special type of service agreement that is ignored when a bill is produced for an account.

The topics in this section provide detailed information about proposal SAs.

Proposal SAs Contain Pricing Terms

The pricing terms (e.g., rates, contract quantities, riders, bill factor values, etc.) used to generate a quote detail's simulated bill segments reside on a special type of service agreement (SA) referred to as a "proposal SA". Proposal SAs are like real SAs in many respects. In fact, you can view and change a proposal SAs pricing terms using the same transaction used to maintain real service agreements (i.e., [service agreement maintenance](#)).

NOTE:

Quote details are rather empty. A quote detail doesn't contain the pricing terms or template consumption. Rather, a quote detail references a proposal SA and the proposal SA contains the pricing terms and template consumption.

Legal Terms and Conditions May Be Specified On Both Proposal And Real SAs

In addition to containing pricing terms, proposal SAs also contain the legal terms and conditions (T&Cs) that govern the proposal.

Proposal Service Agreement

SA Type: **Electric**

72 Market Street
San Fran., CA

Rate: **EQ-10**

Quantity Type	Value
Subscribed Demand	10
Hedge Percentage	15

Terms & Conditions

This quote requires a commitment of at least 6 months. Early cancellation results in a fee of 2 times the average bill amount.

This quote was calculated using historical market prices. The historical market prices should not be assumed to be the same in the future

Your master list of terms and conditions are defined when you setup your control tables. The system defaults a service agreement's T&Cs from the [start option](#) used to initially create it. You can change a SA's T&Cs at will.

NOTE:

Real SAs and proposal SAs can reference T&Cs. Both proposal and real SAs can reference T&Cs. The T&Cs on a proposal SA are those that will apply if the customer accepts the related quote detail. The T&Cs on a real SA are those that apply while the SA is active.

Proposal SAs Contain Billing Scenarios And Template Consumption

In addition to the pricing terms and the legal terms and conditions, a proposal SA also contains [billing scenarios](#). A billing scenario defines:

- The number of simulated bill segments that will be generated when a quote detail is produced for the proposal SA.
- The bill period of each simulated bill segment.
- The amount of consumption to be priced under each simulated bill segment. Note this statement is only true for non-interval consumption. *Note: Proposal SAs that use interval consumption are not supported in C2M. Load curves and TOU mapping are handled in Oracle Utilities Meter Data Management.*

A proposal SA's billing scenarios can be created as follows:

- A plug-in spot exists on SA type called Proposal SA Creation. Algorithms plugged into this spot can setup billing scenarios. Refer to [Enabling The Automatic Generation Of Billing Scenarios](#) for more information about how to do this.
- A user can add / change / delete billing scenarios on a proposal SA using [Service Agreement - Billing Scenario](#).

Proposal SAs Differ From Real SAs

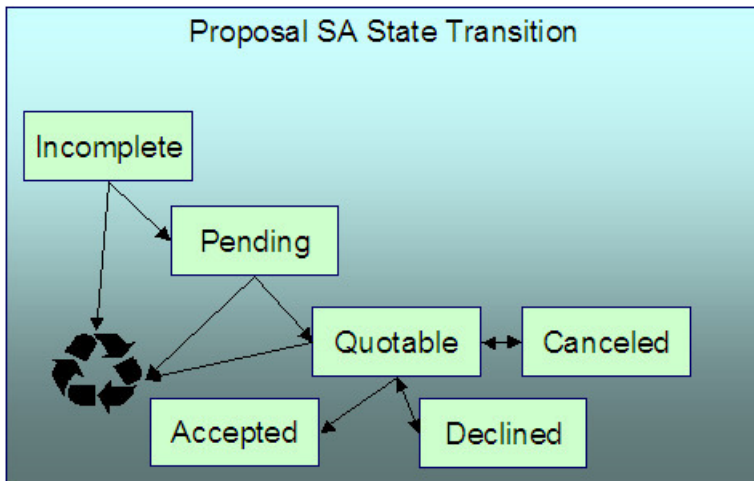

A proposal SA is just like any other SA in that it contains the pricing terms that are used to generate how much the customer owes for service. In fact, the [service agreement maintenance transaction](#) is used to maintain both types of service agreements (however, you cannot use this transaction to create a proposal SA; proposal SAs can only be created using the [order transaction](#)).

However, there are differences between proposal SAs and real SAs:

- Billing ignores proposal SAs.
- Proposal SAs cannot have financial transactions.
- Proposal SAs are not subject to credit and collections.
- Proposal SAs do not appear on lists of "active" SAs in the system's various zones, grids and trees.
- Fieldwork is not performed for proposal SAs.
- A proposal SA's state transition is very different from a real SA. Refer to [The Lifecycle Of A Service Agreement](#) for an illustration of a real SAs state transition. Refer to [Proposal SA State Transition](#) for an illustration of a proposal SAs state transition.

Proposal SA State Transition

The following diagram shows the possible lifecycle of a proposal SA.

You should never see an Incomplete proposal SA as this is a transitory state used when a proposal is first initiated using the [Order](#) transaction. The system always transitions such proposal SAs to the Pending state. Please note that when a proposal SA becomes Pending, the system executes any Proposal SA Creation algorithms plugged in on the proposal SA's SA type. You might use such algorithms to generate billing scenarios or initiate a workflow process that requests template consumption from the prospect.

A proposal SA exists in the Pending state while you are working on the proposal. For example, you might want to leave the proposal SA in this state while you wait for the prospect to send you their historical consumption.

A proposal SA is Quotable when a quote detail can be generated for it (at least one billing scenario must be linked to the proposal SA before it can become Quotable). Note, proposal SAs can be modified when they are Quotable.

NOTE:

Automatically transitioning a proposal SA to the Quotable state when it's first created. As described earlier, you can setup a proposal SA creation algorithm to automatically create billing scenarios when a proposal SA is created. The base package algorithm can also automatically transition the proposal SA to the Quotable state (thus making it ready for quotation). Refer to [Enabling The Automatic Generation Of Billing Scenarios](#) for more information.

A proposal SA becomes Accepted when a customer accepts one of its quote details.

A proposal SA becomes Declined when a customer declines one of its quote details (or its quote expires). A Declined proposal SA can be "reopened" (by making it Quotable). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

A proposal SA becomes Canceled when a quote detail is withdrawn (or its quote expires). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

Incomplete, Pending and Quotable proposal SAs may be deleted.

Orders Are Used To Create Proposal SAs

Proposal SAs can only be created using the [order](#) transaction. This transaction allows a user to pose eligibility-oriented questions to a customer or prospect. The system determines which [packages](#) of goods and services for which they are eligible based on the answers to the questions. If the customer is interested in receiving a package, one or more SAs (real and/or proposal) are created using the [SAs To Create](#) information defined on the selected package.

NOTE:

You must setup campaigns and packages before you can create an order. If you are not familiar with the [order](#) transaction, you should take the time to form an intuitive understanding of the concepts described under [Sales & Marketing](#). With this knowledge in place, you can design and set up the campaigns and packages necessary to allow an order to create proposal SAs. Keep in mind that a single switch controls whether real SAs or a proposal SAs are created when a package is selected on the order transaction. This switch resides on [Package - SAs To Create](#).

A package could create a combination of real and proposal SAs. When a customer elects to take a package of goods and services (via the [order](#) transaction), the system creates a service agreement for each SA type / start options defined on the package's [SAs To Create](#). It is possible to setup a package to create both real and proposal SAs. For example, the customer may be calling you to start electric service, but they may also be interested in seeing a proposal for gas service.

You don't create special SA types for proposal SAs. The SA type on a proposal SA is the same as the SA type on the real SA that's created when the proposal SA is accepted. This is because the business rules on your SA types govern both real and proposal SAs.

You don't need special start options for proposal SAs. The start options that you setup to default information onto new, real service agreements are also referenced on the [SA To Create](#) information used to create proposal SAs.

Proposal SAs May Be Grouped Under An Umbrella Agreement

Each proposal SA may be part of a larger contract for multiple services that you are negotiating with a customer or group of customers. You may use an [umbrella agreement](#) and its collection of terms of service records to group together multiple proposal service agreements.

Creating Quotes And Quote Details

Once an account has quotable proposal SAs, you can generate a quote for the account using the quote maintenance transaction. When you generate a quote for an account, you can include quote details for any / all of the account's quotable proposal SAs.

The logic used to create a quote detail's simulated bill segments is not hard-coded. Rather, the system calls the algorithm plugged in on the proposal SA's [SA type](#) in the Proposal SA - Bill Segment Generation plug-in spot. Refer to [Enabling The Generation Of Simulated Bill Segments](#) for information about this plug-in spot.

The major difference between a bill segment linked to a quote detail and one linked to a bill is that a quote detail's bill segments are calculated using simulated consumption. This means that the financial information on quote details is not a guess - it's what the bill would be if a given amount of consumption was priced using the pricing terms (as long as you opt to use rate application to calculate the simulated bill segments).

In addition to this major difference, there are a few minor differences between a real bill segment and a simulated bill segment:

- A quote detail bill segment does not have a foreign key to a bill. Rather, it references a quote detail.
- A quote detail bill segment's prime key is inherited from its quote detail (rather than its bill).
- A quote detail bill segment can never have a financial transaction linked to it.
- A quote detail bill segment doesn't have read details.
- A quote detail bill segment's state transition is simpler (it's either in the Error state or OK).

Completing A Quote Creates Quote Routings (And More)

When a quote's quote details are all OK, you change the status of the quote to complete to indicate the quote is ready to be sent to the customer or prospect.

When a quote is completed, the system creates a [quote routing](#) for each person who receives a copy of the account's quotes. When you indicate a person should receive a copy of the account's quotes, you define the routing method (e.g., email, fax, post) and the appropriate address.

NOTE:

Recipients of quotes. You define who receives a copy of an account's quotes on the [Account - Persons](#) page. The system assumes (by default) that the main person linked to the account should receive the account's quotes. You can subsequently indicate any person linked to the account should receive its quotes (and turn off the creation of quotes for the main person). In addition, you can manually add additional quote routings to a quote if you need to send the quote to individuals not currently linked to the account. Refer to [How To Reprint A Quote](#) for more information.

The information that appears on the quote routing record is controlled by the [quote route type](#) specified on the respective account / person information:

- If the quote route type's routing method is email or fax and the system has been configured to use notification preferences for quote routing, a quote routing is created for each active contact preference whose notification type is associated with the **quote route type** specified on the respective account / person information. Refer to *Bill and Quote Routing in Designing Notification Types* for more information. Otherwise, quote routings are created as follows:
 - If the quote route type indicates the person's quotes are routed via fax, the person's fax number is used as the routing information. The system knows which of a person's person contacts is a fax number is by the contact routing or which of a person's phone numbers is a fax number by the phone type.

- If the quote route type indicates the person's quotes are routed via email, the person's [Email address](#) is used as the routing information. The system knows which of a person's person contacts is an email or knows where to find the person email.
- If the quote route type indicates the person's quotes are routed via the postal service, the address constituents are populated with the address specified on the **bill** address source that is also specified on the [account / person information](#). Note, if the person has a [seasonal address](#) effective on the business date, the seasonal address will be used regardless of the value of **bill address source**.

Regardless of whether the quote is routed via fax, email or post; the routing record is also stamped with the batch process and run number that performs the download of the quote information. The batch process is defined on the quote route type. Refer to [Printing Quotes](#) for more information about this batch process.

In addition to creating routing information at completion time, the system executes any quote completion algorithms plugged in on the account's customer class. For example, you may want to create a workflow process to manage the processing of the quote. To do this, you plug in a Quote Completion Algorithm that creates a workflow process on the respective [customer class](#).

Accepting / Declining Quote Details

A customer can accept or decline each quote detail on a quote.

When a quote detail is accepted, the system:

- Changes the state of the related proposal SA to accepted.
- Executes the Proposal SA - Acceptance algorithms plugged in on the proposal SA's SA type. The base package algorithm creates a real SA by copying the information from the proposal SA. The real SA is created in the pending start state. This new SA behaves similarly to a pending start SA that's created via the [Order](#) or [Start/Stop](#) transactions (e.g., field activities are initiated if the SA type has been setup accordingly).

When a quote detail is declined, the user must supply a decline reason. The system then changes the state of the related proposal SA to declined.

FASTPATH:

Refer to [Proposal SA State Transition](#) for more information about a proposal SA's states.

NOTE:

Reopening a declined proposal SA. If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the [service agreement maintenance transaction](#).

Rejecting an entire quote. If all details on a quote are being declined, you can simply change the state of the quote to closed rather than reject each quote detail. Refer to [Closing Quotes](#) for more information.

Tinkering With Proposal SAs After Quote Generation

The system allows a quotable proposal SA to be changed, EVEN IF QUOTE DETAILS HAVE BEEN GENERATED. This is intentional as otherwise you would have to create an entirely new proposal SA if you wanted to send another quote for slightly different terms. Your technical team could always introduce a user exit to prevent this from happening if you really didn't want this to take place.

Because the system allows this, a potential issue is that the customer may end up accepting a proposal SA that differs from the terms on their quote (e.g., you could change the SA after the quote detail is generated). For this reason, we snapshot the

version number of the proposal SA on the quote detail at the time it's generated. If a proposal SA is accepted and its version number differs from the value on its quote details, a warning is produced.

A warning is also issued if you change a proposal SA and a quote detail exists (reminding you to generate a new quote / quote detail).

In addition to the above, it's also important to understand that the system intentionally allows multiple quotes to reference a given proposal SA. This allows you to leave multiple quotes open that reference the same proposal SA(s).

Closing Quotes

Every quote has an expiration date. The [CLOSEQTE](#) background process closes quotes on their expiration date. This process changes the state of all related proposal SAs to canceled or declined (an input parameter of this process controls which state is used).

You can also close a quote real time using the quote maintenance transaction. When you do this, the system asks if the related proposal SAs should be left as quotable or if they should be changed to canceled or declined.

NOTE:

Reopening a declined proposal SA. If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the [service agreement maintenance transaction](#).

Alerts

The [alert zone](#) highlights if:

- The selected account has pending or complete quotes. Refer to [Quote Lifecycle](#) for more information.
- The selected account has pending or quotable proposal SAs. Refer to [Proposal SA State Transition](#) for more information.

Trees

The [account tree](#) highlights:

- The existence of non-closed quotes
- The existence of proposal SAs and their related quote details

Printing Quotes

The contents of this section describe the technical implementation of printing quotes.

Quote Routings Are Created For Each Recipient Of A Quote

Refer to [Completing A Quote Creates Quote Routings](#) for a description of how the system constructs the information used to route a quote to one or more recipients.

Quote Route Types Control The Information Merged Onto Quotes

Every quote routing references a [quote route type](#).

The quote route type controls the following quote functions:

- It contains an algorithm that is responsible for extracting the information merged onto your quotes. Specifically, algorithms of this type create the "flat file records" that are passed to your quote-print software. Algorithms of this type are called under the following scenarios:
 - The background process that builds the flat file that's passed to your quote-print software calls these algorithms to construct the "flat file records" for each quote. Refer to [Technical Implementation of Printing Quotes In Batch](#) for the details.
 - If your quote-print software has the ability to construct a real-time image of a quote (in a PDF), you can plug in an Online Quote Display algorithm on the [Installation Record](#). This type of algorithm calls the quote's dispatch group extract algorithm to extract the information that is merged onto the quote. Refer to [Technical Implementation Of Online Quote Display](#) for the details.
- Refer to [The Quote Extract Records](#) for examples of the record layouts passed to the document composition application.
- It contains the ID of the background process that builds the flat file that's passed to your quote-print software. The base package example of this background process ([QUOTROUT](#)) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file.

NOTE: CIS Division can override the extract algorithm and/or the background process found on the quote route type. The system processes first check the quote's account's CIS Division for an override specific for the quote route type.

Technical Implementation Of Online Quote Display

Users can view an image of any quote if you set up the following:

- Plug in an Online Quote Display construction algorithm on the [Installation Record](#). Refer to ONQD-DOC1 for an example of such an algorithm. Note if your quote-print software is not capable of producing a PDF containing an image of a quote, users will not be able to view images of quotes.
- Plug in the appropriate extract algorithm on each [quote route type](#). Algorithms of this type format the records that contain the information that is passed to your printing software. Refer to QTEX-EX for an example of such an algorithm.

When you plug in these algorithms, a button appears on [Quote - Main](#). When a user clicks this button, the following takes place:

- The installation record's Online Quote Display algorithm is executed.
- This algorithm calls the quote's route type's extract algorithm. This algorithm constructs the information that's merged onto the quote and returns it to the Online Quote Display algorithm. This algorithm, in turn, passes it to the quote-print software.
- The quote-print software renders an image of the quote in a PDF and returns it to the Online Quote Display algorithm.
- And finally, the Online Quote Display algorithm displays the PDF in a browser session. Note that the client must have Adobe Acrobat Reader installed to view PDF files.

Technical Implementation Of Printing Quotes In Batch

The batch process that extracts quote information reads all quote routing records in a given run number that are marked with its batch control ID. For each quote routing record, it creates numerous records on a flat file. These records contain the information that is merged onto your quotes.

The base package example of this process ([QUOTROUT](#)) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file. Refer to [Quote Route Types Control The Information On Quotes](#) for more information.

NOTE:

If your software doesn't support online quote display. The algorithm that formats quote extract records that's plugged in on [quote route type](#) serves two purposes: 1) it formats the records used to construct online images of a quote, and 2) it formats the records downloaded to your quote print software in batch. If your quote printing software does not support the rendering of quote images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that both formats the extract records and downloads them (and then specify this batch process on your quote route type).

Reproducing The Quote Print Flat File

You can reproduce the flat file at any time. Simply request the quote production background process and specify the run number associated with the historic run.

How To Reprint A Quote (For The Original Recipients or For Someone New)

A copy of a quote is sent to every individual / business specified in the [quote's routing details](#). The system creates the routing details when a quote is completed. Refer to [Completing A Quote Creates Quote Routings](#) for more information about how this information is compiled during quote completion.

If you want to reprint a quote OR if you want to send a quote to someone other than the original recipients:

- Navigate to the [Quote - Main](#) page.
- Transfer to the [Quote - Quote Routings](#) tab.
- Insert a new row (click the + button). Note that you can only insert information on a quote that is Complete.
- Specify the name and address to which the quote should be sent. If you want to send the quote to someone other than the original recipient, specify the individual's name and address.
- Save the quote.

If a quote is Complete but the print process hasn't yet executed, you may change the name and address on the original routing details; you don't have to insert a new routing row.

The Quote Extract Records

Numerous different types of records are interfaced to the document composition application. However, they all share a common structure:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application quote template.
- The next X bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed quote appear in the correct order in the interface file.

- The next 12 bytes are called the **Mailing Key**. This field is used to control the order in which the formatted quotes are printed.
- The remaining bytes contain the **QuoteInformation** that appears on the printed quote. The type of information differs for each type of record.

The topics in this section describe each component.

Printer Key (Record Types)

The following table defines each printer key (i.e., record type) on the quote print flat file.

Record Type	Description	Notes
0010	Global extract information	Required. 1 per flat file
0100	Quote record	Required. 1 per Quote.
0200	Quote Detail record	1 per quote detail.
0300	Terms and Conditions record	1 per terms and conditions linked to the proposal SA.
0400	Bill segment record	1 per bill segment linked to the quote detail.
0500	Bill calculation header	1 per bill calculation header linked to the bill segment.
0600	Bill calculation line	1 per bill calculation line linked to the bill calculation header.
0700	End of record type 0500	1 for each bill calculation header
0800	Read detail	1 for each meter read detail linked to the bill segment.
0900	SQ detail	1 for each service quantity detail linked to the bill segment.
1000	End of record type 0400	1 for each bill segment.
1100	End of record type 0200	1 for each quote detail.
9999	End of record type 0100	1 for each quote.

Sort Key

The following table defines the structure of the sort key that appears on each quote print record. Please note that different components are filled in for each printer key.

Field Name	Format	Source/Value/Description
Quote ID	A12	
Sequence Number	N2	The sequence number of the account / person information associated with this quote routing information.
Quote record group	A2	10 Quote 20 Quote Detail

		30 Quote end
Quote Detail ID	A12	
Quote Detail record group	A2	10 Quote Detail record 20 SA Terms and Conditions 30 Bill Segment 40 Quote Detail record end
SA T&C Short Description	A60	
Bill Segment End Date	A10	
Bill Segment Id	A12	
Bill Segment Group	A2	10 Bill segment 20 Bill segment calculation group 30 Bill segment read detail 40 Bill segment SQ detail 50 Bill segment end
Bill Calc Header Sequence	N2	
Bill Calc Header Group	A2	10 Bill calculation header 20 Bill calculation line 30 Bill calculation end
Line Seq	N4	Defines order of rows for similar record types

Mailing Key

The following table defines the structure of the mailing key that appears on each quote print record.

Field Name	Format	Source/Value/Description
Postal code	A12	This is the postal code on the quote routing record.

Quote Information

The topics in this section describe the information that appears on each on each quote print record. The following links are provided so that you can move easily to specific topic within this section:

- [Global Extract Information \(0010\) Record Definition](#)
- [Quote \(0100\) Record Definition](#)
- [Quote Detail \(0200\) Record Definition](#)
- [SA Terms and Conditions \(0300\) Record Definition](#)
- [Bill Segment \(0400\) Record Definition](#)
- [Bill Calculation Header \(0500\) Record Definition](#)
- [Bill Calculation Line \(0600\) Record Definition](#)

- [End of Bill Calculation Header \(0700\) Record Definition](#)
- [Bill Segment Read \(0800\) Record Definition](#)
- [Bill Segment SQ \(0900\) Record Definition](#)
- [End of Bill Segment \(1000\) Record Definition](#)
- [End of Quote Detail \(1100\) Record Definition](#)
- [End of Quote \(9999\) Record Definition](#)
- [Address Sub-Record Definition](#)

Global Extract Information (0010) Record Definition

This is a "header" record that contains information about the extract run as a whole.

NOTE:

Please be aware that if you do not sort your extract file by **CIS Sort Key** after it is produced, this record will physically be the last record on the extract file.

Field Name	Format	Source/Value/Description
BATCH_CD	A8	Batch Control Code of the extract process.
BATCH_NBR	N10	Batch Number of the extract process
BATCH_RERUN_NBR	N10	Batch Rerun number of the extract process.
QTE_CNT	N10	Count of quotes on this extract.
EXTRACT_DTTM	A26	System time of extraction.
QUOTE_ID_START	A12	This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract.
QUOTE_ID_END	A12	This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract.
THREAD_NBR	N10	This field is only used if quotes are extracted in batch. It contains the thread number in which the quote was extracted.
THREAD_CNT	N10	This field is only used if quotes are extracted in batch. It contains the total number of threads that were extracted.

Address Sub-Record Definition

The address that appears in both the quote record (0100) and the quote detail record (0200) is composed of the following:

Field Name	Format	Description
COUNTRY	A3	
ADDRESS1	A64	Refer to Completing A Quote Creates Quote Routings for a description of conditions when this field will contain a fax number or an Email address rather than the first line of a postal address (this only occurs for a bill record (0100)).
ADDRESS2	A64	
ADDRESS3	A64	
ADDRESS4	A64	
CITY	A30	
NUM1	A6	
NUM2	A4	
HOUSE_TYPE	A2	
COUNTY	A30	
STATE	A6	
POSTAL	A12	
GEO_CODE	A11	

[Top of Page](#)

Maintaining Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts the quote, real service agreements are created.

FASTPATH:

Refer to [The Big Picture Of Quotations](#) for background information about quotes.

The topics in this section describe how to maintain quotes.

The Lifecycle Of A Quote And Quote Detail

The topics in this section describe the lifecycle of the various quote objects.

Quote Lifecycle

The following diagram shows the possible lifecycle of a quote.

Pending A quote starts its life in the Pending state. Refer to [Creating Quotes And Quote Details](#) for more information.

A quote remains Pending until you Cancel or Complete it.

You may delete a Pending quote. Deleting a pending quote also deletes its quote details.

Canceled You cancel a quote if you want a record of a Pending quote that was never sent to a customer.

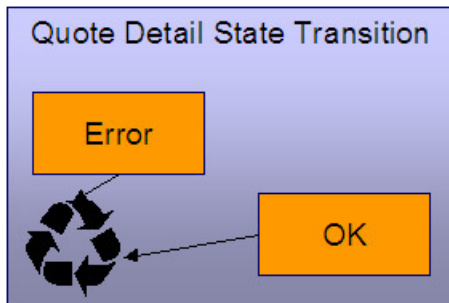

Complete A quote becomes Complete when it is ready to be sent to a customer. No changes may be made to a Complete quote. Refer to [Completing A Quote](#) for a description of what happens when a quote is completed.

A Complete quote may be reopened. You would only do this if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote details, and then recomplete the quote.

Closed A Complete quote becomes Closed when its terms are no longer valid. Refer to [Closing Quotes](#) for more information.

Quote Detail Lifecycle

The following diagram shows the possible lifecycle of a quote detail.

When a quote detail is generated, it is placed in the Error or Ok state depending on whether the system successfully generated simulated bill segments for each billing scenario linked to the related proposal SA. A quote detail may be deleted if its parent quote is Pending. Refer to [Creating Quotes And Quote Details](#) for more information.

Quote - Main

This page is used to maintain quotes. This page provides many diverse functions:

- You can [generate](#), [complete](#), [close](#), reopen, and cancel a quote.
- You can regenerate and delete quote details.
- You can [accept](#), [decline](#) and cancel the proposal SAs that contribute a quote detail to the quote.

You should not attempt to use this transaction until you are comfortable with the concepts described under [The Big Picture of Quotations](#).

Open this page using **Menu > Sales & Marketing > Quote > Search**.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

Account ID identifies the customer or prospect associated with the quote. The name of the account's main customer appears adjacent.

Quote Status contains the state of the quote. Refer to [Quote Lifecycle](#) for information about the valid values and the state transition rules.

If your system has been configured to display an online image of a quote, a **Display Quote** button appears adjacent to the quote's status. When clicked, an online image of the quote is displayed. Refer to [Technical Implementation Of Online Quote Production](#) for how to enable this feature.

Expiration Date / Time identifies when the quote's terms are no longer valid. Refer to [Closing Quotes](#) for how the system uses this information to automatically close a quote.

Refer to [Quote Actions](#) for a description of each **Quote Action** button.

This transaction has sophisticated logic that can be used to perform mass updates to the quote's quote details and their related proposal SAs. These mass update actions are executed by selecting quoted details (in the grid) and then clicking the desired action button at the bottom the page. The remainder of this section describes how to use this mass update functionality.

The **Select All** / **Clear All** buttons are used to select / unselect the quote details. These buttons are disabled when the quote is Closed.

NOTE:

100 quote details at a time. Clicking **Select All** selects the first 100 quote details in the grid. If more than 100 quote details exist, you must select them in batches.

The grid that follows contains the quote details linked to the quote. The following information appears in the grid:

- **Select box.** Before you can perform any of the mass update actions at the bottom of the page, at least one quote detail must be selected. This field is disabled when the quote is Closed. You can use the **Select All** and **Clear All** buttons to change the value of the switch for all quote details in the grid.
- **Click the go to button** to transfer to the [Quote - Quote Detail](#) tab with the corresponding quote detail positioned in the scroll. On this page, you can see the details of the quote detail's simulated bill segments (and, from there, drill down into the details of each bill segment).
- The **Quote Detail Info** column contains a concatenation of a quote detail's division, SA type, start option, status, start date, and premise information (this information comes from the quote detail's proposal SA).
- The **Total Amount** column contains the sum of the quote detail's simulated bill segments.
- The **Remarks** column highlights special circumstances associated with the quote detail.
 - Proposal SA has been changed since the quote was created appears if the proposal SA was modified after the quote detail was generated. If you'd like to recalculate this quote detail, select this row and click the **Regenerate** button at the bottom of the page to regenerate the quote detail's simulated bill segments.
 - Quote detail contains bill segments in error appears if any of the simulated bill segments linked to the quote detail are in error. Click the adjacent go to button to transfer to the [Quote - Quote Detail](#) tab where the state of each simulated bill segment is shown. You can correct simulated bill segments that are in error by **Regenerating** the quote detail (and you do this by selecting the quote detail and clicking the Regenerate button at the bottom of the page).

The **Quote Detail Actions** and **Proposal SA Actions** can be used to perform mass updates to the selected quote details in the grid. Refer to [Quote Detail Actions](#) and [Proposal SA Actions](#) for the details.

Action Buttons On Quote Main

The topics in this section describe the various action buttons on the [Quote - Main](#) page.

Quote Actions

The topics in this section describe the **Quote Action** buttons on the [Quote - Main](#) page. The following links are provided so that you can move easily to specific topic within this section:

- [Generate](#)
- [Complete](#)
- [Close](#)
- [Reopen](#)
- [Cancel \(Quote\)](#)

Generate

The **Generate** button causes one or more quote details to be created for the account's Quotable proposal SAs. This button is enabled when there is at least one Quotable proposal SA linked to the selected **Account ID**.

When clicked, the **Generate Quote** window opens.

You must specify the following parameters to generate quote details:

- Indicate if quote details should be created for All Proposal SAs or for a Specific Proposal SA.
- If you indicated a quote detail should be generated for a Specific Proposal SA, also specify the **Proposal SA ID**.

After specifying the parameters, click **Generate** to create the quote details for quotable proposal SAs.

FASTPATH:

Refer to [Creating Quotes And Quote Details](#) for more information.

WARNING:

If the quote has existing quote details for the designated proposal SAs, they are deleted when you generate quote details (i.e., the system regenerates existing quote details). You can also regenerate quote details by selecting them on the Main page and clicking the **Regenerate** button.

[Top of Page](#)

Complete

The **Complete** button causes the quote to become complete. This button is enabled when the quote is pending and all quote details linked to the quote are OK.

FASTPATH:

Refer to [Completing A Quote Creates Quote Routings](#) for a description of what happens during quote completion.

[Top of Page](#)

Close

A quote is closed when its terms are no longer valid (i.e., when the related proposal SAs can no longer be accepted). Most quotes are closed automatically by the system (refer to [Closing Quotes](#) for how this takes place).

If you want to close a quote real time, click the **Close** button. When this button is clicked, the system opens the **Close Quote** window and asks if anything should be done with the related proposal SAs.

In the resulting window, you must specify one of the following **Proposal SA Actions**:

- Choose No Action if you don't want to change the status of the related proposal SAs.
- Choose Decline if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to declined . You must also define a **Decline Reason**.
- Choose Cancel if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to canceled .

[Top of Page](#)

Reopen

The **Reopen** button causes a quote to return to the pending state. You would only reopen a quote if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote detail, and then recomplete the quote.

This button is enabled if the quote is complete.

[Top of Page](#)

Cancel (Quote)

The **Cancel** button causes the quote to become canceled. You would cancel a quote if you want a record of a pending quote that was never sent to a customer. This button is enabled when the quote is pending.

Canceling the quote does NOT cancel the related proposal SAs. If you want to cancel the related proposal SAs, you have the following options:

- You can click the [Close](#) button rather than the **Cancel** button. When you close a quote, you are given the option of also canceling the proposal SAs that contributed a quote detail to the quote.
- Before canceling the quote, you can select the quote details and click the [Cancel](#) button at the bottom of the page (in the Proposal SA Actions section). When you click this button, the system cancels the proposal SAs linked to the quote details.
- You can transfer to the [Quote - Quote Details](#) tab and then drill down to the each proposal SA (using the SA context menu button). This transfers you to [Service Agreement - Main](#) where you can cancel the proposal SA.

Quote Detail Actions

The topics in this section describe the **Quote Detail Action** buttons on the [Quote - Main](#) page. These buttons are used to perform a given action to the quote details that are selected in the quote details grid.

- The **Regenerate** button is used to delete and recreate the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.
- The **Delete** button is used to delete the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.

Proposal SA Actions

The topics in this section describe the various **Proposal SA Action** buttons on the [Quote - Main](#) page. These buttons are used to perform a given action to the proposal SAs associated with the selected quote details.

The **Accept** button is used to accept the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

When you accept a proposal SA, you are asked to supply the **Start Date** of the real service agreement that will be created.

Refer to [Accepting / Declining Quote Details](#) for more information about how accepting a quote detail causes a real service agreement to be created.

Decline

The **Decline** button is used to decline the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected. When you decline a proposal SA, you are asked to supply a **Decline Reason**.

Refer to [Accepting / Declining Quote Details](#) for more information about declining a quote detail.

Cancel

The **Cancel** button is used to cancel the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

Quote - Quote Details

This page is used to view a summary of the simulated bill segments linked to a quote detail.

Open this page using **Menu > Sales & Marketing > Quote > Search** and navigate to the **Quote Details** page to define this information. You can also display a quote detail by clicking the respective go to button in the quote details grid on the main tab.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Details** scroll contains one entry for every quote detail linked to the quote (a summary of these quote details also appears on the Main tab). The remainder of this section describes the information displayed for each quote detail.

NOTE:

You don't have to use the scroll. If the quote has many quote details, you don't have to use the scroll to work through them. Rather, you can use the go to button in the quote details grid on the main tab to position the respective quote detail in the following scroll. Also note, you can use Alt - and Alt + to scroll to the next and previous quote details in the scroll.

You cannot maintain quote details on this page. All maintenance functions (generate, delete, accept, decline and cancel) are performed on the **Main** tab.

Premise Info is the address of the main premise associated with the service agreement (as defined on the service agreement's characteristic premise). It's important to note that the service agreement may cover service at multiple premises, but only one may be defined as the main premise.

Quote Detail ID is the system-assigned unique identifier of the quote detail.

SA Info is a concatenation of the proposal SA's division, SA type, start option (if any), status and start date.

SA Version is a snapshot of the proposal SA's version number at the time the quote detail was generated. This information is used by the system to detect if the proposal SA was modified after the quote detail was created.

Total Amount is the sum of the quote detail's simulated bill segments.

Create Date / Time is the date and time the quote detail was generated.

Remarks highlight special circumstances associated with the quote detail. Please see the description of this field on the main tab for more information.

The grid contains a row for each simulated bill segment linked to the quote detail. The following information appears in the grid:

- The first go to button transfers you to the [bill segment page](#) where the details of the simulated bill segment are shown.
- **Bill Segment Period** defines the start and end dates of the simulated bill segment.
- **Amount** contains the amount of the bill segment.
- **Remarks** highlight special circumstances associated with the bill segment.
- **Billing Scenario ID** allows you to go to the proposal [SA's billing scenario](#) where you can tinker with consumption and the bill segment period used to generate this bill segment. Refer to [Proposal SAs Contain Billing Scenarios](#) for more information.

Quote - Quote Routings

This page is used to view the recipients of a quote. Refer to [Printing Quotes](#) for a discussion of how this information is used to produce quote images.

This page is also used to request a new copy of a quote.

NOTE:

No routing information until completion. A quote has no routing information until it is complete. At [completion time](#), the system creates a routing detail for every person linked to the account that receives a copy of its quotes. Refer to [Printing Quotes](#) for more information about how this information is constructed.

Use [Menu](#) > [Sales & Marketing](#) > [Quote](#) > [Search](#) and navigate to the [Quote Routings](#) page.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Routing Information** scroll contains an entry for each recipient of the quote. This information is disabled after the quote has been routed to the recipient. The remainder of this discussion describes the fields that can be defined for each recipient of the quote.

Person ID identifies the person who was originally associated with the routing record. You may change the **Person ID** to any person in the system as this information is only used to default the recipient's name and address information, below.

The **Quote Routing Parameters** area contains information explaining how and when the quote is routed to the recipient. This information is gray when the quote routing information has been extracted or if a quote is reopened:

- **Quote Route Type** is the method used to transmit the quote to the customer. This information defaults from [Account - Person Information](#).
- **Batch Control** is the identifier of the batch of quotes in which the recipient's copy was downloaded. Embedded in this identifier is the batch control ID and the batch number. Note, this batch process is defined on the Quote Route Type or CIS Division.
- **Sequence** is the system-assigned identifier assigned to this quote routing.
- Turn on **Do Not Extract** if the quote should not be routed to the individual for whatever reason.
- **Reprint** is checked if an operator created this routing. This switch is populated by the system and is always protected.
- **Extract Date/Time** is the date and time the quote was downloaded. This information only appears after the download has commenced.

The **Mailing Address Information** area contains the recipient's name and address.

- If the recipient has an [override mailing name](#), **Name1**, **Name2** and **Name3** contain the person's override mailing name. Otherwise, **Name1** contains the recipient's primary name (this name might also include a prefix or suffix if the related [Account - Person](#) relationship has these fields defined).
- The remaining fields are the recipient's address. Refer to [Completing A Quote Creates Quote Routings \(And More\)](#) for information about how the system constructs the recipient's address
- If the recipient's address is a mailing address (as opposed to fax or email), the **Country** associated with the address controls the fields that appear in the address. Refer to [Defining Countries](#) for more information on the address constituents.
- If a user manually adds a routing record, the mailing address information defaults from the information on the current routing record.
- If a user specifies a **Person ID** that is linked to the quote's account, the **Quote Route Type** defined for this person on the account is defaulted.
- If a user specifies a **Person ID** that is not linked to the quote's account, the **Quote Route Type** on the [installation record](#) is defaulted. Note, if the quote route indicates the quote is routed via the postal service, the system will only be able to default the person's address if the person has an override mailing address on their [correspondence information](#).
- If the user changes the **Quote Route Type** after the initial default, the system populates the address information as described above.

Service Credits

"Service credits" is a term used to describe a special program designed to reward a customer for service along with benefits related to such a program. For each program that a customer participates in, there is a service credit membership record. Service credit events are used to record the "points" earned and redeemed for the membership. The topics in this section provide further details related to the service credit functionality.

FASTPATH:

For information about designing and setting up your control tables for configuring service credit functionality, refer to [Designing Your Service Credit Options](#).

NOTE:

Service credits are optional. Service credits may not be set up in your system; they are only used if your company offers rewards programs to customers.

Penalty Points. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

The Big Picture Of Service Credit Membership

If a customer is participating in a rewards program, the customer has a service credit membership. The topics in this section provide background information about a variety of service credit membership features and functions.

Who are the Members?

Each membership has one or more "members". The members are defined by the accounts linked to the membership and by the financially responsible person(s) linked to each account.

A typical membership is linked to only one account. However, in some cases more than one account is linked to the membership. For example, a customer may have one account for residential service and one for commercial service, but both accounts are part of the same membership. In this example, one person with multiple accounts is linked to the membership, so there is only one member.

For each account linked to the membership, the service related to the account may be used to calculate the accumulated credits for the membership. Refer to [How Are Service Credits Earned?](#) for more information.

NOTE:

An account may not be linked to more than one membership of the SAME membership type at a given point in time. In other words, an account may not have two United Airlines frequent flier memberships (otherwise, the account would accumulate double miles). However, an account may be linked to more than one membership if they are of different membership types. For example, an account may have a capital credits membership and a United Airlines frequent flier membership.

When you find a customer's record on [Control Central - Search](#), you are transferred to the [Account Information](#) portal. One of the zones on this page contains information about memberships for the customer.

NOTE:

Portal Preferences. The service credit membership zone only appears if you have modified your preferences to display this zone. Refer to [Portal Preferences](#) for more information.

Joint Membership

It is possible for more than one person to belong to the same membership. These persons may be linked to the same account or to different accounts. A typical scenario would be a married couple that shares in a membership. This is considered a "joint" membership.

The number of "members" for a membership is mainly for information purposes and typically has no bearing on the service credit amounts calculated for the membership. There may be legal restrictions or business practice restrictions controlling how you may set up your members. For example:

- In an airline's frequent flier program, a separate frequent flier account would exist for each customer. It is possible for you to create a frequent flier membership with more than one "member", but for the system, the important information is the external frequent flier miles number linked to the membership. The customer linked to this number accumulates the miles. For this case, your business practice may be that the person with the frequent flier account must be the only financially responsible person.
- For a capital credits membership, you may be required to distinguish between "single" memberships and "joint" memberships. If a single person gets married and would like the spouse to be added as a member, your practice may be to expire the single membership and to create a new "joint" membership to include both spouses.

NOTE:

Co-op Members. Do not confuse the "members" of a co-op with the members linked to a service credit membership. At a cooperative, most customers are considered "members" of the co-op. However, in the system, separate membership records are created for each single or joint membership.

Changing the Membership Accounts

The link between the accounts and the membership is NOT effective dated. This means that if the list of accounts for a membership changes, you need to stop the membership and start a new one with the new list of accounts.

NOTE:

Stopping Memberships. Stopping a membership does not necessarily prevent new service credits from accumulating. Refer to [Stopping a Membership vs. Inactivating a Membership](#) for more information.

Membership Application

Your business practice may dictate that the customer complete an enrollment form. Depending on your practice, the form may need to be received prior to starting membership or it may simply be a mechanism to gather supplemental information once the membership has begun.

Either way, you may consider setting up the system to handle forms as follows:

- Design your membership type to include a creation algorithm that generates a letter when the membership is created. The letter template could include the form to be filled out.

- Create the new membership in pending status. The letter and form are sent to the customer and the pending status indicates that you are waiting for the completed form. Refer to the [Lifecycle of a Membership](#) for more information.
- When the paperwork is received, change the status of the membership to active.

NOTE:

Membership Events for Pending Memberships. The system allows events to be created for pending memberships assuming that paperwork is supplemental information that should not prevent service credits from accumulating. If your business practice dictates that the paperwork must be received prior to accumulating service credits, the algorithm or background process that creates events for memberships of this type should be coded to only create events for active memberships. Refer to [How Events Are Created](#) for more information.

Creation of a Membership

Memberships may be created using the [membership](#) page when a customer has signed up for a special program. In addition, it may be your business practice to automatically create a membership under certain circumstances when a customer has signed up for service.

For example, if you are a co-op, perhaps every new customer is automatically enrolled in a capital credits membership. Or perhaps signing up for cable service automatically entitles your customers to membership in the free pay-per-view movies program. For these cases, the recommendation is to use the [order](#) page to start service for your customer and to use questions and miscellaneous fields to record information needed to set up the new membership correctly. Refer to [Using Campaigns & Packages to Create a Membership](#).

Membership Fees

Some memberships may require a fee to be paid by the customer when joining. The behavior of this fee may differ depending on whether it is refundable or not.

- If the fee is nonrefundable, you create an SA with a simple adjustment or a one time billable charge to levy the fee. Refer to [Defining Control Tables for a Nonrefundable Fee](#).
- If the fee is refundable, in addition to defining the SA to hold the fee, you need to put code in place to initiate the refund. Refer to [Setting Up a Refundable Fee](#) for more information.

Stopping a Membership vs. Inactivating a Membership

You may stop a membership by entering an end date for the membership. However, depending on how events are created for your membership, stopping the membership may not prevent new events from being created. For example:

- If you stop a frequent flier membership on May 15th and a bill is subsequently created for the period May 1st through June 1st, your business rules may dictate that frequent flier miles should be accumulated for this bill because the membership was active for part of the period covered by the bill.
- For a capital credits membership, capital credit allocations are calculated for the prior year. If a membership stopped in the middle of the previous year, the membership should still get capital credits for the part of the year that the membership was still in effect.
- Capital credit retirements are calculated based on capital credit allocations accumulated in the past. If a membership has been expired, the members are still eligible for retirement amounts for the accumulated capital credit allocations. These retirements may continue for many years after a membership is stopped.

NOTE:

Membership Status. For all the above scenarios, the system assumes that the status of the membership remains active.

You may have some circumstances where you do not want new events to accumulate after a membership is stopped. To prevent new events from being created, you must change the status of the membership to inactive.

If a customer moves away or otherwise stops service with your company, your business rules dictate whether or not the membership should be stopped or changed to inactive. The following issues must be considered:

- Will service credit events still get created for these memberships? If so, is that acceptable?
 - For frequent flier memberships, the miles are calculated based on new bill amounts for the membership's service agreements. If the SAs that contribute to the membership are expired, no new bills are generated so no new miles are accumulated.
 - For capital credits, after a customer moves away, the capital credit allocation for the final year of the customer's service may still need to be calculated. In addition, this customer is eligible for the capital credit retirement amounts, even though they are no longer a customer.
 - What happens if the customer returns to your company and signs on for service again? Assuming that the same account number is used, is it ok for the membership to be automatically reinstated? Or should the customer reapply? If the customer should reapply, you may consider updating the membership with a stop date when the customer originally stopped service.
-

NOTE:

There is nothing in the system logic that automatically updates the membership stop date or the status when service agreements that contribute to the membership are stopped.

The Big Picture of SC Events

The service credit events record the accumulation and redemption of awards earned by the membership. The topics in this section provide background information about a variety of service credit event features and functions.

NOTE:

Events. For convenience, this document often refers to service credit events simply as "events".

Event Amounts May Contribute to a Balance

The event amount may be positive or negative, based on whether the event is accumulating points earned for the membership or redeeming points for the membership. For some types of memberships, these credit and debit amounts should be added together to produce the overall balance for the membership.

For some types of memberships, a balance is not applicable. This is true for memberships where the redemption of the points does not occur within the system. For example, if the membership accumulates frequent flier miles on behalf of an airline, the customer redeems the earned miles with the airline, not with your company. As a result, there is no need to calculate a balance for the membership.

If you want the system to calculate a balance, you must set a switch on the [membership type](#) page. For memberships that calculate a balance, the balance may be viewed on the membership page.

Events May Indicate a Fiscal Year

For some types of memberships, the amount of each event is associated with a specific fiscal year. This is true for capital credit memberships where capital credit allocations are calculated for a fiscal year. When the capital credits are redeemed (also called retired), the retirement events must also indicate a fiscal year. Because all events for this type of membership are related to a fiscal year, the system can calculate the balance for the events by fiscal year.

If you want the system to require a fiscal year for every event in the membership, you must set a switch on the [membership type](#) page. For memberships that calculate a balance and indicate a fiscal year, the balance for each fiscal year may be viewed on the membership page.

Events May Indicate a Subcategory

For some types of memberships, the amount of each event is further grouped by a subcategory. This is common for capital credit memberships where multiple capital credit allocations are calculated. For example, each year, you may calculate allocations for generation and for transmission. Events for memberships of this type must indicate a subcategory.

Cooperatives that allocate capital credits for more than one subcategory, typically want to view the balance of the events over time broken down into these subcategories. When the capital credits are redeemed or retired, the retirement events must also indicate a subcategory. Because all events for this type of membership are related to a subcategory, the system can calculate the balance for the events by subcategory.

NOTE:

Partial Retirement. For some cooperatives, it is common that certain capital credit allocations are never retired. Refer to [Partial Retirement](#) for more information.

If you want the system to require a subcategory for every event in the membership, you must define the valid subcategories on the [membership type](#) page. For memberships that calculate a balance and indicate a subcategory, the balance for each subcategory may be viewed on the membership page.

NOTE:

Calculating Subcategory Balances. If events for your membership indicate a subcategory and fiscal year, balances for the membership are calculated for both groupings.

An Event May Cause Other Actions to Occur

When an event is generated, there are often other actions that need to take place. For example:

- If an event is created that allocates points for the customer, you may want to generate a temporary message on the customer's next bill.
- If a capital credit allocation event is created, the general ledger is affected so an adjustment must be created to post to the general ledger. Refer to [Financial Transactions for an Event](#) for more information.
- If an event is created to add frequent flier miles, the event must be marked for extraction so that the information is sent to the appropriate airline. Refer to [Interface Membership Information to a Third Party](#) for more information.
- If an event to retire capital credits is created, the customer's balance is affected so an adjustment must be created to transfer the capital credit to the members' service agreements. Refer to [Financial Transactions for an Event](#) for more information.

The system relies on algorithms linked to the event type to perform the actions described above and any other action that may be required by your business.

FASTPATH:

Refer to [Service Credit Event Types](#) for more information about the algorithms provided with the base product.

NOTE:

Event Cancellation Algorithms. The event type also defines algorithms to be executed when an event is canceled.

Financial Transactions for an Event

An event may be related to financial transactions. There are two types of financial transactions that may be linked to the event:

- Financial transactions that contributed to the event. These are bills, payments or adjustments that caused the event to be created. For example, if you generate an event for frequent flier miles as a result of some amount billed for the customer, the bill segments associated with the billed amount are linked to the event. The FTs are linked to the event for audit purposes.
- Financial transactions that are created by the event. In [an event may cause other actions to occur](#), we saw examples where an event completion algorithm may cause adjustments to be created. The FT ID for these adjustments is linked to the event as audit.

NOTE:

Automatically Canceling Event Financial Transaction. The created by financial transactions may get canceled if the event is canceled AND you have plugged in an appropriate [Event Cancellation Algorithm](#).

For financial transactions that are created by the event, the system must post the financial transactions to one or more appropriate service agreements. The service agreement to use depends on your business rules. For example:

- If the event affects the balance of accounts linked to the membership, the event completion algorithm may create adjustments for [service agreements that contribute to the membership](#).
- If the event affects the general ledger and does not affect any balance for the account, the event completion algorithm simply needs a service agreement to use for the resulting adjustment. Rather than arbitrarily picking any service agreement in this case, a special [miscellaneous service agreement](#) should be linked directly to the membership for such adjustments.

How Events Are Created

Although a user may create an event manually on the [service credit event](#) page, most events are created automatically by an algorithm or by a background process. The following topics further describe these options.

Events Created by an Algorithm

You would design an algorithm to create your events if the event should be triggered by an occurrence in the system, such as starting service or generating a bill. For example, perhaps every time you are billed for electric and/or gas service, the system adds one frequent flier mile for every \$10 spent on service. Refer to [How Are Service Credits Earned?](#) for more information.

The base product provides a bill completion algorithm to create an event as a result of the amount billed for service agreements linked to the membership. Refer to CBCM-SC for more information.

Events Created as a Result of a Background Process

You would use a background process to create the event if the calculation is done periodically or on an ad-hoc basis and does not get triggered by something occurring in the system. For example, the capital credit allocation and retirement processes are typically run once a year, when the business has determined that they are ready to calculate these amounts.

FASTPATH:

Refer to [Allocating Capital Credits](#) and [Capital Credit Retirement](#) for more information.

Creating Pending Events

Events may be created in pending or complete status. Only complete events cause the completion event algorithms to run and [cause other actions to occur](#). You may use the status of pending if you want to review the calculated amount prior to completing the event.

For example, when a cooperative runs the background process to [allocate capital credits](#), it may create the new events in the pending status. This allows the co-op to review the total amount of capital credits calculated for all members. If this total is in line with the co-op's expectations, they run the background process again creating the new events in complete status. Only at this point do the completion event algorithms run.

Events May Be Transferred

In some situations, you may want to transfer service credit events from one membership to another on the [service credit event](#) page. For example, if a member dies, you may decide to transfer earned service credits to the membership for a beneficiary. When transferring a service credit:

- The target membership must be of the same membership type as the original membership.
- The original service credit event is canceled and any event cancellation algorithms linked to the [SC event type](#) are executed.
- A new service credit event is created and completed and any event completion algorithms linked to the [SC event type](#) are executed.
- The new service credit event references the original event ID in the **Transferred From** event field.

NOTE:

Contributed to FTs linked to the original event are not transferred to the new event. If you have created by FTs linked to the original event, the recommendation is to ensure that an event cancellation algorithm cancels this FT and that an event completion algorithm for the new event creates an appropriate new FT for the new membership.

CPCRALOC - Allocating Capital Credits

The base product provides a background process (CPCRALOC) that allocates capital credits to members of a cooperative. The result of this process is the creation of new service credit events for capital credit memberships. This background

process is typically run after the profits for the previous year are calculated. During that time, this job could be run a number of times for any of the following reasons:

- At the beginning of the allocation process, you may know the total amount to allocate to all members; however, you may estimate the allocation factor that determines the individual amounts that get distributed to the members. You may need to change your estimate and rerun the process until all the individual allocations add up to the desired total amount. To run the job with the estimated allocation factors, indicate that you want events created as pending. When you confirm the correct allocation factor, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type, subcategory and fiscal year. Refer to [Creating Pending Events](#) for more information.
- If the cooperative has more than one subcategory, the process must be run for each subcategory. In fact, the above trial-and-error process may need to be followed for each subcategory.

You must provide the [service credit event type](#) to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type. To calculate the capital credit allocation, the system finds all applicable bill segments for each [service agreement that contributes to the membership](#).

Capital credit allocations are calculated for a specific [fiscal year](#). The fiscal year is input to the background process and is stamped on any new events created by the process. The system also uses the fiscal year to determine the applicable bill segments for the membership's SAs. It uses the bill segment's accounting date and the [accounting calendar](#) to determine the fiscal year for each bill segment.

NOTE:

Canceled Bill Segments. Any bill segments that were canceled in the fiscal year are included as well.

Accounting Calendar. This process assumes that only one accounting calendar exists for the company. This is the case for companies that operate in a single jurisdiction, which is true for cooperatives.

Allocation Period. If the membership was only effective for part of the fiscal year, the allocations are only calculated for the period of time that the membership was in effect.

For each applicable bill segment, the system determines the SQ total and the total sales amount for each segment. To calculate the totals correctly, a characteristic type and value to identify SQ bill lines must be provided to the background process and a characteristic type and value to identify bill lines contributing to the total sales amount must be provided to the background process.

FASTPATH:

Refer to [Identifying SQ and Sales Information for Historical Bill Segments](#) for more information.

If your membership type indicates subcategories to be used for the events, you must provide a subcategory as input. If you have multiple subcategories for your membership, this process must be run once for each subcategory.

The calculation of the capital credit allocation amount typically uses an allocation factor. This factor is often different for each subcategory. You will probably define a different bill factor for each subcategory and use the appropriate bill factor when submitting the process for each subcategory.

This process also assumes that the allocation factor differs by the customer's revenue class. It assumes that the bill factor's characteristic type is revenue class. Refer to [Designing Bill Factors for Credit Allocation](#) for more information. For each service agreement linked to the membership, the appropriate allocation factor is determined based on the revenue class for the SA type.

Capital credits for the input subcategory are calculated as follows:

Fiscal year sales amount - (fiscal year SQ amount * revenue class allocation factor) = Allocation Amount

The calculated amount is compared against a minimum amount, input to the background process. If the calculated amount is less than the minimum, no event is stored for this amount.

After determining the amount, a new service credit event is created for the membership. The event is stamped with the input subcategory, service credit event type and fiscal year.

The FTs for all the bill segments used to determine the allocation amount are linked to the event as contributed to FTs. Refer to [Financial Transactions for an Event](#) for more information.

NOTE:

Rerunnable Process. This process is restartable and rerunnable. When running the process, for each membership the system checks whether there is already a complete event for the input service credit event type, subcategory and fiscal year. If so, it does not create a new event.

FASTPATH:

Refer to CPCRALOC for more information.

CPCRRETR - Capital Credit Retirement

NOTE:

Calculation Method. There are various calculations that different cooperatives may use when determining the amount to retire. The base product has provided one calculation method.

This background process is run when a cooperative is ready to pay out allocated capital credits to its members. This process is referred to as retirement. The result of this process is the creation of new service credit events for capital credit memberships. Capital credits are paid as the cooperative's financial position permits. During that time, this job could be run a number of times for any of the following reasons:

- You may choose to run the process and [create pending events](#) to review the results prior to finalizing the retirement. When you are happy with the results, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type and subcategory.
- If the cooperative has more than one subcategory, the process may be run separately for each subcategory. You may also run the process with no subcategory indicated and then all subcategories are processed.

NOTE:

Partial Retirement. For some cooperatives there may be capital credits for some allocated amounts that are never retired. If that is the case, simply run this process for each subcategory whose amounts do get retired.

You must provide the [service credit event type](#) to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type.

This process receives a percentage to retire as input. It determines the current balance of all completed events for the subcategory. The retirement amount for the subcategory is calculated as the current balance * input percentage to retire. The process then determines the outstanding balance for each subcategory and fiscal year combination. For every combination that still has a balance, the process creates events to relieve the outstanding balance for the oldest fiscal year first. It creates events for subsequent fiscal years until the full retirement amount is used.

In order for the process to be rerunnable and restartable, a Control ID is used to mark retirement events that are created by the process. The Control ID is input to the routine and is determined by the user. When the process runs, it determines whether an event already exists for the subcategory / Control ID combination. If so, new events are not created for that subcategory. If you run the process multiple times for the reasons described above, you should use the same Control ID each time. This way the system knows that the process is being run again for the same retirement calculation.

FASTPATH:

Refer to CPCRRRETR for more information.

Maintaining Service Credit Memberships and Their Events

The topics in this section describe how to maintain a service credit membership and its events.

FASTPATH:

Refer to [The Big Picture Of Service Credits](#) for background information about service credits.

Service Credit Membership

The topics in this section describe how to maintain service credit memberships. Refer to [The Big Picture Of Service Credit Membership](#) for background information about memberships.

Lifecycle of a Membership

The following diagram shows the possible lifecycle of a service credit membership.

Pending A service credit membership may start out in the Pending state. A membership is typically created in this state if the creation of the membership requires approval or any manual step (e.g. waiting for paperwork) that needs to be completed prior to activation.

NOTE:

Events for Pending Memberships. Service credit events may still be created for membership records in the Pending state.

Active A service credit membership is in the Active state when a customer is actively participating in a service credit membership. A membership may be created in the Active state or it may transition to the Active state from Pending when all the necessary approval or paperwork is complete.

NOTE:

Manual Activation Only. There is no system functionality that automatically changes the status of a membership from Pending to Active. This is a manual step.

Inactive If a customer is no longer actively participating in a service credit membership, change the status to Inactive. This will prevent any new events from being created for the membership.

Service Credit Membership - Main

This page is used to maintain and display general information about a service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search.**

Description of Page

Membership Info and **Membership ID** are displayed on every page. These values only appear after the membership exists on the database. The **ID** is a system-assigned random number. The **Membership Info** is a concatenation of important details about the membership.

Membership Status defines the state of the membership.

FASTPATH:

Refer to [Lifecycle of a Membership](#) for more information about membership status.

Click the **Activate** button to activate a Pending membership. When this button is clicked, the system executes any Membership Activation algorithms that are linked to the [service credit membership type](#).

Click the **Inactivate** button to transition an Active membership to Inactive. When this button is clicked, you are prompted to provide an **Inactive Reason** and the system executes any Membership Inactivation algorithms that are linked to the [service credit membership type](#).

Indicate the **SC Membership Type**. This field is important as it controls numerous aspects of the behavior of the membership and its events.

FASTPATH:

For more information about what the membership type controls, refer to [Setting Up Service Credit Membership Types](#).

Indicate the **Start Date** and **End Date**, which define the period for which this membership is effective. Leave the end date blank if this membership is effective indefinitely. Refer to [Stopping a Membership vs. Inactivating a Membership](#) for more information.

If this membership is related to a record in an external system, use the **External ID** to indicate the unique identifier of the record in the external system.

If events linked to your membership may generate miscellaneous adjustments, indicate the **Service Agreement** to use for these [miscellaneous transactions](#). The account for this service agreement must be one of the accounts linked to the membership.

The **Events** grid displays the events linked to the membership. To view any of the events use the drill down button.

If your SCM type indicates that the membership has a balance, the tree at the bottom displays information about the balance of the membership based on the amounts for completed events. If the SCM Type indicates subcategories and/or a fiscal year is required, subtotals for completed events are also displayed for each subcategory / fiscal year and by fiscal year / subcategory, if applicable. If any pending events exist, the tree includes a node with information about these events.

Service Credit Membership - Account

This page is used to maintain the accounts linked to a service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Account** page.

Description of Page

Indicate the **Account ID** for each account linked to this membership. Typically a membership will be linked to only one account. However, if a person has multiple accounts and the service credits should span the accounts, multiple accounts are linked to the same membership.

The Service Credit Membership zone on the Account Information portal contains information about memberships for the current customer. (When you find one of the customer's records on [Control Central - Search](#), you are automatically transferred to the [Account Information](#) portal.)

NOTE:

Portal Preferences. The Service Credit Membership zone only appears if you have modified your preferences to display this zone.

Service Credit Membership - Characteristics

The characteristics page contains information that describes miscellaneous information about the service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Characteristics** page.

Description of Page

NOTE:

Characteristic Types. You can only choose characteristic types defined as permissible on the service credit membership record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click + to insert a row then fill in the information for each field. The following fields display:

Effective Date Define the date on which the characteristic becomes effective. The effective date defaults from the [Installation Record](#).

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

NOTE:

Default Note. A service credit membership's characteristics default from the [service credit membership type](#).

Service Credit Membership - Membership Tree

The membership tree page displays accounts, SAs and persons linked to the service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Membership Tree** page.

Description of Page

The tree displays each account linked to the membership. For each account, a node exists for:

- Each service agreement whose SA type is included in the service credit [membership type](#) 's SA type collection.
- Each financially responsible person linked to the account. These persons are considered the [members](#).

Maintaining Service Credit Events

Service credit events record credits earned or redeemed for a given membership. The topics in this section describe how to maintain service credit events. Refer to [The Big Picture of Service Credit Events](#) for background information about memberships and their events.

Lifecycle of a Service Credit Event

The following diagram shows the possible lifecycle of a service credit event.

Pending A service credit event may start out in the Pending state. An event is typically created in this state when a review of the event is desired before completing it. Refer to [Creating Pending Events](#) for more information.

Complete A service credit event is typically created in the Complete state. When an event is completed, the system executes any event completion algorithms indicated on the [service credit event type](#).

Canceled If a service credit event is no longer valid, it may be Canceled. When an event is canceled, the system executes any event cancellation algorithms indicated on the [service credit event type](#).

Service Credit Event - Main

Open this page using **Menu > Customer Information > Service Credit Event > Search**.

Description of Page

The **Service Credit Event Info** is a concatenation of important details about the service credit event. The **Service Credit Event ID** is a unique system-assigned random number. These values only appear after the service credit event exists on the database.

Service Credit Event Status defines the state of the service credit event.

FASTPATH:

Refer to [Lifecycle of a Service Credit Event](#) for more information.

Click the **Complete** button to change a Pending event to Complete. When this button is clicked, the system executes any event completion algorithms that are linked to the [service credit event type](#).

Click the **Transfer** button to transfer this event to another membership. When this button is clicked, you are prompted to provide the membership ID to transfer the event to. The new membership must have the same membership type as the original membership. Refer to [Events May Be Transferred](#) for more information.

Click the **Cancel** button to cancel this event. When this button is clicked, the system executes any event cancellation algorithms that are linked to the [service credit event type](#).

The **Create Date/Time** captures the date and time that this event was created. This defaults to the system date/time.

Indicate the service credit **Membership ID** to which this event should be linked.

Indicate the **Service Credit Event Type**. This field may define algorithms to be executed when the event is completed or canceled. Refer to [Setting Up Service Credit Event Types](#) for more information.

If your [service credit membership type](#) indicates one or more subcategories to be associated with events for this type of membership, indicate the appropriate **Subcategory Name** for this event.

If your [service credit membership type](#) indicates that fiscal year is required, indicate the appropriate **Fiscal Year** for this event.

Enter the **Service Credit Event Amount**. If your [service credit membership type](#) indicates that your membership has a balance, this amount is used to calculate the overall balance for the membership as well as a balance for the subcategory and/or fiscal year, if applicable.

If this event was created as a result of a transfer from another membership, the **Transferred From Event ID** is displayed.

If the information about this event may be [downloaded to a third party](#) system, you should have an event completion algorithm that stamps the appropriate **Batch Control** and **Batch Number** onto the event.

The FT collection displays information about [financial transactions related to this event](#). Two different categories of financial transactions may be linked to the event.

- FTs that contributed to this event. These financial transactions played a part in the creation of this event. For example, if frequent flier miles are earned as a result of newly created bill segments, the FTs related to these bill segments are linked to the event and marked as contributed to FTs. This information is purely for audit purposes. It is the responsibility of the algorithm or background process that creates the event to populate the collection of contributed to FTs. Refer to [How Events Are Created](#) for more information.

NOTE:

The amount of the contributed to FTs will not necessarily add up to the amount of the event. Refer to the algorithm or background process that calculates the amount of the event to understand how the event amount is calculated based on the amount of the contributed to FTs

-
- FTs that were created by this event. These financial transactions are created as a result of this event. For example, if you have generated a capital credit allocation event, perhaps you need to post information to the general ledger. An allocation event should therefore generate an adjustment to post the effect on the GL. The adjustment's FT is linked to the event as an audit. In order to create a financial transaction related to this event, you must plug in an appropriate event completion algorithm on your [service credit event type](#).

FASTPATH:

Refer to [An Event May Cause Other Actions to Occur](#) for more information.

Loans

There are many reasons why your company may loan money to customers. For example, your company may loan money to:

- Finance service upgrades (e.g., to change to dual fuel)
- Support economic development (e.g., to extend a power line)
- Promote energy conservation (e.g., customers borrow to insulate their house)

NOTE:

Loans are optional. You need only set up loans if your organization loans money to customers. For information on setting up the system to enable loans, refer to [Defining Loan Options](#).

The Big Picture Of Loans

The topics in this section provide background information about loans.

Loans Are Service Agreements

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA type) contains the loan's terms, including the loan amount, periodic payment amount, the number of amortization periods, the interest rate, and the periodicity of the bills. Loan service agreements are just like other service agreements in many ways:

- The system bills the customer for the periodic payment amount using information on the service agreement.
- The customer pays the billed amount.
- If the customer doesn't pay, [credit and collections](#) may start a collection process to encourage the customer to pay (depending upon how the loan debt class has been set up on your system).

Loan service agreements differ from other service agreements in the following ways:

- Loans have [interest charges](#).
- Loans have [amortization schedules](#).
- Loan SAs are maintained on a separate transaction (refer to [Loan - Main](#) for more information).

NOTE:

Loan service agreements are created using Start/Stop. Loan service agreements are created using [start/stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

Loan Interest Charges

When a bill is generated for a loan, the interest charge is calculated using an algorithm. The base package loan interest charge algorithm type (LINT-SI) calculates simple interest based on:

- Unbilled principal (i.e., the payoff balance minus the current balance)
 - The number of billing periods covered by the bill
 - The interest rate
-

NOTE:

No interest on interest and no interest on past due amounts. Just like a classic home loan, the base package algorithm does not calculate interest on interest, nor does it calculate interest on past due amounts. However, your system may be set up to levy a late payment charge.

After the interest charge is calculated, the bill segment FT algorithm generates the financial transactions for the bill. The base package FT algorithm generates a financial transaction that adds the interest charge to the payoff balance. In other words, if the customer wanted to pay off the loan, they would owe the principal balance plus the interest charge.

FASTPATH:

For more information, refer to [Billing For Loans And Interest Calculation](#).

Loan Amortization Schedules

A loan's periodic payment amount is calculated such that the customer repays the loan in equal amounts over the term of the loan (with the exception of the first and last bill segments, which are typically for different amounts). The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

The amortization schedule is a theoretical projection of the future. The term theoretical is used because the customer's actual payments can cause the schedule to change. For example, if a customer overpays a bill, the loan's length decreases and the amount of principal and interest in each scheduled payment changes.

A loan's amortization schedule is calculated when you click the **Calculate** button on [Loan - Main](#). When this button is clicked, an algorithm plugged in on the loan SA type actually calculates the amortization schedule.

You can view a loan's latest amortization schedule using [Loan - Main](#). You can also change the loan's payment periods or periodic payment amount on this page and recalculate the loan's amortization schedule.

Negative Amortization

The system does not allow you to use a periodic payment amount that is less than the periodic interest amount. If it did, the customer's payoff balance would increase over time (this is referred to as "negative amortization"). There are two methods you can use to specify a payment amount in the system. Depending on which method you use, the system informs you of negative amortization differently:

- If you enter a payment amount that is too small on the Start confirmation page or in the **Renegotiate Future Payments** grid on [Loan maintenance](#), you get an error message when you click the **Calculate** button. You must fix the payment amount before you can start the loan or save your changes.
- If you manually override the **Payment Amount** on [Loan maintenance](#), you can save a payment amount that is too small to cover the interest charges. However, the system notifies you that it is not able to calculate the **Forecasted Schedule** because of negative amortization. Additionally, bill segments for the loan SA are produced in error until the payment amount is adjusted appropriately.

Loan Overpayments

Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan. When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Typically, loan service agreements should be set up so that the overpayment is applied to the principal balance.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to transfer the amount of the credit from the SA's current balance to its payoff balance, thus reducing the principal by the amount of the overpayment.

FASTPATH:

For more information about the adjustments created for loan overpayments, refer to [Overpayments On Loans](#).

NOTE:

Overpayments and interest. The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

The Lifecycle Of A Loan

Loans have the same [lifecycle as other service agreements](#) (e.g., pending start, active, pending stop). You should rarely have to manually change a loan service agreement's status. Why? Just like other service agreements, the system changes the status behind-the-scenes when various events take place. For example, loans in the pending start state are automatically activated by a system background process.

If you need to manually change a loan service agreement's status (e.g., you need to cancel a loan that was inadvertently started), you can do so from [Service Agreement - Main](#).

Finalizing And Closing A Loan

A loan SA is automatically stopped when the last bill segment is generated for the loan. If the remaining principal balance (plus accrued interest) is less than or equal to the loan payment amount, the SA status is changed to pending stop and the bill segment is marked as the closing bill segment. The SA can then be stopped by the user (manually using the SA page) or by the SA activation background process. When the customer pays the last bill, the loan SA is closed.

FASTPATH:

For more information about transitioning SAs from pending stopped, refer to [Finalizing Pending Stops](#).

Navigating To The Loan Maintenance Page

Any of the following methods can be used to navigate to the [Loan Maintenance](#) transaction:

- A user can set up a [favorite link](#) associated with the loan transaction.

- Via any of the following menus:
 - Account context menu
 - Service agreement context menu
 - Menu

NOTE:

Alerts and Loans. If the loan SA type is set up with an alert, the [Alert Zone](#) highlights if a loan exists for the current account. You are transferred to the SA maintenance transaction (not the loan maintenance transaction) if you drill down on the alert.

Loan Maintenance

You can use loan maintenance to view the loan's amortization schedule and financial history as well as to change the terms of a loan, including the loan amount (prior to SA activation only), interest rate, payment amount and number of payment periods.

NOTE:

Starting Loans. You cannot start a loan from Loan - Main; you must use Start/Stop. Refer to [How To Start A Loan Service Agreement](#) for information.

Open **Menu > Customer Information > Loan > Search** to maintain a loan.

Description of Page

The fields at the top of the page are informational only. The **Payoff Balance** is the total amount owed by the customer (excluding any interest that may have accrued since the last bill). The **Current Balance** is the amount currently owed by the customer. The **Principal Balance** is the total principal amount left unbilled. Refer to [Payoff Balance and Current Balance for Loans](#) for more information.

The **Loan Amount** is the amount originally loaned to the customer. The **Standard Interest Rate** is the standard interest rate defined on the loan's SA type. If the SA type allows, the standard interest rate may be overridden by a start option and/or manually. The **Next Payment Amount** is the effective periodic payment amount as of the next bill.

The **Payment(s)** shows the number of payments that were used to calculate the original loan schedule.

The **Override Interest Rate** grid is used to override the standard interest rate. The interest rate can only be modified if the loan's SA type allows it. Note that changing the interest rate changes the loan amortization schedule. To override the interest rate:

- Specify an **End Date** for the override rate in effect if there is one.
- Click + and specify the **Start Date** and the new **Interest Rate**. You can also specify the **End Date** of the new override rate, but this is not required.

The **Payment Amount** grid is used to maintain the effective periodic payment amount. Note that changing the payment amount changes the amortization schedule. To change the payment amount:

- Click + and specify the **Effective Date** and the new payment **Amount**.

NOTE:

Entering a payment amount that is too small. If you save a payment amount that is too small to cover the periodic interest charges, this causes [negative amortization](#). The system is not able to recalculate the amortization schedule and bill segments are produced in error until the problem is corrected.

The **History** grid shows the loan's financial history in reverse chronological order. The financial history grid displays the following information:

- The **Arrears Date** is used to compute how many days old the debt is. In the context of a loan, debt only refers to the billed amount (the amount the customer needs to pay to stay current).
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.
- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.
- **Payoff Amount** is the effect of the FT on the service agreement's payoff balance. The value is grayed out if it is the same as the current amount.
- **Payoff Balance** is the total amount owed by the customer. The value is grayed out if it is the same as the current balance.

WARNING:

If you do not understand the difference between payoff balance and current balance, refer to [Payoff Balance And Current Balance For Loans](#).

The **Forecasted Schedule** displays the loan amortization schedule. The first row of the schedule shows the current cumulative interest, current cumulative principal and the current principal balance. All other rows show the future amortization schedule based on the loan details. The forecasted schedule includes the following information:

- The **Loan Period** displays the forecasted payment period dates based on the billing frequency and the payment periodicity. The Loan Period is blank for the first row, which shows current cumulative amounts.
- The **Amount** displays the projected amount of that payment. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Interest** displays the projected amount of interest in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Principal** displays the projected amount of principal in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Cumulative Interest** is the total interest amount that would theoretically be billed at that loan period.
- The **Cumulative Principal** is the total principal amount that would theoretically be billed at that loan period.
- The **Principal Balance** is the remaining principal balance that would theoretically be remaining at the loan period.

NOTE:

Forecasted schedule. The loan schedule algorithm calculates the values in the forecasted schedule. Depending on the algorithm set up for your installation, the values may have a different meaning.

The **Renegotiate Future Payments** area allows you to change the terms of the loan. You can modify the following options:

- You can modify the **Loan Amount** only if the SA has not been activated. After the SA is activated, this field is for information only.
- The **Interest Rate** allows you to change the interest rate. When changing the interest rate, specify either the number of payment amounts or the payment amount and click Calculate to recalculate the amortization schedule.
- The **Number of Payment Periods** allows you to change the number of periods remaining in the loan's term. The **Frequency** displays the periodicity of the payments. If you change the number of payment periods, use the Calculate button to recalculate the payment amount.
- The **Payment Amount** allows you to change the amount of individual payments. If you change the payment amount, use the Calculate button to recalculate the number of periods.

- The **Calculate** button recalculates the payment amount (when you specify the interest rate and the number of payment periods) or the number of payment periods (when you specify the interest rate and the payment amount) and recomputes the loan amortization schedule based on these new terms.

NOTE:

Implementing New Loan Terms. The changes that you make using **Override Interest Rate, Payment Amount** and **Renegotiate Future Payments** do not take effect until you save the loan. Changes made to the **Renegotiate Future Payments** section are only valid for save after you click Calculate, and they override any other changes.

Saving Renegotiated Future Payments. When you save a loan that has renegotiated payments, the system may add new records for the override interest rate, payment amount, or both. It uses the start date of the next loan period as the start date of the new interest rate and/or as the effective date of the new payment amount. If the loan has not yet been billed, the system updates the interest rate and/or payment amount created when the loan was started.

How To

The topics in this section describe how to perform common loan functions.

How To Start A Loan Service Agreement

Loan service agreements are created using [start/stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above.

Creating a loan service agreement involves the following steps:

- Select the account on Control Central then open Start/Stop.
- Enter a **Start Date** and a **Start Method** of Start a SA.
- Indicate the **CIS Division / SA Type** of the loan service agreement and click the **Start** button.

NOTE: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

- After you click **Start**, the Start Confirmation page appears. When you select a loan service agreement type, the Start Confirmation page displays special fields that allow you to specify the loan's terms.
- Select a loan **Start Option**. The start option includes the adjustment type for booking the principal amount, and can also include defaults for the initial loan amount, periodic payment amount, payment periods, and interest rate. The system uses the information on the start option to populate the service agreement's default parameters. You can manually override these parameters:
 - Enter the **Loan Amount** (the amount that the customer is borrowing). Note that the label for the Total Amount To Bill (e.g., Loan Amount) may appear differently depending on how the SA type was defined.
 - The system can automatically calculate either the payment amount (based on the loan amount and the payment periods) or the payment periods (based on the loan amount and the payment amount). Enter either the **Payment Amount** or the **Payment Periods** and click **Calculate**. Note that the label for the Recurring Charge (e.g., Payment Amount) may appear differently depending on how the SA type was defined.
 - Once the loan parameters are populated, click **Start**.

The loan is created in the pending start state. The next time the SA activation process runs, it will activate the loan SA. If you want to activate the loan immediately, navigate to the service agreement page and click **Activate SA**.

NOTE:

Overriding the Interest Rate. The **Interest Rate** is a display only field. The interest rate is taken from the value of the interest bill factor defined on the SA type or the contract value of the interest bill factor on the start option if one is defined. After starting a loan, you can manually override the interest rate using [Loan - Main](#) if the SA type allows it.

Changing The Loan Amount. You can use loan maintenance to change the loan amount for an SA as long as the SA has not yet been activated. It may be helpful to transfer to [Loan - Main](#), and verify the amortization schedule before activating the SA.

How To Modify The Terms Of A Loan

After a loan is active, you may want to modify its terms. You can change number of payment periods, the payment amount, and the interest rate (if allowed by the SA type). To modify the terms of a loan:

- Navigate to the [Loan maintenance](#) page.
- If you used the account context menu, the loan you want to modify may be displayed. If not, use the search dialog that appears to search for and select the loan you want to modify.
- In the **Renegotiate Future Payments** section, change the interest rate (if allowed), the number of payments, or the payment amount. Note that either the number of payments or payment amount must be blank.
- Click **Calculate**. The **Forecasted Schedule** is recalculated along with either the new payment amount or the new number of payments (depending on which was left blank).
- If the renegotiated payments are satisfactory to the customer, save the changes.

When you save the changes, appropriate entries are made in the **Override Interest Rate** and **Payment Amount** grids.

NOTE:

Saving Loan Modifications. You must save the renegotiated payments after clicking Calculate for the loan modifications to be effective.

How To Adjust Loans

You issue ad hoc adjustments if you need to change a loan's principal and/or current balance outside of the normal billing and payment functions.

An adjustment can:

- Change a loan's payoff balance.
 - Change a loan's current balance (i.e., how much the customer thinks they currently owe).
 - Change both the loan's payoff and current balance.
-

FASTPATH:

For details about the adjustment types to apply, refer to [Adjusting Loan Amounts](#). For information about creating adjustments, refer to [Adjustments](#).

How To Stop A Loan Service Agreement

Normally, a loan SA is automatically stopped when the bill segment for the last payment in the amortization schedule is generated for the loan (refer to [Finalizing And Closing A Loan](#)).

If a customer decides to payoff a loan before the term is complete, you can:

- Transfer to the SA maintenance page for the loan service agreement, specify an **End Date** for the loan, and click Save. This transitions the loan SA to pending stop.

NOTE:

End Date. The loan SA cannot be stopped until the specified end date is reached, so do not specify an end date that is in the future unless you do not want to stop the loan until that date.

Once the loan is in pending stop and the end date has been reached, the system transitions the loan SA to stopped. On the service agreement's normal bill cycle, the system final bills the SA for any outstanding balance plus accrued interest charges.

If you want to stop the loan and create the final bill immediately, complete these additional steps:

- On the loan's SA maintenance page, click the Stop SA button to transition the loan SA to stopped.
- Manually, [create a bill](#) for the loan service agreement. Remember that if you only want to generate a bill segment for a specific service agreement (e.g., the loan service agreement), transfer to the bill segment page. From there, you can generate and freeze a bill segment for a specific service agreement. When finished, return to the bill page and complete the bill.

When the customer pays the final bill, the loan SA is closed by the system.

FASTPATH:

For more information about SA states, refer to [The Lifecycle Of A Service Agreement](#).

Non-Billed Budgets

A Non-Billed Budget (NBB) is a payment plan used to level out a customer's payments over time. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. For example:

- Rather than receive a bill once a quarter, a customer could set up a Non-Billed Budget to pay fortnightly
- Rather than pay two large bills a year, the customer could set up a Non-Billed Budget to pay 10 out of 12 months (sparing themselves during the holiday season)

Non-Billed Budgets can cover one or more service agreements linked to the same account. You can have multiple active Non-Billed Budgets for an account, but any given service agreement can only be covered by a single Non-Billed Budget at any point in time.

NOTE:

Non-Billed Budgets are optional. The business processes described in this section are only relevant if your organization offers Non-Billed Budgets to its customers.

FASTPATH:

For information about setting up non-billed budget functionality for your system, refer to [Defining Non-Billed Budget Options](#).

The Big Picture Of Non-Billed Budgets

The following topics provide background information about Non-Billed Budgets.

Non-Billed Budget Service Agreements

Non-Billed Budgets are initiated by creating a Non-Billed Budget service agreement for a customer. The Non-Billed Budget SA and its SA type maintain the details of the Non-Billed Budget, such as recommendation rules, covered SAs, scheduled payments and credit balance. Non-Billed Budgets are just like other service agreements in some ways:

- Non-Billed Budgets have a current and a payoff balance.
- If the customer doesn't pay a monitored Non-Billed Budget, credit & collections may start a collection process to encourage the customer to pay (depending upon how the debt class has been set up on your system).

Non-Billed Budgets differ from other service agreements in the following ways:

- Non-Billed Budgets have a special role of Non-Billed Budget.
- Non-Billed Budgets have scheduled payments.
- Non-Billed Budgets maintain a list of covered SAs (utility and other service agreements to which the Non-Billed Budget applies)
- Non-Billed Budgets are started and maintained on a separate transaction (refer to [Non-Billed Budget - Main](#) for more information).

Which SAs Are Covered By A Non-Billed Budget?

A Non-Billed Budget can apply towards one or more of the account's billable SAs whose SA type is flagged as Eligible for Non-Billed Budget. SAs can be added to or removed from a Non-Billed Budget at any time. Additionally, an SA can be linked to more than one Non-Billed Budget as long as the Non-Billed Budgets to which it is linked do not have overlapping start and end dates.

A list of the SAs covered by a non-billed budget is maintained with the Non-Billed Budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Non-Billed Budgets Versus Other Plans For Payment

Unlike a regular budget but like a payment plan, a Non-Billed Budget has one or more scheduled payments. However, unlike payment plans, bills are not produced for the scheduled payment amounts. Instead, customers are simply notified of the payment schedule and it is their responsibility to make the scheduled payments. In general, the following statements highlight the differences between Non-Billed Budgets and other payment plans.

- There is a payment schedule that is not dependent on billing, unlike [budget plans](#).
- Non-Billed Budgets are not limited to SAs of a single debt class, unlike [pay plans](#).
- Debt is not transferred from regular SAs to the non-billed budgets, unlike [payment arrangements](#).

WARNING:

Non-Billed Budgets and Budget Plans! An SA should not be on a Non-Billed Budget if it is on a [budget plan](#). A Non-Billed Budget overrides any budget functionality in most cases. However, placing an SA that is on a budget on a Non-Billed Budget may result in indeterminate results. For example, when the Non-Billed Budget is broken, the stop algorithm for the Non-Billed Budget syncs current and payoff balances for those utility SAs that were covered by the Non-Billed Budget.

There Are Two Types Of Non-Billed Budgets

There are two types of Non-Billed Budgets: monitored and unmonitored. As the terms suggest, the difference between monitored and unmonitored Non-Billed Budgets is whether they are monitored by the account debt monitor. However, this also means that monitored and unmonitored Non-Billed Budgets receive different financial treatment by the system.

In general, monitored Non-Billed Budgets have their current balances monitored by the account debt monitor while the current balances of any covered SAs are zero (and therefore don't violate any debt collection criteria). With monitored Non-Billed Budgets, customers make required prepayments that are applied towards their utility bills (until the Non-Billed Budget is stopped). They are responsible for making sure the payments on their Non-Billed Budget are up to date, but they do not have to payoff any balances on covered SAs.

Unmonitored Non-Billed Budgets do not have their current balances monitored by the account debt monitor while the current balances of any covered SAs are maintained and therefore subject to the account debt monitor. When customers are set up on an unmonitored Non-Billed Budget, the payments that they make towards the budget are optional. They are, however, financially responsible for paying the current balances of any covered SAs.

FASTPATH:

Refer to [Financial Transactions For Unmonitored Non-Billed Budgets](#) for detailed information about the financial differences between monitored and unmonitored Non-Billed Budgets.

NOTE:

SA Type Determines Monitored Status. The SA type that you select when setting up a Non-Billed Budget determines whether it is monitored or unmonitored (i.e., it's a setting on the SA type). Your company may choose to implement only monitored non-billed budgets, only unmonitored Non-Billed Budgets, or both.

Navigating To The Non-Billed Budget Maintenance Page

Any of the following methods can be used to navigate to the [Non-billed Budget Maintenance](#) transaction:

- An alert in the [Alert Zone](#) highlights if a Non-Billed Budget exists for the current account. You are transferred to the non-billed budget transaction if you drill down on the alert.
- You can setup an order's [campaign](#) to automatically transfer a user to the Non-Billed Budget transaction whenever an order is completed for a given SA. This might be useful for campaigns that are associated with services that are typically on a Non-Billed Budget.
- A user can setup a [favorite link](#) associated with the Non-Billed Budget transaction.
- Via any of the following menus:
 - Account context menu
 - Service agreement context menu
 - Menu menu

Recommending Scheduled Payments

When creating a Non-Billed Budget, you must select a recommendation rule. The recommendation rule establishes the amount to be paid and the dates on which the payments are due. In other words, the recommendation rule creates a recommended payment schedule.

The recommendation rules that you can use are specific to your implementation. The recommendation rule that you select can have default values for its parameters. If your implementation allows, you can manually override one or more of these default values. For example, you may be able to specify the period covered by the Non-Billed Budget and the day of the month on which the payments are due.

If your implementation allows, you can manually modify the recommended payment schedule to suit the needs of a particular customer.

FASTPATH:

Refer to [Designing Recommendation Rules](#) for more information.

Maintaining Non-Billed Budgets

Non-Billed Budget service agreements are started and maintained on a different transaction than other SAs. The topics in this section explain how to start and maintain Non-Billed Budgets.

Non-Billed Budget - Main

The Main page contains basic information about the Non-Billed Budget. Open **Menu > Customer Information > Non-Billed Budget > Search** to maintain this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The **SA ID** is a system assigned random number that stays with a service agreement for life. The **Non-Billed Budget SA** information is a concatenation of important details about the service agreement and its account.

The **Account ID** is identification of the account that is financially responsible for the service agreement.

Indicate the **CIS Division** and **SA Type**. These fields control aspects of the service agreement's behavior, such as whether the Non-Billed Budget is monitored or unmonitored. These fields are gray when the status is not Pending Start.

NOTE: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

FASTPATH:

For more information about Non-Billed Budget SA types, refer to [Defining Non-Billed Budget Options](#).

If **Scheduled Payment Auto Pay** is Included in Auto Pay and the account is set up for automatic payment, the scheduled payments are covered by auto pay. If Excluded from Auto Pay, the scheduled payments are excluded from auto pay if it is set up for the account.

Recommendation Rule is used to create a recommended payment amount and payment schedule. The SA type controls which recommendation rules are allowed for the Non-Billed Budget SA.

Current Balance indicates the amount the customer currently owes on the Non-Billed Budget. If the Non-Billed Budget is unmonitored, the current balance is always zero.

Payoff Balance displays the total amount the customer would owe if they wanted to close the service agreement. For Non-Billed Budgets, the payoff balance typically represents an accumulated credit that has not yet been distributed to the covered SAs (at bill completion time or when the Non-Billed Budget is stopped).

The **Start Date** defines when the financial relationship begins. The **End Date** is a display only field that indicates when the financial relationship terminates. The **Expiration Date** is the date on which the SA expires. The **Renewal Date** is the date on which the SA is scheduled to be renewed by the SA renewal background process. If the SA is not renewed by the expiration date, the stop process is initiated.

The **Recommendation Rule Parameter Values** grid specifies the parameters and their values to use for the selected recommendation rule:

- **Parameter** is the name of the parameter from the recommendation rule algorithm type.
- **Value** is the value used for the parameter. If the recommendation rule allows, you can override the default values by specifying your own.

NOTE:

The recommendation rule's payment schedule algorithm type (NBPS-MON) controls the number and type of parameters. The recommendation rule controls the default values and whether they can be overridden.

The **Covered Service Agreements** grid lists the utility and other SAs that are on the Non-Billed Budget. You must create the list of covered SAs before the recommendation rule can recommend a payment amount and list of scheduled payments. The grid displays the **SA ID**, **SA Information**, **Current Balance** and **Payoff Balance** for covered SAs.

The scheduled payments grid displays the scheduled payments created by the recommendation rule (after you click the Recommend NBB button). You can manually create or modify the **Scheduled Date** and or **Scheduled Amount** of any scheduled payment in the list. The **Total of Scheduled Payments** shows the total of all scheduled payments in the list.

FASTPATH:

Refer to [Scheduled And Actual Payments On The Non-Billed Budget](#) for more information on what occurs when the base [Non-Billed Budget scheduled payment background process](#) processes scheduled payments that are due.

In the Action grid:

- Click **Recommend** to create a recommended payment schedule based on the recommendation rule.
- Click **Renew** to manually renew the Non-Billed Budget. This executes the SA renewal algorithm for the SA type and returns new renewal and expiration dates for the SA.
- Click **Break** to manually cancel the Non-Billed Budget. This executes the break Non-Billed Budget algorithm defined for the SA type, and changes the status of the SA to pending stop.

Non-Billed Budget - History

The Financial History page displays the Non-Billed Budget's historical financial transactions. Open **Menu > Customer Information > Non-Billed Budget > Search** and navigate to the **History** page to view this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The SA ID is a system assigned random number that stays with a

service agreement for life. The Non-Billed Budget SA information is a concatenation of important details about the service agreement and its account.

The **Account ID** identifies who is financially responsible for the service agreement.

The grid shows the Non-Billed Budget's financial history in reverse chronological order, including:

- The **Arrears Date** is used to compute how many days old the debt is. For monitored Non-Billed Budgets, debt refers to the scheduled payment amounts (i.e., the customer only owes the scheduled payment amounts up to the most recent scheduled payment date). The arrears date for a schedule payment is the scheduled payment date.
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.
- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.

How To

The topics in this section describe how to perform common Non-Billed Budget functions.

How To Start A Non-Billed Budget Service Agreement

To set up a new Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account is not already specified, select the **Account** for which you want to start the Non-Billed Budget.
- Define the **CIS Division** and **SA Type** to use for the Non-Billed Budget service agreement.
- If necessary, change the **Start Date** (the current date is defaulted).
- Select the **Recommendation Rule** to use and modify any of the default parameters to meet the needs of the customer.
- Verify the list of **Covered Service Agreements**. All the account's SAs that are eligible for Non-Billed Budget are listed. Click  to remove unwanted SAs from the list.
- Click **Recommend**.
- On the pop-up dialog, specify the **Schedule Start Date** and click **Recommend**.
- Make any necessary changes to the expiration date, renewal date and scheduled payments grid and click Save.

How To Cancel / Stop Non-Billed Budget SAs

To stop a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to stop is not specified, select the **Account** of the Non-Billed Budget you want to stop.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to stop.
- Click **Break**.

How To Renew Non-Billed Budgets

Most Non-Billed Budgets are renewed automatically by a background process. However, you may manually renew Non-Billed Budgets that are eligible for renewal if desired.

To renew a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to renew is not specified, select the **account** of the Non-Billed Budget you want to renew.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to renew.
- If desired, change the recommendation rule or any of the parameters.
- Click **Renew**.

The new expiration and renewal dates are calculated and the new payment schedule is appended to the list of scheduled payments.

How To Set Up Automatic Payment For A Non-Billed Budget

If a customer wants to pay their non-billed budget scheduled payments automatically:

- Set up the account for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)).
- Navigate to the Non-Billed Budget Maintenance page and select the Non-Billed Budget for the account.
- Set the **Scheduled Payment Auto Pay** field to indicate that the scheduled payments are Included in Auto Pay.

Case Management

NOTE:

Separate module. The Case Management functionality is associated with a separate Case Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

Your organization can use case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

NOTE:

Your implementation controls how your cases behave. Since virtually all aspects of case management functionality are controlled by your implementation, you can use it to handle a myriad of business requirements. Refer to [Defining Case Management Options](#) for the details.

Background Topics

The topics in this section provide background information about case management functionality.

Case Type

A case is controlled by the case type that it references. Some aspects of the case that are controlled by the case type include:

- The [lifecycle](#) of the case
- The [applicability](#) of a person, account, and/or premise on the case
- Which [fields are required](#) during the various stages of a case's life
- Which users can [access cases](#) of a given type
- Additional processing that should take place when a case enters or leaves a given state

Refer to [Case Type Controls Everything](#) for a description of the business rules that you control when you set up your case types.

Creating Cases

To create a case, open the [case management](#) page in add mode, select the appropriate case type, fill in the other necessary fields, and click save. Oracle Utilities Customer Care and Billing also includes scripts that can help create cases. Refer to [Scripts and Cases](#) for more information.

You can also develop plug-ins and user exits to so that the system will create cases when specific events take place. For example, you could set the system to create a case when an umbrella agreement is ready for renewal or when a quote is created.

Please refer to [Maintaining Cases](#) for a detailed description of the case page and field descriptions.

Log Information

A case log contains an entry for every recorded event during the lifecycle of the case. There are two types of log entries:

- **Automatic entries.** The system automatically creates an entry in the log when a case is created or there is a [status change](#). Users cannot modify or delete these log entries.
- **Manual entries.** Users can add manual entries to record significant events at their discretion.

Refer to [Case - Main](#) for the page used to view the log.

Refer to [Case Statistics for a Given Status](#) for information about a report that uses the log to provide productivity statistics.

Alerts

The [alert zone](#) will highlight if the person / account / premise in context have cases in a state that is configured as "alertable" if you plug-in the appropriate algorithm on the installation record. Refer to [Alert Info Is Controlled By An Installation Plug-In](#) for the details.

To Do's and Cases

You can configure the system to inform users of cases that require their attention. Refer to [To Do's and Cases](#) for the details.

Reports

Several reports summarize case information. Refer to the [Reports](#) chapter for the details.

Maintaining Cases

Your organization can use the case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

NOTE:

Since an implementation can configure virtually every aspect of a case, the look and feel of the case management page are dynamic based on how [case types](#) have been configured.

Case - Main

Open the case management page by selecting **Menu > Customer Information > Case > Search**.

Main Information

Case Info contains a concatenation of important information about the case. **CaseID** is the system-assigned unique identifier of the case. These values only appear after the case is added to the database.

NOTE:

Formatting may be performed by a plug-in. Refer to [Case Info May Be Formatted By An Algorithm](#) for more information.

Case Type defines the type of case. This field is protected after the case has been added. Refer to [Case Type Controls Everything](#) for more information.

NOTE: Available case types can be restricted by CIS Division. The restriction of case type by CIS division is dynamic. It is based on the account in context, the premise in context, or the current user. The restriction of case type is applied using these rules in sequence.

- If there is an account in context and that account has a CIS Division, that CIS Division is used to restrict the case types that appear.
 - If there is a premise in context and that premise has a CIS Division, that CIS Division is used to restrict the case types that appear. Note: If there are both an account and premise in context, the account CIS Division is used.
 - If there is no account or premise in context with a CIS Division and the current user is associated with CIS Division(s) those CIS Division(s) are used to restrict the case types that appear. See [Users and CIS Division](#) for more information.
-

Status shows the current state of the case. Refer to [Case Lifecycle](#) for more information.

If the case has any To Do entries associated with it, a hyperlink will appear summarizing the number and status of the entries. You can select the link to view these entries. Refer to [To Do's and Cases](#) for more information.

Date / Time Opened shows when the case was created. If the case is in a final state, the **Date / Time Closed** will also be shown. Refer to [One Initial State and Multiple Final States](#) for more information.

Script references the business process assistant script that can help you work on the case. You can click on the hyperlink to execute this script. This field is hidden if no script is associated with this case's current Status. Refer to [Scripts and Cases](#) for more information.

The **Actions** section contains buttons you can use to action the case. This area is suppressed if no actions can be performed for the case given its current status. A button will be gray if you do not have security rights to the action. Refer to [Buttons Are Used To Transition A Case](#) for more information.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. If the case has been automatically transitioned to its current state the following message area appears right after the action area. If an error is encountered in the process a corresponding error message is displayed in the Auto-transition Message Area. Refer to [Automatic Transition Rules](#) for more information.

NOTE:

The Auto-transition Message Area only appears when a case has just been automatically transitioned to its current state online. It only remains visible until the data for the case is refreshed.

Use the **Comments** area to describe anything interesting or unusual about the case.

Person references the person associated with this case. This field is suppressed if the Case Type indicates that a person is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Person currently displayed in the Dashboard.

Account references the account associated with this case. This field is suppressed if the Case Type indicates that an account is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Account currently displayed in the Dashboard.

Premise references the premise associated with this case. This field is suppressed if the Case Type indicates that a premise is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Premise currently displayed in the Dashboard.

NOTE:

The case type controls the relationship validation among person, account, and premise.

Responsible User references the user who has overall responsibility for the case. This field is suppressed if the Case Type indicates that a responsible user is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final).

The **Contact Information** area is used to define how to contact the individual who initiated the case. These fields are suppressed if contact information is not allowed on cases of this type. The fields cannot be modified if the case is in a closed status. The following information can be defined.

Contact Person references the person who should be contacted. This defaults to the Person defined above.

Preferred Contact Method indicates how the person prefers to be contacted. The following options are available:

- Not Applicable. If the person doesn't want to be contacted (or the contact method is unusual), use this option. You might want to consider describing the situation in the Contact Instructions.
- Person Contact. If this method is selected, select a person contact related to the Person link to the customer contact. The customer contact must contain a Person to use this method.
- Postal. If this method is selected, the Contact Person's address appears. Refer to [Where Does The Address Come From](#) for a description of which address the system displays.

The following methods appear when the Legacy Person Phone and Email **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

- Email. If this method is selected, the Contact Person's email address appears adjacent.
- Phone. If this method is selected, the Contact Person's phone number appears.
- Fax. If this method is selected, the Contact Person's fax number appears (the system knows which of a person's phone numbers is a fax number by the phone type).
- SMS. If this method is selected, the Contact Person's short message service (SMS) information displays.

NOTE: While on a case, users can add a person contact by selecting Add Person Contact from a Person Context menu. This will open a portal-based page that allows a person contact to be added. This process will not lose context or information that has been added to the case. The new person contact can be used within the case.

Contact Instructions indicates any special instructions indicated for when or how to return a call.

Callback Phone Type, Callback Phone Number, and Extension indicate the actual phone number and phone type that should be used to call.

Characteristics

The **Characteristics** grid contains fields that contain important information about the case. This grid is suppressed if the Case Type does not use characteristics. This grid is protected if the case is closed (i.e., if its status is defined as being final).

You can only choose **Characteristic Types** defined as permissible for this case type. Refer to [Additional Information](#) for more information. If you attempt to use an **Action** to transition a case into a status that requires additional information, a pop-up will prompt you for the additional fields. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Case - Log

To view the log entries associated with a case, open by selecting **Menu > Customer Information > Case > Search** and navigate to the **Log** page.

Description of Page

The **Log** grid displays log entries (in reverse chronological order) that audit the progress of the case. Please note the following about the entries in this grid:

- The system automatically creates log entries when a case is created, every time its status changes, or whenever an error occurs during the transition of a case. Algorithms plugged into a case type state can also be configured to create log entries. You cannot modify or delete the log entries.
- You can manually add a log entry by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
- **Log Date/Time** contains the date and time the log entry was created.
- **Details** contains user-specified or system-generated information about the log entry.
- **Related Object** is populated on log entries that were created to record the creation of some other object. For example, if a case plug-in creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
- **Log User** contains the user who caused the log entry to be created.
- **Log Type** indicates how the log entry was created. The possible values are:
 - Created. Only one entry per case will be of this type. This entry is automatically created by the system when the case is created.
 - User Details. A user creates this type of entry manually.
 - Status Transition. This type of entry is created by the system each time the case's status is changed (as a result of pressing one of the Action buttons).
 - System. An algorithm on the case type state may be designed/configured to create this type of entry when it does something auditable. For example, an algorithm that creates a customer contact could insert a log entry to show that it did this (it will also populate the FK to the customer contact, which will appear in the **Related Object** column).
 - Transition Error. The background status transition process creates an entry of this type if an error occurs when automatically updating a case to a subsequent status (as directed by either an Enter Status algorithm or an Auto-Transition algorithm). An entry of this type lists the case states involved with the failed transition, and the algorithm in which the error was generated.
 - Exception. The background status transition process creates an entry of this type under the same circumstances as a Transition Error. A log entry of this type indicates why the background transition failed.

NOTE:

The values for this field are customizable using the Lookup table. This field name is CASE_LOG_TYPE_FLG.

Premise Management

NOTE:

Separate module. The Premise Management functionality is associated with a separate Premise Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The premise management functionality facilitates the following:

- Grouping premises together under a single parent premise

- Quick & efficient setup and maintenance of apartment complexes and high-rises
- A single view of properties for a landlord, including service status
- Ability to change the landlord or service status for a group of premises in one transaction
- And more...

The topics in this section describe premise management functionality.

Overview

The topics in this section provide background information about premise management functionality.

Define Premise Hierarchy

Premise management allows you to define premise hierarchy. For example, you could also have the notion of

- A building
- Multiple floors
- Multiple apartments per floor

To define this hierarchy you must create a [premise](#) for each level in the hierarchy and for each "child" premise, indicate its appropriate parent premise. Once you have set up your premise hierarchies, you may view the hierarchies on trees on the premise page and on the control central [premise tree](#).

In addition, the system provides the following [alerts](#):

- When viewing a parent premise, an alert indicates how many child premises exist
- When viewing a child premise, an alert indicates that it is linked to a parent premise.

Manage Premises for a Landlord

The premise management page provides the ability to view all the premises for the landlord along with information about the accounts linked to each premise.

You may use this page to assign, change or remove the landlord agreement for multiple premises in a single action. For example if a landlord sells their properties to another person, this page facilitates updating all premises with one action rather than changing the landlord for each premise separately. For example, if the landlord sells only a portion of their properties.

This page may also be used to start or stop service for one or more premises for the landlord. For example, a landlord plans to sell a high-rise apartment complex with 100 apartments. Imagine that 8 of these apartments are vacant and the landlord's account is currently paying for any usage to these apartments. In addition to changing the landlord agreement for all 100 apartments to the new landlord, the service for the vacant apartments should be transferred to the new landlord. A user can go to premise management, use the search criteria to view all premises for this landlord in a given apartment complex whose service is currently being paid for by the landlord and start service for these premise for the new landlord. (Using the back-to-back start/stop functionality, service will be stopped for the old landlord.)

Manage Groups of Premises

The powerful search criteria on the premise management page allows you to view different groups of premises based on any combination of account information, landlord information, parent premise address information and general geographic type information. You may also define search criteria such as "premises **not** linked to account 1234567890" or "premises linked to **any** landlord" or "premises **not** linked to any parent premise". For example, you could display all premises in a given latitude / longitude that are not linked to any parent premise.

Once your search results display the desired list of premises, you could perform mass updates such as assigning a parent premise or starting service. Following are examples of situations where this page would be helpful:

- The developer of a high-rise condominium complex is ready to start service for a group of condos. A user uses the premise management search criteria to display the premises linked to a give parent premise (representing the condo complex) that are not linked to any account. The user selects the premises in this list that the developer would like to start and starts service for all premises at once.
- There is a shopping mall in your service territory and each store in an individual premise. You may decide to define a parent premise for the entire shopping mall and link each store's premise to the parent. Once the parent premise is defined, a user navigates to the premise management page and displays the individual premises based on a similar address or based on a similar geographic type. The user then assigns the parent premise for all the individual premises using a single action.

Premise Management Page

This page allows you to display a list of premises using a combination of search criteria. In addition, you can perform actions on one or more of the resulting premises, including:

- Assigning a parent premise to one or more premises
- Removing the link to a parent premise from one or more premises
- Assigning a landlord to one or more premises
- Removing the link to a landlord from one or more premises
- Start service for one or more premises
- Stop service for one or more premises

Open this page using **Menu > Customer Information > Premise Management**.

Description of Page

The top half of the page is where you enter the criteria used to search for premises.

NOTE:

Multiple search criteria may be specified. You can search for premises using a combination of search criteria. For example, if you enter both a **Parent Premise Filter** of Linked To Any Premise and an **Account Filter** of Not Linked to Any Account; only those premises that have a parent premise but are not linked to an account will be displayed.

At least one positive criterion is required. You may not define your search criteria to only use filter values that start with "Not Linked...". At least one "positive" filter value is required.

The following table describes each of the different search methods.

Search Method	Description
Landlord Filter	Use this filter to narrow down your search based on landlord. Enter one of the following values: Not Applicable

	<p>Linked To This Landlord - for this option, you must enter a Landlord Agreement</p> <p>Not Linked To This Landlord - for this option, you must enter a Landlord Agreement</p> <p>Linked To Any Landlord</p> <p>Not Linked To Any Landlord.</p> <p>A filter value of Not Applicable defaults.</p>
Parent Premise Filter	<p>Use this filter to narrow down your search based on parent premise. Enter one of the following values:</p> <p>Not Applicable</p> <p>Linked To This Parent Premise - for this option, you must enter a Premise ID for the parent premise</p> <p>Not Linked To This Parent Premise - for this option, you must enter a Premise ID for the parent premise</p> <p>Linked To Any Parent Premise</p> <p>Not Linked To Any Parent Premise.</p> <p>A filter value of Not Applicable defaults.</p>
Account Filter	<p>Use this filter to narrow down your search based on account. Enter one of the following values:</p> <p>Not Applicable</p> <p>Linked To This Account - for this option, you must enter an Account ID</p> <p>Not Linked To This Account - for this option, you must enter an Account ID</p> <p>Linked To Any Account</p> <p>Not Linked To Any Account.</p> <p>A filter value of Not Applicable defaults.</p>
Premise Filter	<p>Use this filter to narrow down your search based on account. Enter one of the following values:</p> <p>Located At This Address - for this option, you must enter address constituents</p> <p>Located At This Geographic Type / Value - for this option, you must enter a Geo Type and Value</p> <p>Not Applicable</p> <p>Show This Specific Premise - for this option, you must enter a Premise ID</p> <p>A filter value of Not Applicable defaults.</p>

The **Select All** / **Clear All** buttons are used to select premises if you plan on issuing any of the mass update actions at the bottom of the page. Refer to the description of the "mass update" actions below for more information.

NOTE:

50 premises at a time. Clicking **Select All** selects the first 50 premises in the grid. If more than 50 premises exist, you must select them in batches.

The grid that follows contains the premises that match your search criteria. The following information appears in the grid:

- **Select box.** Use this checkbox to select premises for mass update actions.
- The **Premise Information** column shows information about each premise. Click the hyperlink to transfer to the [Premise](#) page where you can update information about the premise in question.
- The **Account Information** column shows information about all accounts linked to the premise, if any. Only accounts with non-canceled, non-closed service agreements linked to this premise are displayed. The column displays the name of the customer's main person followed by a list of status values for any of the account's service agreements linked to this premise. For example, you may see Customer A (pending stop), Customer B (pending start). If multiple service agreements linked to the account & premise have the same status, the status is only displayed once.
- The **Parent Premise Information** column displays information about the premise's parent premise, if one exists.
- The **Landlord Information** column displays the landlord agreement description for the premise's landlord, if there is one.

This transaction has sophisticated logic that can be used to perform "mass updates" to the premises that appear in the grid using the buttons at the bottom of the page. The buttons are enabled if you select at least one row from the premise grid. The following points describe these mass update actions:

Start Service

The **Start Service** button is used to start service for one or more premises. When clicked, the **Start SA Groups Confirmation** window opens.

NOTE:

Similar to Start/Stop. This page is similar to the Start SA Confirmation page that appears on start/stop. The differences are to accommodate starting multiple premises.

In order to start service for the selected premises, select the **Account ID**.

The **Start Date** is the date on which the service is scheduled to start.

Use **Start Requested By** to indicate the name of the person who requested the start.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also be started for this account.

Click **Show SA Groups** to populate the remainder of the page.

The **Service Points** section summarizes the service points that exist for all the chosen premises. A row is displayed for each different **SP Type** along with a **Count** of the number of service points of that type. By default, all rows are checked, assuming that you want to start service for all service points (and the SA Groups To Start scroll below displays proposed SAs to start for each SP type). You may uncheck any SP Type row if you do not wish to start service for that SP type. Click **Show SA Groups** to rebuild the SA Groups To Start information.

WARNING:

This page displays summary information about the service agreements and service points that are being turned on. It is recommended that you start groups of premises that have similar service point configurations. If you attempt to start service for many premises, each with different service point configurations, the start logic may be very complicated to verify on this page.

The **SA Groups To Start** scroll contains an entry for every service agreement that will be created if you click the **Start** button. If you do not want a service agreement to be created, click the - button or uncheck **Start this SA Group**. If you would like to start service agreements that are not SP-based service agreements (for example a deposit or a connection charge), click the + button to add a new SA group. The system assumes that you want to create a new service agreement for each selected premise.

Turn on the **Start this SA Group** switch if you want service agreements of this type to be created. If this is the first customer at the selected premises, this switch is checked for all service agreements that appear in the scroll. For each premise that was linked to a previous customer, this switch is on only for those types of service agreements used by the previous customer(s). (We assume the new customers only want the services used by the previous customers). Service agreements that are possible, but were not used by the previous customers, appear in the scroll with this switch turned off.

If Start This SA Group is checked, the system displays a message indicating the number of service agreements (for the number of service points) that will be created if you choose Start.

For a description of the remaining fields, refer to [Start/Stop - Start Confirmation](#).

Click **Start**. Standard [start](#) logic is followed when clicking start.

NOTE:

The start button is disabled if changes are made to fields on the page that may impact the SA Groups To Start collection. You must click **Show SA Groups** to rebuild the SA groups and enable the start button.

Stop Service

The **Stop Service** button is used to stop service for one or more premises.

NOTE:

that this functionality stops service for any account linked to the selected premises. If you want to stop service at the selected premises for only certain accounts, use the account filter criteria to narrow down the selection of premises prior to clicking Stop Service.

When clicked, the **Stop SA Group Confirmation** window opens.

In order to stop service for the selected premises, enter a **Stop Date**.

Enter a **Restrict to Account** if you want to stop only service agreements linked to this account. If not specified, all active services agreements for the premise are stopped regardless of the account.

Use **Stop Requested By** to indicate the name of the person who requested the stop.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be stopped.

Click **Show SA Groups** to populate the remainder of the page.

The system builds a collection of service agreements currently linked to the service points for the selected premises. The grid contains the **CIS Division** and **SA Type** for each SA "group" and displays the number of service agreements in the **SA Group Summary**.

By default, the system checks each SA group assuming that you want to stop service for all SAs. You may uncheck any of the SA groups to not stop service for those SAs.

Click **Stop**. Standard [stop](#) logic is followed when clicking stop.

NOTE:

The stop button is disabled if changes are made to fields on the page that may impact the SA collection. You must click **Show SA Groups** to rebuild the SA collection and enable the stop button.

Assign Parent Premise

The **Assign Parent Premise** button is used to assign a parent premise to one or more premises. When clicked, the **Assign Parent Premise** window opens.

Specify the **Parent Premise ID** and click **Assign**.

Remove Parent Premise

The **Remove Parent Premise** button is used to remove the parent premise from one or more premises. When clicked, the parent premise ID of all selected premises is reset.

Assign Landlord

The **Assign Landlord** button is used to assign a landlord to one or more premises. When clicked, the **Assign Landlord** window opens.

Specify the **Landlord** agreement ID.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be assigned this landlord.

Click **Assign**.

Remove Landlord

The **Remove Landlord** button is used to remove the landlord agreement from one or more premises. When clicked, the **Remove Landlord** window opens.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also have their landlord agreement removed.

Click **Remove**.

Umbrella Agreement Management

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

NOTE:

Separate module. The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

Overview Of Umbrella Agreement & Terms Of Service

An umbrella agreement is used to group together terms for a contract. It contains high level information about the contract such as the effective dates, the renewal date, if applicable and an account management group, if applicable. You may also define characteristics and [contacts](#) for the umbrella agreement.

The terms of the umbrella agreement are defined using one or more terms of service (TOS) records. For each TOS record, you must link one or more service agreements to indicate the services covered under the TOS.

UA

ID: 41786547792 Des cr: McDonald's Contract
 UA Type: Large Cust Contract Period: 01-Oct-04 – 03-Sep-04

Terms of Service ID: 4553269781
 Des cr: Grouping of McDonald's electric services
 TOS Type: Electric Template SA: n/a

SA	Description
3994822544	CA/E-COM, ECOM-1, Active, 8-1-98
3994829303	CA/E-COM, ECOM-1, Active, 2-14-99

Covered Entity	Value	Description
Person	1548779358	McDonald's Corp
Service Type	E	Electric

Terms of Service ID: 455324166
 Des cr: Grouping of McDonald's gas services
 TOS Type: Gas Template SA: n/a

SA	Description
3994827536	CA/G-COM, GCOM-1, Active, 8-1-98
3994822521	CA/G-COM, GCOM-1, Active, 2-14-99

Covered Entity	Value	Description
Person	1548779358	McDonald's Corp
Service Type	G	Gas

The Terms of Service may point to a 'template service agreement' as a way to specify the rating terms and conditions to be used by all service agreements linked to the TOS. If a TOS does not define a template SA, then the TOS is used largely as a grouping mechanism rather than a billing mechanism.

Umbrella agreements and their terms of service records are used to support specific business scenarios that your organization supports.

TOS Covered Entities

Your implementation may configure a Terms of Service type to require that entities "covered" by the terms of service record be referenced on the TOS. For example, imagine that you define an umbrella agreement to provide special discounts to all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement, you may link the person record representing the McDonalds corporate entity as a covered entity for the TOS.

NOTE:

that there is no base product functionality that uses this collection. However, your implementation may use this information in an algorithm, for example, it could be used in a campaign / package eligibility algorithm.

Refer to [Terms Of Service Covered Entities](#) for information about defining covered entities for a terms of service type.

Rate Terms Overridden By Terms Of Service

Your organization may require rate information to be temporarily overridden for a service agreement that is linked to a TOS. In order to do this, the TOS record must reference a template SA. Refer to [Overriding Rate Terms](#) for information about defining your Terms of Service types to support template service agreements.

The topics in this section further describe the possible rate term overrides that may occur when a service agreement is linked to a terms of service record.

Rate Schedule Override by TOS

If a service agreement is linked to a terms of service, you may configure the system to use the rate schedule from the terms of service record's template SA rather than the one from the customer's service agreement. The customer's SA type controls this option.

FASTPATH:

Refer to [Configure SA Types for Umbrella Agreements](#) for more information.

If a service agreement is linked to a terms of service record, the rate information tree on the service agreement's rate info tab tells the user whether the rate from the service agreement or from the template SA on the TOS is currently applicable.

If a given service agreement's rate schedule is being taken from the terms of service record's template SA, then the override rate schedule is used not just in bill calculations, but for any logic that requires the service agreement's rate schedule. For example, one of the recommended budget amount algorithms may estimate consumption and apply the service agreement's rate. In this case, the rate used by the algorithm is the one linked to the terms of service record's template SA.

Override Of Other Rate Terms By TOS

There are other terms associated with a rate that may change when linking a service agreement to a terms of service record that has a template SA. These include contract riders, contract terms and tax exemptions.

When applying the rate to create the customer's bill segment, if a bill factor on any of the calculation rules indicates that it is eligible for tax exemptions, contract terms or contract riders, a flag on the bill factor indicates where the system should look for the appropriate value. The Terms of Service Usage flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

FASTPATH:

Refer to [Configure Bill Factors for Umbrella Agreements](#) for more information.

NOTE:

Independent of rate source. The flag values on the bill factors are independent of the rate source setting for the SA type. For example, your implementation may configure the SA type's rate source to indicate that rate should be taken from the TOS template SA. However, if a bill factor is eligible for tax exemptions, your implementation may configure the bill factor to indicate that the exemption information should be taken from the customer's SA, not the template SA.

Umbrella Agreement Renewal

Although umbrella agreement records require an end date, your organization probably allows for renewal of agreements. A renewal may involve full re-negotiation of all terms, or may be as simple as extending the current terms. If umbrella

agreements of a given type are eligible to be renewed, you configure the UA type to indicate how to calculate the renewal date and which algorithm to execute when the renewal date is reached.

Umbrella Agreement Renewal Background Process

The UA renewal background process ([UARENEW](#)) finds complete umbrella agreements whose renewal date has arrived and executes the renewal algorithm for the associated UA type.

NOTE:

It is the responsibility of the renewal algorithm to update the renewal date as per the business practice. Refer to [Renewable Umbrella Agreements](#) for more information.

Umbrella Agreements & Proposals

Umbrella agreements and their terms of service records may reference proposal service agreements. This functionality allows you to create the full contract for your customer during the quoting stage.

Additional Umbrella Agreement Topics

The following topics describe additional functionality related to umbrella agreements.

Umbrella Agreement Alerts

The [alert zone](#) will highlight if any of the account's SAs are linked to an effective umbrella agreement (via a non-canceled terms of service record).

Orders And Umbrella Agreements

When starting new service for a given account and premise, you may know ahead of time that the new service should be linked to an existing umbrella agreement. For example, perhaps all the service in a specific low income housing area qualifies for a special negotiated contract for the next year.

The system provides algorithms to allow you to add a new service agreement to an existing terms of service record when using the [Order](#) transaction to start service.

Refer to [Configure A Campaign To Link An SA To A Terms Of Service](#) for more information.

Umbrella Agreement Reports

The system supplies a [Report](#) providing umbrella agreement information for one or more umbrella agreements.

Umbrella Agreement Maintenance

Umbrella agreements help you manage your contracts by allowing you to group together service agreements for the contract with one or more terms of service records for the umbrella agreement.

Lifecycle Of An Umbrella Agreement

The following diagram illustrates the lifecycle of an umbrella agreement.

Pending The umbrella agreement is created in pending status.

You may delete a pending umbrella agreement. Deleting a UA also deletes its terms of service records.

Complete Only complete umbrella agreements are considered effective. You may transition a UA to complete if there is at least one terms of service record linked to it and if none of its TOS records are in pending status.

Under unusual circumstances, a complete umbrella agreement may be changed back to pending to correct errors.

Umbrella Agreement - Main

Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search.**

Description of Page

Umbrella Agreement Info contains a concatenation of important information about the umbrella agreement. **Umbrella AgreementID** is the system-assigned unique identifier of the umbrella agreement. These values only appear after the UA is added to the database.

Umbrella Agreement Status shows the current state of the UA. The buttons adjacent to the status allow you to transition the UA's status.

- Click **Complete** to change the status of a pending umbrella agreement to complete.
- Click **Reopen** to change the status of a complete umbrella agreement back to pending.

FASTPATH:

Refer to [Lifecycle of an Umbrella Agreement](#) for more information.

Enter a **Description** for the umbrella agreement.

The **Umbrella Agreement Type** defines the type of umbrella agreement. Refer to [Setting Up Umbrella Agreement Types](#) for more information.

The **Start Date** and **End Date** define the effective dates of the contract. If the UA type is renewable, the **Renewal Date** indicates the date the umbrella agreement is processed by the [renewal background process](#).

You may assign an **AccountManagement Group** to this umbrella agreement. The AMG controls the roles assigned to [To Do entries](#) associated with the umbrella agreement. Refer to [Setting Up Account Management Groups](#) for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

This bottom of this page contains a [tree](#) that shows the various objects linked to the umbrella agreement. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Umbrella Agreement - Contacts

The contacts page defines persons associated with the umbrella agreement. Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search** and navigate to the **Contacts** page.

Description of Page

The contacts collection allows you to define persons that are associated with the umbrella agreement. For each contact, define the **Person ID** for the person record that contains the demographic information for the contact. For each contact, use the **Comments** to define information about the contact.

Umbrella Agreement - Characteristics

The characteristics page contains information that describes miscellaneous information about the umbrella agreement. Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search** and navigate to the **Characteristics** page.

Description of Page

NOTE:

Characteristic Types. You can only choose characteristic types defined on umbrella agreement's [umbrella agreement type](#).

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

NOTE:

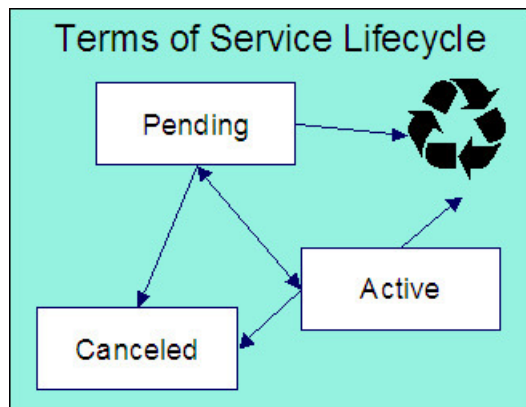

Default Note. An umbrella agreement's characteristics default from the [umbrella agreement type](#).

Terms Of Service Maintenance

A terms of service (TOS) record defines one or more service agreements participating in a given umbrella agreement. The TOS record may also reference a template SA that could be used to override rate terms for the participating service agreements.

Lifecycle Of Terms Of Service

The following diagram illustrates the lifecycle of a terms of service record.

Pending The terms of service record is created in pending status. You may delete a pending TOS. If you want to keep a record of the TOS, you may cancel it rather than deleting it.

Active Only active terms of service records are considered effective. Change the status to active when you have entered all the desired information for this TOS. You may delete an active terms of service if the umbrella agreement is still pending. (Otherwise you must cancel the TOS.)

Canceled You may cancel a pending or active terms of service if it should no longer be used. Canceling a terms of service record unlinks all its service agreements.

Terms Of Service - Main

Open this page using **Menu > Umbrella Agreement Management > Terms of Service > Search**.

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of ServiceID** is the system-assigned unique identifier of the terms of service record. These values only appear after the TOS is added to the database.

The **Umbrella Agreement ID** defines the umbrella agreement to which this terms of service is linked.

Status shows the current state of the terms of service record. The buttons adjacent to the status allow you to transition the TOS record's status.

- Click **Activate** to change the status of a pending terms of service record to active.
- Click **Pend** to change the status of an active terms of service record back to pending.
- Click **Cancel** to change the status of a pending or active terms of service record to canceled.

FASTPATH:

Refer to [Lifecycle Of Terms of Service](#) for more information.

Enter a **Description** for the terms of service record.

The **Terms of Service Type** defines the type of terms of service record. Refer to [Setting Up Terms of Service Types](#) for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

The **Characteristics** collection contains information that describes miscellaneous information about the terms of service record.

NOTE:

Characteristic Types. You can only choose characteristic types defined on the terms of service record's [terms of service type](#).

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

NOTE:

Default Note. A terms of service record's characteristics default from the [terms of service type](#).

The **Covered Entities** collection allows you to define specific entities that are "covered" by this terms of service record. Refer to [TOS Covered Entities](#) for more information.

NOTE:

Characteristic Types. You can only choose covered entity characteristic types defined on the terms of service record's [terms of service type](#).

The following fields display:

Covered Entity Characteristic Type Indicate the type of characteristic used to define this covered entity type.

Characteristic Value Indicate the value of the characteristic used to define the covered entity value.

NOTE:

Default Note. A terms of service record's covered entity types default from the [terms of service type](#).

Terms Of Service - SAs

This page is used to maintain the service agreements linked to the terms of service record.

Open this page using **Menu > Umbrella Agreement Management > Terms of Service > Search** and navigate to the SAs page.

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of ServiceID** is the system-assigned unique identifier of the terms of service record.

The filters control the service agreements that appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:
 - Account. Use this option to restrict service agreements to those linked to a given **Account ID**.
 - Address. Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - All. Use this option if you do not wish to restrict service agreements based on service agreement attributes.
 - All Proposals. Use this option to restrict service agreements to only proposal service agreements.

- All Real SAs. Use this option to restrict service agreements to only "real" service agreements (i.e., not proposal SAs).
- Geographic Type. Use this option to restrict service agreements to those linked to service points associated with a given **Geographic Type** and **Geographic Value**.
- SA Type. Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.
- Specific SA. Use this option to reference a specific **SA ID**.
- Use **Status Filter** to restrict the service agreements based on their status. Status values for both proposal service agreements and regular service agreements are included in the filter. The following options are available:
 - All. This option shows all service agreements, including proposal service agreements, regardless of status.
 - Refer to [Service Agreement Lifecycle](#) for the various status values for real service agreements.
 - Refer to [Proposal SA State Transition](#) for more information about status values for proposal service agreements.

Don't forget to click the search button after changing the filters.

The grid that follows contains the **Service Agreements** that match your search criteria along with its **Account Info**.

Use the "+" to link new service agreements to the terms of service record.

NOTE:

Link SA Using Order. You may also [link a service agreement to a TOS through orders](#) if you have configured an appropriate campaign and package.

Note you may remove a service agreement from the TOS using the delete button as long as the change has not been committed to the database. As soon as the SA's link to the TOS has been committed to the database, you must use the **Remove** action to unlink the service agreement.

The **Select All / Clear All** buttons are used to select service agreements if you plan on issuing the mass update action **Remove** at the bottom of the page. Clicking **Remove** removes the service agreement from the terms of service record.

Overdue Financial Obligations

The system periodically monitors how much your customers owe to ensure they haven't violated your overdue rules. When a violation is detected, the system creates an overdue process. The overdue process contains the events meant to prod the customer to pay (e.g., letters, disconnect field activities, To Do entries, write-off outstanding debt, etc.). This section describes how to manage your overdue (i.e., collections) processing.

NOTE:

The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with the algorithms that support collecting on overdue bills. If your organization practices [balance-forward accounting](#) (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under [Credit and Collections](#).

Overdue Processing Background Information

In the section, [The Big Picture Of Overdue Processing](#), we describe how overdue processing works and how to set up the control tables that automate most functions. You will find that many of your questions regarding when and how overdue and cut processes are created and canceled are described in this section.

Overdue Process Maintenance

An overdue process is a series of events (e.g., letters, To Do entries) meant to encourage an account to pay its delinquent debt. The topics in this section describe the pages on which overdue processes are maintained.

FASTPATH:

Refer to [The Big Picture Of Overdue Processes](#) for background information.

Overdue Process - Main

The Main page contains core overdue process information. Open this page using **Menu > Credit & Collection. > Overdue Process > Search**

Description of Page

NOTE:

Refer to [How To Perform Common Overdue Process Functions](#) for more instructions describing how to use this page.

Overdue Process contains a concatenation of important information about the process. **Overdue ProcessID** is the system-assigned unique identifier of the process. These values only appear after the overdue process is added to the database.

NOTE:

Summary information may be overridden. Refer to [Overdue Process Information Is Overridable](#) for how your implementation can override the summary information that appears throughout the system.

Account ID identifies the overdue process's account.

NOTE:

Multiple overdue processes may be linked to an account. It's important to be aware that it's possible for multiple, active overdue processes to be linked to an account. The [Alert zone](#) will contain a summary of the account's overdue processes.

Status defines the state of the overdue process. The following values may exist:

- Active, Events Pending. Overdue processes are initially created in this state. An overdue process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. An overdue process will exist in this state when it's been manually canceled by a user. Navigate to the **Log** tab to see when this happened and who did it.
- Inactive, Canceled by System. An overdue process will exist in this state when it's been canceled by the system (typically because the overdue obligations were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. An overdue process will exist in this state when the system completes its last event. Navigate to the **Log** tab to see when this happened.

The **Cancel** button appears if the overdue process is Active, Events Pending and the process's **Overdue Process Template** has a Cancel Logic plug-in. Click this button to [cancel the process](#).

The **Trigger Events** button appears if the overdue process is Active, Events Pending. Click this button to activate all pending events that are [ready for activation](#).

NOTE:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

Overdue Process Template defines the template that was used to [create the overdue process's events](#). You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

NOTE:

Changing the template. If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the overdue process. This field is protected after the overdue process is saved on the database. This field is used to derive the trigger date of some overdue events when the process is first created. Subsequent changes to the start date change the trigger dates on the events accordingly.

Inactive Date/Time is the date and time that the overdue process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the **Log** tab.

Base Date is reserved for future releases. This field is protected when the overdue process is Inactive.

Enter any **Comments** about the overdue process. This field is protected when the overdue process is Inactive.

The **Collecting On** grid holds the [overdue objects](#). For example, if this process manages overdue bills, the grid contains a list of the bills being collected on by this process. This grid is unprotected when the process is Active . The following points describe the columns that appear in the grid:

- Press the + button to add a new overdue object to the process.
- Press the - button to remove an overdue object to the process.
- The next column contains the unique identifier of the overdue object. For example, if this process manages overdue bills, this column will contain the bill ID. The type of object that's specified in this column is control by the [overdue process template](#).
- **Original Amount** contains the [original amount](#) of the overdue object.
- **Unpaid Amount** contains the [unpaid amount](#) of the overdue object.

The [Trees](#) at the bottom of the page shows a variety of information about the overdue process including its events and cut processes. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Overdue Process - Events

This page contains the activities that are performed to persuade the customer to pay the outstanding debt. Open this page using **Menu > Credit & Collection > Overdue Process > Search** and navigate to the **Events** page.

Description of Page

NOTE:

Refer to [How To Perform Common Overdue Process Functions](#) for more instructions describing how to use this page.

Refer to the first tab for a description of **Overdue Process** and **Overdue Process ID**.

The **Overdue Events** scroll contains the process's overdue events. Refer to [Overdue Processes Are Created From Templates](#) for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the [state of the event](#).
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Overdue Event Type** has a Cancel Logic plug-in. Click this button to cancel the event.
- The **Overdue Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
 - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0, this event will be activated immediately after the dependent events are completed / cancelled. Refer to [Calendar vs Work Days](#) for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled , you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

NOTE:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Overdue Process - Log

This page contains [log entries](#) that highlight significant events in the process's life. Open this page using **Menu > Credit & Collection > Overdue Process > Search** and navigate to the **Log** page.

Description of Page

Please note the following about the entries in this grid:

- The system automatically creates log entries when significant events occur. Refer to [Overdue Log](#) for more information.
- You can manually add a log entry to an Active process by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
 - **Date/Time** contains the date and time the log entry was created.
 - **Details** contain the user-specified or system-generated information about the log entry.
 - **Relate Object** is populated on log entries that were created to record the creation of some other object. For example, if an overdue event creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
 - **Related Process / Event** appears if the log entry was created by an overdue event, a cut process or a cut event. It references the unique identifier of the process / event.
 - **Log User** contains the user who caused the log entry to be created.
 - **Log Type** indicates how the log entry was created. The possible values are:
 - User. A user manually created this entry.

- System. This system created this entry.

How To Perform Common Overdue Process Functions

The topics in this section describe how to perform common overdue process maintenance functions. Refer to [The Big Picture Of Overdue Processing](#) for high-level information about overdue processing.

How To Create An Overdue Process

99.9% of all overdue processes are created by the [Overdue Monitor](#) and require no human intervention. The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new overdue process.
- After the account is populated on Control Central, choose the **Overdue Process** + option on the account context menu to transfer to the overdue process transaction in add mode for the account.
- After the [Overdue Process - Main](#) page appears, specify the appropriate **Overdue Process Template**. The template is used to default the process's events (the template also controls numerous business rules, for example, when it will be canceled, how it will be canceled, etc). Refer to [How To Change Overdue Events](#) for a description of how you can override these events.
- Enter the overdue object(s) in the **Collecting On** grid. You must define at least one object.
- Save the overdue process.

How To Change Overdue Events

When an overdue process is first created, it has one or more overdue events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when an overdue process is initiated are defined on the overdue process's overdue process template. The following points describe how to add / change / delete events on an overdue process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the overdue process whose events need to be changed.
- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. Note, an account's Active overdue processes can be selected from the [Alerts zone](#).
- To add a new event, transfer to the [Overdue Process - Events](#) tab and press the + button in the **Overdue Events** scroll. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
 - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
 - Choose a **Status** of Pending.
 - Choose the desired **Overdue Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
 - specify the sequences of the dependent events in **Event Dependencies** and
 - specify the how many days after the completion of the last dependent event that the new event should be triggered.

- If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on [Overdue Process - Main](#). This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.
- To change an existing event, click on the event in the tree on [Overdue Process - Main](#). This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the overdue process.

How To Cancel An Overdue Process

The system will cancel an overdue process when the [cancel criteria defined on the overdue process are satisfied](#). The following points describe how to manually cancel an overdue process.

- Use **Control Central** to choose the account with the overdue process to be cancelled.
- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. A list of all overdue processes associated with the account appears. If only one overdue process exists, it is automatically selected for you. Note, an account's Active overdue processes can be selected from the [Alerts zone](#).
- On the **Main** tab, click Cancel and answer any prompts.

Cut Process Maintenance

A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement. The topics in this section describe the pages on which cut processes are maintained.

FASTPATH:

Refer to [The Big Picture Of Cut Processes](#) for background information.

Cut Process - Main

The Main page contains core cut process information. Open this page using **Menu > Credit & Collections > Cut Process > Search**.

Description of Page

NOTE:

Refer to [How To Perform Common Cut Process Functions](#) for more instructions describing how to use this page.

Cut Process contains a concatenation of important information about the process. **Cut ProcessID** is the system-assigned unique identifier of the process. These values only appear after the cut process is added to the database.

NOTE:

Summary information may be overridden. Refer to [Cut Process Information Is Overridable](#) for how your implementation can override the summary information that appears throughout the system.

Overdue Process and **Overdue Event** define overdue event that created the process. Refer to [Cut Processes Exist Under An Overdue Process](#) for more information.

Service Agreement identifies the service agreement being cut.

Premise identifies the service agreement's characteristic premise (if any).

NOTE:

Multiple cut processes may be linked to an overdue process / event. It's important to be aware that it's possible for multiple, active cut processes to be linked to the overdue event. You can see all cut processes associated with an overdue process on the tree of [Overdue Process - Main](#). The [Alert zone](#) will contain a summary of the account's cut processes.

Status defines the state of the cut process. The following values may exist:

- Active, Events Pending. Cut processes are initially created in this state. A cut process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. A cut process will exist in this state when it's been manually canceled by a user. Navigate to the overdue process's **Log** tab to see when this happened and who did it.
- Inactive, Canceled by System. A cut process will exist in this state when it's been canceled by the system (typically because the overdue obligations on the overdue process were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. A cut process will exist in this state when the system completes its last event. Navigate to the overdue process's **Log** tab to see when this happened.

The **Cancel** button appears if the cut process is Active, Events Pending and the process's **Cut Process Template** has a Cancel Logic plug-in. Click this button to [cancel the process](#).

The **Trigger Events** button appears if the cut process is Active, Events Pending. Click this button to activate all pending events that are [ready for activation](#).

NOTE:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Cut Process Template defines the template that was used to [create the cut process's events](#). You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

NOTE:

Changing the template. If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the cut process. This field is protected after the cut process is saved on the database. This field is used to derive the trigger date of some cut events when the process is first created. If you need to subsequently change the trigger date on the events, navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

- Change the **Cut Process Template** to something (anything). Doing this causes the **Start Date/Time** to become unprotected.
 - Specify the base date of the cut events in the newly unprotected **Start Date/Time**.
-

- Change the **Cut Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Start Date/Time**.

Inactive Date/Time is the date and time that the cut process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the overdue process's [Log](#) tab.

Enter any **Comments** about the cut process. This field is protected when the cut process is Inactive .

The [tree](#) at the bottom of the page shows a variety of information about the cut process including its events. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Cut Process - Events

This page contains the activities that are performed to cut the service agreement. Open this page using **Menu > Credit & Collection > Cut Process > Search** and navigate to the **Events** page.

Description of Page

NOTE:

Refer to [How To Perform Common Cut Process Functions](#) for more instructions describing how to use this page.

Refer to the first tab for a description of **Cut Process** and **Cut Process ID**.

The **Cut Events** scroll contains the process's cut events. Refer to [Cut Processes Are Created From Templates](#) for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the [state of the event](#).
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Cut Event Type** has a Cancel Logic plugin. Click this button to cancel the event.
- The **Cut Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
 - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0 (zero), this event will be activated immediately after the dependent events are completed / cancelled. Refer to [Calendar vs Work Days](#) for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled , you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

NOTE:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

How To Perform Common Cut Process Functions

The topics in this section describe how to perform common cut process maintenance functions. Refer to [The Big Picture Of Cut Processing](#) for high-level information about cut processing.

How To Create A Cut Process

Cut processes are created when an overdue event is activated. You cannot create an ad hoc cut process.

How To Change Cut Events

When a cut process is first created, it has one or more cut events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when a cut process is initiated are defined on the cut process's cut process template. The following points describe how to add / change / delete events on a cut process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the cut process whose events need to be changed.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menus to transfer to the cut process transaction in update mode. Note, an account's Active cut processes can be selected from the [Credit and Collections zone](#).
- To add a new event, transfer to the [Cut Process - Events](#) tab and press the + button in the **Cut Events** scroll. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
 - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
 - Choose a **Status** of Pending.
 - Choose the desired **Cut Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
 - specify the sequences of the dependent events in **Event Dependencies** and
 - specify the how many days after the completion of the last dependent event that the new event should be triggered.
- If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on [Cut Process - Main](#). This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.
- To change an existing event, click on the event in the tree on [Cut Process - Main](#). This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the cut process.

How To Cancel A Cut Process

The system will cancel a cut process when the [cancel criteria defined on the overdue process are satisfied](#). The following points describe how to manually cancel a cut process.

- Use **Control Central** to choose the account with the cut process to be cancelled.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menu to transfer to the cut process transaction in update mode for the account. A list of all cut processes associated with the account appears. If only one cut process exists, it is automatically selected for you. Note, an account's Active cut processes can be selected from the [Credit and Collections zone](#).
- On the **Main** tab, click Cancel and answer any prompts.

Payment Arrangement for Bills

A payment arrangement is an agreement with a customer to payoff severely overdue debt in installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

Organizations that practice [open-item accounting](#) who collect on overdue bills may allow customers to pay off their overdue bills in installments by setting up a payment arrangement for one or more bills. This transaction is used to maintain bill-oriented payment arrangements.

FASTPATH:

Refer to [Bill-Oriented Payment Arrangements](#) for background information.

Open this page using **Menu > Credit & Collection > Payment Arrangement for Bills > Search** page.

Description of Page

The **SA** (service agreement) **Info** is a concatenation of important details about the payment arrangement service agreement (PA SA). The **SAID** is the unique identifier of the PA SA. These values only appear after the PA SA exists on the database.

The **Current Balance** that appears beneath **SA Info** contains the PA SA's current balance. When you initially set up a PA SA this balance will be zero. It is only non-zero if the customer has not paid a billed installment.

Payoff Balance beneath **SA Info** contains the PA SA's payoff balance. The payoff balance is the total amount to be paid off over the PA SA's life. It is only non-zero after delinquent funds have been transferred to the PA SA. This balance is only displayed when it differs from the **Current Balance**.

FASTPATH:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Account ID is the account associated with the PA SA.

The occurrences of **Current** and **Payoff Balance** beneath **Account** are the account's respective balances. These values are displayed to help you confirm exactly how much the customer currently owes versus how much they will have to payoff over time (remember, after you transfer funds to a payment arrangement, the amount transferred is reduced from the account's current balance).

The **Unpaid Bills** grid contains a row for each of the account's unpaid bills.

Adjacent to each Unpaid Bill is its **Unpaid Amount** and a check box used to select the bill. Every selected bill's unpaid amount will be transferred to the PA SA when you click the **Create** button.

WARNING:

The system automatically indicates that all unpaid debt should be transferred to the payment arrangement. It does this by checking each bill by default.

Total Candidates is the sum of ALL unpaid bills (not just the selected bills).

New Payoff Balance contains the PA SA's payoff balance. This is the total amount of debt that will be paid off over the lifetime of the PA SA. This value equals the current payoff balance on the PA SA plus all selected debt from the **Candidate SAs** scroll.

The next fields work in unison.

- If you want to define the number of future bills that the customer has to payoff the selected unpaid amount, enter the number of **Installments**. When you tab out of the field, the system sets the **Arrange Amount** equal to **New Payoff Balance / Installments**.

NOTE:

Arrange Amount may not add up. The **Arrange Amount** is rounded up so that if you multiply the number of installments by the calculated installment amount, the result will be greater than the PA SA's payoff amount. Don't worry - only the actual dollar amount of the PA SA's total debt will be billed by the system. The last installment will be slightly lower than the other installments.

- If you want to define the amount charged on future bills to payoff the unpaid amount, enter the **Arrange Amount**. For example, if the customer agrees to pay off their delinquent debt by paying an additional \$50 on each bill, you'd enter "50" in this field. Note - If you enter a dollar amount in this field and tab out, the system will calculate the number of installments and display the number in the **Installments** field.

Define the **CISDivision** and **SA Type** of the payment arrangement service agreement.

NOTE:

Payment arrangement SA types. There is a field on SA type called [Special Role](#). Only those SA types with a role of Payment Arrangement may be selected.

Clicking the **Create** (or **Change**) button causes the system to perform the following:

- It creates / updates a payment arrangement service agreement (PA SA). It sets the installment amount on this service agreement equal to the installment amount specified on the page.
- It transfers unpaid debt from the selected bills to the PA SA. The adjustment type used to transfer these funds is defined on the PA SA's SA type.
- It links the "transfer from" adjustments to the unpaid financial transactions on the bills. This will cause the unpaid FT's to be linked to Balanced match events. This means that any Active Overdue Processes for the bills should Inactivate (i.e., cancel) because the bills will no longer be consider unpaid. Refer to [How Are Overdue Processes Cancelled](#) for more information..
- It reduces the current balance on the PA SA by the amount of debt transferred to the PA SA. Why? Because when delinquent debt is transferred to the PA SA, its current balance increases. Because current balance contains the amount the customer currently owes, this balance must be reduced because the customer is going to pay off the debt in installments (and therefore they don't currently owe anything). The adjustment type used to transfer these funds is defined on the PA SA's SA type.

Clicking **Break** causes the PA SA to become broken. Please refer to the note below for what transpires when a PA is broken.

NOTE:

Break logic is in a plug-in. Please be aware that the logic that is executed when a payment arrangement is broken exists in a plug-in algorithm (plugged-in on the account's [Collection Class Overdue Rules](#)). The base package algorithm

performs many functions (refer to [Breaking A Bill Oriented Payment Arrangement](#) for the details). The bottom line is that when a PA SA is broken, the originating bills will have their debt reinstated and this will again be subject to the [Overdue Monitor](#). Because this logic is in a plug-in, you can develop alternative logic and plug it in if the base package logic is not satisfactory.

Clicking **Cancel** causes the PA SA to become canceled. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken.

How To Set Up A Payment Arrangement

To set up a new payment arrangement:

- Open [Payment Arrangement for Bills](#) in add mode.
- Select the **Account** in question.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills**).
- Enter the number of **Installments** or the **Arrange Amount**.
- Define the **CIS Division** and **SA Type** of the new payment arrangement service agreement.
- Click the **Create** button.

How To Add Additional Debt To A Payment Arrangement

To transfer additional debt to an existing payment arrangement:

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills** amounts).
- Enter the number of **Installments** or the **Arrange Amount**.
- Click the **Change** button.

NOTE:

After transfer. After transferring the funds to the payment arrangement service agreement, confirm the account's payoff and current balances make sense (the payoff balance is the total amount of debt that the account will eventually have to payoff, the current balance is how much they currently owe. The account's payoff and current balances are displayed in the page's second section. If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

How To Break A Payment Arrangement

You would break a payment arrangement when a customer doesn't make the agreed payments. Typically, your overdue processes will break a payment arrangement behind-the-scenes if a customer doesn't pay. Refer to [Breaking A Bill Oriented Payment Arrangement](#) for information about how the system monitors payment arrangements.

If you want to manually break a payment arrangement,

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Click the **Break** button.

How To Cancel A Payment Arrangement

You would cancel a payment arrangement if you made a mistake and never intended to set up the payment arrangement in the first place. To cancel a payment arrangement

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Click the **Cancel** button.

Rebate Claims

The Rebate Claims feature allows you to search, view, and maintain rebate claims submitted as part of a conservation program.

FASTPATH:

For more information about conservation programs, see [Conservation Programs](#).

Rebate Claim Query Portal

You use the Rebate Claim Query Portal to search for rebate claims. Use the following procedure to search for rebate claims:

- Select **Menu > Customer Information > Rebate Claim > Search** to open the Rebate Claim Query portal.
- Enter search criteria in the Rebate Claim Search zone and click **Refresh**. You can search by:
 - Customer Name
 - Account ID
 - Conservation Program
 - Start and End Dates
- A list of rebate claims matching the search criteria appears, displaying the following for each:
 - Claim Date
 - Rebate Claim (Status, Claim Date, Conservation Program, and Total Amount)
 - Account (Name, Customer Class, Current Balance, and Account ID)
 - Total Rebate Amount

- To view a rebate claim, click the **Rebate Claim** link. The selected rebate claim opens in the Rebate Claim portal.

Rebate Claim Portal

You use the Rebate Claim portal to view, edit, and maintain rebate claims. To add a rebate claim, open **Menu > Customer Information > Rebate Claim > Search**.

The topics in this section describe the base-package zones that appear on the Rebate Claim portal.

Rebate Claim Zone

You use the Rebate Claim zone to view the details of rebate claims. The Rebate Claim zone opens when you first create a new rebate claim, or when you select a rebate claim on the Rebate Claim Search zone. The Rebate Claim zone displays the following information about the selected rebate claim:

- **Basic Information:** information about the claim, including:
 - Conservation Program
 - Status (Pending, Issue Detected, Approval in Progress, Receipt Verification, Complete, or Canceled)
 - Rebate Claim number
 - Claim Date
 - Total Rebate Amount
- **Customer Details:** details about the customer who submitted the claim, including:
 - Person
 - Account
 - Premise
 - Mailing Address
- **Contact Details:** contact information for customer who submitted the claim, including:
 - Name
 - Phone Number
 - Fax Number
 - Email Address
- **Premise Information:** information about the physical premise of the customer who submitted the claim, including:
 - Premise Property Type
 - Residential Property Type
 - Building Vintage
- **Payment Release Authorization Details:** details about the person to whom the rebate payment should be made, including:
 - Authorized By
 - Authorization Date
 - Payee Name
 - Phone Number

- Mailing Address
- Issue Details: issues related to the rebate claim, including manually submitted issues as well as those detected through the Verify action.
- Approval Details: details related to users assigned to approve the rebate claim, including:
 - Current Approver
- Reject Details: details related to why a claim was rejected, including:
 - Reject Reason
 - Date Rejected
 - Rejected By

To view a different rebate claim, select the rebate claim from the **Select a Rebate Claim** drop- down list and click **Go**.

Rebate Claim Status

Rebate claims are assigned a status to indicate the current state of the claim within the system. Valid statuses include:

- **Pending** indicates the claim is pending. This is the initial state of a rebate claim when first created.
- **Issue Detected** indicates that one or more issues have been detected with the claim. Issues can include those manually created as well as issues detected through the Verify action.
- **Approval in Progress** indicates the claim is awaiting approval.
- **Receipt Verification** indicates that receipts associated with the rebate claim's claim lines need verification.
- **Complete** indicates the claim was approved and is complete.
- **Rejected** indicates the claim was rejected.
- **Canceled** indicates the claim has been canceled.

Rebate Claim Actions

You can perform a number of actions on a rebate claim, including:

- **Edit:** Used to edit the details of the rebate claim.
- **Verify:** Used to verify the supplied details of the rebate claim, and change its status to either Approval in Progress (if the claim passes the verification) or Issue Detected (if any issues are detected). This helps ensure the rebate claim has been properly set up.
- **Approve:** Used to approve a submitted rebate claim, and change its status to Complete or Receipt Verification (if receipts had not been previously verified).
- **Reject:** Used to reject a submitted rebate claim, and change its status to Complete.
- **Issue Detected:** Used to note an issue related to the rebate claim, and change its status to Issue Detected.
- **Cancel:** Cancels a rebate claim, changing its status to Canceled.

The actions available are based on the current status of the rebate claim. The table below summarizes the actions available at each status.

Status	Valid Action
Pending	Edit, Verify, Issue Detected, Cancel

Issue Detected	Edit, Verify, Cancel
Approval in Progress	Approve, Reject, Issue Detected
Receipt Verification	Issue Detected
Completed	None
Rejected	Issue Detected
Canceled	None

Editing Rebate Claims

Use the following procedure to edit a rebate claim:

- Click **Edit**.
- Edit the details of the rebate claim as needed.
- Click **Save**.

Verifying Rebate Claims

To verify a rebate claim, click **Verify**.

Approving Rebate Claims

To approve a rebate claim, click **Approve**.

Rejecting Rebate Claims

Use the following procedure to reject a rebate claim:

- Click **Reject**.
- Select the **Reject Reason** on the Reject Rebate Claim dialog.
- Click **OK**. To close the dialog without rejecting the claim, click **Cancel**.

Noting Issues Related to a Rebate Claim

Use the following procedure to note an issue related to a rebate claim:

- Click **Issue Detected**.
- Enter details about the issue in the Comments field of the Issue Comments dialog.
- Click **OK**. To close the dialog without saving the comment, click **Cancel**.

Canceling Rebate Claims

Use the following procedure to cancel a rebate claim:

- Click **Cancel**.
- Select the **Cancel Reason** on the Cancel Rebate Claim dialog.
- Click **OK**. To close the dialog without cancelling the rebate claim, click **Cancel**.

Adding Rebate Claims

You can also add rebate claims from the Rebate Claim Query portal. Use the following procedure to add a rebate claim:

- Select **Menu > Customer Information > Rebate Claim > Add**, or click **Add** on the title bar of the Rebate Claim Search zone. The user is navigated to Control Central to select the customer filling the rebate claim. Click **Continue** once the correct account is in context.
- Select the Conservation Program associated with the rebate claim and click **OK**.
- Complete the Rebate Claim details, including:
 - Claim Date for the rebate claim
 - Customer Details
 - Contact Details
 - Premise Information
 - Payment Release Authorization Details
- Click **Save**. The rebate claim is displayed on the Rebate Claim portal.
- Edit the claim as needed in the Rebate Claim zone.
- Add claim lines to the claim using the Rebate Claim Line zone.

Rebate Claim Line Zone

You use the Rebate Claim Line zone to add, view, and edit rebate claim lines associated with a rebate claim. A rebate claim can have one or more claim lines, one for each item for which a rebate is requested. For example, if a customer purchases new energy efficient appliances (such as a washing machine and dryer), the rebate claim they submit would have a rebate claim line for each appliance. The Rebate Claim Line zone displays the following details for each claim line:

- Rebate Definition
- Manufacturer/Model
- Rebate Amount
- Icons to Edit, Delete, and Verify claim lines

Adding Rebate Claim Lines

Use the following procedure to add a rebate claim line to a rebate claim:

- Click **Add Rebate Claim Line** in the title bar of the Rebate Claim Line zone.
- Select the **Service Agreement** associated with the claim line from the dropdown list.
- Select the **Rebate Definition** for the claim line from the dropdown list. This list is filtered based on the Conservation Program associated with the rebate claim.
- Select the **Manufacturer/Model** for the claim line from the dropdown list. This list is filtered by the Rebate Definition selected.
- Enter the **Install Date** for the claim line.
- Enter the **Number of Units** being claimed.
- Click **Save**. To return to the Rebate Claim Line zone without adding the claim line, click **Cancel**.

Deleting Rebate Claim Lines

Use the following procedure to delete a rebate claim line from a rebate claim:

- Click the delete icon for the claim line you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the claim line, click **Cancel**.

NOTE:

You can delete a rebate claim line only when the rebate claim is in Pending status.

Editing Rebate Claim Lines

Use the following procedure to edit an existing rebate claim line on a rebate claim:

- Click the edit icon for the claim line you wish to edit.
- Edit the details of the claim line as appropriate.
- If you are revising the data based on updated information, check the **Data Revised** checkbox and select the reason for the revision from the **Data Revised Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.
- If the claim line contained bad data, check the **Bad Line** checkbox and select the reason for the revision from the **Bad Line Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.
- Click **Save**. To return to the Rebate Claim Line zone without changing the claim line, click **Cancel**.

NOTE:

You can edit a rebate claim line only when the rebate claim is in Pending status. In addition, you cannot edit a rebate claim line after it has been verified.

Verifying Rebate Claim Lines

Use the following procedure to verify a rebate claim line on a rebate claim:

- Click the **Verify** button for the claim line you wish to verify.
- Verify that the details of the claim line match the submitted receipts.
- Click **Verify**. To return to the Rebate Claim Line zone without adding the claim line, click **Cancel**.

NOTE:

You cannot edit a rebate claim line after it has been verified.

Rebate Claim Log Zone

This is a standard [log zone](#). You use the Rebate Claim Log zone to view logging details associated with a rebate claim.

Adding Rebate Claim Log Entries

Use the following procedure to add a rebate claim log entry:

- Click **Add Log Entry** in the title bar of the Rebate Claim Log zone.
- Enter the log entry details in the Add Rebate Claim User Log dialog.
- Click **OK**. To close the dialog without saving the log entry, click **Cancel**.

Communications

Device Events

About Device Events

Device events are developments that have taken place relative to a device, and can include power outages, power restorations, tampering alerts, command completions, among others.

Attributes used to define device events include the following:

- **Device Event Date/Time:** the date and time of the event. This date/time is flexible in its interpretation. For single events it is the moment the event took place. For events that are paired, like a power up and a power down, it will represent the start of the event when received with the first of the pair and the end of the event when received with the second of the pair. For an event that includes the duration, where the device event end date/time is also supplied, this date/time represents the start date/time.
- **Device Event End Date/Time:** the end date and time of events with durations. This will only be populated if the device event date/time is also populated.
- In addition, device events also reference details specific to the head-end system that sent the event, including the following:
 - **Sender:** the head-end system (defined as a service provider in Oracle Utilities Smart Grid Gateway) from which the event was sent.
 - **External Sender ID:** the external ID for the head-end system that sent the event.
 - **External Event Name:** the external, head-end-specific name for the event. This name is translated into a "standard" event name within Oracle Utilities Smart Grid Gateway.
 - **External Source Identifier:** an identifier for the source of the event.

Standard Event Names

When the system is loading a device event, it first determines which head-end system sent it, and then determines which device produced it. The system then maps the device event name sent by the head-end system to a standard event name that corresponds to the event. Standard event names are beneficial because the event names sent by head-end systems vary, even when the events are essentially the same. What one head-end system calls "Primary Power Down," another system may call "Last Gasp." Creating a standard event name, such as "Power Outage - Device," makes it easier to send the device events to an external system such as Oracle Utilities Network Management System. In this way, the external systems that receive the events do not need to be configured to accept all of the possible names for a single type of event.

Refer to [Understanding Device Event Types](#) for additional information about how the device events are mapped using standard event names.

Processing Device Events

Device Events received from external systems are processed through two major stages:

- **Device Event Seeder:** This is the common interface point that receives all device event information and performs critical validations and conversions. During this process the device event seeder identifies the appropriate specific device event business object for further processing. The choice is made based on the originating external system and the type of event being received. For example, a device event for a "Last Gasp" would result in the paired event first device event being selected.
- If for some reason the device event seeder encounters an error an instance of the device event eeder will be created to manage the resolution of that error.
- **Specific Device Event:** Each specific device event has the appropriate logic for the type of event that has been received. A tamper event might create a service issue monitor while a "Last Gasp" might create an outage activity.

Device Event Seeder Processing

The device event seeder receives device event data in a common structure, however, the content of the data (identifiers, date/times, etc) can vary depending on the system and the particular device that generated it. To accurately translate the external content to values understood by the system the device event seeder leverages the configuration of the service provider (aka head end or external system) and the device.

The service provider specifies the following inputs into device event seeder processing:

- **Identifier Types:** Each device event must identify the device the event has been generated from. The system supports a multitude of identifiers for the device. The service provider configuration specifies which identifier type is used for the device which enables the device event seeder to search for the correct destination for the device event. For example, a service provider might indicate that devices are identified by a serial number.
- **Date/Time Format:** The service provider configuration will identify whether the date/times that were sent included specific time zone designations. This allows the system to accurately handle any time zone conversions that may be necessary.
- **Processing Methods:** A service provider has the following processing methods that are used in the evaluation of the device event:
 - Device Event Mapping - Maps a given external device event name to a standard event name. That standard event name is eventually used to identify the appropriate device event for specific processing.
 - Time Zone Translation - Identifies the extendable lookup to be used in mapping the service provider specific time zone to the interval time zone.

The device specifies the following inputs into IMD Seeder processing:

- **Incoming Data Shift:** This value is either specified directly on the device or can be defaulted via fallback on the device type. It identifies whether the incoming date/time information has is "Shifted" meaning it has been adjusted for Daylight Savings Time (DST) when in effect, or it is "Not Shifted" which means it will never be adjusted for DST. This plays an important role in the date/time processing since all incoming device event date/times will be stored without an adjustment for DST.

With these inputs the device event seeder is able to translate the external identifiers into the appropriate identifiers to tie the device event to the originating device in the system..

Device Event Seeder Critical Validations

For device events to continue on to specific device event processing they must pass the critical validations:

- The device must be identified.
- The device event must have an event date/time.

If either of the critical validations fails the device event processing will be halted and an instance of the device event seeder will be created

Note: There is special logic that exists for handling the situation where either the device event date/time or the device event end date/time falls on the duplicate hour that occurs when a time zone transitions out of daylight savings time.

Device Event Seeder Time Zone Translation and Conversion

To provide the most accurate tracking of device events all device event data is stored in a single time zone without an adjustment for Daylight Savings Time (DST). As utilities can have multiple head end systems that each send date/time information in different ways and some utilities operate in multiple time zones the device event seeder contains functionality to convert incoming date/times from a source time zone into the time zone of Oracle Utilities Meter Data Management (as indicated by the base time zone)

There are three components to identifying the source time zone of the incoming device event:

- **Service Provider IMD Import Date/Time Format:** When the device event date/times are sent in a format that identifies the time zone for each date/time the date/times will be delivered to the device event seeder already converted.
- **Incoming Data Shift:** This indicates whether the date/times will be adjusted for DST while it is in effect. A value of "Always in Local Time" indicates that the date/times are adjusted for DST. A value of "Always in Standard Time" indicates that the date/times are not adjusted for DST
- **Time Zone:** The time zone of the incoming data is identified using the follow order of precedence:
 1. The time zone as indicated by the device event data
 2. The service point time zone
 3. The device configuration time zone
 4. The base time zone

Once the time zone and the data shift of the incoming date/times is identified all date/times will be converted from that time zone and shift into the base time zone in standard time.

Specific Device Event Processing

Types of Device Events

Standard

Momentary device events, such as a tamper alert, are processed using the standard device event. These device events do not provide any special processing.

Paired Device Events

Device events with a duration are defined using paired event device events: paired event first and paired event last. With the first of the pair representing the start of the event, and the last of the pair representing the end of the event. Events of this type can be configured to create or complete activities that represent the event. For example, a "Last Gasp" event might create an outage activity that is completed when "Power Restoration" event is received.

When pairs of events arrive in rapid succession (such as a last gasp followed quickly by a power restoration), these "paired event" business objects are designed to prevent them from being sent to subscribing applications.

Communication Response

The communication response is a special type of event used for head end systems that respond to smart meter commands with device events. When received these events create a communication in that will initiate the completion of the originating smart meter command.

Refer to [About Communication In](#) for more information on a communication in.

Sending Device Events to Subscribing Systems

When device events are received, they are typically passed onto to another subscribing system, such as Oracle Utilities Meter Data Management, a customer information system (such as Oracle Utilities Customer Care and Billing), an outage system (such as Oracle Utilities Network Management System), or some other application.

The means of sending device event information to subscribing system is defined in the "How to Send Device Event Related Information" processing method for the service provider representing the subscribing system. Device event information can be sent via outbound communication business object, outbound communication, or batch process.

The method for sending device events to subscribing systems (business object, outbound message, or batch process) can be defined for each device event category, and can be overridden for individual device event types (including the ability to exclude specific device event types within a category). In addition, a default event processing method can be also be configured that applies when methods of transmission aren't specified at the individual category level.

The "Subscribe to Device Event" business service is used to process device event subscription requests, and allow external applications to manage the categories of events they receive.

Refer to [About Device Event Notification Suppressions](#) for more information on a suppression device event notifications.

Creating Service Issue Monitors and Service Investigative Orders

Device events can be configured to create service issue monitors and service investigative orders. The service issue monitor type to create is defined on the device event type. When a device event is received, an Enter algorithm on the device event's Processed state creates the service issue monitor, based on the Service Issue Monitor Type specified for the device event type.

Refer to [Understanding Service Task Types](#) for more information on configuring service issue monitor types.

Device Event Prioritization

By default, device events are created and/or received into the system in an initial state is "Pending" and are transitioned to subsequent states via the batch processing. This batch processing can be skipped by setting the Execution Method flag on the device event to "Real Time" (DIRT), in which case an Enter algorithm transitions the device event to the next state in its lifecycle immediately. This feature can be used to prioritize processing of certain types of device events.

The Execution Method flag can be set in in unsolicited device events sent from the head-end system, or can be inserted during Oracle Utilities Smart Grid Gateway Adapter processing.

Oracle Utilities Smart Grid Gateway Adapters set this flag to "Real Time" on all device events created as the result of smart meter commands.

Activities

About Activities

Activities cover a range of functional process within the system from smart meter commands, synchronization of consumption between related measuring components, service order management activities, and statistics and aggregations.

The table below provides the full list of activity type categories supported and a brief description of how they are used:

Activity Type Category	Activities of this type category are used to
Bulk Activity	Initiate a smart meter command for a group of meters using Oracle Utilities Smart Grid Gateway
Command Request	Initiate a smart meter command for an individual meter using Oracle Utilities Smart Grid Gateway
Consumption Sync	Trigger related measuring component estimation synchronization
Device Event Activity	Represent a device event. These are used when viewing usage and events with the Oracle Utilities Meter Data Management 360 Degree View.
Dimension Scanner	Trigger dimension scanning when aggregating usage, statistics, and other data.
Error Activity	Represent errors in activity processing.
Extract Request	Retrieve usage and device events from a head-end system using Oracle Utilities Smart Grid Gateway
Field Activity	Initiate field work via a message to an external field work system. Activities of this type are most often created by a request orchestration activity.
Meter Read Download Activity	Download a list of meters to be read.
Multi Device Command Request	Initiate a smart meter command for multiple meters (for head-end systems that support multi-device commands) using Oracle Utilities Smart Grid Gateway
Non-Dispatchable Activity	Represent steps or stages in a larger process in which the system is waiting for a resolution from another system. Examples include "Wait for Measurement" or "Wait for Scheduled Read."
Orchestration Maintenance	Update or cancel an active service order activity.
Payload Statistics	Calculate processing statistics for usage and device event import processing
Request Orchestration	Orchestrate the steps necessary to fulfill a service request, based on the current state of the service point related to the request.
Suppression	Suppress sending of device events to subscribing systems (such as Oracle Utilities Network Management System)
Usage Transaction Correction Processor	Trigger correction processing for usage transactions when corrected usage is received that would impact an existing usage transaction

Maintaining Activities

You use the **Activity** portal to view and maintain activities.

Refer to [About Activities](#) for additional functional information.

You can access the portal by selecting **Main, Communication, Activity**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When creating new activities using this portal, if the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal will be available.

This portal includes the following zones:

- **Activity:** defines the basic attributes of the activity
- **Field Activity Attachments:** lists attachments related to the activity (displayed only if the current activity is a field activity)
- **Activity Hierarchy:** a tree that displays the activity and related activities (including field activities and smart meter commands), inbound and outbound communications, and completion events
- **Activity Related Completion Event:** lists completion events (if any) related to the activity

Manually Completing Service Order Field Activities

Service order field activities in the "Communication in Progress" state can be manually completed or canceled by clicking **Complete** in the **Record Actions** section of the **Activity** zone. This opens the **Field Activity Manual Completion** page where the user can enter appropriate details to manually complete the field activity (such as completion information, service point information, device information, and so on). When submitted, this page creates an inbound communication and transitions the field activity to the next state as appropriate.

Note: Implementations can define custom service scripts for each field task type in the **Manual FA Completion Controls** section on the Field Task Type extendable lookup to customize the sections displayed on the **Field Activity Manual Completion** page.

Communications

About Communication Out

These transactions are typically created from an activity and are tasked with sending a message to an external system. They follow one of two communication patterns:

- **Two-way:** these messages are sent to the external system without an expectation of an immediate response, or a response is received but it is only an acknowledgement of a successful receipt of the message. The true response to the message is expected to be received in a process detached from the communication out. For the full lifecycle of the communication to be complete a communication in must be received.
- **One-way:** these messages are sent to the external system and responded to in full within a single transaction. No communication in will be received.

The format of the message sent to the external system is typically driven by a processing method for that external system and the transportation method is controlled by the external system's message options.

If an error is encountered sending the message to the external system the communication out can perform automated retry of the messages for a configurable rate of retry and number of retry attempts.

For one-way communications the communication out will be responsible for creating the completion event.

Once the message has been communicated and a response received the outbound communication will update the initiating activity with the result.

NOTE:

Refer to the following topics for additional information on communications functionality:

- [Understanding Processing Methods](#) for additional information on how processing methods are configured.
 - See [About Completion Events](#) for details on completion events.
 - See [External Systems](#) in the Oracle Utilities Application Framework *Administrative User Guide* for additional information on configuring communication between your system and external systems.
-

About Communication In

These transactions represent a message sent from an external system and are received in two situations:

- In response to a communication that had been sent to the external system. This is the most common usage of the communication in.
- An unsolicited message received from an external system such as a real time event. Note: this is not a common pattern.
- Upon receipt the communication in will link itself to the communication out that initiated it. The response message will then be validated to ensure that it is technically and functionally correct.
- For many smart meter commands and field activities executed by service order management the communication in is responsible for creating the appropriate completion events. For example, if the response was for the On Demand Read smart meter command a completion event will be created that will generate the appropriate initial measurement data.
- Similar to the communication out a communication in that encounters an error can perform an automated retry with a configurable rate of retry and number of retry attempts.

Maintaining Communications

The Communication portal is used to maintain communication in and communication out records.

Refer to [About Communication Out](#) and [About Communication In](#) for additional functional information.

You can access the portal from the **Main > Communication > Communication**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Communication**: defines the basic attributes of the Communication
- **Communication Hierarchy**: a tree that displays the communication and related activities (including field activities and smart meter commands), inbound and outbound communications, and completion events.

Completion Events

About Completion Events

Completion events are used to implement the outcome of an activity. They are created by either the communication out (for one-way communication) or the communication in (for two-way communication). Completion events are executed by the activity orchestrating the communication with the external system.

Some examples of the tasks a completion event will perform are:

- Commissioning, decommissioning, connecting, disconnecting a smart meter
- Installing or Removing a meter or item

- Creating initial measurement data
- Updating a device or service point

Maintaining Completion Events

The Completion Event portal is used to maintain completion events.

Refer to [About Completion Events](#) additional functional information.

You can access the portal from the **Main > Communication > Completion Event**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Completion Event**: defines the basic attributes of the Completion Event
- **Completion Event Related Objects**: displays data related to the completion event such as a device, service point, or initial measurement.

Notification Suppressions

About Device Event Notification Suppressions

When a device event is processed by the system it can be sent to one or many external applications interested in being notified about the event. A prime example of this is the Outage Management System subscribing to any device events related to a meter either losing power or regaining power.

There are situations, such as a field worker performing maintenance on a meter or on a node that impacts many meters, that will result in a large amount of device events being created, processed, and distributed to subscribers.

Device event notification suppressions provides a way for a subscribing system, in anticipation of scheduled maintenance, to suppress notification of certain device events (power down, power up, tamper, etc) from one or more meters.

Maintaining Notification Suppressions

The **Activity** portal is used to maintain notification suppressions records.

Refer to [About Device Event Notification Suppressions](#) for additional functional information.

You can access the portal from the **Main > Communication > Notification Suppression**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Activity**: defines the basic attributes of a notification suppression activity

Integrations

Business Flags

About Business Flags

Business flags provide a view into the status of a service point across applications (e.g. Oracle Utilities Meter Data Management, Oracle Utilities Analytics Insights, Oracle Utilities Customer Care and Billing). Business flags are currently available in two forms:

- **Service Point Business Flags:** are often informational in nature but also allow for manual investigation to be taken.
- **Service Point Monitor Business Flags:** are seen as symptomatic of an issue that needs to be investigated. These business flags feed into a service issue monitor and may result in a service investigative order being created.

For additional details see [About Business Flags](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Business Flag Allowed Actions

Allowed actions are implemented presented to the user as selectable options that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity:** This will initiate a field activity associated to the business flag's service point. The type of field task will be selected by the user. Note: this option requires Oracle Utilities Service Order Management.
- **Request Customer Notification:** This will initiate a message to the appropriate external system (e.g. Oracle Utilities Customer Care and Billing) that will identify a notification to be sent to the customer. The type of communication will be determined by the notification type selected by the user.

Note: not all business flags support allowed actions and not all business flags that support allowed actions support all allowed actions.

Maintaining Business Flags

Information for this functionality is available in the [Business Flags](#) section in the Oracle Utilities Application Framework *Administrative User Guide*.

Oracle Utilities Analytics Insights

Using the Meter Insights Investigation Viewer

The Meter Insights and Investigations functionality leverages the Oracle Utilities Analytics Insights business flag integration to support receipt of revenue protection events (referred to as "insights") from Oracle Utilities Analytics Insights for research and investigation using Oracle Utilities Meter Data Management (or Oracle Utilities Meter Solution Cloud Service). Revenue protection insights sent from Oracle Utilities Analytics Insights for investigation are events that suggest potential theft or loss of revenue such as unexpected consumption from an inactive meter, evidence of meter tampering, discovery of an improperly installed meter (such as a meter installed upside down or in reverse), and so on. Insights received from Oracle Utilities Analytics Insights create business flags, which in turn create related Meter Insight Investigation service tasks (referred to as "investigations"). Business users can use the **Meter Insights Investigations Viewer** portal to search, view, and investigate these investigations. This portal is intended to provide as much investigative information as possible so as to allow the user to complete as much work as possible without leaving the portal.

Searching

Use the following procedure to search for investigations:

1. Navigate to the portal by selecting **Main**, then **Insights**, then **Meter Insights Investigation Viewer**.

By default the **Investigations** zone displays search results for unassigned records and records assigned to the current user.

2. To search by specific search criteria or display the search criteria and filters, click the **Show Filters** link or icon. The **Investigations** zone expands to display the available search filters, including:

- Business Flag Type
- Address (including City and Postal Code)
- Average Daily Usage
- Priority
- Service Type
- Service Point Type
- Assigned to User ID
- Flags to include Unassigned records, and investigations with current active field activities.

3. Enter your search criteria and click **Search**.

The **Investigations** zone displays a default set of data about each investigation. To select the information to display for each, click the **Display** link or icon, select or deselect the data you wish to view or hide, and click **Display**.

Viewing Service Issue Monitors and Consumption

To view additional information about an investigation, click the **Expand Section** icon in the far left column. The section expands to display:

- Comments
- Service Point Information
- Field Work Information
- A list of insights (business flags) related to the investigation
- Consumption (a section similar to the **Final Values Overlay** zone in the **360 Degree View** portal)

To view additional information about the investigation, service point, or field activity, click the icon at the end of its information string. A new browser window will open displaying the **Service Task**, **Service Point** tab of the **360 Degree View** portal or **Activity** portal (respectively). This allows the user to investigate the issue in more detail as needed without having to navigate away from the **Meter Insights Investigations Viewer** portal.

To expand the **Consumption** section, click the **Expand Section - Consumption** icon on the far right side of the **Consumption** section heading. The section expands to display the following:

- **Parameters:** The default parameters used to display consumption for the service point. This includes **Measuring Component**, **Value Identifier Type**, **Start Date/Time**, **End Date/Time**, **Final Values Overlay Profile**, and **Event Bar Profile**. These values are based on the **Consumption Data Source** parameters on the investigation's **Investigation Type** (Service Task Type). The measuring component and value identifier type is based on service point type, interval/scalar flag, and UOM/TOU/SQI combination, and the date range is based on the start and end dates of the investigation and the **Days Before to Graph** and **Days After to Graph** parameters.
- **Values to Graph:** A list of measuring components to graph, including measuring components defined in the current **Final Values Overlay Profile**, as well as other measuring components selected by the user.

- **Measurement Data:** A graph and tabular display of the consumption and values to graph, and event bars based on the current **Event Bar Profile**.

To change the displayed consumption, adjust the **Parameters** and **Values to Graph** and click **Load** (in the **Parameters** section).

Working With Investigations

Users can also add comments, assign a recipient for To Do entries, and change the status of investigations from this portal.

- To add or edit a comment, click the **Edit** icon in the second column from the left. The **Edit** icon is replaced by a checkmark icon and an "X" icon, and a **Comments** box opens. Enter or edit the comment text and click the checkmark icon. To delete a comment, click the "X" icon.

Comments are saved on the Investigation, and can be viewed from the **Log** tab on the **Service Task** portal.

- To assign a recipient for To Do entries, click the **Edit** icon in the second column from the left. The **Edit** icon is replaced by a checkmark icon and an "X" icon, and the **Assigned To** column displays a drop-down list. Select the user to which To Do entries should be assigned, and click the checkmark icon.
- To change the status of the investigation, click the icon in the **Action** column. A popup menu will open displaying available options including:
 - **Initiate Field Work:** Select this to create a field activity to investigate the issue from the field (this transitions the investigation to the Waiting for Field Work state).
 - **Issue Resolved:** Select this if the issue has been resolved (this transitions the investigation to the Issue Resolved state).
 - **No Issue:** Select this if there is no issue (this transitions the investigation to the No Issue state).
 - **Inconclusive:** Select this if/when the investigation is inconclusive (this transitions the investigation to the Inconclusive state).
 - **Discarded:** Select this to discard issue (this transitions the investigation to the Discarded state).

See [Meter Insights and Investigation Processing](#) in the *Administrative User Guide* for more information about what happens when the investigation enters one of these states.

Aggregations

Standard Aggregations

About Aggregations

Aggregations are measurements that represent a summarization of other measurements from a set of devices, items, and/or measuring components. For example, an aggregation may be based on the sum of the electric consumption of all residential customers in a particular postal code within the utility's service territory. The group of related measuring components for which measurements are summarized are referred to as constituent measuring components.

Every type of aggregation has one or more dimensions. For example, an aggregation might be defined with three dimensions as follows:

- Substation
- Feeder
- Transformer

Aggregations are defined by aggregator measuring components. A separate aggregator measuring component should be defined for every distinct combination of dimensions for a given type of aggregation. For example, the transformer aggregation described above would require an aggregator measuring component for every distinct combination of substation / feeder / transformer found among the electric Service Points.

Aggregations can also be aggregated. For example, the aggregator measuring components for each substation / feeder / transformer combination can in turn be used to aggregate consumption at each substation / feeder combination. In this case, a distinct aggregator measuring component would be defined for each unique substation / feeder combination. Likewise, the aggregator measuring components for each substation / feeder combination could be used to aggregate consumption at each substation, in which case, distinct aggregator measuring components would be defined for every unique substation. Finally, the aggregator measuring components for each substation can be used to aggregate total consumption for all substations, with an aggregator measuring component defined to represent the entire service area.

Aggregation Calculations

The system periodically aggregates consumption via batch process, using a deferred monitor on the aggregator measuring components. In addition, users can re-aggregate data in real-time if they don't wish to wait for the batch process, or if the original aggregation needs to be re-calculated due to incorrect data. Users can also create ad hoc aggregations "on the fly" and these will persist in the database in the same manner as other aggregations.

Understanding Aggregation Periods

The start and end dates and times for aggregation calculations are based on the following:

- Aggregation Horizon
- Aggregation Lag
- Aggregation Cut Off Time

Whenever aggregation is performed for an aggregator measuring component, consumption is aggregated for every day in its "Aggregation Horizon." The "Aggregation Horizon" is the number of days during which there's a potential change in measurement data for one or more of the measuring components associated an aggregator measuring component.

Aggregation calculations typically lag behind the current date by a few days to give the system time to upload and perform validations and create final measurements. The amount of lag time is referred to as the "Aggregation Lag" and is the number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the end of the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.

Aggregation is always performed through a given "through time" (such as 12:00 AM) rather than through the actual time of the aggregation calculation. This time is referred to as the "Aggregation Cut Off Time." For example, the stop time for aggregation calculations with an Aggregation Lag of 2, and an Aggregation Cut Off Time of 10:00 PM will always be 10:00 PM 2 days prior to the date on which the calculations are performed. In the above examples, aggregations performed on January 9 would have an end date/time of 10:00 PM on January 7, and aggregations performed on January 10 would have an end date/time of 10:00 PM on January 8.

Aggregation and Re-Aggregation

The use of the aggregation horizon means that aggregated totals for some days will be re-aggregated until those days are no longer covered by the aggregation horizon. For example, with an aggregation horizon of 5 days and an aggregation lag of 2 days, on the night of January 9 the aggregation period would be January 3 through January 7 (as in the above example).

On the night of January 10, the horizon will shift 1 day (to January 4 through January 8, again as above). This means the following:

- The totals for January 3 calculated on January 9 will be untouched (January 3 now falls outside the aggregation horizon)
- The totals for January 4 through January 7 will be re-derived because corrections may have occurred (and they still fall within the aggregation horizon)
- The totals for January 8 will be calculated for the first time (because it now is within the aggregation horizon).

Manually Read Meters and Aggregation Lag

Aggregations that include manually read meters often have much longer aggregation lags than those for automatically read meters. This allows more time for manual meter readings to be imported into the system for use in aggregations.

For example, suppose a situation where manual meter reads arrive approximately 1 month after the date of the reading. In this case, it wouldn't be until a meter read upload on February 7 that the last manual reads including consumption from January 6 will exist. Since we don't want to perform aggregations for January 6 until there's a decent chance that all consumption for that date exists, an aggregation lag of 32 days ensures that the data for January 6 is in the system when the aggregation is performed on February 7.

When An Aggregator Measuring Component Contains Both Manual and AMI Measuring Components

The previous section suggests that if an aggregator measuring component contains both manually read and AMI measuring components, the aggregator measuring component should have a long lag time rather than the short time shown in the earlier example.

While this is one possible approach, an alternative approach could allow users to see timely aggregations of the AMI channels and only lag the manual channels. To do this they could configure the system as follows:

- Create an aggregator measuring component that only aggregates manual measuring component types (horizon: 5 days, lag: 31 days)
- Create a separate aggregator measuring component that only aggregates interval measuring component type: 5 days types (horizon: 5 days, lag: 2 days)
- Create a third aggregator measuring component that aggregates the above aggregator measuring component types (horizon: 5 days, lag 31 days)

Expanding The Aggregation Horizon Periodically

Even with a 30-ish day aggregation lag, it's possible for an account with several months of estimated consumption to have its consumption "invalidated" when real readings arrive whose dial readings are less than the estimated readings (or when major retroactive data change takes place). Another similar situation is when a user manually corrects consumption after the aggregation horizon has moved forward.

To address situations like these, the use of ad-hoc aggregations with a user-specified aggregation horizon supports the notion of periodically (such as once a month or once a week) aggregating with a long aggregation horizon (up to 90 days) to catch as many retroactive changes as possible.

A Note About Using Non-Effective Dated Dimensions

Be aware that whenever aggregation takes place, the system uses master data that exists as of that date. For example, if an aggregation is performed using non effective-dated master data attributes (for example, aggregating by measuring component type) and a measuring component's type is changed, all days in the aggregation horizon will reflect the change regardless of when the user makes the change, because the measuring component type relationship is not effective-dated.

The impact of this depends on the nature of the change:

- If the master data was wrong, this provides a way to re-aggregate the data to accurately reflect the master data.
- If the change occurred effective as of a given date (but there's no effective dated attribute), this can result in incorrect aggregation values.

Because of this, it is recommended that where possible dimensions used in aggregations be effective-dated. For information on configuration, reference the related section for [Aggregations](#) in the Administration Guide.

Creating Aggregators

There are two ways in which aggregator measuring components are created:

- **Automatically:** The system will periodically create new aggregator measuring components when new "dimensional values" are detected. For example, if a new substation is added to the system, a new aggregator measuring component will be created for the substation.
- **Manually:** An end-user can create an aggregator measuring component at their discretion

Automatic Creation of Aggregator Measuring Components

The system automatically creates aggregator measuring components when it detects new instances of the dimension(s) being aggregated. This activity is referred to as dimension scanning. For example, if the system is configured to aggregate individual substations, a user will NOT have to manually set up an aggregator measuring component when a new substation is referenced on a service point. Rather, the system will create the new aggregator when it detects a substation on a service point that doesn't have an aggregator measuring component.

Similarly, if is configured to aggregate distinct combinations of rate class (on usage subscription type) and postal code (on service point), the system will create an aggregator measuring component when it detects new combinations of rate class and postal code.

The periodic monitoring to ensure sufficient aggregation measuring components exist is implemented via monitoring algorithms on a related activity business object that references a corresponding measuring component type. This means that there must be a separate activity type / activity combination for every type of aggregation performed. These monitor algorithms include:

- A Monitor algorithm on the Active state that simply transitions the activity to the transitory Scan state. Users can manually transition the activity to the Scan state by clicking the "Scan" button on the activity.
- An Enter algorithm on the Scan state finds the distinct combinations of dimensional values for this type of aggregation and checks that an aggregator measuring component that references the activity's aggregator measuring component type exists for every instance and creates new aggregator measuring components as appropriate. The algorithm also populates the dimensional values on the new measuring components (mapped to searchable characteristics), and sets the Consumption Aggregated Through Date/Time field on the new aggregator measuring components to the current date and the Aggregation Cut Off Time on the aggregator measuring component type.

Hard-Wiring Service Types for Aggregations

If the dimensions used for aggregation do not include at least one service type-specific dimension (for example, in the case of aggregating by postal code only) AND the aggregation should not commingle measurements of different service types, it's important to:

- Declare the specific service type for the aggregation on the dimension scanner activity instance
- Declare the desired service type-specific measuring component types on the aggregator measuring component type

For example, if an electric and gas implementation aggregates consumption by postal code, they will need 2 activities: one will reference the Electric service type and the desired aggregator measuring component type, the other will reference the Gas service type and its aggregator measuring component type. The aggregator measuring components will have two dimensional attributes: postal code and service type.

Manual Creation Of Aggregator Measuring Components

Users can also create aggregator measuring component manually. This is useful when an ad hoc aggregation for an ad hoc time period is required, or when there is no activity that automatically creates instances of a given combination of dimensions. To do this, the user simply clicks the "Add" link on the Aggregator Search zone title bar. The BPA script:

- Prompts the user to define the type of aggregation (this will present a list of measuring component types whose measuring component category is aggregator)
- Prompts the user to define the dimensional value(s), the desired aggregation time, and if this aggregation should be performed indefinitely or if it is a "one time"

Base Product Aggregators

A number of standard aggregation processes are delivered as part of the base product. These provide a means of aggregating measurement data by postal code and service type for both physical meters and items.

Aggregator Name	Description
Aggregator - Postal and Service Type	Aggregates measurement quantities for constituent measuring components from physical meter based on postal code and service type dimensions.
Item Aggregator - Postal and Service Type	Aggregates measurement quantities for constituent measuring component from items based on postal code and service type dimensions.

Aggregators Used With Analytics

Other aggregators shown below are delivered for use by Oracle Utilities Analytics and Oracle Utilities Analytics Visualization (OUAV). These aggregate measurement data (including quantities and counts) for constituent measuring components based on the following dimensions: Postal, City, Head-End, Device Type, Usage Calculation Group, Market and Service Provider, and Service Type.

Aggregator Name	Description
Measurement Measured Quantity Aggregator OUAV Subject Area: Meter - Aggregated Measurement Quantity	Aggregates measurement quantities and distributes the constituents' measurements across Value Identifiers based on condition codes.
Measurement Quality Count Aggregator OUAV Subject Area: Meter - Aggregated Measurement Count	Aggregates measurement counts and distributes the constituents' counts across Value Identifiers based on condition codes.
Measurement Timeliness Count Aggregator OUAV Subject Area: Meter - Aggregated Timeliness Count	Aggregates measurement counts that arrived on time or are late.
Measurement Timeliness Quantity Aggregator OUAV Subject Area: Meter - Aggregated Timeliness Quantity	Aggregates measurement quantities that arrived on time or are late.

See the [Oracle Utilities Analytics Visualization User Guide](#) for more information about the OUAV Subject Areas.

Maintaining Aggregations

This portal is used to display and maintain Aggregations.

Refer to [About Aggregations](#) for additional functional information.

You can access the portal from the **Main > Totals and Trends > Consumption Statistics**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component**: defines the basic attributes of the aggregator measuring component.
- **Measuring Component Attributes**: displays attributes that describe the dimensions and criteria for the aggregation measuring component (applies to dynamic aggregation measuring components only)
- **Measurements — Interval**: displays aggregated measurement data for the selected aggregator measuring component.
- **Interval - Audit View**: allows users to view an interval measurement curve for a given period overlaid with the count of audit records for each individual measurement.
- **Final Values Overlay**: displays final measurements for a measuring component, and provides the ability to overlay the graphed data with final measurements from other measuring components.
- **Time of Use Overlay**: displays an overlay of the TOU periods on a final interval measurement along with totalized TOU consumption based on a user-defined time period and TOU map
- **Related Measuring Component Sets**: lists measuring components sets of which the aggregator measuring component is a member (applies to dynamic aggregation measuring components only)
- **Usage Subscriptions Directly Linked to MC**: lists usage subscriptions that are directly linked to current measuring component

A few functions are available in many of these zones that allow you to interact with the measurement data. For more information of these functions refer to the [Applying Measurement Functions](#) section.

Dynamic Aggregation

Dynamic Aggregation Overview

Standard aggregation processing uses specific algorithms configured to work with a specified set of dimensions. For example, the base package Service Type and Postal aggregation uses specific algorithms for dimension scanning and finding constituent measuring components. In contrast, dynamic aggregation uses dynamic queries for the dimension scanning, find constituents, and aggregation processes.

Dynamic aggregation can be used for analysis (to view aggregated data to understand load demand, for instance) as well as settlement processing performed by Oracle Utilities Market Settlements Management.

Dynamic aggregation results can be viewed using Oracle Utilities Analytics Visualization. See [Viewing Dynamic Aggregation Results Using Oracle Utilities Analytics Visualization](#) and the [Oracle Utilities Analytics Visualization User Guide](#) for more information.

Understanding Dynamic Aggregation Execution

This section provides an overview of how dynamic aggregation processing is executed, including descriptions of the different types of dynamic aggregation processing and the different types of data that can be aggregated.

Dynamic Aggregation Execution: Aggregation Groups and Aggregation Group Runs

Aggregation processing is managed via aggregation groups. [Aggregation Groups](#) outline the sequence of aggregations that must occur for a given aggregation process. Each aggregation group includes a set of [Measuring Component Sets](#), each of which has one or more related [Aggregation Measuring Components](#).

When processing is initiated for an aggregation group, the system creates an Aggregation Group Run record to track the status and progress of the aggregation processing. This record is used to manage the aggregation process for each group and track which Measuring Component Sets should be executed next and when the aggregation is complete.

The following steps outlines the aggregation process:

1. The Dimension Scan and Aggregation monitor batch control (D1-DSAEM) initiates processing for all Aggregation Groups. This should be scheduled at least once per day. This monitor process runs all monitor algorithms on each aggregation group. The base package aggregation group has two monitor algorithms:
 - Aggregation Group Run Maintenance (D1-AGRM)
2. The Aggregation Group Run Maintenance algorithm verifies if the Aggregation Group is ready to aggregate by looking at the processing timetable defined for the aggregation group and the last scheduled execution. If it is time for the next aggregation then the algorithm creates a pending Aggregation Group Run which will then be used to track the status of the Measuring Component Sets for the aggregation.
3. At the completion of the Dimension Scanner and Aggregation monitor batch process, the Submit Dimension Scanner Batch (D1-SUBDIMSCN) post-processing algorithm searches for any Aggregation Group Run entries that are in progress where the next Measuring Component Set is not manual. If at least one is found then it will initiate the Aggregation Group Dimension Scanner batch process (D1-AGDS).
4. The Aggregation Group Dimension Scanner batch process identifies the next Measuring Component Set for each Aggregation Group Run that is in progress. If that next Measuring Component Set is not manual then it will retrieve each Aggregation Measuring Component for the Measuring Component Set and execute the monitor algorithms for that Aggregation Measuring Component. These include an aggregation algorithm (specific to the type of data to be aggregated such as interval, billed quantities, etc.) and in some cases a value derivation algorithm.
5. For each Aggregation Measuring Component that is monitored by the Aggregation Group Dimension Scanner batch process, the aggregation process:
 - a. Executes the appropriate Find Constituents algorithm to find the list of constituents that are to be aggregated
 - b. Extracts the data for those constituents that should be aggregated
 - c. Executes the appropriate aggregation algorithm against that data and store the results
 - d. Executes validation algorithms if applicable
 - e. Executes value derivation algorithms if applicable
6. The Aggregate Next Measuring Component Set (D1-AGGNXMCS) post-processing algorithm on the Aggregation Group Dimension Scanner batch process updates the Aggregation Group Run the batch information for each Measuring Component Set that was aggregated, and requests the Dimension Scan and Aggregation monitor batch process to run again.
7. This again executes the monitor algorithms for all the Aggregation Groups which will do one of several things:
 - If the Aggregation Group Run is in progress and the next Measuring Component Set is Automatic then nothing will happen.
 - If the Aggregation Group Run is in progress and the next Measuring Component Set is Manual it will create a To Do.
 - If the Aggregation Group Run does not have a next Measuring Component Set, it will set the Aggregation Group Run to Complete

NOTE: The Dimension Scanner algorithm will be executed again but since there will not be a pending Aggregation Group Run it will not do anything.

8. Once all Measuring Component Sets are complete the Aggregation Group Run Maintenance algorithm marks the Aggregation Group Run as complete.

Aggregation Scheduling

Refer to [Understanding Aggregation Periods](#) for basics about aggregation periods.

Aggregation Scheduling for Aggregation Groups can be based on either a Defined Lag, or a Processing Timetable.

- **Defined Lag** scheduling uses the following parameters:
 - **Aggregation Cut Off Time:** The end time for aggregation calculations performed for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This is used to ensure a consistent end time for aggregation periods. This is especially useful when aggregating other aggregations.
 - **Aggregation Lag:** The number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.
 - **Aggregation Horizon:** The number of days in the aggregation period for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This reflects the time period during which there's a potential change in measurement data for one or more of the measuring components associated with Aggregation Measuring Components. This together with the Aggregation Lag is used to determine the start and end dates of an aggregation period.
- **Processing Timetable** scheduling uses a Processing Timetable Type to drive aggregation schedule.

With dynamic aggregation, the aggregation period is consistent for all members of an Aggregation Group when an aggregation is performed. This is despite the fact that there may be differences between Measuring Component Sets and even Measuring Components within an Measuring Component Set as to how far the data has been aggregated through. In addition, individual Aggregation Measuring Components all use the same aggregation period when aggregation is performed.

Dynamic Aggregation Processing

This section provides additional details around the specific types of processing used with dynamic aggregation.

Similar to standard aggregation, dynamic aggregation processing comprises three primary types of processes:

- **Dimension Scanning:** a process that searches for unique combinations of dimensions that are not yet represented by an Aggregation Measuring Component.
- **Find Constituents:** a process that finds all source data to be aggregated for a given Aggregation Measuring Component, based on the Aggregation Measuring Component's dimensions.
- **Aggregation:** a process that aggregates source data that corresponds to the Aggregation Measuring Component's dimensions.

Dynamic aggregation processing is driven by the following types of administrative data:

- **Data Sources** define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or other sources of data.
- **Aggregation Measuring Component Types** define the most important properties of aggregation measuring components used to store aggregated data.
- **Aggregation Groups** define the ordering of a series of related aggregations and the schedule of aggregation.
- **Measuring Component Sets** define the dimensions and criteria by which aggregation will be performed.

Refer to [Dynamic Aggregation Configuration Overview](#) for more information about configuration of this data.

Dynamic SQL

Dynamic aggregation uses dynamic SQL queries to perform dimension scanning, find constituents, and aggregation processing. These dynamic queries are based on configuration of:

- [Data Sources](#)
- [Aggregation Measuring Component Types](#)
- [Measuring Component Sets](#)

The Source of Dynamic SQL

Data sources provide template SQL that is used as the basis for dynamic queries. This template SQL is extended by additional SQL generated from the data source configuration as well as configuration defined for measuring component sets, measuring components, and measuring component types that reference the data source. The ways in which the template SQL is extended is based on the type of process:

- **Dimension Scanning:** The data source template SQL is extended by the criteria, dimensions, and individually managed items configured on the measuring component sets being processed.
- **Find Constituents:** The data source template SQL is extended by attributes defined on the aggregation measuring components being processed.
- **Aggregation:** The data source template SQL is extended by the value identifiers defined on the measuring component type of the aggregation measuring components being processed.

Dimension Scanning

The dimension scanning process analyzes master data to identify unique dimension combinations and create an aggregation measuring component for each. Several objects play a role in this process:

- The Aggregation Group holds the monitor algorithm that performs the scanning
- The Data Source defines the template SQL for identifying dimensions
- Measuring Component Sets define the dimensions and criteria for identifying the dimension combinations

See [Dynamic SQL](#) for more about the role of data sources and measuring component sets in generating dynamic SQL queries for dimension scanning.

This process is executed when aggregation is initiated for an Aggregation Group. This process should be run on a frequent basis (daily or more frequent) and should be executed prior to aggregation processing being run. Each time it is executed the dimension scanning process takes the following high level steps:

1. Identifies all Measuring Component Sets for the Aggregation Group that are not imported from an external source
2. Identifies all yet to be represented dimension combinations
3. Creates an Aggregation Measuring Component based on the Measuring Component Set's Measuring Component Type for each dimension combination identified in step 2.
4. Adds Attributes for each Aggregation Measuring Component created to describe the dimensions and criteria for that Measuring Component
5. Adds an entry in the Measuring Component Set participants table for each Aggregation Measuring Component created

This processing is performed by a monitor algorithm (Aggregation Group Dimension Scanner: D1-AGDS) on the Finalized status of the Aggregation Group business object.

Find Constituents

The Find Constituents process finds all source data to be aggregated for a given aggregation measuring component, based on the Aggregation Measuring Component's dimensions. The queries used for this process are based on data source template SQL extended by attributes defined on the Aggregation Measuring Components being processed.

The Find Constituents process is initiated by the aggregation algorithm on the Aggregation Measuring Component (each type of Aggregation Measuring Component — interval, item, billed quantities — has its own aggregation algorithm), and is performed by algorithms defined for the Find Constituents system event on the Aggregation Measuring Component business object.

This process differs slightly when finding constituents for interval and scalar measurements stored on measuring components, item data, and billed quantities.

Measuring Components

The Find Constituents process for measuring components uses the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm which retrieves data based on the following:

- Attributes on the Aggregation Measuring Component based on the Measuring Component Set configuration
- Measuring Component Types on the Data Source

Measuring component constituents are inserted into a global temporary table (GTT1) with the following information:

- Measuring Component ID
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

NOTE: The aggregation period for each is adjusted by the source Measuring Component's installation history.

Items

The Find Constituents process for items uses the Find Constituents for Items (D1-FICONITEM) algorithm which retrieves data based on the following:

- Attributes on the Measuring Component based on the Measuring Component Set configuration
- Item Types / Service Point Types on the Data Source (for badged vs. unbadged items, respectively)

Item constituents are inserted into a global temporary table (GTT3) with the following information:

- Maintenance Object (Device or Service Point)
- Device Type: Item Type
- Item Count
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

NOTE: The aggregation period for each is adjusted by the source Item's installation history.

Billed Quantities

The Find Constituents process for billed quantities uses the Find Constituents for Billing Data (D1-FINDCONSB) algorithm which retrieves data based on the following:

- Attributes on the Aggregation Measuring Component based on the Measuring Component Set configuration
- Usage Subscription Types on the Data Source

Billed quantity constituents are inserted into a global temporary table (GTT5) with the following information:

- Usage Subscription ID
- Usage ID
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

NOTE: The aggregation period for each is adjusted by the source Usage Subscription's installation history.

Aggregation Calculation

The aggregation calculations process aggregates source data that correspond to the Aggregation Measuring Component's dimensions. The queries used for this process are based on data source template SQL extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Components being processed.

The aggregation calculation process is initiated by Aggregation by MC Set Monitor batch process (D1-AMCS), and is performed by monitor algorithms defined on the Active state of the Aggregation Measuring Component business object. The algorithms used by each type of Aggregation Measuring Component are as follows:

Aggregation Measuring Component Business Object	Aggregation Algorithm
Dynamic Aggregator - Billed Quantities (D1-AggBilledServiceQuantities)	Aggregate Billed Service Quantities (D1_AGGBSQ)
Dynamic Aggregator - Composite (D1-AggregatorComposite)	Aggregate Interval Measurements (D1_AGGINT)
Dynamic Aggregator - Customer Quantities (D1-AggregatorCustomerQuantity)	Aggregate Customer Specific Quantities (D1_AGGCSQ)
Dynamic Aggregator - Interval (D1-AggregatorInterval)	Aggregate Interval Measurements (D1_AGGINT)
Dynamic Aggregator - Items (D1-AggregatorItems)	Aggregate Item Data (D1_AGGITEM)
Dynamic Aggregator - Scalar (D1-AggregatorScalar)	Aggregate Scalar (D1_AGGSCLR)

See [Types of Aggregation](#) for more information about aggregation calculations for each type.

Other Calculations

In addition to basic aggregation processing, other calculations can be performed on aggregated measurements as needed. For instance, a common step in aggregating data for use in market settlements is applying a loss factor to aggregated data to reflect system losses (line loss, etc.) between generation-level quantities and end consumption quantities.

These types of calculations can be performed by value derivation algorithms. These are algorithms based on the Derive Aggregated Quantity Using a Formula (D1-DERAGGQTY) algorithm type which apply a configured formula to aggregated measurement values. For instance, to apply a loss factor, an algorithm can retrieve effective-dated factor values for a loss factor and multiply each aggregated measurement value by the appropriate factor value.

The Execute Aggregation Value Derivation (D1-EAGGVALD) algorithm on Aggregation Measuring Components executes any value derivation algorithms specified for Value Identifiers on the Aggregation Measuring Component Type.

Foundation and Composite Aggregation

Dynamic aggregation supports two “levels” of aggregation. Aggregating source data, from measuring components, items, or billed quantities is referred to as “Foundation” aggregation. Aggregation of aggregated data is known as “Composite” aggregation. Composite aggregation provides the ability to aggregate data from a set of other aggregations.

The diagram below illustrates a simple example of the relationship between foundation and composite measuring component sets. Each of the three foundation measuring component sets has a number of aggregation measuring component participants that aggregate data based on a set of dimensions and a particular supplier and rate class. Those in turn are participants in the composite measuring component set that aggregates based on the supplier (including data for all rate classes).

A common scenario where composite aggregation would be used is to consolidate data across several foundation aggregation measuring component sets that pulled data from a set of data sources ordered by precedence such that the best data was sourced when available and when not the aggregations fell back to a lesser quality data source:

- Foundation: Interval measurements from usage subscriptions and / or service points
- Foundation: Scalar measurement from usage subscriptions and / or service points
- Foundation: Interval measurements from estimations (backcasted using actual weather)
- Composite: Aggregation by supplier

In this example the goal of the first aggregation would be to retrieve as much interval data as possible where that interval data covered the entire period being settled for. The second aggregation would take scalar data for those instances where interval data was not available and apply a profile to produce the appropriate intervals. The third aggregation would fill in any remaining gaps that were not covered by interval or scalar data with estimations based various forecasting models.

At the completion of those first three aggregations there would be the full resolution of data for the customer base. However, the values would be spread out across many aggregation measuring components tied to those measuring component sets. This is where the composite aggregation functionality comes into play. The composite aggregation measuring component would reference the first three foundation aggregations and sum together the data from each aggregation into a single instance that represents the total usage for the period being settled.

Let’s look at a slightly more involved example. The diagram below illustrates a set of foundation aggregations based on:

- Rate Class
- Strata
- Procurement Class

This shows how the physical measuring component data (designated by Customer A, Customer B, etc.) will be aggregated into separate aggregation measuring components based on source of data (interval or scalar). Then it shows how those aggregations are then aggregated to produce a total number that represents all 3 aggregation sources merged together.

Types of Aggregations

This section describes the processing used by different types of aggregations, including:

- Aggregating Measurement Data (Interval and Scalar)
- Aggregating Item Data
- Aggregating Billed Service Quantities
- Aggregating Aggregated Data (Composite Aggregation)

Aggregating Measurement Data

Aggregating measurement data involves identifying constituent measuring components for an Aggregation Measuring Component, identifying the measurement data that falls within the aggregation period, and aggregating that data. The process varies slightly between interval and scalar measuring components.

Interval Measuring Components

Aggregation of interval measurements is handled by the Aggregate Interval Measurements (D1_AGGINT) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm and populates the GTT1 global temporary table (see [Find Constituents](#) for more details about this process).
- It deletes any constituents from the GTT1 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT1, the algorithm inserts its measurements for the aggregation period into the GTT2 global temporary table. If the SPI and UOM are different from that of the Aggregation Measuring Component, the measurements are converted to a common SPI using Axis Conversion.
- It performs aggregation calculations on the measurement data in the GTT2 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Scalar Measuring Components

Aggregation of scalar measurements is handled by the Aggregate Scalar Measurements (D1_AGGSCS) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm and populates the GTT1 global temporary table (see [Find Constituents](#) for more details about this process).
- It deletes any constituents from the GTT1 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT1, the algorithm inserts its measurements for the aggregation period into the GTT2 global temporary table. If the UOM is different from that of the Aggregation Measuring Component, the measurement is converted to a common UOM before being inserted into GTT1.
- It performs aggregation calculations on the measurement data in the GTT2 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It applies a profile to the aggregated scalar values to create interval measurements with the same SPI as the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Item Data

Aggregating item data involves identifying constituent items for an Aggregation Measuring Component, calculate item measurement data for the aggregation period, and aggregating that data.

Aggregation of interval measurements is handled by the Aggregate Item Data (D1_AGGITEM) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Items (D1-FICONITEM) algorithm and populates the GTT3 global temporary table with groups of device types (for badged items) and/or service point types (for unbadged items) (see [Find Constituents](#) for more details about this process).
- It deletes any constituents from the GTT3 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT3, the algorithm calculates measurements for the aggregation period and inserts them into the GTT4 global temporary table by applying the item counts for each group to the item interval (profile) data. If the SPI and UOM are different from that of the Aggregation Measuring Component, the measurements are converted to a common SPI using Axis Conversion.
- It performs aggregation calculations on the measurement data in the GTT4 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Billed Quantities

Aggregating billed service quantities involves identifying constituent usage transactions for an Aggregation Measuring Component, retrieving the service quantity data that falls within the aggregation period, and aggregating that data.

Aggregation of billed quantities is handled by the Aggregate Billed Service Quantities (D1_AGGBSQ) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Billing Data (D1-FINDCONSB) algorithm and populates the GTT5 global temporary table (see [Find Constituents](#) for more details about this process).
- It deletes any constituents from the GTT5 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT5, the algorithm retrieves billing data for the aggregation period (based on the service quantity configuration on the data source) and inserts it into the GTT6 global temporary table. If the UOM is different from that of the Aggregation Measuring Component, the service quantities are converted to a common UOM.
- It performs aggregation calculations on the measurement data in the GTT6 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It applies a profile to the aggregated values to create interval measurements with the same SPI as the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Aggregated Data

Aggregating aggregated data, also known as composite aggregation, involves identifying constituent aggregation measuring components for a composite Aggregation Measuring Component, identifying the measurement data that falls within the aggregation period, and aggregating that data.

Composite aggregation is very similar to aggregating interval measurement data, and uses the Aggregate Interval Measurements (D1_AGGINT) Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm.

Aggregation Measuring Components

About Aggregation Measuring Components

Aggregation Measuring Components are measuring components used to store aggregated data. Aggregation measuring components do not use initial measurements. Aggregated measurements are stored in the Measurement or Aggregation Measurement table (based on the Measurement Business Object defined for the aggregation measuring component's type).

Aggregation Measuring Components are defined by the following:

- **Initiating Measuring Component Set:** The measuring component set that triggered creation of the aggregation measuring component via the Dimension Scanning process (see [Dimension Scanning](#) for more information).
- **Processing Information:** Details of aggregation processing for the aggregation measuring component, including the date and time through which aggregation has been performed.
- **VEE Groups:** The VEE groups used when performing validation, editing, and estimation for the aggregation measuring component.
- **Measuring Component Attributes:** Attributes that describe the dimensions and criteria for the aggregation measuring component (identified by the Dimension Scanning process)

The base package includes the following aggregation measuring component business objects for use with dynamic aggregation:

- **Aggregator Interval (D1–AggregatorInterval):** Used to aggregate interval measurements from interval measuring components
- **Aggregator Scalar (D1–AggregatorScalar):** Used to aggregate scalar measurements from scalar measuring components
- **Aggregator Items Measuring Component (D1–AggregatorItems):** Used to aggregate item data
- **Aggregator Billed Service Quantities (D1–AggBilledServiceQuantities):** Used to aggregate billed service quantities from usage transactions
- **Aggregator Customer Quantities (D1–AggregatorCustomerQuantity):** Used to aggregate specific types of customer quantities such as Peak Load Contribution (PLC) and usage factors
- **Aggregator Composite (D1–AggregatorComposite):** Used to aggregate aggregated data from aggregation measuring components (composite aggregation)

These business objects define the Find Constituents and Aggregation algorithms used for aggregation calculations.

Maintaining Aggregation Measuring Components

You use the **Totals and Trends View** portal to maintain aggregation measuring components.

Refer to [About Aggregation Measuring Components](#) for additional information.

You can access this portal by selecting an aggregation measuring component from the **Measuring Component Set Participants** zone in the **Measuring Component Set** portal. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Measuring Component:** This zone displays the basic attributes of the aggregation measuring component
- **Measuring Component Attributes:** This zone displays attributes that describe the dimensions and criteria for the aggregation measuring component
- **Related Measuring Component Sets:** This zone displays the measuring component sets related to the aggregation measuring component
- **Final Values Overlay:** This zone graphs final measurements for a measuring component, and provides the ability to overlay the graphed data with final measurements from other measuring components. The zone also permits overlaying data from the same measuring component for different time periods, as well as data from measuring components that measuring different quantities, such as temperature.
- **Interval - Audit View:** This zone allows users to view an interval measurement curve for a given period overlaid with the count of audit records for each individual measurement. It also allows users to magnify a portion of the curve and see how the measurements looked at different points in time.
- **Measurements - Interval:** This zone displays measurement details for the aggregation measuring component
- **Usage Subscriptions Directly Linked to MC:** This zone displays usage subscriptions that are directly linked to the aggregation measuring component
- **Time of Use Overlay:** This zone displays an overlay of the TOU periods on measurement data along with totalized TOU consumption based on a user-defined time period and TOU map

Master Data Sync

The synchronization of master data into Oracle Utilities Meter Data Management is covered in detail in the [Integrations](#) section of the *Oracle Utilities Meter Solution Administrative User Guide*.

Outage Storm Mode

About Outage Storm Mode

Unfortunately, utilities and their customers are often subject to natural disasters that cause disruptions to AMI networks. These outage events can be related to hurricanes, tornadoes, ice storms, earthquakes, tsunamis, etc. During these severe outages, AMI systems do not always provide outage and restoration events from the devices. Without these outage and restoration events, Oracle Utilities Meter Data Management processes could estimate measurements that would be billed by the CIS. This will lead to unhappy customers, potentially bad press, and lots of manual cleanup work after the fact.

While this is a problem for major outage events, this can also occur with smaller outages (smaller blackouts, planned outages, etc.). This can potentially become an issue anytime the AMI network has a significant number of devices failing to communicate.

This module includes outage processing to improve estimation accuracy during major outages. The system will automatically stop estimations when the number of meter readings coming is less than a user defined tolerance. This tolerance is based on a significant drop in the read percentage for all devices in a similar postal code, service type, and Head End. Estimations will automatically resume when the device returns to normal operation. This can occur through a number

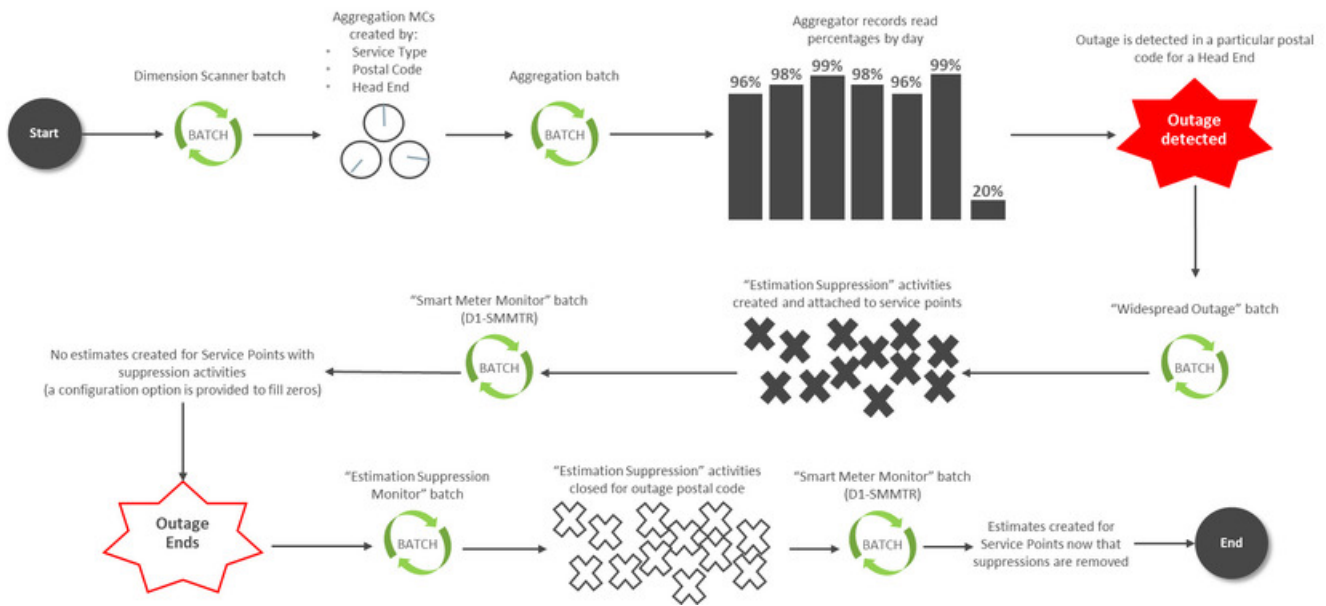

of actions: read percentage for the surrounding area returns to normal, regular data is received from the device, or a power restoration device event is received from the device.

Oracle Utilities Meter Data Management also includes the ability to manually override "storm mode". This override will allow estimations to resume even if the outage hasn't been fully resolved. This will be useful if network fixes take too long and the utility has decided that customers should be billed on an estimate after a few days pass.

NOTE: For information on configuration, reference the related section for [Outage Storm Mode](#) in the Administration Guide.

The diagram below illustrates the primary flow for Outage Storm Mode processing. The steps include:

1. The **Dimension Scanner** batch (D1-ADS) monitors the **Meter Communication Tracking Dimension Scanner** business object. New Aggregator Measuring Components will be created for every applicable Service Type, Postal Code, and Head End in the system.
2. The **Aggregation Monitor** batch (D2-AGG) runs to execute the logic for the **Meter Communication Tracking Aggregator** Measuring Component. This logic will aggregate all meters for the defined Service Type, Postal Code, and Head End. Once the read percentage is found for that day then a measurement will be created for the Aggregator Measuring Component.
3. The **Widespread Outage** batch (D2-WSO) runs to determine if any of the "Meter Communication Tracking Aggregator" Measuring Components have dropped below the defined threshold on the MDM Master Configuration. If it has dropped enough, then an **Estimation Suppression** Activity is created for each of the affected Service Points and the "Meter Communication Tracking Aggregator" Measuring Component is set to an "Active Outage" indicator.
4. If the **Smart Meter Monitor** batch (D1-SMMTR) runs to generate estimates while an Estimation Suppression Activity is active for a Service Point, then the Service Point will either be skipped for estimation or will have zero consumption filled for all data with a condition code of "No Read - Outage Fill".
5. There are a number of methods available to resume normal operation and close out the Estimation Suppression Activity. These include the following:
 - a. The read percentage reaches a "normal level" again as defined in the MDM Master Configuration. This will be detected by the **Widespread Outage** batch (D2-WSO).
 - b. When non-estimated data is received from a device, this will close out an open Estimation Suppression Activity.
 - c. If the **Standard Event Name** Extendable Lookup is configured with the End Estimation Suppression algorithm (D2-EN-ESTSUP), then any Power Up event this is configured for will close out an open Estimation Suppression Activity.
 - d. Estimation Suppression Activities can also be closed manually by a user by navigating to the Activity, using the "Edit" button", and add an End Date.
6. The **Estimation Suppression Monitor** batch (D2-ESTSU) runs for all Estimation Suppression Activities to determine if the related "Meter Communication Tracking Aggregator" Measuring Component is no longer in a state of "Active Outage". If the widespread outage has ended, then the Estimation Suppression activity will be set with an end date.
7. The next time the **Smart Meter Monitor** batch (D1-SMMTR) runs it will generate estimated data as normally configured.

In order to determine if an area is experiencing a widespread outage, the median read percentage of prior days is used as the basis for comparison. The median was chosen instead of the average to help reduce the impact of outlier values. This is illustrated in the example below.

Reviewing Widespread Outages

Anytime a **Meter Communication Tracking Aggregator** Measuring Component is marked with an indicator of "Active Outage", a To Do will be generated for user review. The base To Do Type for this is "Widespread Outage" (D2-WSOTD). This To Do is meant to serve as a warning to users that one of the areas in the service territory is experiencing a widespread outage.

If there is a desire to continue processing as normal and not have estimation suppressed, then you can override the Meter Communication Tracking Aggregator by hitting the "Force Complete Outage" button while reviewing the To Do. This will mark the Widespread Outage Indicator as "User Override" and will allow estimation to continue normally.

Dashboards

About Dashboards

Dashboards provide a broad view of numerous metrics used with Oracle Utilities Customer To Meter. The data presented on each dashboard is tailored to provide operational as well as analytical information for management. On some graphs, drill down options are provided to retrieve more detailed information about the metrics provided.

For information on configuration, reference the related section for [Defining Dashboard Options](#) in the *Oracle Utilities Customer To Meter Administrative User Guide*.

Using the Customer Operational Dashboard

This portal is used to display the Customer Operational Dashboard.

You can access the portal from the **Main > Dashboards > Customer Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The **Billing** tab displays the following zones:

- **Billing Trend:** displays bill completion counts and billed amounts by date.
- **Bill Print Trend:** displays bill print counts by date.
- **Open Bill Issues Trend:** displays open bill issue counts by date.

The **Payment** tab displays the following zones:

- **Payment Trend - All Sources:** displays payment counts and payment amounts from all sources.
- **Payment Trend - Upload:** displays upload payment counts and payment amounts.

The **To Do** tab displays the following zones:

- **To Do Completion By User:** displays To Do completion counts by user.
- **To Do Work Time By User:** displays average To Do work time by user.

The **Batch Performance** tab shows a series of zones related to any defined Performance Targets for batches. More information on Performance Targets can be found in the Framework guide.

Refer to [About Dashboards](#) for additional functional information. For information on configuration, refer to the related section for [Configuring the Customer Operational Dashboard](#) in the *Oracle Utilities Customer To Meter Administrative User Guide*.

Refer to each zone's embedded help for more information.

Using the Meter Operational Dashboard

This portal is used to display the Meter Operational Dashboard.

You can access the portal by selecting **Main , Dashboards, Meter Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The **Meter Operational Dashboard** contains three tabs:

- [Operations](#)
- [Batch Performance](#)
- [Meter Health Check](#)

Using the Operations Tab

The **Operations** tab displays the following zones:

- **IMD Loading Trend:** displays the count of initial measurement data that's loaded each day by Head End system.
- **Device Event Loading Trend:** displays the count of device event data that's loaded each day by Head End system.
- **Incomplete IMDs by Status:** displays a set of counts for initial measurement data by status.
- **Incomplete IMDs Trend:** displays a set of counts for initial measurement data for each day by status
- **VEE To Dos by Exception Type:** displays a set of counts for VEE Exceptions by Exception Type that also still have a To Do that's incomplete.
- **VEE To Dos Trend:** displays a set of counts for VEE Exceptions by Exception Type for each day that also still have a To Do that's incomplete.
- **Usage Transactions by Status:** displays a set of counts for usage transactions by status.
- **Usage Transactions Trend:** displays a set of counts for usage transactions for each day by status.
- **Usage Transaction To Dos by Exception:** displays a set of counts for Usage Transaction Exceptions by Exception Type that also still have a To Do that's incomplete.
- **Usage Transaction To Dos Trend:** displays a set of counts for Usage Transaction Exceptions by Exception Type for each day that also still have a To Do that's incomplete.

Click **Configure** to navigate to the MDM Operational Dashboard Configuration master configuration. See [Configuring the Meter Operational Dashboard](#) in the *Administrative User Guide* for information regarding configuration of the dashboard.

Filtering by Division

Data displayed in the zones on the **Operations** tab (except the **IMD Loading Trend** and **Device Event Loading Trend** zones) can be filtered by Division. To enable filtering by Division set the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration to "Yes". If this is set to "No" the zones display data for all divisions.

When filtering is enabled, the **Division** drop-down list allows the user to select the Division for which they wish to view data. Available divisions are based on the divisions assigned to the user in the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal. The division marked "Use As Primary" is the default.

Using the Batch Performance Tab

The **Batch Performance** tab shows a series of zones related to any defined batch-based Performance Targets

Click **Configure** to navigate to the **Performance Target** portal. See [Measuring Performance](#) in the *Administrative User Guide* for information.

Using the Meter Health Check Tab

The **Meter Health Check** tab includes a set of zones displaying data related to initial measurement processing and quality. These include:

- [IMD Processing Trend](#)
- [IMD Processing Detail](#)
- [IMD Quality Trend](#)
- [IMD Quality Detail](#)

Click **Configure** to navigate to the Meter Health Check Dashboard Configuration master configuration. See [Configuring the Meter Health Check Dashboard](#) in the *Administrative User Guide* for information regarding configuration of the dashboard.

IMD Processing Trend

The **IMD Processing Trend** zone displays the number of initial measurements and calculated numbers of constituent measurements for each day in the selected time period. The x-axis displays individual dates during the selected period. The left y-axis shows the average and maximum number of measurements per initial measurement. The right y-axis shows the number of initial measurements. The graph shows the following:

- **IMD Records:** The number of initial measurements processed on each day in the selected time period.
- **Average Measurements:** The average number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.
- **Maximum Measurements:** The maximum number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the largest number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.

You can filter the data displayed using the following controls:

- **Period View:** Specifies the range of data displayed. Options include Thirty Days, Seven Days, Three Days, or One Day. The default is "Seven Days".
- **Interval/Scalar:** Specifies whether the graph should display only interval initial measurements, scalar initial measurements, or both. The default is "Show All".
- **Business Object:** Specifies the initial measurement business object(s) related to the initial measurements displayed in the graph. The default is "Show All".
- **Status:** Specifies the status (Pending, VEE Ready, Exception, Error, Finalized, and so on) of the initial measurements displayed in the graph. The default is "Show All".
- **Data Source:** Specifies the data source (if any) of the initial measurements displayed in the graph. The default is "Show All".

Click on the labels on the legend below the graph to hide/show specific metrics.

This zone displays data from statistics snapshots based on the IMD Processing Snapshot - Hourly (D1-IMDProcessingHourly) business object. The **Snapshot Date/Time** drop-down list (in the lower right corner of the zone) lists all currently available snapshots based on this business object. Filtering options are based on data available in the snapshot. For example, if all of the initial measurements processed for a specific snapshot are all interval initial measurements, the "scalar" option wouldn't appear in the **Interval/Scalar** drop-down list.

Other metrics, including File Count (the number of payload files processed) and Total Measurements, Average Age, and Maximum Age can be viewed from the statistics snapshot.

Click **Capture** (next to **Snapshot Date/Time** in the lower right corner of the zone) to navigate to the **Statistics Control** portal where you can view a list of snapshots for the statistics control, view details of a specific snapshot, and create a new snapshot if needed.

IMD Processing Detail

The **IMD Processing Detail** zone displays details from the most recent snapshot based on the IMD Processing Snapshot - Hourly (D1-IMDProcessingHourly) business object. By default this zone displays a tabular view of the data from the

snapshot, with each row in the table representing a unique combination of business object, interval/scalar flag, and status. This table includes the following:

- **Date Time:** The date and time on which the initial measurements captured in the row were processed
- **Business Object:** The business object of the initial measurements captured in the row
- **Interval/Scalar:** A flag designating if the data captured in the row is interval (D1IN) or scalar (DISC)
- **Status:** The status of the initial measurements captured in the row
- **Description:** A description of the initial measurements captured in the row
- **IMD Records:** The number of initial measurements processed for the unique combination of business object, interval/scalar, and status captured in the row
- **Average Measurements:** The average number of measurements (Total Measurements divided by IMD Records) per initial measurement captured in the row
- **Maximum Measurements:** The maximum number of measurements per initial measurement captured in the row
- **Total Measurements:** The total number of measurements values in the initial measurements captured in the row

To view a bar chart version of this data, click the **Bar** icon (to the upper right of the table).

IMD Quality Trend

The **IMD Quality Trend** zone displays the number of Validation, Editing, and Estimation (VEE) exceptions and calculated numbers of measurements for each day in the selected time period. The x-axis displays individual dates during the selected period. The left y-axis shows the average and maximum number of measurements per initial measurement. The right y-axis shows the number of VEE exceptions. The graph shows the following:

- **VEE Exceptions:** The number of VEE exceptions processed on each day in the selected time period.
- **Average Measurements:** The average number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.
- **Maximum Measurements:** The maximum number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the largest number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.

You can filter the data displayed using the following controls:

- **Period View:** Specifies the range of data displayed. Options include Thirty Days, Seven Days, Three Days, or One Day. The default is "Seven Days".
- **Interval/Scalar:** Specifies whether the graph should display data for only interval initial measurements, scalar initial measurements, or both. The default is "Show All".
- **Business Object:** Specifies the initial measurement business object(s) related to the data displayed in the graph. The default is "Show All".
- **Exception Type:** Specifies the exception type (Insufficient Input Data, Device Identifier Discrepancy, and so on) of the VEE exceptions displayed in the graph. The default is "Show All".
- **Data Source:** Specifies the data source (if any) of the data displayed in the graph. The default is "Show All".

Click on the labels on the legend below the graph to hide/show specific metrics.

This zone displays data from statistics snapshots based on the IMD Quality Snapshot - Hourly (D1-IMDQualityHourly) business object. The **Snapshot Date/Time** drop-down list (in the lower right corner of the zone) lists all currently available snapshots based on this business object. Filtering options are based on data available in the snapshot. For example, if all

of the VEE exceptions processed for a specific snapshot are all based on interval initial measurements, the "scalar" option wouldn't appear in the **Interval/Scalar** drop-down list.

Other metrics, including File Count (the number of payload files processed) and Total Measurements, Average Age, and Maximum Age can be viewed from the statistics snapshot.

Click **Capture** (next to **Snapshot Date/Time** in the lower right corner of the zone) to navigate to the **Statistics Control** portal where you can view a list of snapshots for the statistics control, view details of a specific snapshot, and create a new snapshot if needed.

IMD Quality Details

The **IMD Quality Detail** zone displays details from the most recent snapshot based on the IMD Quality Snapshot - Hourly (D1-IMDQualityHourly) business object. By default this zone displays a tabular view of the data from the snapshot, with each row in the table representing a unique combination of business object, interval/scalar flag, and status. This table includes the following:

- **Date Time:** The date and time on which the VEE exceptions captured in the row were processed
- **Business Object:** The business object of the initial measurements on which the VEE exceptions captured in the row are based
- **Interval /Scalar:** A flag designating if the VEE exceptions captured in the row are based on interval (D1IN) or scalar (D1SC) initial measurements
- **Exception Type:** The exception type of the VEE exceptions captured in the row
- **Description:** A description of the VEE exception type captured in the row
- **VEE Exceptions:** The number of VEE exceptions processed for the unique combination of business object, interval/scalar, and exception type captured in the row
- **Average Measurements:** The average number of measurements (Total Measurements divided by VEE Exceptions) per initial measurement on which the VEE exceptions captured in the row are based
- **Maximum Measurements:** The maximum number of measurements per initial measurement on which the VEE exceptions captured in the row are based
- **Total Measurements:** The total number of measurements values in the initial measurements on which the VEE exceptions captured in the row are based

To view a bar chart version of this data, click the **Bar** icon (to the upper right of the table).

Using the Service Order Operational Dashboard

This portal is used to display the Service Order Operational Dashboard.

You can access the portal from the **Main > Dashboards > Service Order Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The following zones may appear as part of the portal's **Main** tab page:

- **In-Flight Activities By Type:** shows the distribution of in-flight Activities (in progress or in error) by Activity Type.
- **In-Flight Activity Trend:** shows the number of activities that are in-flight on a given day.
- **In-Flight Activities with Issues:** presents a bar chart that indicates the number of activities with issues.
- **In-Flight Activity Status Distribution:** presents a pie chart that displays the distribution of statuses of in-flight activities.
- **Efficiency Trend for In-Flight Activities:** presents a stacked bar chart that displays the distribution of in-flight activity processing efficiency relative to configurable tolerance.

- **Service Order To Do Summary:** this zone uses horizontal bars to highlight the relative number of open To Dos for a set of To Do Types related to Service Order Management.

Refer to [About Dashboards](#) for additional functional information. For information on configuration, refer to the related section for [Configuring the Service Order Operational Dashboard](#) in the Administrative User's Guide.

Using the Service Order Trends Dashboard

This portal is used to display the Service Order Operational Dashboard.

You can access the portal from the **Main > Dashboards > Service Order Trends Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The following zones may appear as part of the portal's **Main** tab page:

- **Orchestration Issues Trend:** contains a stacked bar chart showing issues by category and Activity Type.
- **Issue Distribution Over Time:** contains a pie chart showing the distribution of activity issues over a range of days.
- **Activity Success Trend:** shows successful activities over a range of days.
- **Activity Creation Trend:** shows activities created over a range of days.
- **Activity Completion Efficiency Over Time:** shows the efficiency of activity completion over a range of days.

Refer to [About Dashboards](#) for additional functional information. For information on configuration, refer to the related section for [Configuring the Service Order Trends Dashboard](#) in the Administration Guide.

Totals and Trends

Processing Statistics

About Processing Statistics

Upload statistics (or upload stats) are statistics related to the uploading of initial measurement data and device events sent from a head-end system.

Upload statistics are defined as activities in Oracle Utilities Smart Grid Gateway.

There are three types of upload statistics activities:

Payload Statistics: Contains statistics related to a specific payload (file) containing one or more initial measurements or device events. Payload Statistics activities contain:

- Basic information about the payload (head-end system, file name, and status)
- Middleware statistics including specifics about the file, the total number of initial measurements or device events processed, the number of initial measurement or device events errors, and total processing time
- Initial measurement statistics including the number of initial measurements processed
- Device event statistics including the number of device events processed

Payload Error Notification: Contains details concerning processing errors encountered in an individual payload (file) containing one or more initial measurements or device events. Payload Error Notification activities are related to Payload Statistics activities.

Payload Summary: Contains processing summary statistics for an individual payload (file) containing one or more initial measurements or device events. Payload Summary activities are related to Payload Statistics activities, and are used to update related payload statistics upon the completion of payload processing.

Upload statistics activities are created during processing of payload files as follows:

- When processing begins for a payload, a Payload Statistics activity is created to record the process.
- If an error occurs during processing, a Payload Error Notification activity is created.
- When payload processing is complete, a Payload Summary activity is created, which in turn, updates the Payload Statistics activity with details concerning the processing of the payload, including (the start and end time of the processing, the total processing time, the number of initial measurements or device events processed, and the number of initial measurement or device event errors (if any)).

About Head-End System Processing Statistics

Head-end system processing statistics are summarized processing statistics for payloads received from a given head-end system.

As Oracle Utilities Smart Grid Gateway processes payloads containing initial measurements or device events, statistics for each payload are captured in Payload Statistics activities. Over time, payload statistics for each head-end system are summarized to allow administrators to view statistics summary for the head-end system.

Head-end system processing statistics are stored as aggregated measurements for aggregator measuring components. A separate aggregator measuring component must be set up for each head-end system for which processing statistics will be aggregated.

Consumption Statistics

Please refer to the [About Aggregation](#) section for information on consumption statistics.

Time Zone Support

Daylight Savings Time Support

This section describes how the Oracle Utilities Service and Measurement Data Foundation and its related products support Daylight Saving Time (DST).

All date/times in the system are displayed adjusted for daylight savings time (when in effect). However, not all date/times in the system are stored in daylight savings time:

- Stored in Standard (not adjusted for DST): data that is highly sensitive to DST shifts are stored in standard time without any shifts, this means they have a consistent 24 hour day each day all year and avoid issues that arise from a skipped hour when transitioning to DST and a duplicate hour when transitioning out of DST. For example: initial measurement data, final measurements, device events, TOU map data.
- These date/times are adjusted for daylight savings time prior to being displayed to a user.
- Stored in Legal (adjusted for DST): data that is not as sensitive to DST time shifts are stored in legal time. For example, device configurations, service points, installation events, usage subscriptions, usage transactions.

Adjusting Date/times Upon Receipt

The two largest sources of imported data to the system can be sent in a mixture of date/time formats some in legal time some in standard time:

- Initial Measurement Data
- Device Events

Since both sets of data are sent by head end systems and each head end system handles date/times differently, potentially even differing by device, the interface must be extremely flexible in how it handles date/times. In order to ensure data is accurately stored and processed the system must know how a given meter sends date/time information. This is defined on the device through the Incoming Data Shift field:

- Always in Standard Time: No special handling is required.
- Always in Legal Time: All date/times for the initial measurement data or device event will be converted from legal time into standard time.
- In circumstances where a date/time is received in legal time and it falls on the duplicate hour that occurs when DST ends special logic will be executed to identify whether that hour is the first (still in DST) or second (no longer in DST) of the duplicate hours. If for some reason it cannot be identified which hour it is the transaction will go into error.

Daylight Savings Time Interval Conversion Examples

The following examples show how data received legal time will be shifted into standard time for an interval meter that is read on an hourly basis.

Daylight Savings not in Effect

Date/Time Received in Legal	Date/Time Stored in Standard
01/14/2010 12:00AM	01/14/2010 12:00AM
01/14/2010 1:00AM	01/14/2010 1:00AM
01/14/2010 2:00AM	01/14/2010 2:00AM
01/14/2010 3:00AM	01/14/2010 3:00AM
01/14/2010 4:00AM	01/14/2010 4:00AM
01/14/2010 5:00AM	01/14/2010 5:00AM

Daylight Savings Starts (Spring Forward) - No 2AM interval

Date/Time Received in Legal	Date/Time Stored in Standard
03/14/2010 12:00AM	03/14/2010 12:00AM
03/14/2010 1:00AM	03/14/2010 1:00AM
03/14/2010 3:00AM	03/14/2010 2:00AM
03/14/2010 4:00AM	03/14/2010 3:00AM
03/14/2010 5:00AM	03/14/2010 4:00AM
03/14/2010 6:00AM	03/14/2010 5:00AM

Daylight Savings in Effect

Date/Time Received in Legal	Date/Time Stored in Standard
06/14/2010 12:00AM	06/13/2010 11:00PM

06/14/2010 1:00AM	06/14/2010 12:00AM
06/14/2010 2:00AM	06/14/2010 1:00AM
06/14/2010 3:00AM	06/14/2010 2:00AM
06/14/2010 4:00AM	06/14/2010 3:00AM
06/14/2010 5:00AM	06/14/2010 4:00AM

Daylight Savings Ends (Fallback) - Duplicate 1AM

Date/Time Received in Legal	Date/Time Stored in Standard
11/7/2010 12:00AM	11/6/2010 11:00PM
11/7/2010 1:00AM	11/7/2010 12:00AM
11/7/2010 1:00AM	11/7/2010 100AM
11/7/2010 2:00AM	11/7/2010 2:00AM
11/7/2010 3:00AM	11/7/2010 3:00AM
11/7/2010 4:00AM	11/7/2010 4:00AM

Daylight Savings Impact on Periodic Estimation

In periodic estimation both the interval and scalar versions can be impacted by daylight savings time:

- Interval periodic estimation using the "Predictable Cut-off" method.
- All scalar periodic estimation

Refer to [About Periodic Estimation](#) for more information about the impact of Daylight Savings Time on periodic estimation.

Multiple Time Zone Support

Some utilities have operations in more than a single time zone. When operating in multiple time zones, Oracle Utilities Meter Data Management and Smart Grid Gateway provide the following high level functionality:

- The ability to receive data in any time zone and convert it to the common time zone used by Oracle Utilities Meter Data Management (as defined by the base time zone)
- The ability to display functional date/times in the time zone of a given device, service point, usage subscription
- The ability to define what time zone a measuring component, device configuration, service point, or usage subscription resides in
- The ability to aggregate data across time zones into a single time zone or without respect to a time zone (see Aggregations on page E-17 for more information).
- The ability to export data to an external system with the appropriate time zone information to enable the external system to consume data from different service points in different time zones

By default, the system assumes only a single time zone is supported. To enable support for multiple time zones it requires that adding the appropriate entry to the general system configuration feature configuration.

Refer to [Configuring Feature Configurations](#) for additional on the feature configuration options available.

Date/Time Storage and Display

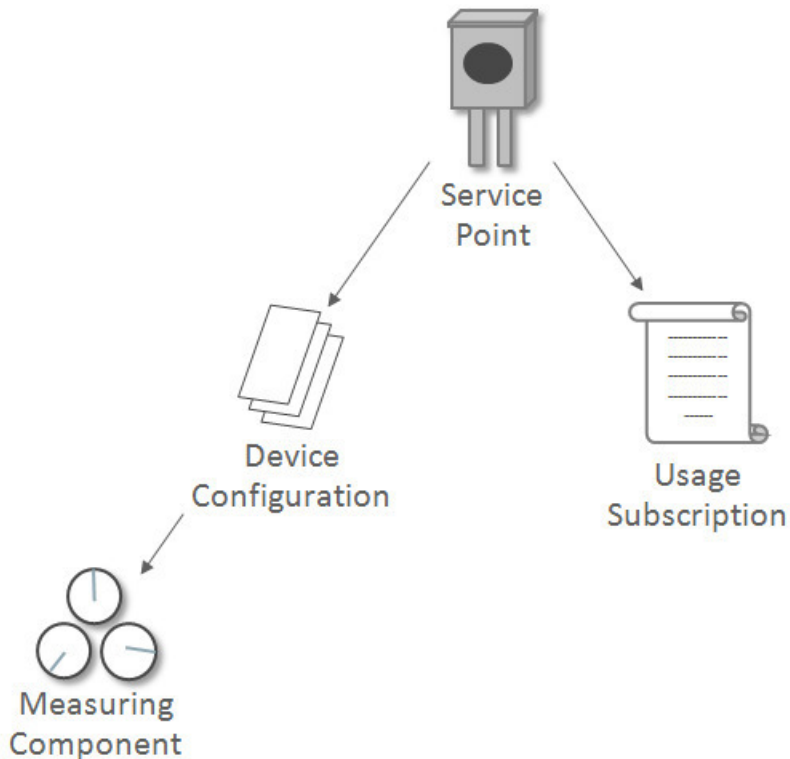

All date/times in the system are stored in the base time zone. Date/times are stored in either standard time or legal time and this determination is made based on the type of data (e.g. measurements are in standard but installation event date/times are in legal).

All date/times are displayed in legal time. Those date/times that are key functional date/times related to a device, service point, or usage subscription will be displayed in the legal time of the time zone the device resides in.

Refer to the [Glossary of Terms](#) for a more detailed definition of Standard and Legal time.

Time Zone Hierarchy and Maintenance

A time zone can be defined at many points within the device to usage subscription hierarchy. This enables the time zone to be accurately portrayed based on the installation status of that device (e.g. not installed, installed but not billed, billed). At each stage of the hierarchy the time zones must match.

Once the hierarchy has been established no one portion of that hierarchy can be changed to a time zone that differs from the other levels of the hierarchy. In order to change the time zone for an established device to usage subscription hierarchy the change must be done to the service point. Once the service point time zone has been changed the system will cascade that change to all other levels of the hierarchy.

If a device has been installed at a service point in order for it to be moved to a different service point in a different time zone. It will require that a new device configuration be created for time zone of the new service point since a device configuration cannot be associated to two different service points each with a different time zone from the device configuration.

Note: If the time zone for a device that has existing measurements has been changed there will be no automatic adjustments made to the underlying measurement data. If the measurement data must be changed it will require manual intervention.

Note: Although measuring component has time zone it is not populated on physical devices that are installed at service points. This time zone is used for standalone measuring components.

Impacts on Aggregations

In aggregation there are two use cases for how data should be aggregated for service points that exist in differing time zones:

- **Absolute Time:** If a time zone is provided on the measuring component or measuring component type, then the aggregation horizon date/times will be used across service points of differing time zones. For example the 4/1/2010 12AM interval in US/Pacific would be combined with the 4/1/2010 3AM interval in US/Eastern. Since all date/times are stored in the base time zone there is no need to do time zone conversions.
- **Local Time:** If no time zone is specified, consumption is aggregated by converting the aggregation horizon to the appropriate time zone for each service point. For example the 4/1/2010 12AM interval in US/Pacific would be combined with the 4/1/2010 12AM interval in US/Eastern.

Aggregation Measuring Components in general do not have any time zone related dependencies with other master configuration objects. However, when an aggregator is listed as a direct channel measuring component on a usage subscription it share the same time zone as the Usage Subscription.

Impacts on TOU Map Generation

The date and times defined on a [Time of Use Mapping Templates](#) (TOU) do not have a time zone associated to them and will be interpreted based on the time zone of the TOU map type of the specific TOU Map being processed. This allows for a single definition of a TOU schedule that can be applied across many different time zones.

During the generation of the TOU map data for a given TOU map template the date/times will be converted from the time zone of the TOU map to the time zone defined in the base time zone defined on the [installation options - framework](#). For example, if 1/1/2010 5:00PM was considered to be "On Peak" and the system time zone was UTC -08:00 and the TOU map time zone was UTC -05:00 then the TOU map data entry would be written as 1/1/2010 2:00PM.

Impacts on Factors

Factor effective dates do not have a time zone associated to them and are assumed to be in the local time zone of the data being validated. For example a factor effective 4/1/2010 12:00AM would be considered to be effective 4/1/2010 12:00AM UTC -08:00 and 4/1/2010 12:00AM UTC -05:00 based on the time zones of the respective meters. This allows a single factor to apply to many time zones and behave uniformly.

Impacts on Holidays

Holiday effective dates do not have a time zone associated to them and are assumed to be in the local time zone of the data being validated. For example a holiday on 12/25/2010 would be considered to be effective beginning 12/25/2010 12:00AM UTC -08:00 and 12/25/2010 12:00AM UTC -05:00 based on the time zones of the respective meters.

Impacts on Periodic Estimation

Refer to [About Periodic Estimation](#) for more information about the impact of Daylight Savings Time on periodic estimation.

Impacts on Initial Measurement Creation Online

When creating initial measurements online from the 360 Degree View portals, initial measurements are created as appropriate for measuring components with time zones other than the base time zone.

For example, if you copy measurements from a measuring component in one time zone to a measuring component in a different time zone, the measurements are being moved in absolute time (i.e. the 3:00 PM in UTC -08:00 would be changed 6:00PM in UTC -05:00).

Impacts on Items

The consumption for "badged" and "unbadged" items is driven by configuration on the device type service quantity and the multi-item section of the service point:

- **Device Type Service Quantity:** the effective date of the service quantity does not have a time zone and is assumed to be in the local time zone of the service point it is associated to (whether through a install event for "badged" items or by being directly configured on the service point). For example an effective date time of 1/1/2010 5:00PM would be considered to be effective beginning 1/1/2010 5:00PM UTC -08:00 and 1/1/2010 5:00PM UTC -05:00 based on the time zones of the respective meters
- **Service Point Multi-Item:** the start date time and end date time of the multi-item list are stored in legal time of the base time zone and displayed in the legal time of the service point's time zone.

Service Issue Monitors

About Service Issue Monitors

Service Issue Monitors are service tasks that analyze service points to determine if service is needed. If service is determined to be needed, the Service Issue Monitor creates a Service Investigative Order.

Device events, VEE exceptions, failed smart meter commands, and other events can trigger the creation of a service issue monitor (the type of service issue monitor created is based on the Service Issue Monitor Type specified on the device event type, exception type, or activity type). Once created, service issue monitors analyze the service point where the device associated with the device event, VEE exception, or failed command, based on evaluation criteria specified on the service issue monitor's type. If the criteria are met (in other words, if a specified number of command failures, device events, or VEE exceptions are found for the service point), the service issue monitor creates a service investigative order.

Service Issue Monitor Creation

This section provides an overview of the process that takes place when service issue monitors are created.

NOTE: The process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

1. One (or more) of the following takes place:
 - A device event or reader remark is received, whose type specifies a Service Issues Monitor Type
 - A VEE exception whose type specifies a Service Issues Monitor Type is generated during VEE processing
 - A usage transaction exception generated during usage calculation
 - A smart meter command fails whose type specifies a Service Issues Monitor Type
 - A business flag is received whose type specifies a Service Issue Monitor Type
2. The object received in item (1) creates a service issue monitor based on the referenced Service Issue Monitor Type
3. The service issue monitors analyzes the service point based on the Discard Rules and Evaluation Criteria defined on the service issue monitor's type to determine if a service investigative order should be created or if the service issue monitor should be discarded.

The "Discard Rules" on the service issue monitor's type are evaluated to determine if the new service issue monitor should be discarded (new service issue monitors are always discarded when created if an existing service investigative order initiated by a service issue monitor of the same type exists for the service point.)

If the service issue monitor type was configured to require approval, the service issue monitor generates a To Do to notify the appropriate individuals that approval is necessary.

If the service issue monitor is approved or if no approval was necessary the service investigative order will be continue.

4. The service issue monitor then executes the evaluation criteria defined on the service issue monitor's type. If those criteria are met the Service Investigative Order activity is created. If the criteria are not met the service issue monitor is discarded.
5. If the service issue monitor has completion criteria defined the service issue monitor will wait for the service investigative order to complete. Once complete the the service issue monitor will execute the completion criteria to evaluate if the service investigative order achieved the desired results.

If either there were no completion criteria or they were satisfied the service issue monitor will complete.

If the completion criteria were not satisfied the service issue monitor enter an inconclusive investigation state from which manual intervention will be required.

About Service Investigative Orders

Service investigative orders are activities created by a service issue monitor when a specified set of events have occurred at a service point. The type of activity created by the service issue monitor is defined on the service issue monitor's type.

Service issue monitors are often configured to create field activities that are in turn sent to an external field work system.

Oracle Utilities Rate Cloud Service

Overview

Oracle Utilities Rate Cloud Service provides access to the rate calculation functionality of Oracle Utilities Customer Cloud Service. This includes the ability to configure and test rate calculations via the user interface, as well as the ability to trigger the rate calculation process from an external system.

This section describes the functionality provided with Oracle Utilities Rate Cloud Service.

Note: Oracle Utilities Rate Cloud Service supports rate calculation for traditional scalar or volume-based billing quantities only. It does not include capabilities for generating billing determinants from interval data input.

Setting Up Rates with Oracle Utilities Rate Cloud Service

Oracle Utilities Rate Cloud Service provides access to pages, portals, and zones used to create and maintain rates and rate configuration data, including:

- Bill Factors
- Bill Factor Values
- Calculation Groups
- Calculation Line Category Types
- Calculation Rules
- Rate Schedules

Refer to the [Rates](#) chapter of the *Business User Guide* for detailed information about setting up the above types of configuration data. Note: Some fields and options used with the above types of configuration data are not applicable when using Oracle Utilities Rate Cloud Service when compared to using Oracle Utilities Customer Cloud Service.

Using Rate Check with Oracle Utilities Rate Cloud Service

In addition to rate configuration functionality, Oracle Utilities Rate Cloud Service includes access to the Rate Check feature, which allows users to test their rates.

When using Rate Check, service quantities and characteristic types/values must be provided by the user and entered via the user interface. Oracle Utilities Rate Cloud Service does not support the use of the Rate Check feature based on service agreements, bill segments, or service points.

Refer to the [Rate Check](#) section in the **Rates** chapter of the *Business User Guide* for more information about using the Rate Check feature.

Oracle Utilities Billing Cloud Service

Overview

Oracle Utilities Billing Cloud Service provides access to the billing functionality of Oracle Utilities Customer to Meter, which is the foundational component of Oracle Utilities Customer Cloud Service. This includes the ability to manage customer information, load validated measurement data, calculate billing determinants, configure and test rate calculations, calculate billing charges, aggregate billing related data.

Oracle Utilities Billing Cloud Service is intended for customers who

- May not require a full customer information system implementation
- Customers whose legacy customer information system does not support specific billing capabilities that they may now require such as net-metered billing, billing for electric vehicle charging events, advanced billing for specific customer segments (commercial or industrial), and so on.

This section describes the functionality provided with Oracle Utilities Billing Cloud Service.

Billing Cloud Service Functional Areas

This page outlines the functional areas available with Oracle Utilities Billing Cloud Service. The menus provided with Oracle Utilities Billing Cloud Service display only those menu items that correspond to capabilities that are available with the cloud service.

NOTE: Not all fields and field values available in Oracle Utilities Customer to Meter associated with these menu items are used with Oracle Utilities Billing Cloud Service.

The functional areas listed below are organized based on the main **Menu**.

- 360 Search
- Communication
- Control Central
- Customer Information
- Dashboards
- Data Synchronization
- Device

- Device Installation
- Financial
- Financial Query
- Initial Measurement Data
- Initial Measurement Snapshot
- Market Transaction Management
- Process Flow
- Rates
- Service Task
- To Do
- Total and Trends
- Umbrella Agreement Management
- Usage
- My Preferences
- Tools
- Integration

Refer to specific chapter and sections in the *Business User Guide* for more information about working with these above listed functional areas.

Settlement

Understanding Market Settlement

Market settlement is the process of reconciling the difference between a supplier's energy purchases and its customer's usage. Suppliers purchase energy via bilateral contracts and day-ahead market transactions. Any differences between these purchases and supplier customer usage must be determined by the market and charged or credited at real time prices. The supplier's customer usage is not directly determined by the market, but by numerous other market participants that track customer supplier enrollments, aggregate customer usage to the supplier, and submit supplier's usage schedule to the market. This process is called load settlement, and is the primary purpose of Oracle Utilities Market Settlements Management.

The market participant responsible for load settlement can differ per market. For example, load settlement for a large portion of the Texas market is performed by an Independent System Operator (ISO) known as the Electric Reliability Council of Texas (ERCOT), whereas in the PJM market (encompassing Pennsylvania, New Jersey, and Maryland) load settlement is the responsibility of the Electric Distribution Company (EDC). While there are significant differences between markets in how load settlement is performed, the high-level process steps are basically the same.

Load settlement starts with the bottom up aggregation of actual load or estimated load for individual customer accounts or service points. Distribution and transmission losses are added in to calculate an unreconciled load amount. The market determines the total generation supplied to a zone and the difference with the unreconciled load is referred to as Unaccounted for Energy (UFE). The UFE is then allocated to suppliers on a load ratio share basis.

The load settlement process is typically performed multiple times. The “preliminary” load settlement is done soon after the Operational Day and is often based on estimated load. The “final” load settlement is done around 60 days after the Operational Day, so that actual data has been received and customer bills issued.

About Market Settlement Processing

Market settlement is the process of deriving billing determinants to be used in supplier billing based on the results of a data aggregation processes.

The load settlement process also involves calculating imbalances. An imbalance is the difference between two load shapes representing different estimates of the same period, typically a scheduled load shape and an actual load shape. Imbalances are typically used when money has changed hands based on an estimate that has been improved or finalized by the settlement process. Because the second estimate has more accurate data, the allocations performed by the first process have to be modified.

Imbalance shapes can be further divided by applying bands and TOU components. Bands are error tolerances around zero that allow for differential pricing of the imbalance curve by how well or poorly the scheduled estimate matched the actual usage. Time of Use periods are often defined, allowing a higher penalty for faulty forecasting during higher-priced, on-peak periods. Whether an imbalance calculation is performed and how it is performed varies greatly from market to market.

The following sections provide details regarding some of the specific processing used in settlement processing.

Importing Data

In addition to customer-level data such as meter readings or billed service quantities (which are used aggregation), settlement processing also involves other data that must be available to the application. For example:

- UFE calculations use both aggregated data and overall system, or zonal, load data
- Estimations and forecasting often use weather data
- Settlement billing requires pricing data

Data of these types can be imported into the system from external sources via a number of ways:

- For external sources that send data on a regular basis, data can be imported in a manner similar to how measurement data is received head end systems. See [Processing Initial Measurement Data](#) in this guide and [Data Import - Message Driven Bean Configuration](#) in the *Oracle Utilities Meter Solution Administrative User Guide* for more information.
- For external systems that send data upon request, data can be requested via measuring component data requests. Requests of this type can be either scheduled or performed manually. See [Requesting Measurement Data](#) in this guide for more information.
- For external systems that make data available for use but don't support sending the data directly, data can be imported manually in a comma separated values (CSV) format. See [Uploading Measurement Data](#) in this guide for more information.

Forecasting and Estimating Usage

Some settlement processes, such as initial settlement, often have to be performed before actual usage has been received or calculated for service points participating in the settlement market. In these cases, usage must be estimated, and in some cases, forecasted before aggregation and other settlement calculations can happen. A forecast is the term used when estimating usage data for future dates based on historical or profile data. Backcasting is the term used for estimating data for dates in the past. These can also be based on historical and/or profile data.

Two specific methods used for forecasting and backcasting include:

- **Profile Estimation:** This method uses profile data that represents typical usage for the service point to estimate usage. In some cases, profile data can also be adjusted based on scalar usage for the same service point.
- **Proxy Day Estimation:** This process compares data between measuring components to identify an historical day that most closely matches the date for which data is needed and uses data from that historical day to estimate usage

Aggregating Data

Aggregation involves summing real or assigned (profiled or deemed) interval data to a user-defined aggregation level for further processing. Aggregation may occur at a variety of levels for a variety of reasons, including reporting requirements and applying losses and other factors at an aggregated level up to the market participation level. Aggregation is typically used to build ground-up estimates of load for energy market participants for forecasting, scheduling, and settlement.

Aggregation is performed using the [Dynamic Aggregation](#) feature of the Oracle Utilities Meter Solution.

Aggregation Levels

Because aggregation involves summing up interval data to a specified level for processing, it's important to understand what is meant by the term "aggregation level" Put simply, an aggregation level is any point along the distribution chain to which entities below that point are summed. For instance, if you were going to sum up all the accounts that are related to a specific bus, that bus would be an aggregation level. Similarly, if you were going to aggregate all the energy used by all the accounts for a given Energy Service Provider (ESP), that ESP would be an aggregation level. In general, aggregation is usually performed at a level below you on the distribution chain from generators to end users.

The entities and/or market participants that serve as aggregation levels are specific to the particular area and market in which your utility is operating, but can include the following:

Energy Service Providers (ESP)

Energy Service Providers (ESPs) sell power to customers. They may generate it and/or buy it from other sources. ESPs are also referred to as Retail Energy Providers (REPs) or simply suppliers.

Distribution Companies (DisCo)

A distribution company is responsible for the delivery of power to all customers in its service territory (Jurisdiction), regardless of who the customers have selected as their suppliers. The DisCo owns and operates the distribution lines that bring electricity into homes and businesses, and is responsible for metering, billing, and service calls. However, a DisCo may or may not be affiliated with a customer's power supplier. Distribution companies are also referred to as Operating Companies, Utility Distribution Companies (UDCs), or Local Distribution Companies (LDCs).

Schedule/Service Coordinators (SC)

Schedule Coordinators (or Service Coordinators) are responsible for creating schedules of energy usage that represent the estimated usage for a future time period (most often one day) for a given segment of the market. Schedules are most often based on results generated during the load profiling process, but can also be based on historical usage information and other data.

Independent System Operators (ISO)

An Independent System Operator (ISO) is a non-profit corporation that manages the regional power grid to coordinate the generation and transmission of energy. Its goal is to guarantee a safe and reliable power supply, and to ensure that all suppliers get nondiscriminatory access to the transmission system (while the ISO controls the power grid, commercial entities still own it). In the U.S. market, ISOs are regulated by the Federal Energy Regulatory Commission (FERC).

The various aggregation levels used in settlement processing are defined by [Aggregation Groups](#), [Measuring Component Sets](#), and [Aggregation Measuring Components](#).

Aggregation Dimensions

In addition to aggregating data by aggregation levels, it is useful to be able to aggregate by other factors, such as customer class, voltage class, or loss class. These and other factors are referred as dimensions and are referenced on [measuring component sets](#). Some common aggregation dimensions are described below. Note that these are provided as examples of common aggregation dimensions only.

Specific markets may require aggregation dimensions other than those listed here.

Customer Class

A customer class represents a ‘type’ of customer or account. Three common customer classes include residential, commercial, and industrial, but others are also prevalent. In addition, there may be multiple types of residential, commercial, or industrial classes, representing distinct types of accounts within each of those broad categories. For instance, residential customers might be divided into apartments, condominiums, and houses.

Voltage Class

A voltage class represents a group of customers or accounts based on the type of voltage used by the end users in that group. Voltage classes differ by market and region, but some common voltage classes include Transmission, Primary, and Secondary. Aggregating by voltage class is often performed for reporting purposes, to track usage of a given voltage type within the system.

Loss Class

A loss class represents a group of customers or accounts based on the type of loss (transmission loss, distribution loss, etc.) associated with those accounts. Loss is often related to voltage levels, and so correlations between loss classes and voltage classes are common. Aggregation by loss class is used when calculating losses in the overall settlement process, and allows different loss calculation algorithms to be used with different loss classes, as appropriate.

Rate Class

A rate class represents a group of customers or accounts based on pricing. Rate classes can be based on a number of characteristics, including usage, territory, or even voltage type.

These and other dimensions are typically defined as attributes or characteristics of usage subscriptions, service points, devices, or measuring components.

Applying Losses

Markets typically operate using generation-level determinants, meaning that the individual metered entity data must be adjusted for system losses in order to compare the market participant load to the system load, market participant schedules, etc. Loss calculations can vary from simple to complex, ranging from an annual percentage by rate class or voltage level, to seasonal or time of use loss factors, to hourly dynamic loss factor calculations based on system conditions. Loss factors can be applied at the metered level or any aggregation level, as needed. In addition, losses can be applied to generators in markets where generation losses are calculated and used.

Applying losses to aggregated data is performed via value derivation algorithms. These are algorithms which apply a configured formula to aggregated measurement values. For instance, to apply a loss factor, an algorithm can retrieve effective-dated factor values for a loss factor and multiply each aggregated measurement value by the appropriate factor value. Value derivation algorithms can retrieve values from all types of factors, including multi-variable factors defined for settlement units. See [Aggregation Calculation — Other Calculations](#) for more information about how losses can be applied during data aggregation.

Unaccounted for Energy (UFE) Calculations

Unaccounted for Energy (UFE) is calculated by comparing the known system load to the sum of all market participant estimates from the estimation, aggregation, and loss adjustment processes. Because the market participant estimates will never perfectly match the system load, these estimates are fine-tuned by allocating a portion of the total UFE to each

estimate. Allocation methods differ, but in general each market participant is allocated a portion of the system UFE for each hour based on the ratio of that particular estimate's load in that hour to the total of all estimated loads in that hour. This process forces the total of all estimates to match the system load. Some markets use different UFE allocation methods, including differential allocation of UFE to interval metered loads apart from profiled loads, and adjusting the profile methodologies to minimize UFE where possible.

UFE calculations are performed as part of the settlement calculation process, and can be performed using the [Measuring Component Set Calculation Rule](#) settlement calculation rule defined in a [Bulk Settlement Calculation Group](#) executed via the Measuring Component Set Calculation (D1-MCSCA) batch process.

For smaller markets, UFE calculations can be performed using a chained sequence of [Array Math](#) and [Vector and Service Quantity Math](#) settlement calculation rules. At a basic level, this sequence looks like this:

1. Sum the market participant load from aggregation results (using Array Math)
2. Subtract the market participant load from the system load to derive the total UFE for the calculation period (using Vector and Service Quantity Math)
3. Allocate the total UFE to the various market participants as appropriate (using Array Math)

NOTE: The results of UFE calculations are also used in other settlement calculations. These three steps represent part of a larger set of calculations.

Allocating Load via Market Products, Awards, and Contracts

Distribution companies operating in deregulated markets are often designated as the Provider of Last Resort (POLR) for customers that either have not selected a supplier or have been dropped by a supplier. If allowed by legal and market rules, the distribution company can elect to outsource the responsibility of supplying POLR load to qualified wholesalers.

The POLR consumers will still, either directly or indirectly, receive bills for distribution services from and pay the distribution company, but the wholesaler takes responsibility for procuring and serving the POLR load, for which they receive payments from the distribution company.

A simple example of the POLR allocation process might involve the following steps:

1. Subtract all other suppliers from the zonal load to get the remaining POLR load.
2. Allow for the distribution company to separate out any owned generation.
3. Divide POLR load amongst awarded wholesale contracts.

Details of these transactions would be sent to the market operator by contract ID.

These awards of POLR load can be defined in the application by [Market Products](#) (which belong to a [Market Product Set](#)), [Market Awards](#), and [Market Contracts](#).

To elaborate on the example above, a market product set might the following set of market products:

- A product and award to carve out load from the POLR load for one or more suppliers. This would be a “Fixed Profile” award.
- A product and award to carve out a percentage of the remaining POLR load for owned generation. This would be a “Percentage” award.
- A product and awards that distribute the remaining POLR into various bundles of tranches (chunks of load) to wholesalers. These would be “Tranche” awards.

The following diagram illustrates the way in which this distribution would work.

Example of energy load being split between awards

POLR Load: 1,000 MWh
Remaining Load: 1,000 MWh

The [Market Award Allocation](#) settlement calculation rule is used to perform the allocation of load the designated market products and awards. This rule is part of a larger settlement calculation process, using settlement quantities (the POLR load) calculated by other rules (such as [Array Math](#) and [Vector and Service Quantity Math](#)). The Market Award Allocation rule allocates those quantities to the products within a specified [Market Product Set](#), and saves the results for export to the appropriate market participants.

Viewing Settlement Calculation Results

You can view settlement calculation results using the Cube Viewer feature of the Oracle Utilities Application Framework. See [Creating Cube Views](#) in the *Oracle Utilities Application Framework Administrative User Guide* for information about configuring cube views.

Viewing and Managing Settlement Processes

You can use the Process Flows feature of the Oracle Utilities Application Framework to create, view, and manage settlement processes. See [Process Flows](#) in the *Oracle Utilities Application Framework Administrative User Guide* for information about configuring cube views.

Settlement Data Snapshots

Settlement data snapshots capture data as of a specific point in time for use in aggregation and settlement calculations. For instance, data snapshots can capture data such as:

- The state of a settlement account (a Settlement Item) as of the last time something about the account changed
- The state of a settlement account as of the last time the account was billed
- Metered measurement data used for initial settlement
- Billed measurement data used for final settlement

There are two general categories of settlement data snapshots:

- Attribute Data Snapshots
- Measurement Data Snapshots

Attribute Values

About Attribute Values

Attribute values represent an instance of an attribute group's values, captured as part of an attribute data snapshot for a settlement item. An individual attribute values record is created for each unique combination of values that exists for the attributes defined in the attribute group.

Attribute values records are created when attribute data snapshots are created or updated for a settlement item.

Attribute values are defined by:

- **Attribute Group:** The attribute group that defines the attributes captured by the attribute values record
- **Division:** The division to which the settlement item captured by the attribute values record belongs
- **Market:** The market in which the settlement item captured by the attribute values record participants.

- **Market Participant:** The market participant associated with the settlement item captured by the attribute values record
- **Rate Class :** The rate class code for the settlement item captured by the attribute values record.
- **Status:** The status of the attribute values record
- **Values:** The specific values captured in the attribute values record, defined by the record's attribute group

Maintaining Attribute Values

You use the **Attribute Value** portal to view and maintain attribute values records.

Refer to [About Attribute Values](#) for additional functional information.

You can access the portal by selecting **Main**, then **Customer Information**, then **Attribute Values**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Attribute Values:** This zone displays the attribute values record.

Attribute Data Snapshots

About Attribute Data Snapshots

Attribute data snapshots are used to capture account data for a settlement item as of a specific point in time, such as the last time an attribute on the account changed or the last time it was billed.

Attribute data snapshots are defined by:

- **Attribute Data Snapshot Type:** The attribute data snapshot type for this snapshot.
- **Division:** The division to which the settlement account captured by the attribute data snapshot belongs.
- **Attribute Value:** The attribute value record that contains attribute values for the attribute data snapshot
- **Status:** The status of the attribute data snapshot
- **Market:** The market in which the settlement account captured by the attribute data snapshot participants.
- **Settlement Item:** The parent settlement item for the attribute data snapshot.
- **Transaction ID:** The transaction ID for the transaction which triggered creation of the data snapshot (such as a usage subscription or account).
- **Start Effective Date/Time:** The start date/time for period represented by the data snapshot.
- **Stop Effective Date/Time:** The stop date/time for period represented by the data snapshot.
- **Time Zone:** The time zone of the settlement account captured by the attribute data snapshot
- **Identifiers:** The specific identifier types and values for the attribute data snapshot's settlement item

Creating Attribute Data Snapshots

Attribute data snapshots are created via batch processing. Attribute data snapshots are typically generated daily (or on some other regular schedule) via the Capture Attribute Data Snapshot (D1-CADS) batch control. This batch process invokes the Capture Attribute Data Snapshot (D1-CAPADS) monitor algorithm on the Active state of the Settlement Item business object.

Attribute data snapshots are created for each change in one of the attributes that has been configured on the Attribute Data Snapshot Type and Attribute Group. The snapshot captures the value of all of the attributes at the time of that change. For

example, for Attribute Data Snapshot Type configured to track Market Participant, Rate Class, and a Characteristic, if the Characteristic value were updated with a new more recently effective value then a snapshot would be created that would capture all 3 fields values (the Market Participant, Rate Class, and new Characteristic value)..

The type of attribute data snapshot(s) created are defined on the the Settlement Item's Settlement Item Type.

Maintaining Attribute Data Snapshots

You use the **Attribute Data Snapshot** portal to view and maintain attribute data snapshots.

Refer to [About Attribute Data Snapshots](#) for additional functional information.

You can access the portal by selecting **Main**, then **Customer Information**, then **Attribute Data Snapshot**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Attribute Data Snapshot:** This zone displays the attribute data snapshot.

Measurement Data Snapshots

About Measurement Data Snapshots

Measurement data snapshots are used to capture measurement data for settlement accounts as of a specific point in time, such as the when the data was used for initial settlement or when the account was billed.

Measurement data snapshots can be created either as part of Meter Data Management usage transaction processing or batch processing. See [Creating Measurement Data Snapshots](#) for more information.

There are two main types of measurement data snapshots: Interval and Scalar.

Interval Measurement Data Snapshots

Interval measurement data snapshots are defined by:

- **Measurement Data Snapshot Type:** The measurement data snapshot type for this snapshot
- **Usage Subscription:** The usage subscription associated with the measurement data captured by the measurement data snapshot
- **Service Point ID:** The service point associated with the measurement data captured by the measurement data snapshot
- **Measuring Component ID:** The measuring component from which the measurement data captured by the measurement data snapshot originated
- **Transaction ID:** The transaction ID for the transaction which triggered creation of the data snapshot (such as an initial measurement, usage transaction, or bill)
- **Start Date/Time:** The start date/time for period represented by the data snapshot
- **Stop Date/Time:** The stop date/time for period represented by the data snapshot
- **Start Date Local :** The start date/time for period represented by the data snapshot represented in local time (if different), used in aggregation processing
- **Missing Interval:** A flag that indicates if the measurement data snapshot contains missing interval
- **Irregular Data:** A flag that indicates if the measurement data snapshot contains irregular data

- **Values:** The interval values for the measurement data captured by the measurement data snapshot. See below for more information about interval measurement data snapshot values.

Interval Measurement Data Snapshot Values

The UOM, TOU, and SQI used to identify measurement values are defined on the measurement data snapshot's type.

Interval measurement data snapshots can contain up to 100 interval values. The interval size of the intervals captured on the data snapshot is defined on the measurement data snapshot's type. The table below lists the maximum duration of snapshots for different common interval sizes (rounded down and based on 96 intervals).

Interval Size	Maximum Measurement Snapshot Duration (rounded down)
01:00:00 (1 hour intervals)	4 days
00:30:00 (30 minute intervals)	2 days
00:15:00 (15 minute intervals)	1 day
00:05:00 (5 minute intervals)	8 hours

Scalar Measurement Data Snapshots

Scalar measurement data snapshots are defined by:

- **Measurement Data Snapshot Type:** The measurement data snapshot type for this snapshot
- **Usage Subscription:** The usage subscription associated with the measurement data captured by the measurement data snapshot
- **Service Point ID:** The service point associated with the measurement data captured by the measurement data snapshot
- **Measuring Component ID:** The measuring component from which the measurement data captured by the measurement data snapshot originated
- **Transaction ID:** The transaction ID for the transaction which triggered creation of the data snapshot (such as an initial measurement, usage transaction, or bill)
- **Start Date/Time:** The start date/time for the period represented by the data snapshot
- **Stop Date/Time:** The stop date/time for the period represented by the data snapshot
- **Start Date Local :** The start date/time for period represented by the data snapshot represented in local time (if different), used in aggregation processing
- **Stop Date Local :** The stop date/time for period represented by the data snapshot represented in local time (if different), used in aggregation processing
- **Irregular Data:** A flag that indicates if the measurement data snapshot contains irregular data
- **Last Updated:** The date and time on which the measurement data snapshot was last updated
- **Unit of Measure:** The unit of measurement (UOM) for the measurement data captured by the measurement data snapshot
- **Time of Use:** The time of use (TOU) for the measurement data captured by the measurement data snapshot
- **Service Quantity Identifier:** The service quantity identifier (SQI) for the measurement data captured by the measurement data snapshot
- **Value:** The scalar value for the measurement data captured by the measurement data snapshot

Creating Measurement Data Snapshots

Measurement data snapshots can be created either via batch extract processing or as part of usage transaction processing. Batch extract processing is typically run daily (or on some other regular basis) and is used primarily for initial settlement calculations. Usage transaction processing is most often used to create "final" or "billed" measurements used with final settlement calculations.

Both approaches support creation of measurement data snapshots for use with implementations in which Meter Data Management and Market Settlements Management are installed in separate application environments, or in a single application environment.

Batch Extract Processing

As noted above, batch extract processing is typically run daily (or on some other regular basis). Measurement data snapshot creation via batch extract processing is based on configuration of two types of objects:

- Consumption Extract Types
- Batch Controls

There are three types of batch extract processing based on the type of measurement data: interval measurements, scalar measurements, and items. The table below outlines the consumption extract type business objects and batch controls used for each type of data.

Data Type	Consumption Extract Type Business Object	Batch Control
Interval	US Extract Intervals to MDS (D1-ConsExtractTypeInterval)	Extract US Intervals to Measurement Data Snapshots (D1-EUSIM)
Scalar	US Extract Item to MDS (D1-ConsExtractTypeItem)	Extract US Item Consumption to Measurement Data Snapshots (D1-EUITM)
Items	US Extract to Scalar Measurement Snapshot (D1-ConsExtractTypeScalar)	Extract US Scalar Reads to Measurement Data Snapshots (D1-EUSSR)

The following sections provide additional details about the consumption extract types and batch controls used for measurement data snapshot creation.

Consumption Extract Types

Consumption extract types define several parameters used by the measurement data snapshot extract process. As outlined in the table above, there is a separate consumption extract type business object for each type of data.

See [Understanding Consumption Extract Types](#) for general information about consumption extract types.

Measurement data snapshot consumption extract types are defined by the following:

- **Extraction Through Date/Time:** The date and time through which extract requests for this extract type have been processed
- **Extraction Cutoff Time:** The time at which extract requests of this extract type are cutoff
- **Extraction Parameters:** Parameters used in extraction processing, including:
 - **Subscription Type:** The type of subscription (Settlements or CIS) for which extracts of this type are processed.
 - **Request Type:** The request type associated with the extraction type.
 - **Frequency:** The frequency at which extract requests of this extract type are processed. Frequency options include Adhoc and Automated Daily.

- **Measurement Data Snapshot Type:** The [measurement data snapshot type](#) used to create measurement data snapshots based on this extract type. The UOM of the snapshots must be compatible with at least one of the UOMs in the list of **Usage Subscription Types**. In addition, type's UOM / SPI combinations must be compatible with at least one of the UOM / SPI combination listed in the **Usage Subscription Types** list. Used with Scalar and Item consumption extracts only.
- **Extraction Batch Control:** The batch control used to extract the measurement data to measurement data snapshots, based on the type of data to extract and the consumption extract type.

Data Type	Batch Control
Interval	Extract US Intervals to Measurement Data Snapshots (D1-EUSIM)
Scalar	Extract US Item Consumption to Measurement Data Snapshots (D1-EUITM)
Items	Extract US Scalar Reads to Measurement Data Snapshots (D1-EUSSR)

- **Extract To Different Usage Subscription:** A flag that designates whether or not the measurement data snapshot should be extracted to a different usage subscription such as one used by Market Settlements Management. Options include:
 - **No:** The extract will reference the usage subscription for which usage calculations are being processed. This option is used when Meter Data Management and Market Settlements Management are installed in different application environments. In this case, the extract can be exported from Meter Data Management for subsequent import into Market Settlements Management.
 - **Yes:** The extract will reference a different usage subscription such as one used by Market Settlements Management. This option is used when Meter Data Management and Market Settlements Management are installed in the same application environment. In this case, the measurement data snapshot is “exported” within the system to the Settlement Item, where it can be used in data aggregation processing. When this option is selected, the **Source Identifier Type** and **Target Identifier Type** fields must be configured to define how the system will determine the correct settlement usage subscription to use.
- **Irregular Data Flag Mapping:** Ranges of condition codes used to flag data as “irregular”. The value of the **Irregular Data Flag** (based on the IRREGULAR_DATA_FLG lookup) is used to flag data that falls within each range configured. A blank **Irregular Flag** value denotes that the condition range is considered to be "Regular".
- **Usage Subscription Types:** One or more usage subscription types from which the consumption can be extracted and stored into measurement data snapshots
- **Measurement Data Snapshot Types:** One more [measurement data snapshot types](#) used to create measurement data snapshots based on this extract type. The UOM of these snapshots must be compatible with at least one of the UOMs in the list of **Usage Subscription Types**. There must be at least one Measurement Data Snapshot type defined in this list for each UOM / SPI combination listed in the **Usage Subscription Types** list. Used with Interval consumption extracts only.

Consumption Extract Batch Controls

Consumption extract batch controls define the consumption extract type and date range used for the measurement data snapshot creation process. As outlined in the table above, there is a separate consumption extract batch control for each type of data.

All three batch controls use the same parameters:

- **Consumption Extract Type:** The consumption extract type for which the batch will be executed. The consumption extract type business object should align with data type of the batch control (interval, scalar, or item).
- **Start Date/Time:** The start of the period that will be extracted
- **End Date/Time:** The end of the period that will be extracted

Each batch control uses a distinct pair of algorithms to select the records to process (Select Records) and to create the measurement data snapshots (Process Records). The table below outlines the algorithms used with each batch control.

Batch Control	Select Records Algorithm	Process Records Algorithm
Extract US Intervals to Measurement Data Snapshots (D1–EUSIM)	Select Interval Snapshots for CET and Date/Range (D1-CETISSERC)	Create Measurement Data Snapshot Interval (D1-CETISPRRC)
Extract US Item Consumption to Measurement Data Snapshots (D1–EUITM)	Select Scalar Snapshots for CET and Date/Range for Item (D1-CETITEMSR)	Create Measurement Data Snapshot Scalar with Item Consumption (D1-CETITEMPR)
Extract US Scalar Reads to Measurement Data Snapshots (D1–EUSSR)	Select Scalar Snapshots for Consumption Extract Type and Date/Range (D1-CETSCSPSR)	Process Measurement Data Snapshot Scalar Records (D1-CETSCSPPR)

Usage Transaction Processing

Measurement data snapshots can be creating during usage transaction processing through configuration of the Daily Scalar Calculation Rule, Get Interval, Get Item Counts and Consumption, and Get Scalar Details usage calculation rules. When these are configured properly, the usage calculation process calculates service quantities and extracts measurement data for snapshots. See [Understanding Usage Calculation Rules](#) for more information about configuring usage rules to create measurement data snapshots.

Initial Measurement Snapshots

When measurement data snapshots are created via usage transaction processing as a result of a request for billing determinants from a billing system (including the billing functionality in Customer To Meter), initial measurement snapshots are created to “hold” the snapshots while the “Used on Bill” flag on the usage transaction is set to “No”. When the “Used on Bill” flag is updated the “Yes”, the measurement data snapshot is created from the initial measurement snapshot. See

[About Initial Measurement Snapshots](#) for more information.

Maintaining Measurement Data Snapshots

You use the **Settlement Item** portal to view and maintain measurement data snapshots.

Refer to [About Measurement Data Snapshots](#) for additional functional information.

Initial Measurement Snapshots

About Initial Measurement Snapshots

Initial measurement snapshots are used to hold measurement data snapshots until they are ready to be processed. Examples of initial measurement snapshots include:

- Measurement data snapshots created as part of usage transaction processing, but where the usage transaction’s “Used on Bill” flag is set to “No”.
- Imported measurement data snapshots that encounter an error of some sort during import, such as if the Usage Subscription or Settlement Item for the snapshot can’t be found.

Initial measurement snapshots are defined by:

- **Usage Subscription:** The usage subscription related to the initial measurement snapshot (if applicable)

- **Settlement Item:** The settlement related to the initial measurement snapshot (if applicable)
- **Usage Transaction ID:** The usage transaction related to the initial measurement snapshot
- **Status:** The current status of the initial measurement snapshot
- **Transaction ID:** The transaction ID of a related transaction, such as a bill.

Initial measurement snapshots in error can also include the following information:

- **Current Error Message:** An message explaining the error that resulted in the creation of the initial measurement snapshot
- **External System:** The external system that sent the measurement data snapshot
- **Measurement Data Snapshot Type:** The measurement data snapshot's type
- **Service Point ID:** The service point associated with the initial measurement snapshot, if applicable
- **Measuring Component ID:** The measuring component associated with the initial measurement snapshot, if applicable
- **File Name:** The file name for the import file used to create the measurement data snapshot
- **Start Date/Time:** The start date and time for the initial measurement snapshot
- **End Date/Time:** The end date and time for the initial measurement snapshot (applies to scalar snapshots only)

Initial Measurement Snapshot Business Objects

The system includes the following initial measurement snapshot business objects:

- **Initial Measurement Snapshot Export to US (D1–InitMsrmtSnapExporttoUS):** Used for snapshot data during the time period when billing determinants have been sent to the billing system but the billing system has not yet confirmed that they have been used on a finalized bill (the “Used on Bill” flag is set to “No”). This is used when the data is being staged under the Usage Subscription for eventual export to the Settlement Item.
- **Initial Measurement Snapshot Export to SI (D1–InitMsrmtSnapExporttoSI):** Used for snapshot data during the time period when billing determinants have been sent to the billing system but the billing system has not yet confirmed that they have been used on a finalized bill (the “Used on Bill” flag is set to “No”). This is used when the data is being created directly underneath the Settlement Item.
- **Initial Measurement Snapshot Import (D1–InitMsrmtSnapImport):** Used to captures the details of an imported measurement data snapshot that has encountered an error during processing.

Maintaining Initial Measurement Snapshots

You use the **Initial Measurement Snapshot** portal to view and maintain initial measurement snapshots.

Refer to [About Initial Measurement Snapshots](#) for additional functional information.

You can access the portal by selecting **Menu**, then **Initial Measurement Snapshot**. You are brought to a query portal with options for searching. You can search by:

- Initial Measurement Snapshot From
- Initial Measurement Snapshot To
- Show Initial Measurement Snapshot in Error

The following zones may appear as part of the portal's **Main** tab page:

- **Initial Measurement Snapshot:** This zone displays the selected initial measurement snapshot.

Interval Snapshot Mapping

About Interval Snapshot Mapping

Interval snapshot mappings are used to map intervals to a particular point in the day, and are used in the snapshot creation process to align a particular interval with the column it belongs to.

The Interval Snapshot Mapping (D1-IntervalSnapMapping) business service is used to create Interval Snapshot Mapping entries based on the installation time zone. This service takes Seconds Per Interval, Start Date/Time, and End Date/Time as inputs.

Maintaining Interval Snapshot Mapping

You use the **Interval Snapshot Mapping** portal to view and maintain Interval Snapshot Mapping entries.

Refer to [About Interval Snapshot Mapping](#) for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Interval Snapshot Mapping**. You are brought to a query portal with options for searching. You can search by:

- Seconds Per Interval
- Date/Time From
- Date/Time To

The search results include all of the mapping entries that match the provided Seconds Per Interval (if provided) and that fall within the specified date range (if provided).

Creating Interval Snapshot Mapping Entries

The Interval Snapshot Mapping (D1-IntervalSnapMapping) business service is used to create Interval Snapshot Mapping entries based on the installation time zone. This service can be invoked from the **Interval Snapshot Mapping** portal.

To create new Interval Snapshot Mapping entries, either select **Main**, then **Settlement**, then **Interval Snapshot Mapping**, and then **Add**, or click **Add** in the **Interval Snapshot Mapping** portal. The **Create Interval Snapshot Mapping Entries** page opens.

Enter parameters to specify the mapping entries to create, including:

- Seconds Per Interval
- Date/Time From
- Date/Time To

Click **OK**.

Enter appropriate parameters in the search portal to view the new entries.

Settlement Calculations

About Settlement Calculations

Oracle Utilities Market Settlements Management can calculate and publish settlement results calculated from aggregated data to market participants on an ongoing basis. Settlement calculations derive a settlement transaction's service quantities using the aggregated measurement associated with one or more market participants.

Before settlement results can be calculated, you must first create a [Settlement Subscription](#). The settlement subscription defines the external system to which the data should be sent as well as the settlement calculation groups that will be used for

calculation. The settlement calculation rules defined for the settlement calculation groups are responsible for performing the specific calculations, validations, or estimations for settlement results.

Settlement service quantities are derived from aggregated measurement data the calculation period.

The results of all calculations performed by settlement subscriptions are stored as a [Settlement Transaction](#).

The settlement calculation process has a number of different objects that are detailed below that allow for configurability and flexibility in how the process executes.

Settlement Calculation Groups

Settlement calculation groups are collections of settlement calculation rules that are used to calculate service quantities for market participants. During the settlement transaction process, the system executes the settlement calculation rules defined in the settlement calculation group referenced on the settlement subscription. The rules within a settlement calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

For information on configuration, reference the related section for [Configuring Settlement Calculation Groups](#) in the Administrative User Guide.

Settlement Calculation Rules

The specific calculation processing performed on a settlement transaction is defined in individual settlement calculation rules, each performing a specific set of targeted logic. The base product contains many settlement calculation rules you can use in your implementation, but you can also create your own custom settlement calculation rules. Many settlement calculation rules are identical to usage calculation rules used by Oracle Utilities Meter Data Management

For a list of validation settlement calculation rules, reference the [About Usage Validations](#) section. For a list of estimation usage calculation rules, reference the [About Usage Estimations](#) section. For a list of all other usage calculation rules that handle calculation of bill determinants, reference the [Inventory of Other Usage Calculation Rules](#) section.

For information on configuration, reference the related section for [Configuring Settlement Calculation Rules](#) in the Administrative User Guide.

Settlement Transaction Exceptions

Each settlement calculation rule defines an exception type and severity that specify how exceptions are tracked by the system. When a settlement transaction fails some part of a settlement calculation rule, an exception of the type specified for the failed settlement calculation rule is created. A single settlement transaction can have multiple exceptions, one (or more) for each rule that failed. This allows users to see all of the problems detected during the settlement calculation process.

There are three levels of severity for settlement transaction exceptions:

- **Information:** Used to highlight minor issues, but not sufficient to cause the settlement transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the settlement transaction from being exported. Multiple "issue exceptions" can be created during settlement transaction processing. If at least one issue exists after all rules have been applied, the settlement transaction is transitioned to a failure state requiring review and approval.
- **Terminate:** Used to report a severe issue that will cause the settlement calculation process to stop and the settlement transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a settlement transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full settlement period should always be set to Terminate as an Exception Severity.

Note that exceptions are not deleted when a settlement transaction is adjusted or corrected. After any issues are corrected or the settlement transaction is overridden (or manually completed), the exceptions persist in a closed state for reporting purposes.

In addition to exceptions, settlement processing can also trigger the creation of To Do Entries related to issues. If Issue or terminate exceptions exist for an initial measurement, a To Do Entry is created when the settlement transaction is

transitioned to the Exception state. The To Do Type and default To Do Role of this To Do Entry are defined on the Enter system event for the Exception state of the business object used to define the settlement transaction.

To Do Entries created in this way can be routed to different roles depending on the exception's message category and number (using the To Do Type's Message Overrides tab).

For information on configuration, reference the related section for [Configuring Usage Transaction Exception Types](#) in the Administration Guide.

Settlement Calculation Rule Eligibility Criteria

Settlement calculation rule eligibility criteria are user-definable conditions that could cause a given settlement calculation rule to be applied or skipped. This can involve the evaluation of some attribute of the settlement subscription or something else entirely. A settlement calculation rule can have multiple eligibility criteria for determining if the rule should be applied or skipped, based on a user-defined sequence. Eligibility criteria for settlement calculation rules works in the same manner as eligibility criteria for usage calculation rules used by Oracle Utilities Meter Data Management.

For information on configuration, reference the related section for [Configuring Usage Calculation Rules](#) in the Administrative User Guide.

Settlement Subscriptions

About Settlement Subscriptions

Settlement subscriptions track the ongoing need to calculate a set of data, often aggregated load, for the purpose of settling a market and send the results to a recipient.

Settlement subscriptions must reference the following:

- **Recipient:** The identity of the subscribing system. In other words, you must set up a recipient for any system that subscribes to settlement calculations.
- **Settlement Calculation Groups:** The calculation groups used to perform settlement calculations for settlement transactions based on this settlement subscription. Settlement calculation groups can be configured in a specific sequence of execution. In addition, each group can be configured to require approval before the calculation execution proceeds to the next calculation group.

Settlement subscriptions can also reference the following;

- **Factor Overrides:** One or more factors can be used as override values when performing calculations
- **Measuring Components:** One or more measuring components directly linked to the settlement subscription. These are most often aggregation measuring components, but can also include profile measuring components.
- **Measuring Component Sets:** One or more measuring component sets directly linked to the settlement subscription.

Maintaining Settlement Subscriptions

You use the portal **Settlement Subscription** portal to view and maintain settlement subscriptions.

Refer to [About Settlement Subscriptions](#) for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Subscription**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Subscription:** This zone displays basic information about the settlement subscription, including factor overrides, settlement calculation groups, measuring components and measuring component sets.
- **Settlement Transaction:** This zone displays a list of settlement transactions for the settlement subscription.

Settlement Transactions

About Settlement Transactions

Settlement transactions are records of calculations for a settlement subscription. All of the service quantities calculated are stored as part of the settlement transaction.

Settlement Calculation Group Determination

The first step in settlement calculation is to determine the settlement calculation group holding the rules set used in calculating or validating the calculations. There are two ways of configuring the settlement calculation group to use in the processing. It may be specified on the settlement subscription during its creation with an effective and expiration date. If there are no settlement calculation groups in effect for the settlement transaction, the **Fallback Settlement Calculation Group** specified in the settlement subscription type will be used.

Calculation Period

Settlement transaction requests must specify the date range for the settlement transaction. This date range is referred to as the calculation period for the settlement transaction.

Date Breaks

Date breaks are used to break up a settlement period into sub-periods based on the dates on which changes took place for market participants. One approach to this situation would be for the system to create settlement transactions (where each has the desired date range). Another approach is for the system to create single settlement transaction with date breaks that define the date ranges before and after the change.

If a settlement transaction has date break(s), the settlement calculation engine segregates the usage into multiple calculation periods based on the date breaks. If there are no date breaks in the settlement transaction, a single calculation period is created for the entire calculation period.

Service Quantities

Every settlement period created for a settlement transaction contains one or more service quantities. Service quantities are calculated by the settlement calculation group's rules specified for the settlement subscription from which the settlement transaction is created. For example, a settlement transaction might have quantities calculated by a single rule that applies a TOU map to aggregated kWh .

Each service quantity lists details about that quantity, including a UOM (or TOU or SQI as appropriate) and a quantity. In addition, each service quantity also references the source (measuring component) of the quantities (for audit purposes).

Quality Assessment

The [Get Interval Data](#), [Get Scalar Details](#), and [Get Time of Use Mapped Usage](#) calculation rules include a "Perform Measurement Quality Assessment" option that indicates (yes or no) if the measurement conditions of the measurements used when calculating usage should be evaluated and included in the resulting settlement transaction and outbound message. When enabled (set to "Yes"), the calculation rule algorithm evaluates the condition codes of the measurements used in the calculation to determine if they fall within a "Regular" range of conditions (this range is defined by the "Bottom Regular Condition Range" and "Top Regular Condition Range" algorithm parameters). The result of this assessment is displayed in the "Data Quality Assessment" column in the Calculation Periods section which indicates if the service quantity is based on

"regular" or "non-regular" data. (If the "Perform Measurement Quality Assessment" option is disabled, the "Data Quality Assessment" column displays "No Assessment Done"). In addition, the "Source Measurement Quality List" column contains XML that contains a list of measurements aggregated by condition/quality.

Validations

As settlement transactions are created and move through their various states, several validations are performed to ensure proper processing. These include:

- Validating the business object used to create the settlement transaction
- Validating the start and end dates for the settlement transaction
- Validating the settlement transaction's service quantities
- Validating the existing settlement transactions for the same calculation period
- Validating whether or not the settlement transaction can be deleted

Settlement Transaction Communication

Upon completion of calculations (or approval of calculations if the approval is required), settlement transaction results can be exported and sent to market participants. This is done via an outbound communication created by the Create Settlement Transaction Outbound Communication algorithm. This communication is responsible for deriving and gathering the appropriate data to send to the market participant and creating and sending an outbound message.

There are two many ways in which settlement transactions are sent:

- **Contract:** Sending by contract involves sending the results of a settlement transaction to a recipient (such as an ISO) using an identifier from the market contract.
- **Identifier:** Sending by identifier involves sending the results of a settlement transaction to a recipient using an identifier from the market participant.

Communication Types

The type of outbound communication created is based on the **Outbound Communication Type** defined on the settlement transaction's settlement subscription type. Communication types define the following about settlement transaction outbound communications:

- **Communication Flow:** The direction of communications based on this type (outbound or inbound).
- **Suppress Zeros:** Designates whether or not data should be sent for a service quantity of 0.
- **Message Generation Method:** Specifies if messages be sent as a single message to the market or broken down to one message per Identifier/Contract.
- **External Communication Type:** Defines whether the communication type is "Settlement by Contract" or "Settlement by Identifier".
- **Export Data Identification:** Defines combinations of UOM/TOU/SQI that represent the final outcome of the settlement transaction to be passed to the market
- **Reconciliation:** Defines the appropriate identifier or contract to include in the data sent to the market participant:
 - **Contract Reconciliation:** defines the appropriate identifier for the market contract associated with the service quantity. Used when sending data by contract.
 - **Identifier Reconciliation:** Defines the characteristic type for the market participant used to retrieve the appropriate identifier. Used when sending data by identifier.
- **Exception Handling:** Defines how exceptions are handled, including To Do Type and Role, Retry Frequency, and the maximum number of times the system will retry to process the communication

Retrieving Service Quantities

Once created, the outbound communication retrieves a list of service quantities for the settlement transaction and inserts the details into the Settlement Transaction Details list. The specifics of how this is done is based on whether the settlement transaction is sent by contract or by identifier.

Send Settlement Transaction By Contract

Sending data by contract uses outbound communications based on the Send Settlement Transaction by Contract business object. The Retrieve Settlement Transaction SQs Contract algorithm retrieves the list of service quantities that match the UOM/TOU/SQI combination defined on the communication type, and for each service quantity found that has a market contract it will retrieve the identifier for that contract and populate the appropriate details into the Settlement Transaction Details list. The algorithm processes the entire service quantity result set even if it cannot find an identifier for a given contract. This way a user can see all identifier resolution errors at once (instead of needing to fix them one by one to see the next error).

Send Settlement Transaction By Identifier

Sending data by identifier uses outbound communications based on the Send Settlement Transaction by Identifier business object. The Retrieve Settlement Transaction SQs for Identifier algorithm extracts the market participant from the attributes associated to the service quantity's measuring component. The measuring components that will be associated to the service quantity in this instance will be aggregation measuring components that hold a list of dimensions that includes a market participant. The algorithm then retrieves the list of service quantities that match the UOM/TOU/SQI combination defined on the communication type and for each service quantity found that has a measuring component, it retrieves the measuring component's market participant and then retrieve the identifier for that market participant and populate the appropriate details into the Settlement Transaction Details list. The algorithm processes the entire service quantity result set even if it cannot find a market participant or an identifier for a given market participant. This way a user can see all identifier resolution errors at once (instead of needing to fix them one by one to see the next error).

Sending Settlement Transactions to Market Participants

After the outbound communication has retrieved the appropriate service quantities, the outbound message creates an outbound message to the market participant (defined as the **Recipient** on the settlement transaction's settlement subscription or settlement subscription type).

The Send Settlement Transaction Details algorithm creates one more outbound messages based on the outbound message type defined for the market participant's Settlement Transaction Notification processing method (see below for more details).

- If the **Message Generation Method** on the communication type is set to "One Comprehensive Message" the outbound communication creates a single outbound message that contains all the service quantities retrieved.
- If the **Message Generation Method** on the communication type is set to "Multiple Messages Based on Data" the outbound communication creates a separate outbound message for each of the service quantities retrieved.

Configuring Market Participants for Settlement Transaction Communication

To support sending settlement transactions to market participants, the following processing method must be defined for the market participants to which settlement transactions are sent:

Processing Role	Processing Method
Settlement Transaction Notification	How to Send Settlement Subscription Related Information Used to send a settlement transaction outbound message to a market participant.

Processing Role

Processing Method

Default Outbound Message Type: The default outbound message type to create for outbound message sent to market participants. The base package does not include an outbound message business object for this. This must be created based on the requirements of each implementation and market participant.

If appropriate, override outbound message types can be defined for specific settlement subscription types.

In addition, the following objects must be configured to send data requests:

- External System
- Outbound Message Type
- Message Sender

Maintaining Settlement Transactions

You use the portal **Settlement Transaction** portal to view and maintain a settlement transactions.

Refer to [About Settlement Transactions](#) for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Transaction**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Transaction:** This zone displays basic information about the settlement transaction, including processing information and settlement calculation groups.
- **Outbound Communication:** This zone displays a list of outbound communications sent for the settlement transaction.
- **Calculated Data Overview:** This zone displays an overview of calculated data related to the settlement transaction.
- **Calculated Data Details:** This zone provides ability to query the detailed service quantity interval data for the settlement transaction.

A number of important actions are available for a settlement transaction depending on its status:

Action	Allowed Statuses	Details
Approve	Approval In Progress Issue Detected (only when the exceptions are marked to require approval)	Allows a user to bypass any exception or failure message for the settlement transaction and attempt to send it to the requesting system.
Calculate	Approval In Progress Pending	Allows a user to trigger settlement calculations.
Discard	Approval In Progress Export Error Issue Detected	Allows a user to discard the settlement transaction.
Export	Export Error	Allows a user to transition the settlement transaction to the Export status and send the settlement transaction to the recipients.
Export Manually	Export Error	Allows a user to manually export the settlement transaction send it to the recipients.

Override Exception	Issue Detected	Allows a user to override an exception and transition the settlement transaction to the Override Exception state.
Re-Calculate	Issue Detected	Reruns the entire process of calculation along with any validations (all settlement calculation rules) for the settlement transaction.
Supersede	Completed	Allows a user to indicate that the settlement transaction was corrected after being sent. Sets the status of the settlement transaction to Superseded.

Settlement Items

About Settlement Items

Settlement items represent end customer accounts. These are market participants for which settlement calculations are performed, and generally correspond to the market participants which subscribe to settlement calculation results via settlement subscriptions.

Settlement items are defined by the following:

- **Settlement Item Type:** The Settlement Item Type for the settlement item, which defines the business object to use to create the settlement item, the business object to use to capture billed usage for a settlement item (via Settlement Account Billed Usage), and valid service point types.
- **Division:** The division to which the settlement item belongs
- **Access Group:** The access group to which the settlement item belongs (used to limit access to records)
- **Status:** The status of the settlement item
- **Start Date/End Date:** The date range during which the settlement item is active.
- **Main Contact:** The main contact for the settlement item.
- **Time Zone:** The time zone in which the settlement item is active.
- **Measuring Components:** One or more measuring components directly linked to the settlement item. These are most often aggregation measuring components, but can also include profile measuring components.
- **Rate Class:** One or more effective-dated rate classes for the settlement item.

Maintaining Settlement Items

You use the portal **Settlement Item** portal to view and maintain a settlement items.

Refer to [About Settlement Items](#) for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item:** This zone displays basic information about the settlement item, including related service points and measuring components.
- **Settlement Item Quantities:** This zone displays a list of settlement item quantities. See [About Settlement Item Quantities](#) for more information. To add a new quantity, for the settlement item, click **Add** in the zone title bar.

- **Settlement Item Market Participants:** This zone displays a list of settlement item market participants for the settlement item, via a [Settlement Item Market Participant](#). To add a new market participant for the settlement item, click **Add** in the zone title bar.
- **Characteristics:** This zone displays a list of characteristics related to the settlement item.
- **Identifiers:** This zone displays a list of identifiers used with the settlement item.
- **Attribute Data Snapshots:** This zone displays a list of attribute data snapshots created for the settlement item.
- **Interval Measurements:** This zone displays a list of interval measurement data snapshots associated with the settlement item. To add a new interval measurement data snapshot for the settlement item, click **Add** in the zone title bar.
- **Scalar Measurements:** This zone displays a list of scalar measurement data snapshots associated with the settlement item. To add a new scalar measurement data snapshot for the settlement item, click **Add** in the zone title bar.

Settlement Item Quantities

About Settlement Item Quantities

Settlement item quantities are quantities that are stored at the settlement item level. These quantities are calculated at irregular frequencies (such as annually or quarterly) and thus do not make sense as a measured quantity on a device and measuring component. For example, in some deregulated markets the Peak Load Contribution could be stored here and effective dated over time to represent the changing contribution of a given settlement item to the market wide coincidence peaks.

Settlement item quantities are defined by the following:

- **Settlement Item:** The settlement item for which the quantities were calculated
- **Settlement Item Quantity Type:** The Settlement Item Quantity Type used for the record
- **Start Date / End Date:** The date range for the calculated quantity
- **Settlement Item Quantities:** Calculated quantities based on **Settlement Item Quantity Identifiers** configured on the Settlement Item Quantity Type (see [Understanding Settlement Item Quantity Types](#) for more information)

NOTE: There cannot be more than one Settlement Item Quantity for the same Settlement Item and Settlement Item Quantity Type, for the same time period (defined by the Start Date and End Date parameters).

Maintaining Settlement Item Quantities

You use the **Settlement Item Quantity** portal to view and maintain settlement item quantities.

Refer to [About Settlement Item Quantities](#) for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item Quantity**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Quantity:** This zone displays the basic attributes of the settlement item quantity

Settlement Billed Usage

About Settlement Billed Usage

Settlement billed usage represents billed usage for a settlement item. Settlement billed usage is calculated via settlement calculations performed for the settlement subscription associated with the settlement item. Settlement billed usage typically corresponds to settlement transactions.

Settlement billed usage records are defined by the following:

- **Settlement Item:** The settlement item for which the billed usage was calculated
- **Start Date/Time:** The date and time of the start of the billing period for the billed usage
- **End Date/Time:** The date and time of the end of the billing period for the billed usage
- **Billed Usage Periods:** one or more billed usage periods for the current settlement billed usage. A billed usage period is a period of time for which usage is calculated, including details calculated for each billed usage period such as UOM/TOU/SQI and quantities

Maintaining Settlement Billed Usage

You use the portal **Settlement Billed Usage** portal to view and maintain settlement billed usage.

Refer to [About Settlement Billed Usage](#) for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Billed Usage**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Billed Usage:** This zone displays basic information about the settlement billed usage, including billed usage periods.

Settlement Item Market Participants

About Settlement Item Market Participants

Settlement item market participants connects a Market, Market Participant and Settlement Item together over a specified date range. Settlement item market participants can be created either via the **Settlement Item Market Participant** portal, or by adding a market participant to a settlement item via the **Settlement Item** portal.

Settlement item market participants are defined by the following:

- **Settlement Item:** The settlement item for which this settlement item market participant was created.
- **Market Relationship Type:** The market relationship (Distributor, Supplier, etc.) of the market participant and its role within a market.
- **Start Date/Time:** The start date/time for when the record is applicable.
- **End Date/Time:** The end date/time for when the record is applicable.
- **External ID:** An ID for the market participant used by external systems.
- **Market Participant:** The market participant associated with the **Settlement Item**, including an optional ID used by the market participant to uniquely identify the settlement item.

Maintaining Settlement Item Market Participants

You use the **Settlement Item Market Participant** portal to display and maintain settlement item market participants.

Refer to [About Settlement Item Market Participants](#) for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item Market Participant**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Market Participant:** This zone displays the basic attributes of the settlement item market participant.
- **Sub Settlement Items:** This zone lists settlement items for the settlement item market participant.

Market Allocations

Market Contracts

About Market Contracts

Market contract are agreements with the market operator (such as an Independent System Operator, or ISO) related to how settlement calculation results are sent to the market. Market contracts are related to a specific market, have a seller and buyer, as well as a date range for when they are effective.

Market contracts are defined by the following:

- **Market Contract Type:** The [Market Contract Type](#) for the contract. This defines the market in which the contract is in effect and the business object used to create the contract.
- **Contract :** A unique code for the contract, often provided by an external system
- **Start Date / End Date:** The date range during which the contract is in effect
- **Seller:** The market participant that serves as the Seller for the contract.
- **Buyer:** The market participant that serves as the Buyer for the contract.

Maintaining Market Contracts

You use the **Market Contract** portal to view and maintain market contracts.

Refer to [About Market Contracts](#) for additional functional information.

You can access the portal from the **Main > Market > Market Contract**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Contract:** This zone displays basic information about the market contract.
- **Related Market Awards:** This zone displays a list of market awards related to the market contract.

Market Awards

About Market Awards

Market awards are used to allocate load to various market participants.

Market awards are defined by the following:

- **Market Product:** The [Market Product](#) associated with the award
- **Award Class:** The type of award. The base package supports three award classes: Tranche Awards, Percentage Awards, and Fixed Profile Awards.
 - **Tranche Awards:** Tranches are used to handle a whole number division of load. For example, an agreement may be reached that the Provider of Last Resort (POLR) load for a zone should be broken into 64 tranches, or exactly 64 chunks of load that can be purchased. In this example, the load could be broken up in the following manner: Contract #1234 buys 12 tranches, Contract #1235 buys 1 tranche, and Contract #1236 buys 51 tranches (each of these three would be a market award) A factor can be used to define different tranche quantities over time for the same market award.
 - **Percentage Awards:** Percentage Awards allocate a percentage of the remaining load. A factor can be used to define a different percentage over time for the same market award.
 - **Fixed Profile Awards:** Fixed Profile Awards leverage a profile measuring component to designate an amount that must be allocated from the overall load to this market award. A factor can be used to define different profiles over time for the same market award.
- **Start Date / End Date:** The date range for the market award
- **Award Details:** Details of the award, including the source (Static Value or Factor) and quantity (either a fixed value or factor value)
- **Characteristics:** Characteristics for the award, if appropriate

Maintaining Market Awards

You use the **Market Award** portal to view and maintain market awards based on [Market Products](#) with a **Product Class** of “Contract Fulfillment”.

Refer to [About Market Awards](#) for additional functional information.

You can access the portal from the **Main > Market > Market Award**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Award:** This zone displays basic information about the market award, including **Award Details**, related market **Contracts**, and **Characteristics**.

Maintaining Market Allocations

You use the **Market Allocation** portal to view and maintain market awards based on [Market Products](#) with a **Product Class** of “Parent Allocation”.

Refer to [About Market Awards](#) for additional functional information.

You can access the portal by selecting **Main**, then **Market**, then **Market Award**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the **Market Allocation** portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Allocation:** This zone displays basic information about the market award, including **Award Details**, and **Characteristics**.

Market Products

About Market Products

Market products are used to allocate market awards to market participants. Market products are referenced by the [Market Award Allocation](#) settlement calculation rule via a parent Market Product Set. Market products of class "Parent Allocation" can have child products. This allows definition of hierarchies of market products and related awards,

Market products are defined by the following:

- **Market Product Set:** The [Market Product Set](#) to which the Market Product is associated.
- **Market Product Type:** The [Market Product Type](#) for the market product. This defines the business object used to create the market product and its market awards. For formula-based products, the market product type also defines the formula used to calculate award allocation.
- **Product Code:** A unique code for the product, often provided by an external system
- **Product Class:** The type of product. The base package supports two product classes: Parent Allocation or Contract Fulfillment:
 - **Parent Allocation:** Indicates that the market product is a parent level product that divides out a certain allocation of the total amount to be then divided further amongst child products.
 - **Contract Fulfillment:** Indicates that the market product ties to an "end result" award that can then be tied to a Market Contract
- **Execution Sequence:** Defines the sequence in which the market product will be executed within its parent Market Product Set
- **Awards:** One or more [Market Awards](#) associated with the market product. These define how load and procurement are allocated when the market product is processed by the [Market Award Allocation](#) settlement calculation rule.

Maintaining Market Products

You use the **Market Product** portal to view and maintain market products.

Refer to [About Market Products](#) for additional functional information.

You can access the portal from the **Main > Market > Market Product**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Product:** This zone displays basic information about the market product.
- **Awards:** This zone displays a list of market awards related to the market product.

Data Access Restrictions

Using Data Access Restrictions

The focus for multi-jurisdiction support in Oracle Utilities Meter Data Management is on restricting access to the user interface. This occurs through defining different Access Groups by operating company which then marks the Service Point with the access capabilities. The Service Point has a field named **Access Group** which allows you to define specific access to the Service Point.

If Access Group is set on the Service Point, then the user interface search screens within Oracle Utilities Meter Data Management will only allow users that are assigned to the proper Access Role to be able to access that Service Point.

For additional information see [Defining Access Groups](#).

Defaulting Access Groups on Service Points

If there is a desire to set a default Access Group by jurisdiction, then this can be accomplished on configuration for [Markets](#). When defining a Market there is an option to add a **Default Access Group**. This value will be used to mark any newly created Service Point with the same Access Group value defined on the related Market.

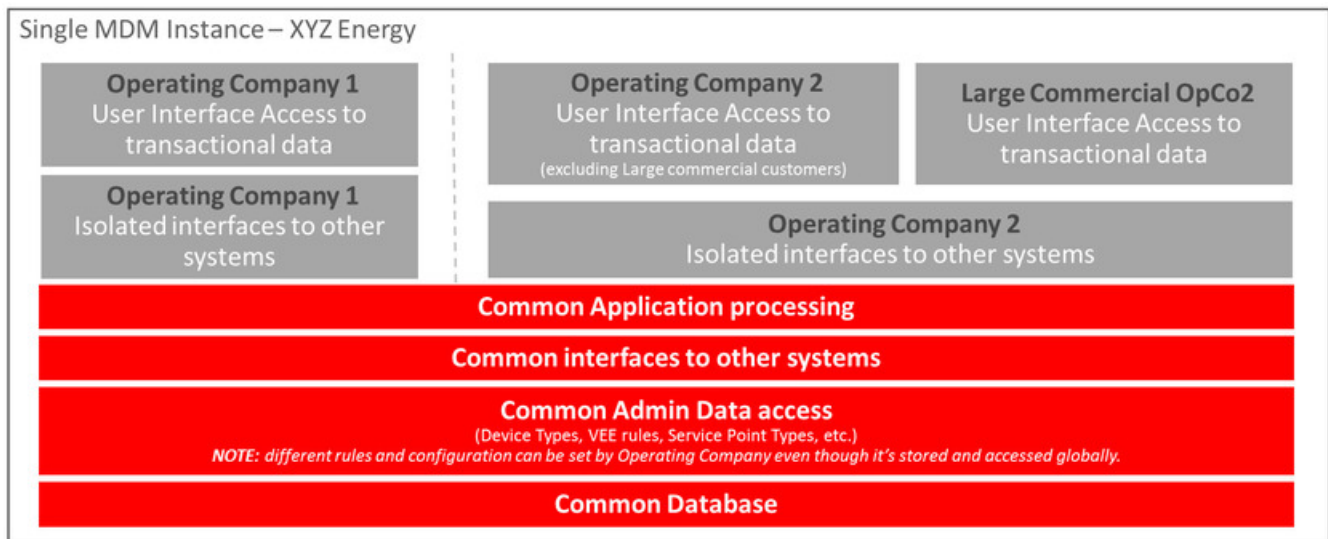

Example Scenarios

Below are some examples of how Data Access Restrictions can be implemented:

Example 1: Split Access by Market - an example utility "ABC Energy" that has 3 operating companies.

Example 2: Isolating Important Customers - an example utility "XYZ Energy" that has 2 operating companies but would also like to isolate access to Large commercial customers for one of the companies.

To Do Processing

There are numerous events that trigger the creation of email-like messages describing work that requires human attention. For example, if a bill segment has an error, a message is created to highlight such. We refer to each message as a **To Do Entry**. In this section, we describe how to view, manage and work To Do entries.

FASTPATH: We recommend familiarizing yourself with the topics described in [The Big Picture of To Do Lists](#) to fully appreciate how To Do entries are managed by the system.

Understanding To Do Processing

The topics in this section provide background information on To Do processing functionality.

To Do Role

Each To Do entry is assigned a specific To Do Role. The role defines the users who may work on the entry. The permissible roles that may be assigned to a To Do entry are defined on the entry's To Do type. One or more users within a role may be designated as a supervisor, who is allowed to assign To Do entries to other people. Supervisors are determined through application security access.

Refer to [To Do Entries Reference A Role](#) to learn more about role assignment.

After an entry is created, its role may be changed to any role defined as valid for the entry's To Do type. Manual changes of a To Do entry's role are recorded on the [To Do entry log](#).

To Do Priority

A To Do entry is associated with a priority level representing its processing order compared to other entries. Refer to [The Priority Of A To Do Entry](#) for more information on how an entry's priority is initially assigned and how it may be automatically updated by the system.

A user may manually override a To Do entry's priority at any time. Once overridden, automatic recalculation of the priority is no longer performed so as not to override the value explicitly set by the user. Manual overrides of a To Do entry's priority are recorded on the [To Do entry log](#).

NOTE: Only users that are currently assigned to a **Being Worked On** To Do entry or ones that are valid for the role of an **Open** To Do entry may manually change the priority.

Work Distribution

This topic goes over the various possible actions a user can take to adjust what role or what user is associated with a To Do entry while it is in a non-complete state.

Adjusting the Role

A To Do entry must always reference a role. When a To Do entry are created in the **Open** state and is associated with a [role](#). The following points highlight ways to adjust the role associated with a To Do entry.

- A user viewing a record on the [To Do Entry](#) page may use the Forward or Send Back action to change the role.
- A supervisor using the [To Do Search](#) page may assign a user not linked to the current role. In this case, the system will update the role to one valid for the assignee.

Assigning a To Do to a User

There are several ways to assign a To Do entry to a user (causing its status to transition to **Being Worked On**):

- The [To Do Management](#) portal provides many filters and viewing options to review To Do entries for a give To Do Type. In addition, it displays a rich amount of detail for the resulting To Do entries, helping users to make decisions. Users may use this page to assign work to themselves and supervisors may use this to assign work to others.
- A supervisor can use the [Supervisor Functions](#) pages to review, assign and reassign To Dos to users.
- A user viewing an entry on the [To Do Entry](#) page may use the Forward to a User or the Send Back action to assign the entry to a different.
- A user may use the [To Do list](#) pages to review and assign To Dos to themselves.
- All of the above assignment functions may also be performed using the [To Do Search](#) page.

The system can also be configured to dynamically assign the highest priority work to users on demand whenever they are available for fixing errors.

NOTE: Assignment on demand is in a plug-in. You can customize the next assignment plug-in on the [installation options](#) to follow your organization's work distribution rules. The product provides an algorithm out of the box (**F1-NEXT-TDNS**) that can assign work solely based on priority. Another algorithm (**F1-NEXT-TDSK**) may be used to only consider To Do entries the user has the proper [skills](#) to resolve. Your implementation may provide a different algorithm based on your own business rules.

One of the main benefits of the assignment on demand approach is that work is allocated real-time based on most current information such as skills, priority, user availability, etc. This also means that work remains unassigned until a user is actually going to work on it making it available to any qualified user.

Assignment "on demand" is possible from the [Current To Do](#) zone on the Dashboard portal. Refer to this zone to learn about all the functions it provides.

Reopening / Unassigning a To Do

It is possible to transition a To Do entry from **Being Worked On** back to **Open**.

- A user viewing a record assigned to them on the [To Do Entry](#) page may use the Forward to a role action to move the entry back to **Open**.

- The **Unassign** button on the [To Do Management](#) portal or the **Reopen** button on the [To Do Search](#) page causes the To Do entry to go back to **Open**.

A User's Current To Do

When you are actively working on a specific To Do entry, there are tools to make this To Do the one that is displayed in the [Current To Do](#) dashboard zone. The act of making a To Do entry your current To Do, also navigates you to the related object (or if the To Do type is configured to launch a script, the script is launched).

If your organization's practice is to assign work to users up front, then a typical approach is that you would start by reviewing a list of entries assigned to you using one of the base pages and drill down on an entry in the list to start working on it. In some pages, there is a way for you to enable a list of To Do Entries that you can work through without needing to return to the query page to get the next entry.

The following points highlight the available base pages and their supported functionality.:

- [To Do Management](#) allows you to use filters to view a list of entries assigned to you or open. (If you plan to work on a To Do entry that is open, you should first assign it to yourself. No action automatically assigns it.) Click the Work List icon in the Action column to populate the [Work List](#) zone in the dashboard with the results of the search. Click the **Work** button to choose the To Do entry you wish to start with. This drills you into the related object and populates the Current To Do zone with this To Do. Use the entries in the Work List zone to subsequently work on other To Do entries.
- [To Do List](#) allows you to start working on a To Do by clicking the entry's message description link. If the To Do entry is Open, this action will assign it to you automatically. Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list.
- [To Do Search](#) allows you to start working on a To Do by clicking the entry's message description link. (If you plan to work on a To Do entry that is open, you should first assign it to yourself. No action automatically assigns it.) Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list.

Before working on a new To Do, if the problem is resolved, use the actions in the Current To Do zone to mark the entry [Complete](#).

Additionally, users may have the option to click on the **Assign me a To Do** button on the Current To Do dashboard zone to request their next task. The returned To Do entry automatically becomes the user's **Current** To Do. This does not enable any work list functionality.

To Do Characteristics

Characteristics are used to associated related information to a To Do entry. Refer to [Linking Additional Information](#) to a To Do Entry for more information.

Several pages in the system allow you to view a To Do entry's characteristic values and / or search for To Do entries by their characteristics.

- The [To Do Management](#) portal includes up to five filters to search for To Do entries by a characteristic value. In addition, the search results display all the current characteristics as name / value pairs.
- The [To Do Entry](#) includes a zone to display any existing characteristics. In addition, if a user is allowed to modify a To Do Entry, the edit dialogue allows a user to add or change characteristics. Note that for manual [To Do types](#), the valid characteristic types are driven by the To Do type. For automated To Do types, if valid To Do characteristic types are configured on the To Do type, only those are available. Otherwise, any valid To Do characteristic type may be linked.
- The [To Do Search](#) allows includes a single characteristic type / value filter.

Related To Do Entries

A user working on a To Do may want to know of other To Dos that may be related to the same problem. If they can be worked by the same user they may get resolved faster. It seems almost impossible to programmatically determine whether two To Dos really stem from the same problem. The user should therefore be presented with a list of potentially related To Dos from which they can select the truly relevant ones.

A To Do entry is considered potentially related to a given To Do if they reference a common entity via a characteristic. For example, if a given To Do references a certain account then any To Do referencing that same account is considered related to it.

NOTE: The common entity is any characteristic value linked to the To Do entry where the characteristic type is a **Foreign Key** and the main table of the foreign key is classified as a **Master** or **Transaction** table.

There are various places where the user is informed as to whether or not the current To Do Entry is related to other To Do Entries.

- To Do entry maintenance displays in insight indicating the number of related To Do Entries for the current To Do. In addition, a Related To Do Entries zone shows information about each related To Do.
- The [Current To Do](#) dashboard zone includes related To Do information and actions.
- The [To Do Management](#) query includes a count of related To Do entries.
- The [To Do Search](#) page supports a **Related To Do filter** that lists all related To Do entries for a given entry.

Complete A To Do

After you finish working on an entry, you can mark it as **Complete**. At this point, you may want to review potentially [related](#) To Do entries and complete those that have been addressed by resolving the problem associated with the current entry.

When you complete a To Do, a [log entry](#) is created that indicates when the To Do was completed and by whom.

There are multiple ways in which you can complete a To Do.

- The [To Do Management](#) page provides many filters in addition to To Do Type. One or more entries may be completed in this page.
- Use the [To Do Entry](#) page to complete a single To Do Entry. The user may also choose to add comments when completing a To Do on this page.
- The [To Do List](#) page allows you to complete one or more selected entries of a specific To Do Type.
- The [To Do Search](#) page allows you to search for To Do entries using various search criteria and complete selected ones.
- You may also use the [Current To Do](#) zone to complete the current entry you are working on and/or all [related](#) entries assigned to you.

NOTE: It is possible for the system to automatically mark an entry as **Complete**. Refer to [The Lifecycle Of A To Do Entry](#) for more information.

Log Entry Events

Any user may add a **User Details** log entry to any To Do at any time (even after it's completed). Refer to [To Do Entry](#) page for more information.

The [To Do Management](#) portal also allows users to add a **User Details** log entry to one or more selected entries.

In addition, there are several log entries created automatically by the system. The following table contains the list of all possible log events.

Event	Log Type	To Do Entry Status	Content of Details	Content of Assigned To (on To Do entry and To Do Log)	Log User ID	Contents of Sent By (on To Do entry)
A To Do is created (by the system or by a user)	Created	Open			ID of user who created the To Do	
A To Do is created (by the system or by a user) in Being Worked On status	Created	Being Worked On		User ID of user who was assigned this To Do	ID of user who created the To Do	Creating user's ID
A To Do is completed (by the system or by a user)	Completed	Complete			ID of user who completed the To Do	
A user takes an open To Do	Assigned	Being Worked On	Selected by user	Assigned To User ID	Assigned To User ID	ID of user who assigned the To Do
A supervisor assigns a To Do to a user (also happens if they reassign)	Assigned	Being Worked On	Assigned to user	Assigned To User ID	ID of user who assigned the To Do	ID of user who assigned the To Do
A user forwards an entry to a user	Forwarded	Being Worked On	<i>Log details entered by user</i>	Forwarded To User ID	ID of user who forwarded the To Do	ID of user who forwarded the To Do
A user forwards an entry to a role	Forwarded	Open	Forwarded to role <i>Role Description (Role ID) + Log details entered by user</i>		ID of user who forwarded the To Do	ID of user who forwarded the To Do
A user sends back a To Do	Sent back	Being Worked On	<i>Log details entered by user</i>	Sent Back To User ID	ID of user who sent back the To Do	ID of user who sent back the To Do
A user adds a log entry	User Details	Status remains the same	<i>Log details entered by user</i>		ID of user who added the entry	
A user manually overrides priority	Override Priority	Status remains the same	Priority changed from <i>old value</i> to <i>new value</i>	Assigned To User ID	ID of user who made the change	
Priority is updated by a calculate priority algorithm	Calculated Priority	Status remains the same	Priority changed from <i>old value</i> to <i>new value</i>		ID of user that added or updated the To Do or the user associated with the Recalculate Priority batch job.	

Managing To Do Entries

This section describes the various pages available to view and work on To Do entries.

To Do Management

The To Do Management portal provides a multi-query zone that includes a search for To Do entries using To Do Type and other To Do information. Users may search for entries using multiple criteria and perform common actions, such as assignment and completion, on selected entries.

It is intended to be used by both supervisors and non-supervisor To Do users. Supervisors are identified by their security access to the portal.

Use **Menu > To Do > To Do Management** to navigate to the portal.

To Do Information Search

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

NOTE: Results are restricted by role. For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The following sections describe the features of this zone.

Search Filters

The following table describes each of the different filters supported by this zone.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection.
To Do Entry Status	Use this filter to restrict the search to To Do entries with a status of Open or Being Worked On . Note that the underlying query excludes completed To Do entries.
Days Old	On the To Do Management portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old. On the To Do Dashboard portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Message	Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been

Search Filter	Description
Characteristic	<p>populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type.</p> <p>Use these filters to restrict the search to To Do entries with a specific Characteristic Type and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown.</p>

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

NOTE: For performance reasons, the search zone is configured to restrict the number of rows retrieved by the query. The 'Total Records' number will indicate whether there are more To Do entries that meet the criteria than can be displayed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined as a parameter to the zone. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [Working On A To Do Entry](#) for more information.

NOTE: Current To Do. Drilling into an entry from this page sets it to be the user's current To Do. Refer to [A User's Current To Do](#) for more information.

CAUTION: Automatic Assignment! When you click the Work button for an open entry, the system changes the status of the entry to **Being Worked On** and assigns it to you.

NOTE: Work List. This column has a Work List icon. Clicking this icon populates the [Work List](#) dashboard zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do and will assign it to you if it is **Open**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the [To Do Search](#) page with the current entry as the Related To Do Filter value.

- **Note** displays a Comment icon  if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string.
- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the [To Do Entry](#) page to view or maintain the current entry.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1 to Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details** [log entry](#) to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is being worked on by another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is being worked on by another user.
- Use the **Complete** button to [complete](#) the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

To Do Supervisor Functions

This section describes several To Do transactions that aid supervisors in the monitoring and assignment of To Do entries.

Supervisor To Do Summary

This Supervisor To Do Summary page summarizes To Do entries by To Do Type. Only entries that are **Open** (i.e., not assigned to a specific user) or **Being Worked On** are summarized.

NOTE: Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to [To Do Entries Reference A Role](#) for more information.

Use **Menu > To Do > Supervisor To Do Summary** to open this page.

Description of Page

This page summarizes all To Do entries that are **Open** or **Being Worked On**.

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Being Worked On** entries. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Open** and **Being Worked On** entries for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Open** entries for the given To Do Type.
- **Being Worked On** contains the number of To Do entries whose status is **Being Worked On**. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Being Worked On** entries for the given To Do Type.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is [user-configurable](#).

Supervisor User Summary

The Supervisor User Summary page summarizes To Do entries by the user who is assigned to work on the entries. Only entries that are **Being Worked On** are summarized.

NOTE: Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to [To Do Entries Reference A Role](#) for more information.

Use **Menu > To Do > Supervisor User Summary** to open this page.

Description of Page

This page contains a grid that displays all assigned To Do entries by User ID and To Do type. It indicates how many To Do entries of the displayed Type are assigned to the user (Assigned this Type) and how many To Do entries in total are assigned to the user (Assigned Total).

Clicking the hyperlinks transfer you to the [Supervisor To Do Assignment](#) transaction. On this transaction, you can assign / reassign To Do entries to a specific user. The difference is that clicking the To Do Type hyperlink causes only **Open** entries to be displayed on the Assignment transaction. Clicking the count in the Assigned this Type column causes **Being Worked On** entries assigned to the displayed user to be shown.

Supervisor To Do Assignment

This page lists To Do entries of a given type and allows a supervisor to assign / reassign them to a designated user.

NOTE: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

Use **Menu > To Do > Supervisor To Do Assignment** to open this page.

Description of Page

This page contains **Open** or **Being Worked On** To Do entries of a given type. These entries can be assigned to a specified user one-by-one or several at a time. The following points describe this functionality:

- You can select a different **To Do Type** by typing in a value or pressing the search button in the upper right corner. An **Info** description of the To Do type appears on the left.

- You can change the list of entries displayed according to their status. Select the **Filter by** status to be All (blank), **Open**, or **Being Worked On**.
- For **Being Worked On** entries, you may also **Filter by User** to limit the search to a specific user assigned to the To Do entries.
- If you want to re-sort the entries by a different value, click the search button adjacent to **Extra Information**. Each row's respective sort value is displayed in the **Extra Information** column.

NOTE: Extra Information. Each To Do list's default **Extra Information** is defined on the list's [To Do Type](#). Also note that each To Do list's available **Extra Information** differs.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.
- Use the checkbox if you want to assign specific entries.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Click the Create Date/Time hyperlink to navigate to the To Do page where additional information is visible and where additional actions are possible.
- Click the number of **Related** entries hyperlink to navigate to the [To Do Search](#) query to list potentially related entries to the current entry.
- **Worked By** shows the user currently assigned to the To Do entry.
- **To Do Entry Status** is the current status of the To Do entry.
- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [Working On A To Do Entry](#) for more information.
- You can assign entries to a user:
 - Enter a user ID or search for a user using the **Assign To User** field. You can only select a user that is associated with a role that is associated with this **To Do Type**. Note that the current number of assignments is displayed adjacent.
 - Select one or more entries to assign to this user and click the **Assign** button. The entries' status becomes **Being Worked On**.

To Do List Functions

This section describes To Do pages that aid users in the assignment and working of entries in To Do lists.

To Do Summary

This page summarizes To Do entries that meet the following qualifications:

- The entry is **Open** and you belong to the entry's To Do role. Refer to [To Do Entries Reference A Role](#) for more information about roles.
- The entry is **Being Worked On** and you are the user to which it is assigned.

Use **Menu > To Do > To Do Summary** to open this page.

Keyboard Shortcut	Alternate Shortcut
Alt+X	Alt+Shift+X

NOTE: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

FASTPATH: Refer to [The Big Picture of To Do Lists](#) for an overview of To Do functionality.

Description of Page

This page is dedicated to a grid that summarizes the To Do entries on which you can work. The following information is displayed:

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Assigned to You** entries. The hyperlink navigates to the [To Do List](#) transaction, setting it to display all **Open** and **Being Worked On** entries assigned to you for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the [To Do List](#) transaction, setting it to display all **Open** entries for the given To Do Type.
- **Assigned to You** contains the number of To Do entries that are assigned to you whose status is **Being Worked On**. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Being Worked On** entries for the given To Do Type.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is [user-configurable](#).

To Do List

This page lists To Do entries of a given type that are either **Open** (e.g., not assigned to a specific user) or are assigned to you.

NOTE: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

NOTE: Restricted by role. Only those entries assigned to a role to which you belong may be seen on this page. Refer to [To Do Entries Reference A Role](#) for more information.

FASTPATH: We recommend familiarizing yourself with the topics described in [The Big Picture of To Do Lists](#) to fully appreciate how To Do entries are managed by the system.

Use **Menu > To Do > To Do List** to open this page.

Description of Page

This page contains a grid that summarizes the To Do entries of a given type on which you can work.

The **Info** section contains a concatenation of the **To Do Type**'s description and the user's name.

The area beneath **Info** provides you with options that control which To Do entries appear and the order in which they are displayed. The following points describe the various options:

- Use **Sort By** to define how you want the To Do entries sorted. The following options are available:
 - **Assigned Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start

from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.

- **Assigned Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.
- **Create Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.
- **Create Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.
- **Extra Information.** This option sorts the To Do entries by the value of the **Extra Info**.
- Use **Extra Info** to choose data related to the To Do Entry that should be used to sort the To Do entries. This information is displayed in each entry's **Extra Information** column.

NOTE: Extra Info. Each To Do types's available **Extra Info** is defined on the [To Do Type Sort Keys](#). Also note that each To Do type's available **Extra Info** differs based on the configuration of the To Do Type.

- Use **Filter by** to restrict the To Do entries based on their status. The following options are available:
 - **All.** This option shows all entries that are **Open** or **Being Worked On**.
 - **Being Worked On.** This option shows all entries that are **Being Worked On** (and assigned to you).
 - **Open.** This option shows all entries that are **Open**.

The grid that follows contains the To Do entries that match your criteria. The following information appears:

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** button to remove the selections in the grid.
- Use the checkbox if you want to mark specific entries as **Completed** or **Being Worked On** using the **Complete** or **Assign** buttons at the bottom.
- A Comment icon  appears if there are comments on the To Do item and a Log Entry icon  appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do has either comments or a special log entry.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- Click the Create Date/Time hyperlink or either of the special icons to navigate to the [To Do entry](#) page.
- Click the number of **Related** entries hyperlink to navigate to the [To Do Search](#) query to list potentially related entries to the current entry.
- **Assigned Date/Time** contains the date and time the To Do entry was assigned to a user. This field is only populated on entries that are **Being Worked On**. If a user assigned the To Do entry, the user ID and name of the user who assigned the To Do entry are displayed beneath the Date/Time.
- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [Working On A To Do Entry](#) for more information.

NOTE: Current To Do. Drilling into an entry from this page sets it to be the user's current To Do. Refer to [A User's Current To Do](#) for more information on how to efficiently scroll through additional entries in your current work list.

CAUTION: Automatic Assignment! When you drill into an entry using the message description hyperlink from this page, the system changes the status of the entry to **Being Worked On** and assigns it to you.

- **To Do Entry Status** is the current status of the To Do entry.
- **Extra Information** contains the data for the entry that corresponds to the Extra Info chosen in the sort options above.
- **To Do ID** contains the unique identifier of the To Do entry.
- If you want to mark one or more entries as **Being Worked On**, check the desired entries and then click the **Assign** button.
- If you want to mark one or more entries as **Completed**, check the desired entries and then click the **Complete** button. Completed entries do not appear on the To Do list (but they are retained on the database for audit purposes).

To Do Entry

Refer to [Understanding To Do Processing](#) for detailed explanations about many To Do entry features.

To view a To Do entry. Use **Menu > To Do > To Do Entry > Search** . You are brought to a query portal with options for searching for a To Do Entry. Note that some query options limit the results. Refer to the inline help for more information.

NOTE: Restricted by role. Any user may change Comments for any To Do Entry. In addition, any user may add user Log details. However, for all other changes and actions, you may only change To Do entries that are assigned to you or ones that are **Open** and assigned to a role to which you belong. Refer to [To Do Entries Reference A Role](#) for more information about roles.

Once a To Do Entry has been selected, you are brought to the maintenance portal to view and maintain the selected record. The inline help provides information about several fields. The following points highlight information about some of the fields that may be visible.

If the To Do entry has non-complete [related entries](#) an insight appears indicating the number of related entries. In addition, details about the related entries are shown in the Related To Do Entries zone.

If the To Do entry was **Created By** a background process, information about that background process appears with a link allowing the user to drill into the batch run, if desired. Refer to [To Dos Created for Object-Specific Error Conditions](#) for more information.

If the To Do type is configured to [To Do Entries May Be Routed Out Of The System](#), the **Extract Info** appears. If the extract process is pending, the information indicates that. Otherwise, if it has run, information about the background process appears with a link allowing the user to drill into the batch run, if desired.

The **Characteristics** collection shows existing characteristics. This collection is maintained using the Edit action for users that are allowed to update this To Do entry. Refer to [To Do Entry Characteristics](#) for more information.

Actions

This page has two special actions.

- Use the **Forward** to assign a To Do to another user or role. When a To Do is forwarded, a log entry indicates who forwarded the To Do, to whom it was forwarded, and the specified reason. The dialogue prompts for whether to send to a User or a Role. The search for User includes information about the number of To Do entries already assigned to this user. When choosing a User, confirm the correct Role. The Details provided are captured in the log entry.
- **Send Back** is only applicable if the **Sent By** user is populated. When a To Do is sent back, a log entry is created that indicates when the To Do was sent back and by whom. If the To Do is **Open**, this dialogue allows you to send it back

to a different role. If the To Do is assigned to you, the dialogue allows you to re-assign the To Do to the person who assigned it to you. The Details provided are captured in the log entry.

Related To Do Entries

If the To Do has [related To Do entries](#), this zone appears with information about the related entries. Use this **Edit** hyperlink to navigate to the [To Do Search](#) query to perform actions on the related entries.

Adding a Manual To Do Entry

If your system is configured with [manual To Do types](#), you can add a To Do entry online.

Open the **Menu > To Do > To Do Entry > Add**.

You are prompted for a **To Do Type**. Only To Do types that are set up for manual usage appear in the list.

The default **To Do Type Priority** is displayed adjacent. Use **Override Priority** to override the default [priority](#) assigned by the system.

Type a **Subject** for your To Do entry. Depending on how the To Do type is set up, the subject may appear as the message in the To Do entry and To Do lists.

Enter a **Comment** to provide a longer description of and more details about the To Do entry.

Send To indicates whether the new To Do will be assigned to a **Role** (the default) or **User**.

The **Role** indicates the role to which this To Do entry will be assigned. Only users of the specified role will be able to view and work on the To Do entry. The role is defaulted from the To Do type. If you want to assign the To Do to a different role, change the specified role. You can only assign the To Do entry to one of the roles specified on the To Do type.

User appears if **Send To** is set to **User**. Use this option if you want to assign the To Do to a specific user. The user must be a member of the selected role.

If the [To Do type](#) defines valid characteristic types, the **Characteristics** collection is visible. If any of the characteristic types are flagged as Default on the To Do type, the characteristic type with its default value (if applicable) are displayed.

To Do Search

This page allows you to search for To Do entries using various search criteria, and perform various actions on selected ones. This page includes completed To Do entries in its search results, when applicable with respect to the filter criteria.

Use **Menu > To Do > To Do Search** to open this page.

NOTE: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

NOTE: No restriction by role. This page returns all To Do entries that meet the search criteria, regardless of the To Do entry's role. Using the search, a user may drill into the details of a To Do entry even if the To Do is not assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The top half of the page is where you enter the criteria used to search for To Do entries.

CAUTION: Try to be as specific as possible when entering search criteria. Why? Because entering open-ended search criteria may have a severe impact on response times.

The following table describes each of the different search filters.

Search Filter	Description
Related To Do	<p>If you're searching for potentially related entries for a given To Do entry, choose Specific To Do for the Related To Do Filter. Enter the To Do ID.</p> <p>A filter value of Not Applicable defaults.</p>
To Do Type	<p>If you're searching for a To Do entry and you know the value of a To Do Type linked to the To Do entry, choose Specific To Do Type for the To Do Type Filter. Enter the To Do Type.</p> <p>A filter value of All defaults.</p>
Char Type	<p>If you're searching for a To Do entry and you know the value of a characteristic linked to the To Do entry, choose Specific Char Type for the Char Type Filter. Enter the Characteristic Type and Characteristic Value.</p> <p>A filter value of Not Applicable defaults.</p> <p>Only characteristic types that include a characteristic entity of To Do Entry and that have been marked to allow searching by characteristic value are available.</p>
User	<p>Use this search method if you know the Created By User, Assigned To User or Completed By User for the To Do entry. Enter the appropriate User Id.</p> <p>A filter value of Not Applicable defaults.</p>
Date Range	<p>Use this field if you're searching for a To Do entry and know the Date Created or Date Completed.</p> <p>A filter value of Date Created defaults. The Start Date/Time defaults to the current date, 12:00AM and the End Date/Time defaults to the current date, 11:59PM.</p> <p>If you enter a Date Range Filter of All, the system ignores this search method.</p>
Status	<p>Use this search method to restrict the search to To Do entries with a specific status value. You may search for To Do entries in the status of Open, Being Worked On or Completed. You may also perform a combination search for To Do entries that have a status value of either Open or Being Worked On.</p> <p>A filter value of All defaults.</p>

NOTE: The system allows any combination of values. The system does not try to validate your search combinations, even if they do not make sense. For example, if you enter a **User Filter** value of **Completed By User** and a **Status Filter** value of **Open**, you will not get an error. In this case, the system will find no records that match your criteria (because To Do entries that are Open do not have a Completed By User).

The system shows the total number of To Do entries that satisfy your search results immediately below the grid.

The first group of To Do entries is displayed in the grid at the bottom of the page.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.
- Use the checkbox if you want to perform actions (see below) on specific entries. Only **Open** or **Being Worked On** entries may be selected.
- A Comment icon  appears if there are comments on the To Do item and a Log Entry icon  appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do item has either comments or a special log entry. Use either icon to navigate to the To Do entry page.
- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Use the hyperlink to navigate to the To Do entry page.
- Click the number of **Related** entries hyperlink to redisplay this page listing potentially related entries to the current entry.

- **Last Assigned Date/Time** contains the date and time the To Do entry was most recently assigned to a user, if applicable, along with the Assigned To user.
- **Message** contains a description of the To Do entry. If the To Do entry is in the status of **Open** or **Being Worked On**, the message description allows you to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [Working On A To Do Entry](#) for more information.

NOTE: Current To Do. Drilling into the page by clicking the Message hyperlink does not automatically assign **Open** To Do entries to the user (as the To Do List page does when clicking on the Message). But it does treat this as the user's current to do, enabling the functionality in the Current To Do dashboard zone. Refer to [A User's Current To Do](#) for more information.

- **Status** contains the current status of the To Do entry.
- **Completion Date/Time** contains the date and time the To Do entry was completed and the user who completed the entry, if applicable.
- **To Do Type** contains a description of the To Do type for the To Do entry.

Actions

- Use the **Assign** button to assign or reassign the selected entries to a user. Enter a user ID or search for a user using the **Assign To User** field. By default this field is populated with the current user's ID. Note that the user's current number of assignments is displayed adjacent. Upon successful processing, the selected entries are assigned to the specified user and the status of **Open** entries becomes **Being Worked On**. Additionally, a corresponding [log entry](#) is added to each To Do.

NOTE: You may only assign To Do entries to yourself or to someone else if you are a valid user in the To Do entry's current role.

NOTE: Only users with **Supervisor Assignment** access rights may reassign entries that are not currently assigned to them.

- Use the **Reopen** button to unassign the selected entries from their users. Upon successful processing, the selected entries become **Open** and a corresponding [log entry](#) is added to each To Do.

NOTE: Only users with **Supervisor Assignment** access rights may unassign entries that are not currently assigned to them and the user must be a valid user in the To Do entry's current role.

- Use the **Complete** button to [complete](#) the selected entries.

To Do Dashboard

This portal provides a high level summary of open and being worked on To Do entries by various criteria. It is intended to be used by both supervisors and non-supervisor To Do users. An implementation may introduce additional zones to this portal as needed.

NOTE: Results are restricted by role. For supervisors, the charts consider To Do entries that are in a role of which the supervisor is a member. For non supervisors, the charts consider open To Do entries that are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

Use **Menu > To Do > To Do Dashboard** to navigate to the portal.

The following zones may appear as part of the portal's **Main** tab page

- **To Do Entries By Role.** This zone summarizes To Do entries by their currently assigned role.
- **To Do Entries By Status.** This zone summarizes To Do entries by their current status.
- **To Do Entries By Priority.** This zone summarizes To Do entries by their priority.
- **To Do Entries By Age.** This zone summarizes To Do entries by age based on age ranges defined for the current user.
- **To Do Entries By Type.** This zone summarizes To Do entries by their to do type.

Selecting a specific slice of data on any of these zones broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action on each zone to reset the filter set by this zone.

The following zone appears as part of the portal's **Details** tab page

- **To Do Details** This zone lists To Do entries that match various criteria and allows the user to work and manage the list.

To Do Details

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

NOTE: Results are restricted by role. For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The following sections describe the features of this zone.

Search Filters

The following table describes each of the different filters supported by this zone.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection.
To Do Entry Status	Use this filter to restrict the search to To Do entries with a status of Open or Being Worked On . Note that the underlying query excludes completed To Do entries.
Days Old	On the To Do Management portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old. On the To Do Dashboard portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.

Search Filter	Description
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Message	Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type.
Characteristic	Use these filters to restrict the search to To Do entries with a specific Characteristic Type and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown.

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

NOTE: For performance reasons, the search zone is configured to restrict the number of rows retrieved by the query. The 'Total Records' number will indicate whether there are more To Do entries that meet the criteria than can be displayed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined as a parameter to the zone. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [Working On A To Do Entry](#) for more information.

NOTE: Current To Do. Drilling into an entry from this page sets it to be the user's current To Do. Refer to [A User's Current To Do](#) for more information.

CAUTION: Automatic Assignment! When you click the Work button for an open entry, the system changes the status of the entry to **Being Worked On** and assigns it to you.

NOTE: Work List. This column has a Work List icon. Clicking this icon populates the [Work List](#) dashboard zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do and will assign it to you if it is **Open**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.

- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the [To Do Search](#) page with the current entry as the Related To Do Filter value.
- **Note** displays a Comment icon  if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string.
- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the [To Do Entry](#) page to view or maintain the current entry.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1 to Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details** [log entry](#) to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is being worked on by another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is being worked on by another user.
- Use the **Complete** button to [complete](#) the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

Reports

About Reports

Reports include operational reports related to device events, validation exceptions, and other operational data. Reports can also be based on devices, measuring components, Service Points, service providers, and other data.

Oracle Utilities Meter Data Management reports are implemented using Oracle Business Intelligence Publisher (BI Publisher), and are administered via Oracle Business Intelligence Publisher and the Report functionality of the Oracle Utilities Application Framework.

Refer to the [Oracle Business Intelligence Publisher documentation](#) for more information about installing Oracle Business Intelligence Publisher and [creating and defining reports](#). For additional details on how reports are defined and administered see [Reporting and Monitoring Tools](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Running Oracle Utilities Meter Data Management Reports

This portal is used to submit a new instance of a Report.

Refer to [About Reports](#) for additional functional information.

You can access the portal from the **Main > Tools > Report Submission**.

First, the appropriate Report code must be selected. The Reports provided out-of-the-box are:

- **Device Events Report:** this report generates a pie graph depicting the percentage of Device Events for each Device Event Type for the specific search criteria.
- **Device VEE Exceptions Report:** this report generates a pie graph depicting the percentage of VEE Exception for Exception Type and Market for the specific search criteria.

Next, enter the parameter values for the report as appropriate and submit the report.

Chapter 1

Administrative User Guides

Framework Administrative User Guide

The topics in this section describe how to administer the Oracle Utilities Application Framework.

General Options

This section describes control tables that are used throughout your product.

Defining Installation Options

The topics in this section describe the various installation options that control various aspects of the system.

Installation Options - Main

Select **Admin > General > Installation Options - Framework** to define system wide installation options.

Description of Page

The **Environment ID** is a unique universal identifier of this instance of the system. When the system is installed, the environment id is populated with a six digit random number. While it is highly unlikely that multiple installs of the system at a given implementation would have the same environment ID, it is the obligation of the implementers to ensure that the environment ID is unique across all installed product environments.

System Owner will be **Customer Modification**.

The **Admin Menu Order** controls how the various control tables are grouped on Admin.

- If you choose **Functional**, each control table appears under a menu item that corresponds with its functional area. Note, the [menu](#) that is used when this option is chosen is the one identified with a menu type of **Admin**.

- If you choose **Alphabetical**, each control table appears under a menu item that corresponds with its first letter, using a Roman alphabet. For example, the Language control table will appear under the L menu item entry.

NOTE: The **Alphabetical** option only supports the Roman alphabet. For languages that do not use the Roman alphabet, the recommendation is to configure the system for the **Functional** setting.

CAUTION: In order to improve response times, installation options are cached the first time they are used after a web server is started. If you change the Admin Menu Order and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. Refer to [Caching Overview](#) for information on how to clear the system login cache (this is the cache in which installation options are stored).

The **Language** should be set to the primary language used by the installation. Note that if multiple languages are supported, each user may define their preferred language.

The **Currency Code** is the default currency code for transactions in the product.

If your product supports effective dated characteristics on any of its objects, define the date to be used as the **Characteristic Default Date** on objects without an implicit start date. The date you enter in this field will default when new characteristics are added to these objects (and the default date can be overridden by the user).

Active Owner displays the owner of newly added system data (system data is data like algorithm types, zones, To Do types, etc.). This will be **Customer Modification** unless you are working within a development region.

Country and **Time Zone** represent the default country and time zone that should be used throughout the application.

CAUTION: In most implementations, the time zone defined here matches the database time zone. However, if there is some reason that the database time zone does not match the installation time zone, an implementation may configure a setting in the properties file to automatically convert data from the database time zone to the time zone defined here when displaying dates. Note that when this property setting is defined, changes to the installation time zone will require the server and the thread pool workers to be restarted in order for the changes to take effect.

Turn on **Seasonal Time Shift** if your company requires seasonal time shift information to be defined. Note that this is currently only applicable to Oracle Customer Care and Billing > Interval Billing functionality.

Installation Options - Messages

Select **Admin > General > Installation Options - Framework** and the **Messages** tab to review or enter messages that will appear throughout the application when a given event occurs.

The **Message** collection contains messages that are used in various parts of the system. For each message, define the **Installation Message Type** and **Installation Message Text**. The following table describes the **Message Types** provided by the framework product and how they are used in the system. Your specific product may have introduced addition message types.

Message Type	How The Message Is Used
Company Title for Reports	This message appears as a title line on the sample reports provided with the system. Generally it is your company name. It is only used if you have installed reporting functionality and are using the sample reports (or have designed your reports to use this message).
Domain Name	The text entered for this message type is meant to identify the environment and can be used for logic where it is useful to indicate the environment for a user. For example, the email sent when a background process finishes includes this information, if populated.

Installation Options - Algorithms

Select **Admin > General > Installation Options - Framework** and the **Algorithms** tab to review or enter the algorithms that should be evoked when a given event occurs.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

CAUTION: These algorithms are typically significant processes. The absence of an algorithm might prevent the system from operating correctly.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Validate Email Attachment	Optional	Algorithms of this type are used to validate the attachments for size and total count while sending attachments using the Email service. Refer to Sending Email for more information
Address Geocoding	Optional	Algorithms of this type use Oracle Locator to retrieve latitude and longitude coordinates using address information.
Attachment Malware Scan	Optional	Algorithms of this type are invoked when adding attachment content. The algorithm receives the attachment ID and is expected to use a malware scanning tool to verify the contents of the attachment. Only one algorithm is allowed. Refer to Enabling Malware Scan for more information.
Global Context	Optional	Algorithms of this type are called whenever the value of one of the global context fields is changed. Algorithms of this type are responsible for populating other global context values based on the new value of the field that was changed. Refer to Global Context Overview for more information.
Guaranteed Delivery	Optional	Algorithms of this type may be called by processes that receive incoming messages that should 'guarantee delivery'. Refer to Guaranteed Delivery for more information. The business service F1-GuaranteedDelivery may be used to invoke this plug-in spot.
Ldap Import	Optional	Algorithms of this type are called for operations on users, groups, and group memberships after they have been processed.
Ldap Import Preprocess	Optional	Algorithms of this type are called to preprocess data retrieved from LDAP.
Next To Do Assignment	Optional	This type of algorithm is used to find the next To Do entry a user should work on. It is called from the Current To Do dashboard zone when the user ask for the next assignment.

System Event	Optional / Required	Description
Reporting Tool	Optional	If your installation has integrated with a third party reporting tool, you may wish to allow your users to submit reports on-line using report submission or to review report history online. This algorithm is used by the two on-line reporting pages to properly invoke the reporting tool from within the system.
SMS Receive	Optional	This type of algorithm is used to provide SMS receive service. Only one algorithm of this type should be plugged in.
SMS Send	Optional	This type of algorithm is used to provide SMS send service. If your installation uses the base algorithm that uses BPEL, you will need to create a feature configuration with the SMS Send Configuration feature type to define your Oracle BPEL server and service call details. If your installation has integrated with a third-party SMS service, you may want to override this algorithm type with your own implementation. Only one algorithm of this type should be plugged in.
To Do Information	Optional	We use the term To Do information to describe the basic information that appears throughout the system to describe a To Do entry . Plug an algorithm into this spot to override the system default "To Do information".
To Do Pre-creation	Optional	These types of algorithms are called when a To Do entry is being added. Refer to Refining a To Do Entry's Details at Creation Time for more information.

Installation Options - Accessible Modules

Select **Admin > General > Installation Options - Framework** and the **Accessible Modules** tab to view the list of accessible modules.

Description of Page

This page displays the full list of the application's function modules. A **Turned Off** indication appears adjacent to a module that is not accessible based on your system's module configuration setup.

FASTPATH: Refer to [Module Configuration](#) for more information on function modules and how to turn off modules that are not applicable to your organization.

Installation Options - Installed Products

Select **Admin > General > Installation Options - Framework** and the **Installed Products** tab to view a read only summary of the products that are installed in the application version that you are logged into.

Description of Page

The **Product Name** indicates the name of the "products" that are installed. The collection should include **Framework**, an entry for your specific product and an entry for **Customer Release**.

Release ID shows the current release of the application that is installed. This field is used by the system to ensure that the software that executes on your application server is consistent with the release level of the database.

The **Release ID Suffix**, **Build Number** and **Patch Number** further describe the details of your specific product release.

NOTE: If you have developed implementation-specific transactions, you can populate the release ID, release ID suffix, build number and patch number for the **Customer Release** entry to define the latest version of implementation-specific logic that has been applied to this environment. The framework provides a script (**F1CustRelM**) to allow these fields to be updated manually. In addition, the **F1-InstallationOptions** inbound web service provides operations to view and update those fields via a REST call. Alternatively, your implementation team may populate these fields as part of their upgrade scripts.

The **Product Status** is used to indicate if a product installed by default in the version you are logged into is **Active** or **Inactive**.

The **Display** column indicates the product whose name and release information should be displayed in the title bar. Only one product sets this value to **Yes**.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

Product Type indicates if the product is a Parallel Application. A parallel application is one that is independent of, and does not conflict with, other parallel applications. Multiple parallel applications can be installed in the same database and application server.

NOTE: About Information. The information on this tab is used to populate the information displayed in the [About](#) window for your product.

Support For Different Languages

User Language

The language English (with the locale en-US) is provided by the system and all system metadata are delivered with an English description or label. The system provides support for defining other languages and supports multiple languages in a single environment. System users can use the system in their preferred language, as long as a translation into that language has been provided. A user sees the system in the language defined on their [user record](#). If enabled, users can use the [Switch Language](#) zone to switch to another supported language real time.

Supporting a New Language

Normally, setting up the system for another language (besides the delivered English language entry) is an implementation issue, not an administrative setup issue. However, there are several online administrative features that are used to set up a new language, and these are described here.

1. **Define a language code and indicate that it is enabled.** For details on this procedure, see [Defining Languages](#).
2. **Install or confirm the existence of a language pack.** For an on-premise installation, if the product supplies a language pack with translations for the system metadata descriptions, follow the instructions for downloading the language pack and installing it into your environment. For a cloud installation, if the product supplies a language pack for a given language, no additional step is needed here. The language pack is already installed.
3. **Copy descriptions of all language-enabled tables from an existing translation (e.g., English).** The copied values act as placeholders while the strings are translated into the new language. It is necessary to do this as a first step in order to create records using the new language code created in the previous step. Language-based descriptions can be copied using a supplied batch process, **F1-LANG**. The batch copies all English labels in the system.

The batch process will also update the new language rows with the translated metadata descriptions from the language pack, if installed.

4. **Translate additional content.** Translatable descriptions and labels for implementation data may be updated / entered in the application. First the user record must be updated to reference the new language. This may be done in one of the following ways:

- a. Switch to the new language using the [Switch Language](#) zone.
- b. If that zone is not available, navigate to the user page, assign the new language code to your User ID, sign out, and sign back in again.

Any online functions that you access will use your new language code. You can change the language code for all users who plan to use/modify the new language.

NOTE: The language pack updates all language entries for base owned system data. If your implementation updates base owned labels and descriptions after applying a language pack, they will be overwritten the next time an updated language pack is applied. Note that most user facing labels and messages support defining an Override Label or Override Description. This information is not updated by the base product and should be utilized if your implementation desires a specific label or description.

Managing Multiple Languages

Once a non-English language has been set up, there are several points to note when adding or updating records that include translatable strings.

- When a new record is added through the user interface or through a REST service call or any other means that goes through the standard maintenance service, the system automatically generates entries for each supported language and copies the text of the entered description to all the generated languages.
- When the translatable string for a record is updated, only the user's language row is updated. The system does not ripple the change to other supported language entries (because it could be overriding a valid translation).
- When your system is upgraded to a new version, the new version typically includes new system data. The upgrade only includes the English language rows. Implementers should run the **F1-LANG** batch program to generate language rows for the your supported languages for this new data. If a new translation pack for your supported language is available at the time of upgrade, then running this process also applies the translated strings. (As mentioned above, for on-premise installations, you need to download and install the language pack before this step). If the language pack is not available at the time of upgrade, then the batch program should be run again when the language pack has been installed.
- New translatable objects may also be included in a patch / hot fix. In this situation, the **F1-LANG** batch program should be run after installing the patch in order to ensure there are language rows for your supported languages. Updated language packs are only provided for full release upgrades and not for hot fixes. So implementations may need to temporarily supply translations for the new strings until you update to the next release with the next updated translation pack.

Customer Language

Your specific product may also support capturing the language of a customer. Such that correspondence sent from the product may be produced in a language set on a customer record. Refer to your specific product's documentation for more information about additional language support.

Defining Languages

Your product may support multiple languages. For example, the field labels, input text, and even outputs and reports can be configured to appear in a localized language. A language code for every potential language exists in the system to supply this information in various languages.

Select **Admin > General > Language** to define a language.

This is a standard [All-in-One portal](#).

When **Language Enable** is checked, the system adds a row for this language whenever a row is added in another language. For example, if you add a new currency code, the system will create language specific record for each language that has been enabled. You would only enable multiple languages if you have users who work in multiple languages. Languages that are configured as enabled, appear in the [Switch Language](#) dashboard zone.

NOTE: For on premise applications, the login page displays all the languages that are enabled, allowing the user to toggle the login instructions in that language. The list of enabled languages is captured on the server at startup time. If a new language is enabled, contact your server administrator to refresh the server in order to see the new language displayed in the login page.

The following two fields control how the contents of grids and search results are sorted by the Java virtual machine (JVM) on your web server:

- The **Locale** is a string containing three portions:
 - ISO language code (lower case, required)
 - ISO country code (upper case, optional)
 - Variant (optional).
- Hyphens separate the various portions, and multiple variants are possible. The specific JVM in use by your particular hardware/OS configuration constrains the available **Locales**. Validating the **Locale** against the JVM is outside the scope of this transaction. This means you are responsible for choosing valid **Locales**.

The following are examples of valid locales:

Locale	Comments
en-US	American English
en-AU	Australian English
pt-BR	Brazilian Portuguese
fr-FR-EURO	European French
ja-JP	Japanese

In addition, the Java collation API can take a **Collator Strength** parameter. This parameter controls whether, for example, upper and lower-case characters are considered equivalent, or how accented characters are sorted. Valid values for collator strength are **PRIMARY**, **SECONDARY**, **TERTIARY**, and **IDENTICAL**. If you leave this field blank, Java will use its default value for the language. We'd like to stress that the impact of each value depends on the language.

Please see <https://docs.oracle.com/javase/7/docs/api/java/text/Collator.html> for more information about the collator strength for your language.

Display Order indicates if this language is written **Left to Right** or **Right to Left**.

Note that all administrative control tables and system metadata that contain language-specific columns (e.g., a description) reference a language code. In addition, other tables may reference the language as a specific column. For example, on the User record you indicate the preferred language of the user.

Defining Countries

The topics in this section describe how to maintain countries.

Country - Main

To add or review Country definitions choose **Admin > General > Country**.

The **Main** page is used to customize the fields and field descriptions that will be displayed everywhere addresses are used in the system. This ensures that the all addresses conform to the customary address format and conventions of the particular country you have defined.

Description of Page

Enter a unique **Country** and **Description** for the country.

The address fields that appear in the **Main** page are localization options that are used to customize address formats so that they conform to address requirements around the world. By indicating that an address field is **Optional**, you make that field available everywhere addresses for this country are used in the system. You can enter your own descriptions for the labels. These labels will appear wherever addresses are maintained in the system.

NOTE: Your specific product may also add the ability to mark an address field as **Required**. If that is available, then the product is also supplying appropriate validation in all places where a user defines an address.

NOTE: For any country where the **State** is enabled, the valid states for the country must be entered on the **Country - State** tab. When entering address constituents on a record that captures this detail, the value for State is verified against the data in the State table. For any country where there is a component of the address that represents a "state" but your implementation does not want to populate the valid states for that country, choose a different field such as County for this constituent (and define an appropriate label). When entering address constituents on a record that captures this detail, no validation is done for the County column.

Country - States

To maintain the states located in a country, choose **Admin > Country > Search** and navigate to the **State** page.

Description of Page

For any country where you have enabled the State switch, use the **State** collection to define the valid states in the **Country**.

- Enter the standard postal abbreviation for the **State** or province.
- Enter a **Description** for this state or province.

Defining Currency Codes

The currency page allows you to define display options related to currency codes that are used by your system. Use **Admin > General > Currency** to define the currency codes in which financial information is denominated.

This is a standard [All-in-One portal](#).

Most attributes are self explanatory.

NOTE: Please contact your specific product to verify whether it supports a currency with more than 2 **Decimals**.

The **External Reference** may be used to define a currency whose currency code is more than three characters. To support that type of currency, define a currency code that uniquely identifies the currency in the system and use the external reference to define the currency code recognized by external products. Note that your specific integration with an external system where financial information is included may need to be adjusted to use the external reference instead of the system's currency code. Refer to the specific documentation for your integrations to confirm.

Defining Time Zones

The following topics describe how to design and set up time zones.

Designing Time Zones

The Time Zone entity is used to define all the time zones where your customers may operate. Each time zone should define an appropriate Time Zone Name. This is a reference to an external source that defines time zones, their relationship to Greenwich Mean Time, whether the time zone follows any shifting for summer / winter time (daylight savings time) and when this shift occurs.

The following sections describe concepts and configuration topics related to managing time zones.

NOTE: Oracle Utilities Customer Care and Billing - Interval Billing applications customers should consult the topic *Time Issues* (search the Help index for "time issues") for specific information relating to that product's interval billing time related functionality.

The Base Time Zone

When designing your time zones, the first thing to determine is the base time zone. You may choose the time zone where the company's main office resides. Once this is done you can link the time zone code to the installation option as the base time zone. Refer to [Installation Options - Main](#) for more information.

NOTE: An attribute in the system properties file may be configured to indicate that the DB session time zone should be synchronized with the value defined on the Installation Options. Refer to the *Server Administration Guide* for more information.

If your company does business beyond your main office's time zone, define the other time zones where you may have customers or other systems with which you exchange data. At this point, your specific product may include configuration tables to capture default time zones, for example based on a postal code or geographic location.

Standard vs. Legal Time

The term **Legal Time** refers to the actual clock time as may be impacted by daylight saving (also called 'local time'). This time line has a gap hour on entry to the daylight saving period and a duplicate hour on exit from it.

The term **Standard Time** refers to a time line without any daylight saving shifts applied to it. This virtual time line has no gap hour on entry to the daylight saving period nor a duplicate hour on exit, i.e. it is continuous and non-ambiguous. As a general rule, it is recommended that all time sensitive data is stored in the standard time of the base time zone as defined on the installation options. This will prevent any confusion when analyzing data and will ensure that your algorithms do not have to perform any time zone or daylight saving shifting of data that may be stored in different time zones.

Depending on your specific product, entities may have their date/time information stored in either of the following options:

- Standard time of the base time zone (also called 'physical time').
- Standard time of another time zone related to the entity's geographical location (also called 'logical time').
- Legal time of the base time zone.

The metadata definition of a [table](#) specifies whether any of its date/time fields are stored in standard time or not. While typically all date/time fields of a table that supports standard time would be stored in the same way the system allows each [field](#) to specify its own option. The metadata definition of such field specifies whether it is base time zone standard time (**Physical Standard Time**), standard time of some other time zone associated with the entity (**Legal Standard Time**) or stored in base time zone legal time (**Referenced Time Zone**).

Storage vs. Display

Regardless of the time zone option used for storing the data in standard time, all date/time information is entered and displayed on the user interface in the legal time of its respective time zone. If a field is defined to be stored in the standard time of the base or other time zone, the user interface is designed to accept the data in the legal time of the respective time

zone and shift it to the standard time of the same time zone before saving the data and performs the reverse shift from standard time back to legal time before displaying the data to the user.

It is important to understand that time zone and daylight saving time conversions to and from standard time are performed behind the scenes as part of the user interface layer. Once data reaches the server it is already in its storage time option. The user should not be aware of these time conversions.

Time shifting between standard and legal times does not happen automatically. When dealing with fields stored in standard time, their data entry and display need to explicitly include time shifting features as part of their user interface and zone configuration.

Date / Time Schema Elements

When defining date / time fields in a business object schema, schema attributes can be used to define whether or not data should be stored in standard time for the base time zone or if it should be stored in the standard time of another time zone (related to the data).

By default data stored in standard time is displayed in the corresponding time zone's legal time. Additional schema attributes can be used to indicate if the display of the time should be shifted to the legal time of a different time zone. For example, if the data is stored in the base time zone but the data is related to a different time zone, the data will be shown in the time zone appropriate for the data (including the appropriate seasonal adjustment). Refer to [Schema Nodes and Attributes- Standard Time Considerations](#) for more information.

Exchanging Date / Time Information With External Systems

Date/time information should be exchanged between systems in standard XSD format as it includes a reference to the time zone of the specified time as an offset from Coordinated Universal Time (UTC). The system automatically converts date/time elements in an inbound message from XSD to internal format and vice versa for an outbound message. The latter is controlled by an explicit date/time format setting on the External System record for the outbound message type.

The offset is determined as followed and it is based on the time zone associated with the element as explicitly defined by the respective inbound or outbound schema:

- Elements defined as stored in the standard time of the base or other time zone would always have the same offset throughout the year as this time line is never shifted for daylight saving. The offset would be the standard offset of that time zone from UTC, i.e. not during daylight saving time.
- Elements stored in the legal time of the base time zone would have the standard offset of the base time zone when the date/time value is outside the daylight saving period and the shifted offset when it is inside that period of time.

User Time Zone

If your company does business in multiple time zones, the user record of each user may reference the time zone of their location. This time zone provides additional information about the location of the user and as such may be used by specific business rules that involve time zone settings.

NOTE: The time zone defined on the user record is not used to automatically display date/time information in the user's time zone. By default, the system displays date/time fields that are stored in standard time in the legal time of their respective time zone and not the user's time zone.

Setting Up Time Zones

Refer to [Designing Time Zones](#) for background information about defining time zones.

Open this page using **Admin > General > Time Zone > Search** .

This is a standard [All-in-One](#) portal.

Refer to the embedded help text for more information on the Time Zone attributes.

Setting Up Seasonal Time Shift

NOTE: The information in this topic applies only to Oracle Utilities Customer Care and Billing - Interval Billing applications.

Open **Admin > General > Seasonal Time Shift > Search** to define the seasonal time shift schedule.

Description of Page

Enter a unique **Seasonal Time Shift** code and **Description** for the seasonal time shift.

The Collection defines the **Effective Date/Time** (in standard time) that a time zone may shift in and out of standard time. If time is changed from standard time on the effective date/time, enter the **Shift in Minutes** that the time changes from standard time (usually **60**). If the time is changed back to standard time on the effective date/time, enter a **Shift in Minutes** of **0**.

Defining Geographic Types

If your company uses geographic coordinates for dispatching or geographic information system integration, you need to setup a geographic (coordinate) type for each type of geographic coordinate you capture on your premises and/or service points (geographic coordinates can be defined on both premises and service points).

NOTE: Product specific. There is no framework functionality that uses this information. Refer to your specific product documentation to verify how this table is used in your specific product. In addition, you can determine if this object is a foreign key on any tables specific to your product. Navigate to the Table page in the application, search for and select the Geographic Type table and use the Relationships tab to view this information.

To define geographic types, open **Admin > Geographic > Geographic Type**.

This is a standard [All-in-One portal](#).

The **Validation Format Algorithm**, if specified, is used to validate that the geographic location entered on the premise and/or service point for the geographic type is in the format as defined in the algorithm. If you require validation, you must set up this [algorithm](#) in the system.

Defining Work Calendar

This portal is used to view and maintain information about a work calendar. Work calendars are used to ensure system-calculated dates fall on a workday.

You can access the portal from **Admin > General > Work Calendar**. You are brought to a query portal with options for searching for a specific calendar. Once a calendar has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Work Calendar.** This zone provides information about the selected calendar.
- **Work Calendar Holidays.** This zone lists the holidays observed by your organization for this calendar. Use the zone actions to add, maintain or duplicate a work holiday entry.

Defining Display Profiles

When you set up your users, you reference a display profile. A user's display profile controls how dates, times, and numbers are displayed. Choose **Admin > General > Display Profile > Search** to maintain display profiles.

Description of Page

Enter a unique **Display Profile** and **Description** to identify the profile.

Enter a **Date Format**. This affects how users view dates and how entered dates are parsed. The following table highlights standard supported date mnemonics and what is displayed at runtime.

Mnemonic	Comments
dd	Day of the month.
d	Day of the month, suppressing the leading 0.
MM	Month number.
M	Month number, suppressing the leading 0.
yyyy	The 4-digit year.
yy	The 2-digit year.
y	Allows entry in either 2 or 4-digit form and is displayed in 2-digit form.

Other characters are displayed as entered. Typically, these other characters should be separators, such as "-", ".", or "/". Separators are optional; a blank space cannot be used.

Examples:

Configuration Format	Sample Output
MM-dd-yyyy	04-09-2001
d/M/yyyy	9/4/2001
yy.MM.dd	01.04.09
MM-dd-y	04-09-01 - In this case you could also enter the date as 04-09-2001

NOTE: For centuries, the default pivot for 2-digit years is **80**. Entry of a 2-digit year greater than or equal to **80** results in the year being interpreted as 19xx. Entry of a 2-digit year less than **80** results in the year being interpreted as 20xx.

In addition, the following date localization functionality is supported. Note that in every case, the date is stored in the database using the Gregorian format. The settings below result in a conversion of the date for the user interface.

- **Hijri Dates**

Entering **iiii** for the year is interpreted as a year entered and displayed in Hijri format. For example, the Gregorian date 2014-05-30 may be entered / displayed as 1435/07/30 for a user whose display profile date format is **iiii/MM/dd**. Note that this functionality relies on date mapping to be defined in the Hijri to Gregorian Date Mapping [master configuration](#) entry. Refer to [Additional Hijri Date Configuration](#) for more information.

- **Taiwanese Dates**

Entering **tttt** for the year is interpreted as a year entered and displayed in Taiwanese format where year 1911 is considered year 0000. For example, if the Gregorian date is 01-01-2005, it is displayed as 01-01-0094 for a user whose display profile date format is **dd-mm-tttt**.

- **Japanese Dates**

There are two options available for configuring Japanese Era date support. The setting **Gyy** for the year is interpreted as a year entered and displayed using an English character for the era followed by the era number. The letter 'T' is used for dates that fall within the *Taisho* era. The letter 'S' is used for dates that fall within the *Showa* era. The letter 'H' is used for dates that fall within the *Heisei* era. The letter 'R' is used for dates that fall within the *Reiwa* era. For example, for a user whose display profile date format is **Gyy/mm/dd** the Gregorian date 2008/01/01 is shown as **H20/01/01**; the

Gregorian date 1986/03/15 is shown as **S61/03/15**. The setting **GGGGyy** is interpreted as a year entered and displayed using Japanese characters for the era followed by the era number.

Japanese date limitations are as follows:

- The years 1912 through the current date are supported.
- Any functionality that displays Month and Year does not support Japanese Era dates. These dates are shown in Gregorian format.
- Graphs that display dates do not support the **GGGGyy** format.

Enter a **Time Format**. The following table highlights standard supported date mnemonics.

Mnemonic	Comments
hh	The hour 1-12.
h	The hour 1-12, suppressing the leading 0.
HH	The hour 0-23.
H	The hour 0-23, suppressing the leading 0.
KK	The hour 0-11.
K	The hour 0-11, suppressing the leading 0.
kk	The hour 1-24.
k	The hour 1-24, suppressing the leading 0.
mm	Minutes.
m	Minutes, suppressing the leading 0.
ss	Seconds.
s	Seconds, suppressing the leading 0.
a	Indicates to include am or pm . This is only needed for 12 hour formats, not 24 hour formats. (hh , h , KK , K). If an am or pm is not entered, it defaults to am .

Examples:

Configuration Format	Sample Output
hh:mma	09:34PM (can be entered as 09:34p)
hh:mm:ss	21:34:00
h:m:s	9:34:0

There are several options for displaying Numbers.

Decimal Symbol defines the separator between the integer and decimal parts of a number. Valid values are "." (a period) or "," (a comma).

Group Symbol defines the means to separate groups of bigger numbers. Valid values are as follows:

- A comma (","). Large numbers group by threes separated by a comma, for example 1,000,000.
- A period ("."). Large numbers group by threes separated by a period, for example 1.000.000.
- **None**. Large numbers do not have any separator, for example 1000000.
- **South Asian**. This option uses a comma for its separator but will group large numbers as follows: the first comma is used for the thousands separation and numbers over 9,999 are grouped with 2 units, for example 10,00,000.
- **Space**. Large numbers group by threes separated by a space, for example 1 000 000.

Negative Format defines how negative values are displayed. Valid values are **-9.9**, **(9.9)**, or **9.9-**.

Currency values can have a different **Negative Format** from other numbers. Valid values are **-S9.9**, **(S9.9)**, or **S9.9-**, where the "S" represents the currency symbol.

Additional Hijri Date Configuration

For implementations that wish to support displaying dates according to the Hijri calendar, besides appropriate configuration in the [Display Profile](#), the mapping between the Hijri dates and the Gregorian dates must be entered. This mapping is defined in the [Hijri to Gregorian Date Mappingmaster configuration](#) record.

The mapping record contains a collection of entries for each year in the Islamic calendar.

For each year, clicking the Expand Zone icon shows the mapping collection with the first date of each month of the Hijri calendar. The corresponding date in the Gregorian calendar should be entered for each row.

Defining Phone Types

Phone types define the format for entering and displaying phone numbers.

To add or review phone types, choose **Admin > General > Phone Type**.

This is a standard [All-in-One portal](#).

The **Phone Number Format Algorithm** for each phone type controls the format for entry and display of phone numbers.

Use **Phone Type Flag** is used to identify phone types that may have specific functionality associated with it. For example if your product had support for sending a facsimile transmittal, identify the phone type that captures a **Fax** number.

Defining Feature Configurations

Some system features are configured by populating options on a "feature configuration". Because various options throughout the system may be controlled by settings in feature configuration, this section does not document all the disparate possible options. The topics below simply describe how to use this transaction in a generic way.

For information about specific features:

- Refer to the detailed description of each option type.
- Use the index in the online help and search for 'feature configuration' to find any specific topics describing feature options in the administration guide.

You can create options to control features that you develop for your implementation. To do this:

- Review the lookup values for the lookup field **EXT_SYS_TYP_FLG**. If your new option can be logically categorized within an existing feature type, note the lookup value. If your new option warrants a new feature type, add a lookup value to this lookup field.
- Define the feature's option types. If you have identified an existing feature type to add the options to, find the lookup with the name **xxxx_OPT_TYP_FLG** where **xxxx** is the lookup value of **EXT_SYS_TYP_FLG** noted above. If you decided to create a new feature type (by adding a new lookup value to the **EXT_SYS_TYP_FLG** lookup, you must create a new lookup with the name **xxxx_OPT_TYP_FLG** where **xxxx** is the new value you defined above.
- Flush all caches.

Feature Configuration - Main

To define your feature configuration, open **Admin > General > Feature Configuration**.

Use the **Feature Configuration Query** portal to search for an existing feature configuration. Once a feature configuration is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter an easily recognizable **Feature Name** code.

Indicate the **Feature Type** for this configuration. For example, if you were setting up the options for the external messages, you'd select **External Messages**.

NOTE: You can add new Feature Types. Refer to the description of the page above for how you can add Feature Types to control features developed for your implementation.

NOTE: Multiple Feature Configurations for a Feature Type. Some Feature Types allow multiple feature configurations. The administration documentation for each feature will tell you when this is possible.

The **Options** grid allows you to configure the feature. To do this, select the **Option Type** and define its **Value**. Set the **Sequence** to **1** unless the option may have more than value. **Detailed Description** may display additional information on the option type.

NOTE: Each option is documented elsewhere. The administration documentation for each feature describes its options and whether an option supports multiple values. Use the index to look for 'feature configuration' to find the various types of feature options.

NOTE: You can add new options to base-package features. Your implementation may want to add additional options to one of the base-package's feature types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do this, display the lookup field that holds the desired feature's options. The lookup field's name is **xxxx_OPT_TYP_FLG** where **xxxx** is the identifier of the feature on the **EXT_SYS_TYP_FLG** lookup value. For example, to add new batch scheduler options, display the lookup field **BS_OPT_TYP_FLG**.

Feature Configuration - Messages

If the feature exists to interface with an external system, you can use this page to define the mapping between error and warning codes in the external system and our system.

Open this page using **Admin > General > Feature Configuration** and navigate to the **Messages** tab.

Description of Page

For each message that may be received from an external system, define the **Feature Message Category** and **Feature Message Code** to identify the message.

A corresponding message must be defined in the [system message](#) tables. For each message identify the **Message Category** and **Message Number**. For each new message, the Message Category defaults to **90000** (because an implementation's messages should be added into this category or greater so as to avoid collisions during upgrades).

Defining Master Configurations

A master configuration is an object that enables an implementation to define configuration for features in the system. It is an alternative to using feature configuration for defining options. A master configuration is defined using a business object. Only one master configuration may exist for a given business object.

Overview / Initial Setup

The product provides one or more master configuration that may be used for configuration. Some examples of base master configuration business objects are as follows

- **Hijri to Gregorian Date Mapping.** This allows an implementation that uses Hijri dates to define the mapping between those dates and Gregorian dates.

- **ILM Configuration.** For implementations that use Information Lifecycle Management, the ILM configuration record defines some parameters used by the process.
- **Migration Assistant Configuration.** For implementations that use the content migration assistant (CMA), the configuration record defines some parameters used by the process.

For a list of all the master configuration records provided by the product, navigate to the master configuration page in the application. To find help topics related to functionality controlled by the master configuration records, use the keyword 'master configuration' in the index.

Implementations may configure the business objects to limit the ones that are visible to users if desired.

- If the master configuration does not apply to your implementation, navigate to the business object for this master configuration and update the Instance Control to **Do not allow new instances**. This ensures that the business object will not be visible to any user for the implementation.
- If a given master configuration record is only relevant for certain users in the system, application security may be used to limit the records visible by a given user. By default the base delivered business objects typically reference the Master Configuration MO application service. This may be overridden to link custom application services to the master configuration BOs to provide more granular security. Users will only see the master configurations that they have security for.

Configuration

To set up a master configuration, open **Admin > General > Master Configuration**.

The topics in this section describe the base-package zones that appear on the Master Configuration portal.

Master Configuration

The Master Configuration List zone lists every category of master configuration.

The following functions are available:

- If a master configuration record exists for a given master configuration business object, the broadcast icon may be used to view details information about the adjacent master configuration. In addition, an edit icon is visible to allow a user to update the record.
- If a master configuration record does not exist for a given master configuration business object, the add icon is visible to allow a user to define the record.

Master Configuration Details

The Master Configuration Details zone contains display-only information about a master configuration.

This zone appears when a master configuration has been broadcast from the Master Configuration zone.

Please see the zone's help text for information about this zone's fields.

Security & User Options

The contents of this section describe how to maintain a user's access rights.

Application Security

The system restricts access to various components of the application using application services. The following sections provide more information about this mechanism.

Understanding Application Security

The contents of this section provide background information about application security.

Application Security

The system restricts access to transactions or explicit services using an [application service](#). The following points highlight what may be secured.

- The following points highlight security related to viewing and modifying individual records in the system:
 - All [maintenance objects](#) define an application service that includes the basic actions available, typically **Add**, **Change**, **Delete**, and **Inquire**. The base product supplies an application service for every maintenance object. Note that the application service for the maintenance object is defined on its related [service program](#).
 - For maintenance objects whose user interface page is not portal-based, the application service also controls whether the menu entry appears. If a user doesn't have access to the maintenance object's application service, the menu item that corresponds with the application service will not be visible.
 - For portal based user interfaces, each main (stand-alone) [portal](#) defines an explicit application service with the access mode **Inquire**, allowing the user interface to be secured independently of the underlying object security. If a user doesn't have access to the portal's application service, the menu item that corresponds with the application service will not be visible. The base product supplies an application service for every portal that is accessible from the menu. Note that the application service for the portal is defined on its related [service program](#), which is derived via its navigation option and navigation key.
 - [Menu items](#) may define an application service / access mode. Typically the security supplied for portals and maintenance objects provides enough granularity to suppress menu items that a user does not have access to. Linking an explicit application service / access mode will further suppress the menu item under one of the following scenarios:
 - Suppress a menu item if the underlying application security for the transaction does not provide enough fine grained control. For example, imagine your implementation creates a special BPA script to add a To Do Entry and would like users to use the special BPA rather than the base supplied Add dialogue for To Do Entry. The underlying security settings for To Do Entry should grant Add access to these users given that the special BPA will still add a record. To suppress the base Add dialogue, link a special application service and access mode for the base supplied menu item for To Do Entry Add. Then define a menu entry for the new special BPA for adding.
 - Suppress the add option if a user does not have add security for the object. By default the product does not suppress the add function if a user does not have add access to the object. Rather, the user is prevented from adding the record at the back-end. If your implementation would like to suppress the menu option, link the object's application service and the Add access mode to the Add menu item.

NOTE: The base product does not typically provide menu items with application services configured. Implementations may add this configuration if one of the above scenarios exist.

- [Zones](#) define an application service.
 - For zones linked to a portal, if a user doesn't have access to the zone's application service, the zone will not be visible on the portal. In most cases the zone is delivered with the same application service as its portal. In special cases, such as the zones on the Dashboard, the product supplies separate application services for each zone allowing implementations to determine at a more granular level which users should have access to which zones.
 - For query zones that are configured on a multi-query zone, if a user doesn't have access to the zone's application service, the zone will not be visible in the dropdown on the multi-query zone. In most cases all zones in a multi-query zone define the same application service as the multi-query zone. The product may supply a special

application service for one or more zones in a multi-query zone if the functionality is special to certain markets or jurisdictions and not applicable to all implementations.

- For zones that are used by business services to perform SQL queries, the product supplies a default application service. Security for these zones is not checked by the product as they are used for internal purposes.
- For portal based pages, individual elements may be shown or hidden based on security using the **oraHasSecurity** function in a UI map's HTML or in UI Hints in a schema. Refer to [Check User's Security Access](#) for more information.
- **Business objects** define an application service. If the business object defines a lifecycle, the application service must include access modes that correspond to each state. In addition, the standard maintenance object access modes of **Add, Change, Delete** and **Inquire** are included. The base product business objects are supplied with appropriate application services. In addition, implementations may override the configured application service if desired.
- **Batch controls** define an application service which provides the ability to secure submission of individual batch processes. The application service must include an access mode of **Execute**. The base product batch controls are supplied with appropriate application services. These services will typically have an ID that matches the batch control ID.
- **Report Definition** records define an application service. The application service must include an access mode of **Submit / View Report**.
- The following objects are securable but are typically executed via internal processes. The security is provided to ensure that any access to the objects from an external source is secured.
 - **BPA scripts** may define an application service with the access mode **Execute**. The base BPA scripts are typically not configured with any application service. An implementation may define one. Note that as mentioned above, a menu item may also be configured with an application service and access mode. This allows for a BPA that is invoked via a menu entry to be secured in more than one way.
 - **Business Services** and **Service Scripts** define an application service with the access mode **Execute**. This is needed for services that may be executed from an external system, for example via an inbound web service. Base business services and service scripts that are linked to an inbound web service are configured with special application service. All other business services and service scripts are delivered with a default application service, which may be overridden by an implementation.
 - Scripts may also check security within an Edit Data step type if there is some functionality that should or should not execute based on a user's security access. The Edit Data step would include a call to the business service **F1-CheckApplicationSecurity**
 - **Service Programs** define an application service. As mentioned above, for Portals and Maintenance Objects, their application service is taken from the related service program. In base, specific application services are released for each of these types of service programs. All other service programs are typically delivered with a default application service, which may be overridden by an implementation. Note that for service programs linked to a Business Service, the application service on the business service takes precedence when invoking the business service.

Users are granted access to application services via [user groups](#). For example, you may create a user group called Senior Management and give it access to senior manager-oriented pages and portals.

- When you grant a user group access to an application service with multiple access modes, you must also define the access modes that are allowed. Often the access modes correspond to an action on a user interface. For example, you may indicate a given user group has **inquire**-only access to an application service, whereas another user group has **add, change, cancel** and **complete** access to the same service. Refer to [action level security](#) for more information.
- If the application service has [field level security](#) enabled, you must also define the user group's security level for each secured field on the transaction.
- And finally, you link individual [users](#) to the user groups to which they belong. When you link a user to a user group, this user inherits all of the user group's access rights.

Action Level Security

When you grant a user group access to an [application service](#), you must indicate the actions to which they have access.

- For application services that only query the database, there is a single action to which you must provide access - this is called **Inquire**.
- For application services that can modify the database, you must define the actions that the user may perform. At a minimum, most maintenance transactions support **Add**, **Change**, and **Inquire** actions. Additional actions are available depending on the application service's functions.

CAUTION: Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a transaction that supports special actions in addition to **Add**, **Change**, and **Inquire** (e.g., **Freeze**, **Complete**, **Cancel**). If you want to give a user access to any of these special actions, you must also give the user access to the **Inquire** and **Change** actions.

Field Level Security

Sometimes transaction and action security is not sufficient. There are situations where you may need to restrict access based on the values of data. For example, in Oracle Utilities Customer Care and Billing you might want to prevent certain users from completing a bill for more than \$10,000. This is referred to as "field level security".

Field level security can be complex and idiosyncratic. Implementing field level security always requires some programming by your implementation group. This programming involves the introduction of the specific field-level logic into the respective application service(s). The recommendation is to use a business object validation algorithm for checking field level security.

NOTE:

The check for field level security must exist in validation logic to ensure that data is not added or updated if it does not pass the field level security rules.

It is not straight forward to implement user interface changes related to field level security, such as protecting elements under certain conditions. This is because overriding the base product delivered user interface to check for implementation specific conditions is not always supported, depending on how the user interface is built, or requires a full duplication of product artifacts, which is not recommended.

The definition of a user's access rights is performed using the same transactions used to define transaction / action level security. This is achieved as follows:

- Create a [security type](#) for each type of field-level security.
- Define the various access levels for each security type. For example, assume you have some users who can complete bills for less than \$300, and other users who can complete bills for less than \$1,000, and still other users who can complete bills for any value. In this scenario, you'd need 3 access levels on this security type:
 - Level 1 (lowest): May authorize bills <= \$300
 - Level 2 (medium): May authorize bills <= \$1,000
 - Level 3 (highest): May authorize all bills
- Link this security type to each [application service](#) where this type of field level security is implemented. This linkage is performed on the [security type](#) transaction.
- Defining each [user group's](#) access level for each security type (this is done for each application service on which the security type is applicable).

NOTE:

Highest value grants highest security. The system expects the highest authorization level value to represent highest security level. Moreover, authorization level is an alphanumeric field so care should be taken to ensure that it's set up correctly.

The Base Package Controls One User, One User Group, And Many Application Services

When the system is initially installed, the following information is delivered:

- Application services for all secured transactions, maintenance objects, business objects, business services, scripts and zones in the base package.
- A user identified by the user id **SYSUSER**.
- A user group identified by the user group code **ALL_SERVICES**. This user group is associated with all supported application services delivered with the base product. This user group is given access to all access modes for all application services (i.e., all actions on all transactions).
- The user **SYSUSER** is linked to the **ALL_SERVICES** user group. This means that this user has access to all transactions and all actions.

You cannot change or remove the information delivered for **ALL_SERVICES**. This information is owned by the base package. It is provided so that an "initial user" has access to the entire system and can setup user groups and users as per your organization's business requirements. It is not recommended to provide your own users with access to the **ALL_SERVICES** user group. Rather, create user groups that are appropriate for the organization's business requirements and define user access to these user groups. If you introduce new transactions, configure them for the appropriate custom user groups.

In addition, **SYSUSER** is provided to allow for an initial user to define appropriate users in your implementation. Once proper administrative users have been defined, it is recommended that **SYSUSER** is updated to set the User Enable setting to Disabled.

When you receive an upgrade:

- New application services are delivered for the new transactions, business objects, zones introduced in the release. The release notes highlights the additions / changes.
- Existing application services are updated with changes in their access modes (e.g., if a new action is added to a transaction, its application service is updated accordingly).
- The **ALL_SERVICES** user group is updated so it can access the new / changed application services.
- Implementations should review the release notes and determine which user groups created for your implementation should be updated with the additions, if applicable.

Importing Security Configuration from an External Source

The product provides support for importing security information from an external source:

- If your organization uses Lightweight Directory Access Protocol (LDAP), you can import your existing LDAP users and groups into the system. Once imported, all user and group functions are available. You can import a user group, or a single user. You can resynchronize your LDAP users and groups at any time.

FASTPATH: For more information refer to [LDAP Integration](#).

- The system provides an integration with Oracle Identity Manager. When a user is created in the identity manager product, its information can automatically be interfaced to the product. Once the user is successfully created in the system, all functions are available.

FASTPATH: For more information refer to [Oracle Identity Manager Integration](#).

Defining Application Services

Please refer to [Application Security](#) for a description of how application services are used when you grant user groups access rights to transactions. Refer to [Action Level Security](#) for more information about the significance of an application service's access modes.

You can access the portal using **Admin > Security > Application Service**. You are brought to a query portal with options for searching for a specific application service. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- The **Application Service** zone provides the information about the application service and its access modes.
- The **Secured Objects** zone displays the object (or objects) that are secured by this application service. Refer to [Application Security](#) for details about the types of objects that may be secured.

The **Application Security** tab includes zones to view and manage which user groups have access to the application service and which ones do not have access. The following zone may appear as part of this tab page:

- The **User Groups Linked** zone lists the user groups that currently have a link to the application service. Note that expired links are included when the zone is first displayed. Use the zone filters to exclude expired links and to limit the user groups shown by user ID, user group ID, and user group description.
- The **User Groups not Linked** zone lists the user groups that do not have a link to the application service. Use the zone filters to limit the user groups shown by user ID, user group ID, and user group description.

Defining Security Types

Security types are used to define the types of [field level security](#).

NOTE: Programming is required. You cannot have field level security without introducing programming code. Refer to [Field Level Security](#) for more information on how security types are used to define field level security.

Security Type - Main

Select **Admin > Security > Security Type** to define your security types.

Description of Page

Enter a unique **Security Type** and **Description**.

Use the **Authorization Level** grid to define the different authorization levels recognized for this security type. Enter an **Authorization Level Number** and its **Description**.

NOTE: Programming is required. Note that the values that you enter are not interpreted by the system itself, but by the user exit code used to implement the special security. Check with the developer of the user exit logic for the correct values. Refer to [Field Level Security](#) for more information on how security types are used to define field level security.

Use the **Application Services** grid to define the application service(s) to which this security type is applicable. If this application service is already associated with user groups, you must update each user group to define their respective security level. This is performed on the User Group portal.

Defining User Groups

A user group is a group of users who have the same degree of security access. Think of a user group as a "role"; associated with a role are:

- The users who play this role
- The application services to which the role's users have access (along with the actions they can execute for each service and their field level security authorization levels).

Refer to [Action Level Security](#) and [Field Level Security](#) for more information about access modes and security types.

CAUTION: Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a transaction that supports actions in addition to **Add**, **Change**, and **Inquire** (e.g., **Freeze**, **Complete**, **Cancel**). If you want to give a user access to any of these additional actions, you must also give the user access to the **Inquire** and **Change** actions.

This portal allows a security administrator to view and manage information about a user group.

You can access the portal from the **Admin Menu > Security > User Group**. You are brought to a query portal with options for searching for a specific user group. Once a user group has been selected you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Application services may not be changed or removed from the **ALL_SERVICES** user group. Refer to [The Base Package Controls One User, One User Group, And Many Application Services](#) for an explanation.

The following zones may appear as part of the portal's **Main** tab page

- **User Group.** This zone provides information about the selected user group.
- **Application Services.** This zone lists application services linked to the selected user group. You may use this zone to edit the information for an specific application service or use mass actions to remove selected services or update their effective date.
- **Add Application Services.** You may use this zone to add application services to the selected user group.

The following zones may appear as part of the portal's **Users** tab page

- **Users.** This zone lists users linked to the selected user group. You may use mass actions to remove selected users or update their effective date.
- **Add Users.** You may use this zone to add users to the selected user group.

The following zones may appear as part of the portal's **Service Manager** tab page

- **Application Service / Access Modes.** This zone lists application service and access mode combinations currently linked to the selected user group. You may use mass action to remove a selected set of records.
- **Add Application Service / Access Modes.** You may use this zone to add application service access mode records.
- **Security Type Authorization.** This zone maintains field level security for application services included in the selected user group.

The following zone may appear as part of the portal's **Secured Components** tab page

- **Application Components.** This zone allows you to review various types of application components secured by the selected user group. The query is similar to the [Application Security Query](#) restricted to the current user group.

Defining Users

The user maintenance transaction is used to define a user's user groups, data access roles, portal preferences, default values, and To Do roles. To access the user maintenance transaction, select **Admin > Security > User**.

The user maintenance transaction is the same transaction invoked when the user launches [Preferences](#) from the user menu or shortcut key.

Application Security Query

This portal allows a security administrator to review application security configurations across users, user groups and the various types of application components they secure.

While application security is configured at the granular level of an application service and its access modes, it is more intuitive to review access rights to top level broader components:

- **Menu line.** Several application services may be related to a single menu line and impact the ability to properly leverage various aspects of its functionality:
 - The application service of the transaction page or portal, which also controls the visibility of the menu line or its 'search' part when the line is composed of 'add' and 'search' items.
 - The application services associated with any zones on that portal.
 - The application service of the underlying maintenance object when applicable, which also controls the 'add' item of the menu line.
 - The application services of business objects for the underlying maintenance object.
 - The application services of portals used to maintain these business objects.
 - The application services of related portals.
 - The application services of related maintenance objects, their business objects and portals.
 - and more

You may review the list of application services associated with a menu line on the **Application Security** tab on the **Menu** portal.

- **Dashboard Zone.** This is a regular or context sensitive zone that the user has access to on the Dashboard area.
- **System.** This is a Toolbar or other system wide option a user is allowed to use.
- **Batch Control.** This is a batch process a user is allowed to submit.
- **Report Definition.** This is a report a user is allowed to submit.
- **Web Service.** This is a web service a user is allowed to invoke.
- **Miscellaneous.** This is a special service that a user is allowed to invoke.
- **Internal.** This is an internal item that is secured by default but is assumed to be called in a context that does not require security check.
- **Unclassified.** Some application services may not be related to any type of application component and as such remain unclassified. For example, there are situations where previously released services are enhanced to be associated with dedicated application service in a later release. In this situation the services may retain their original or even custom application service and the new application services may appear as not associated with any component.

Refer to [Application Security](#) for details about the types of objects that may be secured.

Open this page using **Admin > Security > Application Security Query**.

Row Security

Some products allow you to limit a user's access to specific rows. For example, in Oracle Utilities Customer Care and Billing, row level security prevents users without appropriate rights from accessing specific accounts.

A combination of framework configuration and configuration in your edge product is required for row level security. The following points describe the configuration:

- For each record that should be secured, associate it with an **Access Group**. Note that if your edge product supports row level security, that product is providing a link between the secure-able record and Access Group. Your access groups may be granular and only referenced by one secured record or they may be more broad and be referenced by multiple secured records that require the same type of security restriction.
- To define which users have access to the secured records, you define a **Data Access Role**. For each data access role, define which Access Groups the role has security clearance for. An access group may be linked to one or more data access roles. In addition, define the **Users** that have access rights to these secured records. When you grant a data access role rights to an access group, you are giving all users in the data access role rights to all secured records in all the referenced access groups. A user may belong to many data access roles.

If your edge product supports row level security, it will include logic in the appropriate areas of the system to limit the secured rows that a user may view or maintain based on this configuration. For example, in Oracle Utilities Customer Care and Billing, throughout the system users are only able to view and maintain information about an account and any of its detail if the user is in a Data Access Role for the account's Access Group (or the account is not linked to an Access Group).

FASTPATH: Refer to your product's documentation for more information on row level security, if applicable.

Defining Access Groups

Refer to [The Big Picture of Row Security](#) for a description of how access groups are used to restrict access to specific objects.

Access groups control which groups of users (referred to as Data Access Roles) have rights to accounts (or other objects) associated with the access group. You can access the portal using **Admin > Security > Access Group**. You are brought to a query portal with options for searching for a specific access group. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Access Mode** zone provides the information about the access group and its data access roles.

- The **Data Access Role** collection defines the data access roles whose users have access to the access group's secured objects. Keep in mind that when you add a **Data Access Role** to an **Access Group**, you are granting all users who belong to this role access to all of the objects linked to the access group.

NOTE: You can also use [Data Access Role - Access Group](#) to maintain a data access role's access groups.

- The **To Do Role Assignment** collection may be used to route To Do Entries of a given To Do Type to a specific To Do Role if the objects related to the To Do Entry are associated with the access group. Refer to [Adjusting the To Do Role](#) for more information.

Defining Data Access Roles

FASTPATH: Refer to [The Big Picture of Row Security](#) for a description of how access groups are use to restrict access to specific objects.

The data access role transaction is used to define two things:

- The users who belong to the data access role.
- The access groups whose accounts (or other objects) may be accessed by these users.

Data Access Role - Main

Select **Admin > Security > Data Access Role** to define the users who belong to a data access role.

Description of Page

Enter a unique **Data Access Role** code and **Description** for the data access role.

The scroll area contains the **Users** who belong to this role. A user's data access roles play a part in determining the accounts (or other objects) whose data they can access.

To add additional users to this data access role, press the add button and specify the following:

- Enter the **User ID**. Keep in mind that when you add a **User** to a **Data Access Role**, you are granting this user access to all of the accounts (or other objects) linked to the data access role's access groups.
- Use **Expiration Date** to define when the user's membership in this data access role expires.

NOTE: Also maintained on the user page. You can also use [User - Access Security](#) to maintain a user's membership in data access roles.

Data Access Role - Access Group

Select **Admin > Security > Data Access Role** and navigate to the **Access Groups** tab to define the access groups whose accounts (or other objects) may be accessed by the users in this data access role.

Description of Page

Use the **Access Group** collection to define the access groups whose objects can be accessed by this role's users. Keep in mind that when you add an **Access Group** to a **Data Access Role**, you are granting all users who belong to this role access to all of the accounts (or other objects) linked to the access groups.

NOTE: You can also use [Access Group - Main](#) to maintain an access group's data access roles.

Data Privacy

Personally Identifiable Information (PII) is any information that identifies or could be used in combination with other information to identify an individual. Many countries have data privacy laws governing the use of such information. A key aspect of these laws is an organization's obligation to erase personal information when there is no compelling reason to retain it. This obligation can be fulfilled either by deleting data or altering the data in such a way that it is no longer possible to associate the data with the individual.

Organizations are likely to have other legal obligations that impact how long they retain personal data. For example, there could be financial audit requirements that oblige the organization to retain relevant information for a fixed number of years after termination of a contract.

Object Erasure is designed to address right to erasure issues, with a combination of configuration and processes that may be extended to implement the appropriate policies for the PII within your data.

Encryption and Masking

"Encryption" refers to encrypting data stored in the database using an encryption key. There are two different types of encryption described in the sections below. System encryption refers to columns in the system identified by the product to use encryption. Application encryption refers to the ability for an implementation to configure fields and elements that should be encrypted in the database.

"Masking" refers to overwriting all or part of an un-encrypted field value with a masking character. For example, perhaps only the last 4 digits of a tax ID number are visible with the other digits changed to an asterisk. The system provides support for masking fields on the user interface that may be stored as plain text in the database. In addition, there are cases where encrypted fields are shown to the user interface using masked values rather than the encrypted value.

The following sections provide more information about each feature.

System Encryption

The system automatically encrypts certain fields captured in various option tables or context tables. This is mainly used for passwords. For example, passwords captured in Message Sender context or password

In addition, batch control supports configuring a security option for parameters that capture sensitive information, such as a password. Refer to [Defining Batch Controls](#) for more information.

It is also possible to enable system encryption using the characteristic type **F1-PWD**. However, the maintenance object must include specific code to enable system encryption for characteristics of this type. In Oracle Utilities Application Framework, the only maintenance object that supports this is extendable lookup. Refer to [Extendable Lookup Advanced Topics](#) for more information.

User Interface Masking

The functionality described in this section is used to take data that is stored in plain text in the database and mask the value before it is presented to a user (or an external system). This feature includes the ability to allow some users to view the data unmasked using security configuration. The system allows different masking rules to be applied to different fields. For example, a credit card number can be masked differently than a social security number.

The following topics describe how to mask field values.

Identify the Data to be Masked

Identify the data that is stored as plain text, but should be masked for display to users. For example, imagine that you have identified that Credit Card Numbers and a person's federal ID number (for example, in the United States, the Social Security Number or SSN). Each field identified may be displayed and maintained in different user interfaces throughout the system, but the masking rules for a given field are probably uniform regardless of where the data is displayed.

Primary keys cannot be masked. A field defined as a unique identifier of a row cannot be configured for masking. Masking a field that is part of the primary key causes a problem when attempting to update the record. This restriction also applies to elements that are part of a "list" in an XML column on a maintenance object. One or more elements in the list must be defined as a primary identifier of the list. Be sure that primary key elements in the list are not ones that require masking.

List members that contain different "types". Consider a page with a list that contains a person's identification numbers. You can set up the system so that a person's social security number has different masking rules than their drivers license number. If your implementation has this type of requirement, the list of masked fields should contain an entry for each masking rule.

For each field, if there are some users that may see the data unmasked on one or more of the user interfaces, then security configuration is required. If the value of a field should be masked for all users across all pages in the application, then the security configuration is not needed.

Security Configuration

Define a [security type](#) for each field with two authorization levels:

- **1** - Can only see the element masked
- **2** - Can only see the element unmasked

Link all of the security types to an [application service](#) of your choosing. We recommend linking every masking-oriented security type to a single application service (e.g., **CM_MASK**) as it makes granting access easier.

For each security type, identify which users can see its data unmasked and which users can only see its data masked. If the masked and unmasked users fit into existing user groups, no additional user groups are necessary. Otherwise, create new user groups for the masked and unmasked users.

After the user groups for each security type are defined, link each user group to the application service defined above. When a user group is linked to the application service, you will define the authorization level for each security type linked to the application service. If a user group's users should see the security type's field values unmasked, set the authorization level to 2; otherwise set it to 1.

NOTE: Flush the cache. Remember that any time you change access rights you should [flush the security cache](#) (by entering flushAll.jsp on the URL of the application) if you want the change to take effect immediately.

Configure a Masking Algorithm

A data masking algorithm (using the algorithm entity value of **Feature Configuration - Data Masking**) must be created for each combination of masking rules and security type. These algorithms determine if a user has the rights to view a given field unmasked, and, if not, how the field should be masked.

The base package provides the algorithm type **F1-MASK** whose parameters are designed to handle most masking needs. If certain users may see the data unmasked, parameters capture the application service, security type and authorization level defined above used to evaluate this. In addition, parameters allow you to configure how much of the data to mask, what masking character to use. Refer to the algorithm type description for more information.

Determine How the Fields are Displayed

The masking configuration differs based on how a field is retrieved for access to the user interface. So for the masking of one “logical” field (like a person’s SSN), there may be multiple configuration entries required to cover all the access methods. Review each user interface where a given field is displayed and create the following categories:

- The field is an element that is retrieved by invoking a business object, a business service, or a service script
- The field is displayed on a fixed maintenance page (and is therefore retrieved by invoking a page service)
- The field is displayed on a fixed search page (and is therefore retrieved by invoking a search service)
- The field is stored as an ad hoc characteristic

Create a Feature Configuration for Each Masked Element

Create a feature configuration with a Feature Type of **Data Masking**. An option entry with option type of **Field Masking** is needed for every combination of field to mask and the method used to display the data. The value will contain mnemonics that reference the appropriate data masking algorithm along with configuration that differs depending on how the field is retrieved for display as described below.

Schema Based Object Field Masking

For data that is accessed via a schema-based object call and displayed in a UI map, the field to be masked must reference a meta-data field name in its schema definition: **field="fld_name", alg="algorithm name"**

If the element references an mdField in the schema, that is the field used to identify the masking rule. If there is no mdField reference but only a mapField reference, that is the field used to identify the masking rule. For example, if you want to mask a credit card number, let's assume that field is defined in the schema is the following:

```
<creditCard mdField="CCNBR" mapField="EXT_ACCT_ID"/>
```

In this case, the option value should be **field="CCNBR", alg="algorithm name"**. An option value of **field="EXT_ACCT_ID", alg="algorithm name"** would not result in masking.

A "where" clause may also be specified. This is useful for data that resides in a list where only data of a certain type needs to be masked: **field="fld_name", alg="algorithm name", where="fld_name='value'"**

For example, person can have a collection of IDs and only IDs of type 'SSN' (social security number) should be masked. If the person data including its collection of person IDs is displayed on a UI map via a business object call, let's assume the collection is defined in the following way:

```
<personIds type="list" mapChild=CI_PER_ID">  
  <isPrimaryId mapField="PRIM_SW"/>  
  <idType mapField="ID_TYPE_CD"/>  
  <personIdNumber mapField="PER_ID_NBR"/>  
</personIds>
```

The option value may look like this: **field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"**

Please note the following important points for schema based masking:

- **Limitation of 'where' field** Although the main use of a 'where' clause for schema oriented elements is to mask certain elements in a list based on a 'type', it is also possible to mask a single field in the schema based on the value of another field. For example, imagine that a customer submits a registration form that defines an ID type and ID value. Although this data is not in a list, the implementation may still want to only mask the ID value if the ID type is "SSN". The framework is only able to mask an element in the schema based on a 'where' clause if the element in the 'where' clause is a "sibling" in the schema.
 - If the element to be masked is in a list, the element in the 'where' clause must be in the same list.
 - If an element to be masked maps to a real column in a table, the element in the 'where' clause must also map to a real column in the table.
 - If an element to be masked maps to an XML column in the table as a single element, the element in the 'where' clause must map to the same XML column as a single element.
- **Multiple feature option entries for the same field.** It's possible that different schemas in the system have a similar type of data that may be masked based on different conditions. For example, imagine that an implementation has different schemas that captured or referenced person identifiers in different ways:
 - One schema captures a single person ID without any corresponding "type" record and it should always be masked using Algorithm CM_SSN_MASK:

```
<personSSN mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

- One schema captures a person ID and a corresponding ID Type and it should be masked with Algorithm CM_SSN_MASK if the type is "SSN" and masked with algorithm CM_FEIN_MASK if the type is "FEIN".

```
<personIdType mapXML=BO_DATA_AREA mdField=ID_TYPE_CD/>  
<personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

- One schema captures a person ID and a corresponding ID Type and it has the same masking rules as the previous schema, but a different field name is used for the ID Type code. (This scenario could happen if for example a different label is desired for ID Type on the user interface for this schema.)

```
<personIdType mapXML=BO_DATA_AREA mdField=CM_ID_TYPE/>
```

```
<personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

For this scenario, the feature options may look like this:

1. **field="PER_ID_NBR", alg="CM_SSN_MASK"**
2. **field="PER_ID_NBR", alg="CM_SSN_MASK", where="ID_TYPE_CD='SSN'"**
3. **field="PER_ID_NBR", alg="CM_FEIN_MASK", where="ID_TYPE_CD='FEIN'"**
4. **field="PER_ID_NBR", alg="CM_SSN_MASK", where="CM_ID_TYPE='SSN'"**
5. **field="PER_ID_NBR", alg="CM_FEIN_MASK", where="CM_ID_TYPE='FEIN'"**

For each schema, the system will first find whether the element applies to any masking option. It will find 5 masking options for the field PER_ID_NBR. Then it will determine if any sibling elements match the 'where' clause.

- If more than one sibling element matches a 'where' clause, a runtime error is issued. For example if a schema has an element that references "mdField=ID_TYPE_CD" and an element that references "mdField=CM_ID_TYPE", this is an error. Additionally, if multiple elements reference mdField=ID_TYPE_CD", this is an error.
- If one and only one sibling element matches a 'where' clause, the value of the element is compared to the values defined in the 'where' clause. If it finds a match on the value, the appropriate masking algorithm is applied. If no match is found (for example, the Person ID Type is "LICENSE") the element is displayed as is.
- If no sibling element matches a 'where' clause and a feature option exists with no 'where' clause (option 1 above), then the masking algorithm of the option with no 'where' clause is applied.
- **Changing the value in the 'where' clause.** If your implementation has some users that are allowed to change records where some data is masked based on a condition, it is recommended to design the user interface to reset the masked value when the value in the 'where' clause changes. For example, if a user is prevented from viewing a person's social security number, but the user is allowed to make updates to the person's record, changing the value of the Person ID Type should reset the Person ID Number. This would ensure that the user does not 'unmask' the social security number by simply changing the ID Type.

Records Maintained Using Page Maintenance

For data that is accessed via a page maintenance service call, indicate the table name and the field name where the data resides: **table="table_name", field="fld_name", alg="algorithm name"**

For example if the Person record and its collection of identifiers are displayed and maintained using page maintenance, the option value should be **table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name"**

A "where" clause may also be specified: **table="table_name", field="fld_name", where="fld_name='value'", alg="algorithm name"**

This is useful for data that resides in a child table where only data of a certain type needs to be masked. For the person ID example, **table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"**

Characteristic Data

For data that is stored as a characteristic, simply indicate the characteristic type: **CHAR_TYPE_CD='char type', alg='algorithm name'**

This needs to be defined only once regardless of which characteristic entity the char type may reside on. Note that only ad-hoc characteristics are supported.

Masking Fields in Explorer Zones or Info Strings

In explorer zones data is often retrieved using SQL directly from the database. No masking is applied automatically in this case. If there is data in the explorer zone results that should be masked, the masking must be applied by calling a business service.

Similarly, an MO Info algorithm may not use BO interaction to get data. It may access data using SQL for efficiency purposes. No masking is applied when retrieving data via SQL. To apply masking to a string prior to including it in an info string, the masking must be applied by calling a business service.

The system supplies two business services to be called to determine if masking rules apply for a specific field.

- **F1-TableFieldMask.** Mask a Table field. This business service receives a table name, field name and one or more field values. If masking applies it returns the masked value.
- **F1-SchemaFieldMask.** Mask a Schema field. This business service receives a schema name and type, XPath and field value. If masking applies it returns the masked value.

Search Service Results

For data that is displayed on a 'fixed' search page, it is retrieved via a search service call. Indicate the search name and the appropriate field to mask along with the masking algorithm. For example: **search="SearchServiceName", field="PER_ID_NBR", where="ID_TYPE_CD='SSN'", alg="algorithm name"**

To find the name of the search service, launch the search in question, right click in the filter area and choose **Inspect**. Search for "serviceName". The service name is listed there. To find the field name to mask, search for "Widget Info". There should be two results found, one for the filter area and one for the results area. This results area has the text "SEARCH_RESULTS" as prefix for each field. The field names are the ones after the x\$. Do not reference the x\$ when defining the field name. Note, the "where" statement can only apply to fields that are also part of the search results.

Additional Masking Information

The following points provide additional information to assist in your masking configuration:

- If the demonstration database includes a **Data Masking** feature configuration, review the settings because it will probably contain masking rules that will match your own.
- On data input pages, a user might be able to enter or change masked data, such as a bank account number, but not be able to subsequently see what they added or changed.
- External systems can request information by performing a service call via a web service. Please keep in mind that some web service requests require data to be masked and some do not. For example, a request from an external system to synchronize person information needs the person's social security number unmasked; whereas a request from a web self service application to retrieve the same person information for display purposes needs the person's social security number masked. To implement this type of requirement, different users must be associated with each of the requests and these users must belong to separate user groups with different access rights.
- If a maintenance object (MO) contains a field that holds an XML document and a service call invokes the MO's service program directly, the system will mask individual XML elements in the field if a **Determine BO** algorithm has been plugged into the [maintenance object](#) and the element(s) in the respective BO schema have been secured as described above.

Application Encryption

The functionality described in this section allows implementations to configure fields to encrypt when storing it in the database. This functionality is mutually exclusive from the User Interface Masking functionality described in the previous section. This feature supports encrypting specific elements stored within a CLOB or XML column.

The following points highlight the features of the encryption functionality:

- The encryption key is defined using a keystore, which must be set up in order to use this functionality. For details about setting up the keystore in the system, see the Installation Guide.
- When a field is configured to be encrypted, the encrypted data is stored in a special encryption field that is not the source field (the one exposed to the user on the user interface). The source field captures the data as masked. Because a special field is required to support encryption, the product must provide support for that field to be encrypted.

- For encrypted data that must allow searching, the system supports capturing a hash value in a special field. The product must provide support for this functionality. Besides providing a special field to capture the hash value, base search functionality for that data must also cater for this configuration.
- The system supports encrypting data that is captured as an element within an XML field. If the XML field is provided in a schema owned by the product, then the product must provide specific support for the capture of the encrypted data.

The following sections provide additional information about the support for encryption provided by the framework. Refer to the security chapter of the administration guide for your particular product for more information.

Encrypting and Masking the Data

When a product enables encrypting for a given type of data, a special encryption field should be created to capture the encrypted value. Because encrypting is optional, the source field (the one exposed to the user) should not be this special encrypted field. If encryption is configured, the system will internally populate the encrypted field. The source field will be populated with asterisks by default. That way the masked data is what is shown to the user on page rather than the encrypted value.

The following points highlight how the system behaves when encryption is configured and when it is not. Assume as an example, the field is a credit card number. The user views and populates a field with the field name `CC_NBR`. The table also has a second field `ENCR_CC_NBR`. A user populates the credit card number:

- If encryption is not configured, `CC_NBR` will be updated with the entered credit card number and `ENCR_CC_NBR` will be empty. Note that in this case, an implementation may choose to configure [user interface masking](#).
- If encryption is configured, `CC_NBR` will be updated with ‘*****’ and `ENCR_CC_NBR` will contain the encrypted value. The asterisks for the standard field will fill the full field size up to 50 characters.

If for some reason the standard masking using all asterisks is not desired, the system supports supplying an explicit masking algorithm using the same Feature Configuration - Data Masking plug-in spot used for [User Interface Masking](#).

WARNING: Unlike user interface masking, the masking of encrypted fields is not driven by security. The data stored in the source field for all encrypted data should be masked. Be sure not to configure security authorization logic in algorithms used for this type of masking.

Feature Option Configuration

Create a feature configuration with a Feature Type of **Encryption**. For each source field you are encrypting, enter an option with option type of **Field Encryption**. The value will contain mnemonics that reference the appropriate encryption key alias defined in the keystore along with configuration related to the field and its table location. Unlike the user interface data masking, the configuration for data encryption is related to how the data is stored rather than how it is displayed. In addition, each entry may define an explicit masking algorithm to override the default and if supported, may also define a hash field and hash alias.

For data that is stored in a specific column on a table, an explicit field to capture the encrypted value must exist. Indicate the table name, source field name and encrypted field name along with the alias: **table='table_name', field='fld_name', encryptedField='encr_fld_name', alias='alias key'**

A "where" clause may also be specified when data resides in a child table and only data of a certain type needs to be encrypted.

Example, **table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', alias='key alias', where='ID_TYPE_CD='SSN''**

For data that is stored in an XML column in a record, the source field to be encrypted must reference a meta-data field name in its schema definition along with the element that captures the encrypted data and the alias: **field='field_name', encryptedField='encr_field_name', alias='key alias'**

The syntax for adding a reference to a masking algorithm is **maskAlg='algorithm name'** .

The syntax for adding configuration for capturing a hash value for searching purposes is **hashAlias='hashAliasKey' hashField='HASH_FLD_NAME'**.

The following is an example of configuration that uses all the possible options (specific masking algorithm, where clause and hash field support):

```
table='CI_PER_ID', field='PER_ID_NBR', alias='aliasKey', encryptedField='ENCR_PER_ID_NBR',  
hashAlias='hashAliasKey' hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN', maskAlg='CM-  
PERIDMASK'
```

Searching by an Encrypted Value

If the product supports a hashed value for an encrypted field for searching purposes, the following points highlight explorer zone configuration for this purpose

- The user filter value should reference the source field and should include an additional **encrypt=** mnemonic. For example

```
type=STRING  
label=PER_ID_NBR  
encrypt=[CI_PER_ID, PER_ID_NBR, ID_TYPE_CD, F1]
```

Refer to [User Filters](#) for more information.

- The SQL should include the hashed value in the WHERE clause. Note that because encryption is optional, a product zone that includes searching by a field eligible for encryption will include finding a match for the filter in the source field (as plain text) or in the hashed field. For example:

```
WHERE  
[(F2) (ID.PER_ID_NBR = :F2 OR ID.HASH_PER_ID_NBR = :F2)]
```

Customizing Encryption Algorithm

Although the encryption algorithm to use with a given key can be gleaned from the key in the keystore, there is sometimes extra information associated with an algorithm that might need to be used to encrypt or decrypt data.

The system provides a feature configuration option for the **Encryption** feature type using the option type **Algorithm Info** that can be used to adjust the behavior of the encryption.

- You can modify the default mode and padding of the encryption algorithm.
- If a key will be used to digitally sign anything, the signing algorithm can also be specified for the key.

For details about the syntax, refer to the feature option type's detailed description.

The Approach to Implementing Object Erasure

This section describes the product approach to implementing object erasure for its maintenance objects (MOs).

NOTE: The approach outlined is intended for managing erasure of master data objects. The assumption is that Information Lifecycle Management will be used for archiving any related transactional data.

Various events in the system may signal the need to erase data at some future date. For example, closing an account may indicate the need to erase both the account and person data once there is no longer a need to maintain related financial details. There may also be events that re-establish the business relationship with a person and signal that data marked for erasure should now be retained.

The Object Erasure Schedule is used to capture key details of objects with data that needs to be erased. Records in the schedule are monitored periodically to determine if the date for erasure has been reached and if so, execute the erasure logic. The system will create and maintain records in the schedule when specific events occur for an MO that is marked for erasure.

The system provides the ability to mark an MO as eligible for erasure via a number of MO configuration entries. Included in these is an option that defines the business object for the MO's erasure schedule records. In addition to defining the erasure record elements, this BO defines the monitoring process and the specific erasure logic for the MO.

The following sections provide more information about configuring and managing object erasure.

Configuring a Maintenance Object for Erasure

There are three types of maintenance object configuration entries that define how to manage erasure:

- An option to define the business object for erasure schedule records.
- An option to define the period between the date on which the need for erasure is detected and the date on which erasure should occur. The common logic provided by the system to add or update erasure records uses this option to determine the erasure date.
- One or more entries in the MO algorithm collection for the algorithms that determine whether a record should be scheduled for erasure, according to the current state of the record, and create or update the erasure schedule entries.

Some MOs that would commonly be regarded as eligible for erasure will be installed with a base Erasure BO already configured. The expectation is that the corresponding Erasure Period option and the algorithm for the Manage Erasure Schedule plug-in spot will be set up by your implementation with the appropriate entries for your organization's business rules.

NOTE: The presence of an Erasure Period option is the signal to the system that your implementation has enabled an object for erasure.

It may not be necessary for all master data objects that contain personally identifiable information to manage their own erasure schedule. For example, the event which triggers erasure for a person record may also trigger the creation of erasure schedule entries for the person's other master data records. In this case, only the person maintenance object will need to be configured with a Manage Erasure algorithm (or algorithms). Refer to your product specific documentation for more information on the recommended approaches for your product's master data objects.

Manage Erasure Schedule Algorithm

Algorithms of this type are responsible for determining a record's erasure status and creating or maintaining an entry in the Object Erasure Schedule for the record. They are triggered when certain events occur in the system for maintenance objects that are eligible for erasure. Multiple algorithms can be configured for the plug-in spot.

Depending on the determination made by the algorithm (or algorithms), a number of different actions may need to be taken. For example:

- A new schedule record may need to be added
- An existing schedule record may need to be updated with a new erasure date
- A pending record may need to be discarded if erasure is no longer applicable
- A discarded record may need to be reactivated if erasure now applies again

The base business service **F1-ManageErasureSchedule** performs the common logic to handle the possible actions and is recommended for use by these types of algorithms. The service can also optionally create a log entry for information purposes. Refer to the description of the business service for full details.

In certain circumstances, if one record is scheduled for erasure, other related records may need to be evaluated. The base business service **F1-ManageErasureScheduleDriver** performs the logic to execute an MO's Manage Erasure Schedule algorithms. It can be used to manage any related records from within another algorithm.

This type of algorithm is plugged into the [Maintenance Object — Algorithm](#) collection.

Your product may supply algorithms to manage the schedule for base MOs that are regarded as eligible for erasure. If your organization has special business rules that are evaluated to determine the erasure schedule for an MO, a custom algorithm can be created and applied by the implementation team.

Monitoring the Schedule and Performing Erasure

The erasure schedule is managed using the lifecycle of the erasure record's business object. A deferred monitor process is used to periodically check for records that are due for erasure and transition them from the 'pending erasure' state to the 'erased' state. An enter plug in on the 'erased' state is responsible for performing the erasure logic.

The system provides a 'root' business object for the object erasure schedule (**F1-ErasureScheduleRoot**) which defines the lifecycle that erasure schedule business objects should follow. The system also provides a monitor process (**F1-OESMN**) which is configured on the 'pending erasure' state of the 'root' business object. This process is configured to monitor object erasure schedule records whose erasure date is on or before the batch business date.

Maintenance objects that are eligible for erasure should be configured with an erasure schedule business object that uses the 'root' business object as its parent. The algorithm that performs the erasure processing applicable to that maintenance object must be plugged in on the 'erased' state of the 'child' business object.

The system provides an erasure schedule business object (**F1-ErasureScheduleCommon**) which is designed to erase an object by deleting the main record and any child records. Your product may supply additional erasure schedule business objects for certain use cases. Refer to your product specific documentation for more information.

Erasing User Information By Obfuscation

Some implementations consider the base User object to have personally identifiable information. Erasing user information by deleting the records is not advisable as it can cause referential integrity problems. The recommended approach is to obfuscate the data instead.

The system provides a user erasure business object (**F1-ErasureScheduleUser**) which is designed to support obfuscating a user's identifiable information by removing it or replacing it with a non-identifiable value if the field is required.

If the User maintenance object is configured to be eligible for erasure in your implementation, the manage erasure schedule algorithm for the record will be invoked whenever the **Enable** flag is changed for a record on the User maintenance page. The system provides a base algorithm (**F1-OBJERSUSR**) specifically for the User MO. This algorithm will add an entry to the object erasure schedule if the user record is disabled or deactivate an existing erasure schedule record if a disabled user record is enabled again.

Viewing an Object's Erasure Status

The system provides a portal for viewing and editing an erasure schedule record. The portal is accessed from the **Object Erasure Schedule** dashboard zone. This is a context sensitive zone which only appears when accessing a record for a maintenance object that is configured to be eligible for erasure. It displays the information for the erasure schedule entry for the record in context, if applicable.

To add the zone to an eligible maintenance object:

- Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance object.
- Add the Object Erasure Schedule zone **F1-OBJERSRCD** to that navigation key.

Viewing Erasure Configuration

The Erasure Configuration [All-in-One portal](#) provides the ability to view the maintenance objects that are marked as eligible for erasure and maintain their erasure configuration entries in a single place.

To view a list of the eligible MOs, open **Admin > Security > Erasure Configuration**.

Press the edit icon to open a window in which the configuration values for that row can be changed.

Refer to [The Approach to Implementing Object Erasure](#) for an overview of object erasure configuration.

Archiving the Object Erasure Schedule

The system provides the ability to archive older records in the object erasure schedule using Information Lifecycle Management. The object erasure schedule maintenance object is configured with a base ILM eligibility algorithm and an ILM crawler batch control.

The base object erasure schedule BO is configured to set the ILM archive switch when an erasure schedule record enters a final state and to reset it if the record becomes active again.

Refer to [The Approach to Implementing Information Lifecycle Management](#) for more information on archiving functionality.

Data Redaction on Export

Personal identifiable information (PII) requires special handling when exported out of the application and written to files. Information that is encrypted at the database level remain encrypted and therefore protected when exported. With respect to non-encrypted information, the need to obfuscate it for added protection depends on how the exported data is intended to be used. If the exported information is part of an integration flow with an external system then the data should remain unchanged. However, when exporting data from a production environment for testing purposes sensitive information should be anonymized before they can be imported to a lower environment.

The following are key aspects of this functionality:

- Redaction rules define how specific fields should be redacted when exported.
- When redaction rules exist, data redaction is performed by default by specific export tools. In absence of redaction rules, data is exported in its original form.
- Redaction rules are customer specific and may only be relevant to environments that contain sensitive data. As such, they are not released with the base product. Review your data redaction requirements and configure appropriate rules in relevant environments.
- Certain users may be allowed to export data in a non-redacted form based on application security.

The following sections provide additional information about this topic.

Redaction Rules Are Customer Specific

Redaction rules identify which fields should be redacted and how they should be anonymized. The list of fields to redact and the function to use to manipulate their values are customer specific and therefore are not released with the base product. A sample set of rules are provided as accelerator data for reference only.

It is important that you review your data redaction requirements and configure rules that reflect your business needs.

Redaction By Default

Processes that support data redaction on export do so by default when redaction rules exists. When rules are not defined, data is exported as is. Note that for this reason it is unnecessary to define such rules in lower environments that do not contain sensitive information.

Specific Export Tools Only

Data redaction is supported by the following export tools only:

- **Content Migration Assistant (CMA).** Depending on application security, a user may indicate on a specific data set export request that data should be exported in its original form.
- **General Data Export (GDE) batch processes.** A batch parameter may be used to explicitly request that data is exported in its original form. This option is also protected by application security and enforced at batch submission time.

NOTE: This type of process establishes a single export stream that may be sent to multiple targets. Review these integrations to ensure they do not have conflicting data redaction requirements and set the batch parameter accordingly.

Different Types of Redaction Rules

Sensitive information may reside in various types of storage fields which impact the way they are identified for redaction. You may define rules that target fields on specific tables or provide a more global rules that applies to all references of a specific field.

The application supports the following types of reduction rules:

- **Physical Field.** This type of rule applies to a value residing in a field on a specific table. An optional filter expression may be provided when only records of a certain type needs to be redacted.
- **XML Storage.** This type of rule applies a value associated with the specified field name that resides within an XML storage field on a specific table. This option also supports a filter expression.
- **Reference Field.** This type of rule applies to a value residing anywhere and associated with the specified field name. It does not include fields referenced in XML storage fields.

Redaction Function

A redaction function defines the format by which a value is anonymized. The type of function used depends on the field's data type. For example, to anonymize a numeric field the redaction function should only use numeric values etc.

Refer to the **Redaction Function** extendable lookup for a list of available functions. The base product provides a sample of common functions but the list may be extended by your organization as needed.

Fields May Contain Sensitive Information

The field definition record includes an indication as to whether the field may contained sensitive information or not. Note that the indication does not imply that the field is actually used to capture such data but rather that it can potentially be used this way. Use this indication to review fields that may need to be associated with a redaction rule.

Exporting Non-Redacted Data Requires Security Rights

By default, the aforementioned export tools redact data by default based on existing redaction rules. There are situations where certain users may be allowed to export data in its original form, i.e. request to not apply the redaction rules.

The following points briefly describe the above illustration:

- Some processes always export data as is, i.e. the target consumer needs the raw data. This is irrespective of the user requesting the export.
- Some processes perform data redaction by default and may offer an option for exporting data as is. The option to export data in its original form is secured by application security.

- In this example, process A supports data redaction by default with an option to export non-redacted data. User A has the right to export the data redacted (default) or explicitly request to export it in its original form. User B does not have the right to do so hence their export content is redacted by default.

The option to export data in its original form is associated with the **Do Not Apply Redaction Rules** access mode associated with the following relevant application services:

- For CMA, the additional access mode is associated with the migration data set export's application service. When granted, the user may select the special non-redacted export option when they create the export data set request.
- For GDE batch processes, the access mode is associated with their application service and is tied to the **Do Not Apply Redaction Rules** batch parameter they support. Only users with the proper application security can submit these batches using the special batch parameter option

Defining Redaction Rules

This portal is used to view and maintain rules that define how specific fields that containing personal information should be redacted when exported out of the application. For example, an e-mail address may be redacted by replacing some or all characters with '*'.

Refer to [Data Redaction on Export](#) for more information.

You can access the portal from the **Admin Menu > Security > Redaction Rule**. You are brought to a query portal with options for searching for a specific redaction rule. Once a redaction rule has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rule.** This zone provides information about the selected rule.

Obfuscation Configuration

This portal is used to view and maintain all configuration options related to personal information obfuscation. It includes all masking, encryption and data redaction rules.

You can access the portal from the **Admin Menu > Security > Obfuscation Configuration**.

Refer to [Encryption and Masking](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rules.** This zone lists all redaction rules. You may add a new rule from this zone.
- **Masking.** This zone lists masking options. You may navigate to the masking related feature configuration to review and edit these options.
- **Encryption.** This zone lists encryption options. You may navigate to the encryption related feature configuration to review and edit these options.
- **Review Fields for Redaction Rules.** This zone lists fields that may contain personal identifiable information and are not associated with a redaction rule. Review these fields and add redaction rules when applicable.

Cryptography Keys

Often when communicating information with an external system, cryptography keys are used to exchange encrypted information or confirm that the two communicating parties recognize each other and the information being provided.

The following sections include information about the functionality provided to support this type of security.

Understanding Key Rings

Cryptography keys may be used to provide a signature or credentials to a request so that the system recognizes that the request comes from a trusted party. Keys may also be used to encrypt or decrypt files shared between two parties.

The Key Ring object is provided to reference the keys that are used over time for a given business use case. Only one key or key pair may be active at any given time.

The following sections include information about the functionality provided to support different key ring classes for particular use cases.

RSA Signature Keys

RSA signature key pairs are used in the following cases:

- Certain processes in the system may need to write files to or read files from Oracle Cloud Object Storage. Cloud object storage has its own method for encrypting files, and products using the framework application do not need to define additional configuration for that. However, when communicating with cloud object storage, the application is required to provide a signature key.

Refer to [External File Storage](#) for more information about configuring the system to connect to cloud object storage.

- Customers may need the ability to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal. A signature key is required to support secure communication with the endpoint.

Refer to [User Redirection](#) for more information about configuring the system to enable this type of redirection.

The product provides an RSA Signature Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party.
- Viewing the public key, allowing a user to copy it to register it with cloud object storage.
- Activating the new key pair (to be done after registering the new public key).
- Inactivating an expired key.
- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.

OAuth Keys

The system provides support for sending messages secured by OAuth authentication. To deliver the message, the application is required to provide a client ID and secret. The OAuth secret is sensitive data and needs to be stored securely in the application. The Message Sender configuration provides the ability to store the client ID and an encrypted secret directly in the sender context. Alternatively, the sender context can refer to a key ring that stores those details. Using a key ring allows users to apply new secrets over time without having to update the affected message sender configurations.

Refer to [Message Sender - Context](#) for more information about configuring a message sender for OAuth security.

The product provides an OAuth Keys business object that supports the following functions:

- Defining the external system related to the key ring
- Adding a client ID and secret key. The secret key is stored in an appropriate "secret store".
- Key rotation. For increased security, a new secret key may be entered periodically. The new key automatically becomes the active key.

File Encryption and Signing Keys

For security, files exchanged with third parties may be encrypted, digitally signed or both. This requires the sender and recipient to maintain public/private key pairs and share public keys. The product supports the maintenance and generation of public and private keys in a format suitable for encryption using PGP standards.

The following sections provide additional information about encryption keys.

Encryption Key Pairs

Internal encryption key pairs are used in the following cases:

- Creating a digital signature for an extract file. The signature is encrypted with the private key of the key pair and decrypted by the recipient using the shared public key .
- Decrypting an import file. The expectation is that the sender has encrypted the file data using a temporary key. The temporary key is encrypted using the shared public key and decrypted using the private key.

The product provides an Encryption Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party. Both keys are in formats suitable for PGP encryption.
- Viewing the public key, allowing a user to copy it to register it with third parties.
- Activating the new key pair (to be done after sharing the new public key).
- Inactivating an expired key.
- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.

Public Encryption Keys

External public encryption keys are used in the following cases:

- Verifying the signature of an imported file. The signature is decrypted using the public key provided by the sender.
- Encrypting an extract file. The batch file adapters create a temporary key which is used to encrypt the file data. The temporary key is encrypted using the public key provided by the recipient

The product provides a Public Encryption Key business object that supports the following functions:

- Defining the external system and reference ID related to the key ring.
- Adding a public key to the key ring. The product expects the public key to be in a format suitable for PGP encryption.
- Viewing the public key.
- Inactivating an expired key.
- Key rotation. When new public keys are provided by the external system, the previously active key is set to expiring status. It may be manually inactivated after all messages using that key have been processed.
- Deactivating all keys for the key ring.

Defining Key Rings

Refer to [Understanding Key Rings](#) for an overview of key ring functionality.

To maintain the key rings applicable to your product or implementation, open **Admin > Security > Key Ring**.

This is an [All-in-One portal](#) and includes the standard List and display zones for a key ring.

The information captured on the key ring depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Key Zones

The key zones provide information about the keys that are associated with the key ring. The zones displayed and the available actions depend on the type of key. Refer to embedded help for more information.

Key Rotation

For internal keys, it is recommended to practice key rotation and generate new keys periodically. New key pairs are generated in the **Pending** state. The user should register the public key of the new key pair with the associated third party. Once that is done, the new key should be activated.

For external keys, new public keys are added in the **Active** state. The previously active key is set to **Expiring** and may be inactivated when no further processing needs to refer to it.

User Interface Tools

This section describes tools that impact many aspects of the user interface.

Understanding Portals and Zones

A portal is a page that is comprised of one or more information zones. The base product pages are built using either a fixed page metaphor or using portals and zones.

There are three broad classes of portals:

- **Standalone.** Standalone portals are separate pages where the main tab of the page is built using a portal. These pages are opened using any of the standard methods (e.g., by selecting a menu item, by selecting a favorite link, etc.). Additional tabs for a stand-alone portal may be included using tab page portals.
- **Tab Page.** These types of portals cannot be attached to a menu. They simply define the zones for a tab on a standalone portal.
- **Dashboard.** The dashboard portal is a special portal that appears in the [Dashboard Area](#) on the user's desktop. Its zones contain tools and information that exist on the user's desktop regardless of the transaction. There is only one dashboard portal. This portal and several zones are delivered as part of the base-package. Your implementation can add additional zones to this portal. Please contact customer support if you need to add zones to the dashboard portal.

The contents of this section describe general information about portals and zones.

Portal Page Structure

A portal page has a main tab and may have additional tabs. The page is constructed by first creating a **Standalone** portal, which is also the main portal, followed by creating a **Tab Page** portal for each additional tab and linking it to the main portal. Content is organized on each tab using independent zones.

The entire page is secured by the single application service associated with the main portal.

Portals Are Made Up of Zones

A portal is a page that contains one or more zones, and each zone contains data of some sort. All zones reference a **Zone Type**. The zone type controls the behavior of the zone and the parameters available to configure the zone.

Not All Zones Make Up Portals

Zones may or may not be associated with a portal. The following describes additional uses of zones:

- A data explorer type of zone may implement a search for an entity on an input user interface map. These zones may be referenced on a FK reference record or directly referenced on a UI map.
- A data explorer type of zone may implement a Business Service. The latter may be used for an internal process or used to build a user interface dropdown.
- A zone may be defined as a **Context Sensitive Zone** that appears on the Dashboard when a specific page or portal is in context. This type of zone is not linked to the Dashboard portal but associated with the context page or portal's navigation key.

Configuring Zones for a Portal

The portal includes configuration of how the zones should appear on the portal by default. This includes the following options, all of which may be overridden by an implementation.

- The order in which the zone should appear. An implementation may configure an override sequence to change the order zones on a base delivered portal.
- Whether the zone is visible on the portal. Zones delivered in the base product should be configured to be visible. But an implementation may override this if desired.
- Whether the zone should display initially collapsed or not. A zone's data is only retrieved when it is expanded. As such, a zone may be configured to be initially collapsed when the data is not needed very often. A user can expand the zone when the information is required. Implementations may change the collapsed setting of a base product portal / zone. Refer to [Zones May Appear Initially Collapsed When a Page Opens](#) for more information.

Flexible Layout Control

By default a zone spans the full width of the portal's display area but can be configured in a number of ways using the layout control features on the portal.

These features allow portal designers to have finer-grained control over how zones are laid out, and enables them to achieve a better user experience and a more optimal layout that reduces unused space.

The following highlight key layout control options:

- In addition to the standard half and full width options, 1/4, 3/4, 1/3 and 2/3 width options are also available.
- Better handling of zones that are dynamically hidden by a visibility script. When a zone becomes invisible its space may be reclaimed by a next zone as long as it is of same width or smaller.
- A zone may define the beginning of a new row. This indication allows for a more fixed layout that is not impacted by hidden zones. The new row indication may establish a layout of one, two or three zones displayed vertically.
- Support the following zone height options:
 - **Content (Unlimited Height)** lets the height be determined by content.
 - **Content (Limited Height)** lets the height be determined by content up to a specified maximum limit. This option may be used to achieve a more consistent portal layout, especially when a zone is rendered on long or small devices.
 - **Fixed Height** sets the zone at a specific height regardless of content.
This option too may be used to achieve a more consistent portal layout.
- When a height option is not explicitly selected, zone height is unlimited and determined by content. However, for a data explorer zone, the results grid area itself (not the entire zone) is limited by the zone parameter "height of report" (which has a default value of 50%).

User Preferences

A **Standalone** portal includes configuration to indicate whether or not the portal should appear on a user's portal preferences. The portal will not appear on the user's portal preferences if the **Show on Portal Preferences** setting is set to No. Note that an implementation may change this value for a product delivered portal. This setting is typically enabled for

a portal that provides disparate information where not all zones are applicable to all users or where users may wish to adjust the order of the zones. An example of a portal enabled for portal preferences is the Dashboard portal.

The user can override zone oriented configuration for the portal:

- Which zones appear on that portal
- The order in which the zones appear
- Whether the zones should be initially collapsed when the portal opens.
- The refresh seconds. This is applicable to zones displaying data that changes often.

An implementation can optionally configure the system to define portal preferences on one or more "template" users. When a template user is linked to a "real" user, the real user's preferences are inherited from the "template" user and the "real" user cannot change their preferences. Some implementations opt to work this way to enforce a standard look and feel for users in the same business area.

Refer to [User — Portal Preferences](#) for more information about how users configure their zones.

Removing Zones From Portal

You cannot remove a base product zone from a base product portal. An implementation may override the **Display** setting to prevent a zone from displaying on the portal. In addition, you cannot remove a zone if a user has enabled it on their portal preferences. To remove a zone from the portal list, first make sure that no user has it enabled in their portal preferences.

Granting Access to A Portal

An [application service](#) is associated with each portal. A user must be granted access rights to the respective application service in order to see a portal.

When you add a new **Standalone** portal, the system automatically creates its application service behind the scenes and displays it as part of the portal definition. You'll need to use this application service to grant access to the portal. **Tab Page** portals do not have separate security access. If a user has access to the main stand-alone portal, then the user will have security access to all its tabs.

Please note the following in respect of how application security impacts a user's portals:

- A user's [Portal Preferences](#) page only shows the portals configured to show on user preferences and where they have security access.
- The system's menus only show portals to which a user has security access.
- Users can set up favorite links to all portals, but they must have security rights to the portal's application service in order to invoke the favorite link.

Granting Access to Zones

An [application service](#) is associated with each zone. A user must be granted access rights to the respective application service in order to see a zone on a portal. Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

Please note the following with respect to zone application security:

- For most base product portals, all the zones for all the portals reference the same application service that is used to grant access to the portal. In other words, if the user has access to the page, then the user has access to all the zones on all portals for the page. There may be exceptions to this rule for certain portals.
- For a base product multi-query zones, typically the individual query zones and the multi-query zone reference the same application service that is used to grant access to the main (standalone) portal for the page. However, there may be individual query zones provided with a unique application service. This may occur when the query option is unusual and not applicable to all users or even to all implementations. If a user does not have security access to an individual query zone, that option will not be available in the dropdown.

- For base product portals that are configured to show on portal preferences, it is common that the portal contains different types of zones that may be applicable to different types of users. Typically these types of portals will deliver a unique application service for each zone so that an implementation may configure which user groups are allowed to view each zone. For these types of portals, please note the following:
 - A user's [Portal Preferences](#) page contains a row for a zone regardless of whether the user has access rights to the zone. Because of this, the system displays an indication of the user's access rights to each zone.
 - If a user's access rights to a zone are revoked, the zone will be suppressed when the user navigates to the respective portal.
 - Revoking a user's access rights does not change the user's [portal preferences](#) (i.e., a user can indicate they want to see a zone even if they don't have access to the zone - such a zone just won't appear when the respective portal appears).

Putting Portals on Menus

When you add a new **Standalone** portal, the system automatically creates its navigation option behind the scenes and displays it as part of the portal definition. You'll need to use this navigation option to add the portal to a menu or to allow any other type of navigation method to the portal.

To add a portal to a menu, you must add a [menu item](#) to the desired menu and reference the portal's navigation option on the new menu item. A portal's navigation option can appear on any number of menu items (i.e., you can create several menu items that reference the same portal).

Your users can set up their preferences to include the portal's navigation option on their [Favorite Links](#). This way, they can easily navigate to the portal without going through menus.

Portal Options

Various portal features are controlled by configuration options, such as the ability to include additional applicable actions on the portal's actions bar or the ability to include the standard information description of the maintained entity as part of the portal's title.

NOTE: You can add new option types. Your implementation may want to add additional portal option types. To do that, add your new values to the customizable lookup field **PORTAL_OPT_FLG**.

Setting Up Portals and Zones

The topics in this section describe how to set up portals and zones. Please refer to [The Big Picture of Portals and Zones](#) for background information.

Defining Zone Types

A Zone Types represents a particular type of zone with a specific behavior. For example, a data explorer zone type is used to select data using a specific SQL statement and display the data based on parameter configuration. The zone type defines the Java Class that controls the behavior of the zone and defines the parameters that the Java Class supports. The base product supports many zone types used to build the portal / zone user interface. Implementations may introduce their own zone types.

NOTE: It is not very common for an implementation to introduce their own zone types.

Select **Admin > System > Zone Type** to maintain zone types.

Description of Page

Specify an easily recognizable **Zone Type** code and **Description**. Use the **Detailed Description** to describe in detail what the zone type does.

CAUTION: When adding new zone types, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Owner indicates if this zone type is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a zone type. This information is display-only.

Java Class Name is the Java class responsible for building the zone using the parameters defined below.

Two types of parameters are specified when defining a zone type:

- Parameter values that have a **Usage of Zone** are defined on the zones and control the functionality of each zone governed by the zone type. A **Usage** value of **Zone - Override Allowed** indicates that an implementation may override the parameter value for a base zone.
- Parameter values that have a **Usage of Zone Type** are defined directly on the zone type and control how the zone type operates (e.g., the name of the XSL template, the name of the application service). A **Usage** value of **Zone Type - Override Allowed** indicates that an implementation may override the parameter value for a base zone type.

The following points describe the fields that are defined for each parameter:

- **Sequence** defines the relative position of the parameter.
- **Parameter Name** is the name of the parameter.
- **Description** is a short description that allows you to easily identify the purpose of the parameter.
- **Comments** contain information that you must know about the parameter or its implementation. For parameters with a usage of **Zone** or **Zone - Override Allowed**, this information is visible to the user when viewing or defining this parameter for a zone of this type.
- **Usage** indicates whether the parameter value is defined in a **Zone** of this type or in the **Zone Type**. **Zone - Override Allowed** and **Zone Type - Override Allowed** indicate that override values for the parameters defined in a base zone or base zone type can be entered.
- **Required** is checked to indicate that a zone must define a value for the parameter. It is not checked if a value for the parameter is optional. This field is protected if the **Usage** is **Zone Type** or **Zone Type - Override Allowed**.
- **Parameter Value** is used to define the value of zone type parameters. This field is protected if the **Usage** is **Zone** or **Zone - Override Allowed**.
- **Owner** indicates if this parameter is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a parameter. This information is display-only.

Zone Type Parameter Comments

For the product owned zone type parameters, the parameter's detailed description provides the detail needed for properly configuring the parameter. For the Action parameters (IMPLEMENTOR_ACTION_n), the parameter description is abbreviated. Additional detail about configuring this parameter may be found in the [Zone Action Parameter](#) detailed information. The same details apply.

Defining Zones

This portal is used to view and maintain the configuration of a zone. Implementations may define custom zones or override the descriptions and some parameter values for base product zones.

You can access the portal from the **Admin Menu > System > Zone**. You are brought to a query portal with options for searching for a specific zone. Once a zone record has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Understanding Portals and Zones](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Zone.** This zone provides general information about the selected zone.
- **Query Options.** This zone maintains the list of query options for a Multi-Query zone. The zone is only visible for Multi-Query zones.
- **Filters.** This zone maintains various zone parameters that handle filtering options for a data explorer zone. The zone is only visible for data explorer zones.
- **General Parameters.** This zone maintains various general purpose zone parameters for a data explorer zone.
- **SQLs.** This zone maintains individual SQLs and their related parameters. The zone is only visible for data explorer zones.
- **SQL Configuration.** This zone maintains all the zone parameters related to a specific data explorer SQL. The zone is only visible when a specific SQL is broadcast from the **SQLs** zone.

The following zones may appear as part of the portal's **References** tab page

- **Zone References.** This zone list various configuration entities referencing the current zone.

Overriding Parameter Values

Implementation teams may override the value of selected types of base provided zone parameters. The override parameter value field for base owned zone parameters is only enabled when the related zone type parameter usage is **Zone - Override Allowed**.

For multi-query zones, you may use the override parameter value to add custom query options to a base product owned zone.

Overriding Zone Parameters

Implementations may override the value of a base owned zone parameter only if the zone type definition allows such override. The override parameter value is enabled for a specific base owned parameter when the related zone type parameter usage is set to **Zone - Override Allowed**.

You may use the override parameter capability to provide alternative or additional custom query options for a base owned multi-query zone.

Zone Parameter Details

For most zone parameters, the embedded help for the parameter provides the detailed information needed for configuring the parameter values. For some parameters with very detailed descriptions, the embedded help is abbreviated and more detail is provided here.

Zone Visibility Service Script

All zones support a visibility script that is used to determine if the zone should be displayed to the user or not based on conditions. The script may receive input parameters and is expected to return a Boolean value indicating if the zone should be displayed or not. The embedded help for the **Zone Visibility Service Script** parameter provides details related to the syntax.

The following table highlights some service scripts provided by the product that may be used if applicable to your zone's requirements. This is not an exhaustive list of visibility scripts. There may be others that are specific to a given zone.

Script Code	Description	Comments
F1-ShldShwZn	Zone Visibility - Display Zone in Portal	This script simply returns a value of 'true' and is used when the zone should always appear.
F1-CondShwZn	Zone Visibility - Display Zone in Portal Conditionally	This is used when the condition for showing the zone is based on the population of a context value. This is commonly used when one zone in the portal should only appear after a broadcast of a record from another zone in the portal. For an example of a zone the uses this visibility script, refer to F1-BSFTYPE .
F1-RwCtShwZn	Zone Visibility - Based on Row Count	This is used when the condition for showing the zone is based on the existence of one or more rows that can be determined using SQL. This script accepts a zone code, user filters 1 through 25 and hidden filters 1 through 10. The script returns an indication of 'true' if at least one row count is returned by the zone. To use this visibility script, a specific data explorer zone must be developed for the specific use case. For an example of a zone the uses this visibility script, refer to F1-MIGREQEL .

SQL Statement

Data explorer zones are used to select data to display using one or more SQL statements. The SQL parameters are applicable to the following zone types

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**). The parameter has the description **SQL Statement**.
- Info Data Explorer - Multiple SQLs (**F1-DE**). The parameters follow the description pattern of **SQL Statement x**.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**). The parameters follow the description pattern of **SQL Statement x**.

NOTE: If your implementation has been configured to restrict the functions that may be used when defining an SQL then an error is issued at runtime if there are functions found that are not in the allowlist. The allowlist may be viewed using the **View SQL function allowlist** link in the Tips zone on the zone maintenance page.

NOTE: Zone SQL should take care not to use the following reserved keywords for the table alias. (For example, the table alias in this SQL is 'XX': SELECT 'X' FROM W1_ACTIVITY_TYPE XX.)

Keyword

AT

The following table provides a list of SQL substituted keywords that may be used in the SQL Statement parameters in explorer zones. At execution time, the system determines the database and substitutes the keyword with the database specific syntax:

Keyword	Description	Examples
@toCharacter()	Converts the input to Character data type.	select @toCharacter(batch_cd) as batchCode from ci_batch_ctrl
@toDate()	Converts the input to Date data type.	select @toDate(last_update_dttm) as lastUpdateDate from ci_batch_ctrl

Keyword	Description	Examples
@toNumber()	Converts the input to Number data type.	select @toNumber (next_batch_nbr) from ci_batch_ctrl
@currentDate	Fetches the current date. CAUTION: The Oracle functions SYSDATE and CURRENT_DATE should not be used because they do not properly cater for adjusting dates from the database time zone to the installation time zone, if needed.	select batch_cd, @currentDate as today from ci_batch_ctrl
@currentTimestamp	Fetches the current date / time. CAUTION: The Oracle functions SYSTIMESTAMP and CURRENT_TIMESTAMP should not be used because they do not properly cater for adjusting the date / time from the database time zone to the installation time zone, if needed.	select batch_cd from ci_batch_ctrl where last_update_dttm > @currentTimestamp
@concat	Combines the result list of two or more columns.	select batch_cd @concat next_batch_nbr concatNbr from ci_batch_ctrl
@substr(string, start)	String is the input String that you are trying to get a substring of. Start is the position of the character for the output results.	select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select @substr (batch_cd,3) batchCode from ci_batch_ctrl Result: STCD
@substr(string, start, end)	String is the input String that you are trying to get a substring of. Start is the position of the character for the output results. End is the number of characters required in the output from starting position.	Select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select @substr (batch_cd,3,2) batchCode from ci_batch_ctrl Result: ST
@trim	Trims the white spaces of the output on both sides.	select @trim (batch_cd) as batchCode from ci_batch_ctrl
The following syntax is related to 'fuzzy' searching. It is only applicable if Oracle DB Text is enabled and a context text index has been created. Refer to Advanced Search Options for more information.		
@fuzzy(string, score, numresult, 'weight')	String is the input value for the search. Score is the degree of 'fuzziness'. Valid values are between 1 - 80. The higher the number the more precise the search. Default is 60. Numresults is the number of variations to consider for the string. Valid values are between 1 and 5000. Default is 100. Indicate 'weight' to signal that the results are returned in order of weight. Leave this setting off to indicate that the results are returned in order of score.	Set score to 70, number results to 6, and specify weight. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6, 'weight')) > 0
@fuzzy(string)	This returns a string result from the fuzzy expansion operation where the default value of 60 is assumed for the score and the default value of 100 is assumed for the numresult .	To use default values: select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1))> 0
@fuzzy(string, score)	This returns a string result from the fuzzy expansion operation with the score specified and the default value of 100 for the numresult .	Set score to 70. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70)) > 0
@fuzzy(string, score, numresult)	This returns a string result from the fuzzy expansion operation with the similarity score and the numresults specified.	Set score to 70, number results to 6. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6)) > 0

Column Parameters

Data explorer zones are used to select data to display using one or more SQL statements. For each SQL statement, the zone may configure up to 20 Columns that contain the formatting definition for displaying the output data.

These parameters are applicable to the zone types

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**). The parameters follow the description pattern of **Column x**.
- Info Data Explorer - Multiple SQLs (**F1-DE**). For this zone type, all SQLs are executed and the zone displays a union of all the results. The parameters follow the description pattern of **Column x for SQL y**. There are some mnemonics that do not make sense to differ within rows of the same column. For example, the column label. For these mnemonics, only the value in SQL 1 is considered for that column. The table below indicates which mnemonics follow this rule.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**). For this zone type, only one SQL is executed. The **SQL y Condition** parameter may be used to control this. The system will execute the first SQL whose condition is satisfied (or with no condition populated). The parameters follow the description pattern of **Column x for SQL y**.

The following sections describe the various types of mnemonics.

Contents

- [Source Mnemonics](#)
- [Formatting Mnemonics](#)
- [Click Mnemonics](#)
- [Common Use Cases](#)

Source Mnemonics

This table describe the mnemonics that control how the data in a column is derived.

Mnemonic	Description	Valid Values	Comments
source=	Defines how the column's value is derived.	SQLCOL	Indicates that the source of the column's value comes from a column in the SQL statement. This type of column must also reference the sqlcol= mnemonic.
BO			Indicates that the source of the column's value comes from a business object . This type of column must also reference the bo= , input= and output= mnemonics to define how to interact with the business object.
BS			Indicates that the source of the column's value comes from a business service . This type of column must also reference the bs= , input= and output= mnemonics to define how to interact with the business service.
SS			Indicates that the source of the column's value comes from a service script . This type of column must also reference the ss= , input= and output= mnemonics to define how to interact with the service script.

Mnemonic	Description	Valid Values	Comments
		FORMULA	Indicates that the source of this column's value is calculated using a formula. This type of column must also reference the formula= mnemonic.
		SETFUNC	Indicates that the source of this column's value is calculated using a superset of values from the rows in the SQL statement. This type of column must also reference the setfunc= mnemonic.
		ICON	Indicates that the source of this column's value is a display icon reference (meaning that an icon will be displayed in the column). This type of column must also reference the icon= mnemonic to define the icon reference. NOTE: When using this source mnemonic, the formatting mnemonic type= is not applicable.
		FKREF	Indicates that the source of this column's value is an FK reference (meaning that the FK reference's context menu and information string will be displayed in the column and will be enabled for navigation). This type of column must also reference the fkref= and input= mnemonics to define how the FK reference is called. NOTE: When using this source mnemonic, the formatting mnemonic type= is not applicable. NOTE: To show a foreign key's information but not enable navigation, refer to Common Use Cases for the recommended technique.
		SPECIFIED	Indicates that the source of this column's value is specified by concatenating literals and other column values. This type of column must also reference the spec= mnemonic.
		MSG	Indicates that the source of this column is a message from the message table (along with any

Mnemonic	Description	Valid Values	Comments
			substitution variables). This type of column must also reference the msg= mnemonic.
sqlcol=	Defines the column in the SQL statement when source=SQLCOL .	COLUMN_NAME	Enter the name of a column that is retrieved in the SELECT statement. Note that if the select statement uses an alias for a column, then the alias should be referenced here.
		x	Where x is an integer value that references a column by its relative position in the SELECT statement. For example, sqlcol=3 would display the 3rd column in the SELECT statement).
bo=	Defines the business object to invoke when source=BO . This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the business object.	'Business Object Code'	
bs=	Defines the business service to invoke when source=BS . This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to/received from the business service.	'Business Service Code'	
ss=	Defines the service script to invoke when source=SS . This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the service script.	'Service Script Code'	
fkref=	Defines the FK reference used to retrieve the column's information when source=FKREF . This mnemonic must be used in conjunction with the input= mnemonic to define how information is sent to the FK reference to build the information.	Cx COLUMN_NAME 'FK Reference Code'	This means FK reference code is defined in an earlier column. For example, define C1 if column 1 defines the FK reference value. This means the FK reference was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause. This means the FK Reference is defined directly. For example 'F1-ROLE'.
formula=	Defines the formula to use when source=FORMULA . Examples:	The formula can contain numeric constants, operators and column references.	For column references, use the format Cx where x represents the column number.

Mnemonic	Description	Valid Values	Comments
	<ul style="list-style-type: none"> • formula=C1*.90/C2 • formula=(C1/C2)*100 		Refer to Expression Parser for information about the functions supported.
setfunc=	Defines the function to apply to the rows of a given column when source=SETFUNC .	function(Cx)	<p>Where Cx represents a column whose rows should have the function applied and the function is one of the following:</p> <ul style="list-style-type: none"> • MAX. This derives the maximum value of all rows in the column. • MIN. This derives the minimum value of all rows in the column. • TOT. This derives the sum (total value) of all rows in the column. • ACC. This derives the cumulative total of all rows up to an including the current row.
input=	<p>This is used to define one or more input fields and values passed to business objects, business services, service scripts, and FK references.</p> <p>The syntax is as follows: [ELEMENT_NAME=ELEMENT_REF ELEMENT_NAME=ELEMENT_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the ELEMENT_NAME, which is the name of the element / field in the target. ELEMENT_REF is the value passed in. The next column indicates the possible values for ELEMENT_REF.</p>	<p>Cx</p> <hr/> <p>COLUMN_NAME</p> <hr/> <p>'literal value'</p> <hr/> <p>userTimeZone</p> <hr/> <p>installationTimeZone</p>	<p>Where Cx represents the value of a previous column. If the value to pass is in the first column, reference C1.</p> <hr/> <p>This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <hr/> <p>This means a literal value within the single quotes should be passed in.</p> <hr/> <p>This means the current user's time zone should be passed in. This is typically used with the business service F1-ShiftDateTime to convert data in the storage time zone to the user's time zone for display.</p> <hr/> <p>This means the installation time zone should be passed in. This is typically used with the business service F1-ShiftDateTime to convert data in the storage time zone to the installation time zone for display.</p>
		<p>Examples:</p> <ul style="list-style-type: none"> • input=[USER_ID=C1] • input=[USER_ID=USER_ID] • input=[input/targetTimeZone=userTimeZone] 	
output=	This is used to define the name of the element retrieved from the business object, business service or service script used to populate this column.	elementName	Example: output=personInfo

Mnemonic	Description	Valid Values	Comments
pagingkey=	<p>This mnemonic is only applicable when the Enable Paging parameter has been configured. It indicates that this column is one of the keys used by the SQL statement to orchestrate paging through results. This mnemonic can only be specified when the source=SQLCOL.</p> <p>FASTPATH: Refer to Pagination Configuration for more information.</p>	<p>Y</p> <p>N</p>	<p>This is the default, meaning that you don't need to indicate pagingkey=N at all to indicate that the column is not one of the paging keys.</p>

NOTE: If multiple columns are configured with the same source BO, BS or SS and the same input data, the system caches the output from the first call and reuses the results for subsequent columns.

Formatting Mnemonics

This table describe the mnemonics that control how a column is formatted.

NOTE: For the **F1-DE** zone type, zone displays the union of all the different SQLs.

Mnemonic	Description	Valid Values	Comments
type=	<p>Defines how the column's value is formatted.</p> <p>NOTE: Icon and Foreign Key columns. The source=source mnemonic may be used to indicate a column should be derived from an icon reference or a foreign key (FK) reference. If you use either of these sources, the type= mnemonic is not relevant as either an icon or a context menu / info string will appear in the column.</p>	<p>STRING</p> <hr/> <p>DATE</p> <hr/> <p>TIME</p> <hr/> <p>DATE/TIME</p> <hr/> <p>MONEY</p> <hr/> <p>NUMBER</p>	<p>Columns of this type capture a string. This is the default value.</p> <hr/> <p>Columns of this type capture a date and will be displayed using the user's display profile.</p> <hr/> <p>Columns of this type capture a time (in database format) and will be displayed using the user's display profile.</p> <hr/> <p>Columns of this type capture a date and time (in database format) and will be displayed using the user's display profile.</p> <hr/> <p>Columns of this type capture a monetary field. This type of column may also reference the cur= mnemonic. If the cur mnemonic is not specified, the currency code on the installation record is used.</p> <hr/> <p>Columns of this type capture a numeric field. This type of column may also reference the dec= mnemonic.</p>
label=	<p>Defines the column's override label. The label appears in the column's heading and in the zone's drag and drop area.</p>	<p>FIELD_NAME</p> <hr/> <p>'text'</p>	<p>Enter a valid field name whose label should be used for the column label. This should always be the option used if multiple languages are needed.</p> <hr/> <p>Defines the text directly.</p>

Mnemonic	Description	Valid Values	Comments
	<p>If this mnemonic is not defined, the system uses the column's default label. The source of a column's default label differs depending on the column's source. Note that some sources don't have a default value and omitting this mnemonic will result in a blank label.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will use the column definitions in SQL 1 to define the labels.</p>		
cur=	<p>Defines the currency code applied when type=MONEY if the installation record's currency should not be used.</p>	Cx	This means currency code value is defined in an earlier column. For example, define C1 if column 1 defines the currency code.
		COLUMN_NAME	This means the currency code was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'Currency Code'	This means the currency code is defined directly. For example 'USD'.
dec=	<p>Defines the number of decimal places when type=NUMBER.</p> <p>It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.</p>	nR	<p>Where n is the number of decimal places to show. Suffixing the number of decimal places with R means that the system should round up / down. Simply specifying n (without an R) means that decimal places should be truncated. For example, entering dec=4 will display 4 decimal places and truncate the remainder.</p> <p>NOTE: Formatting only. This mnemonic is only used for formatting, it does not impact the precision used for subsequent calculations. For example, if a column retrieved from the database contains 6 significant digits and dec=0, the column will be shown with no decimal places (truncated), however any references to the column in subsequent calculations will use 6 decimal places. For example, if the column is referenced in a formula or set function, all 6 decimal places will be used.</p>

Mnemonic	Description	Valid Values	Comments
char=	<p>This mnemonic applies special character(s) to the column's value.</p>	'x[]x'	<p>Where x references the literal value to display and [] defines the relative position of the characters (before or after the value).</p> <p>You need only include the [] if you want to position characters in front of the value. For example, char='%' will place a percent sign after the value. If you want to position the word 'minutes' before a value, enter char='minutes []'. If you want to output a value like BUDGET \$123.12 (YTD), enter char='BUDGET [] (YTD)'.</p>
suppress=	<p>This is used to indicate a column should not be displayed.</p> <p>A column would be suppressed if it's only defined for use by subsequent columns, for example, if there is a formula that derives a column using two other columns. In this scenario, the columns referenced in the formula can be suppressed.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p>	<p>true</p> <hr/> <p>false</p>	<p>This is the default, meaning that you don't need to indicate suppress=false at all to indicate that the field should be shown.</p>
suppressSearch=	<p>This is used to indicate a column should not be displayed when the zone is invoked in search mode only.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p>	<p>true</p> <hr/> <p>false</p>	<p>This is the default, meaning that you don't need to indicate suppressSearch=false at all to indicate that the field should be shown.</p>
suppressExport=	<p>This is used to indicate a column should not be downloaded to Excel.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p>	<p>true</p> <hr/> <p>false</p>	<p>This is the default, meaning that you don't need to indicate suppressExport=false at all to indicate that the field should be included in a download.</p>

Mnemonic	Description	Valid Values	Comments
width=	This is used to override the width of a column (number of pixels). The default value is the maximum width of any cell in the column.	n	<p>Where n is a number between 0 and 999.</p> <p>NOTE: If there is no available breaking point in the data, the column will be longer than the specified number of pixels.</p> <p>The length of the column's label (which appears in the column's heading) may also make the width wider than specified.</p> <p>In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will set the width based on the column definitions in SQL 1.</p>
color=	This is used to override the column's text color.	A valid HTML "named" color	<p>For example color=yellow.</p> <p>NOTE: Refer to Color Contrast for information about the use of the HTML color 'red' and its impact on accessibility.</p>
		A valid RGB color model combination	<p>For example color=#E0292F or color=#CCCCCC. Note that the # is required.</p>
bgcolor=	This is used to override the column's background color.	A valid HTML "named" color	Similar to the color= mnemonic.
		A valid RGB color model combination	Similar to the color= mnemonic.
order=	Defines the column's default sort order.	ASC	<p>Indicates that the order is ascending. This is the default meaning that it is not necessary to indicate order=ASC.</p>
		DESC	Indicates that the order is descending.
rowHeader=	Designates the column as a row header for accessibility purposes.	true	<p>By default, the first data column of the data explorer results is identified as the row header, for accessibility tools. If the data in the first column does not uniquely identify the row, use this mnemonic to explicitly mark a different column or multiple columns as the row header.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will look only at the columns in SQL 1 that have this mnemonic defined and apply it to all results for those columns.</p>

Click Mnemonics

This table describe the mnemonics that define whether a column value may be clicked and if so, what should happen.

Mnemonic	Description	Valid Values	Comments
navopt=	<p>Defines the navigation option that references the target transaction or script when the user clicks a column.</p> <p>Note, this mnemonic should be used in conjunction with the context= mnemonic to define what information is sent to the navigation option's target transaction.</p> <p>This mnemonic is ignored if source=FKREF because the FK reference code defines the hyperlink's destination.</p>	Cx	This means navigation option code is defined in an earlier column. For example, define C1 if column 1 defines the navigation option.
		COLUMN_NAME	This means the navigation option was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'Navigation Option Code'	Example: navopt=MAIN_PORTAL This means the navigation option code is defined directly. For example navopt='userMaint' .
context=	<p>This is used to define one or more context fields and values passed to the target navigation option to go along with the navopt= mnemonic.</p> <p>The syntax is as follows: [FIELD_NAME=FIELD_REF FIELD_NAME=FIELD_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME, which is the name of the context field in the navigation option. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.</p>	Cx	Where Cx represents the value of a previous column. For example, if the value to pass is in the first column, reference C1 .
		COLUMN_NAME	This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'literal value'	This means a literal value within the single quotes should be passed in.
bpa=	<p>Indicates that a BPA script should be executed with the user clicks the column and indicates the BPA to execute.</p> <p>Note, this mnemonic should be used in conjunction with the tempstorage= mnemonic to define the temporary storage values that will be initiated when the script is executed.</p> <p>This mnemonic is ignored if source=FKREF because the FK reference code defines the hyperlink's destination.</p>	Cx	Indicates that the BPA script is defined in a previous column.
		COLUMN_NAME	This means the BPA script to execute was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'BPA Script Code'	This means that the BPA script to execute is defined directly.
tempstorage=	This is used to define how temporary storage variables are initiated when the bpa= mnemonic is used.	Cx	Where Cx represents the value of a previous column. For example, if the

Mnemonic	Description	Valid Values	Comments
	<p>The syntax is as follows: [FIELD_NAME=FIELD_REF FIELD_NAME=FIELD_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME, which is the name of the field in temporary storage. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.</p>	<p>COLUMN_NAME</p> <p>'literal value'</p>	<p>value to pass is in the first column, reference C1.</p> <p>This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means a literal value within the single quotes should be passed in.</p>
list=	<p>This is used to enable work list capability for this column.</p> <p>You may optionally populate the listdesc= mnemonic to override the text that will be placed in the worklist zone.</p>	true	<p>Setting list=true will cause the work list icon to appear in the column's header. If a user clicks the column, it will populate all the rows in the output into the work list zone.</p> <p>NOTE: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the output may be showing a union of the results of multiple SQL statements. In this case, if some of the SQL statements configure a given column with list=true, but not all, only the data in the cells for the statements that configure this mnemonic are put into the work list when the user clicks the icon. Also note that when determining which columns should have the worklist icon when building the zone, the system only looks at the configuration for the columns in SQL 1.</p>
listdesc=	This is an optional mnemonic when using the list= mnemonic. It can be used to override the text that is placed in the work list zone.	Cx	Where Cx represents the value of a previous column. For example, if the text to use is in the first column, reference C1 .
listbroadcast=	Indicates that the broadcast information for the column is also to be made available in the work list zone. This means that the work list can be used to broadcast information to a portal in the same manner as a data explorer.	true	Use this setting to turn on the feature.

Common Use Cases

This section provides some common configuration that can be copied and pasted for newly created zones.

Use Case	Code Snippet
<p>Displaying the description of a lookup value that has been retrieved in the SQL statement. The business service checks for an override label.</p>	<pre>source=BS bs='F1-GetLookupDescription' label=FLD_NAME input=[fieldName='FLD_NAME' fieldValue=FLD_NAME] output=description</pre>
<p>Display a foreign key with its information but suppressing the navigation. (This is useful when you have a foreign key that is additional information in a zone but would cause confusion to enable navigation. To display foreign key reference with its information and enabled for navigation, use the source of FKREF as described above.)</p>	<pre>source=BS bs='F1-GetForeignKeyReference' input=[input/fkReference=FK_REF_CD input/fkValue1=BUS_OBJ_CD] output=output/infoDescription label=DESCR</pre>
<p>The first example assumes that you know the FK Reference. The second example uses a business service that receives the maintenance object as input.</p>	<pre>source=BS bs='F1-GetFKReferenceDetails' input=[input/maintenanceObject='F1-EXT LKUP' input/pkValue1=BUS_OBJ_CD input/pkValue2=C1] output=output/infoDescription label=DESCR</pre>
<p>Display a foreign key, including a corresponding navigation link, for generic objects that may or may not have a foreign key reference. If the FK reference exists, its information is shown, otherwise not.</p>	<p>This column gets the navigation details:</p>
<p>Standard foreign key services assume all rows have foreign key details. The service script F1FKInfoOpt provides the same foreign key details but does not error when foreign key details do not exist. To build the foreign key description and link, the script needs to be used twice; one column gets the navigation details and another gets the description. The latter references the navigation details column and invokes a BPA script to perform the dynamic navigation.</p>	<pre>source=SS ss='F1FKInfoOpt' input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7] output=output/navigationOption suppress=true</pre>
	<p>This column constructs the foreign key description and link:</p>
	<pre>source=SS ss='F1FKInfoOpt' input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7] output=output/infoDescription label=F1_APPSEC_COMP_DESCR bpa='F1AsecNav' tempstorage=[navopt=C15 pkField1=C10 pkValue1=C6 pkField2=C11 pkValue2=C7] list=true</pre>

Zone Action

Most zone types provided by the product allow for one or more Zone Actions to be defined to appear in the zone header. An action can appear as a hyperlink, icon or button. The action can also be provided as an HTML string.

NOTE: Zone types also include parameters for actions defined at the zone type level using IMPLEMENTOR_ACTION_n (Action n) parameters. These are rarely used by the product zone types. The actions defined here override any actions defined on the zone type (if present). The details below apply to the zone type level actions as well.

A zone action is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
type=	This mnemonic defines the appearance of the action in the zone header.	LINK	Indicates that the action is shown as a textual hyperlink.
		ICON	Indicates that the action is shown as a graphical icon.
		BUTTON	Indicates that the action is shown as an HTML button.
		ASIS	Indicates that the parameter will provide the HTML to be used for the action.
action=	This mnemonic defines the action to take when the link/icon/button is clicked. This is ignored when the type=ASIS.	NAVIGATION	Indicates that the action is navigation to a page.
		SCRIPT	Indicates that the action is to run a BPA script.
navopt=	Defines the navigation option to use when the action=NAVIGATION .	'NAV_OPT_CD'	Enter a reference to a valid navigation option in single quotes.
bpa=	Defines the script to run when the action=SCRIPT .	'SCRIPT_CD'	Enter a reference to a valid BPA script in single quotes.
icon=	Indicates the icon to use when type=ICON .	DISP_ICON_CD	Enter a reference to a valid display icon.
		'path'	Enter an explicit path to the icon, for example 'images/gotoZone.gif'.
asis=	This is required when the type=ASIS . This provides the ability to precisely define the HTML you wish to have included in the header. All valid HTML is permitted including the use of "ora" css classes and JavaScript functions.	['HTML']	
label=	By default, the label or tooltip will come from the navigation option or BPA script description. Use this mnemonic to override that label.	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.
		'text'	Enter the text directly in single quotes.
context=[target1=source1 target2=source2]	This is used to pass context data when navigating to a page or executing a BPA script. The mnemonic supports passing multiple values. In each case the target context field or BPA script	FIELD_NAME	Indicates that the value should be taken from the field with this name from portal context, global context or the page data model. The mnemonic sourceLoc is used for defining the source.

Mnemonic	Description	Valid Values	Comments
	variable is defined first followed by an equal sign, followed by source data defined using one of the valid values defined in the next column. One or more values may be defined. Each context value is defined separated by spaces. The whole set of context values should be surrounded by square brackets.	xpath 'constant'	Indicates that the value should be taken from a schema field, represented by the Xpath, displayed in this zone. This is valid when the zone is displaying a UI Map. Indicates that the value defined in single quotes should be passed.
sourceLoc=	This mnemonic defines the source of the FIELD_NAME's value in the context mnemonic. If this mnemonic is left blank, the default behavior is as follows: - The portal context is checked. - If no portal context value is found, the global context is checked. - If neither value is available, the field is ignored.	G P D	Indicates that the field's value is retrieved from the global context. Indicates that the field's value is retrieved from the portal context. Indicates that the field's value is retrieved from the page data model.
class=	Use this mnemonic to override the look and feel of the link / icon / button using a different CSS style.	'className1' 'className2'	Enter one or more classes in single quotes. Multiple class names may be provided.
style=	Use this mnemonic to override the look and feel of the action element using the indicated css style.	Standard style= format.	All allowed css style definitions may be used.

Examples:

- **type=BUTTON action=SCRIPT bpa='F1-SET-USER' context=[USER_ID=USER_ID] label=UPDATE_LBL**
- **type=LINK action=NAVIGATION navopt='gotoUser' context=[USER_ID=path(schema/userId)]**
- **type=ASIS asis=['Search']**

NOTE: If the zone type has actions defined and there is a desire to simply remove the zone type actions, the Zone Action can be set with the following configuration: **type=ASIS asis=[]**

User Filters

Data explorer zones include the ability to define User filters to allow a user to enter data to restrict the zone's rows and / or columns. The filters may be defined individually using User Filter parameters 1–25. Alternatively, a UI map may be defined for capturing filters. In this case, the map's input fields must be associated with the zone's filters by specifying the **xpath=** mnemonic on the respective User Filter parameters.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1–DE**)
- Query Data Explorer - Multiple SQLs (**F1–DE-QUERY**)
- Info Data Explorer - Single SQL (**F1–DE-SINGLE**)

A user filter is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
name=	This mnemonic is used if the zone's filter should be pre-populated with a value from global context, portal context or broadcast from another zone.	MD Field Name	
datasource=	<p>This mnemonic defines the source of the filter's pre-populated value defined in the name mnemonic.</p> <p>If this mnemonic is left blank, the default behavior is as follows:</p> <ul style="list-style-type: none"> - If the field has been broadcast from another zone, the broadcast value is used. - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). - If still no value, the global context is checked. - If still no value, no default value is shown. 	<p>G</p> <hr/> <p>P</p> <hr/> <p>D</p>	<p>Indicates that the zone should look for the filter value in global context.</p> <hr/> <p>Indicates that the zone should look for the filter value in portal context.</p> <hr/> <p>Indicates that the zone should look for the filter value in the page data model.</p>
type=	Defines the visual metaphor used to capture the filter values.	<p>DATE</p> <hr/> <p>DATE/TIME</p> <hr/> <p>STRING</p> <hr/> <p>MONEY</p> <hr/> <p>NUMBER</p> <hr/> <p>LOOKUP</p> <hr/> <p>TABLE</p> <hr/> <p>CHARTYPE</p> <hr/> <p>ASIS</p>	<p>Filters of this type capture a date.</p> <hr/> <p>Filters of this type capture a date and time.</p> <hr/> <p>Filters of this type capture a string</p> <hr/> <p>Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic.</p> <hr/> <p>Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic.</p> <hr/> <p>Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic.</p> <hr/> <p>Filters of this type capture an administrative table's value (code and description). This type of filter must also reference the table mnemonic.</p> <hr/> <p>Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic.</p> <hr/> <p>Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement.</p>
label=	Defines the filter's label that appears in the zone's description bar and in the input area.	<p>MD Field Name</p> <hr/> <p>'text'</p>	<p>Enter a valid field name whose label should be used for the filter label. This should always be the option used if multiple languages are needed.</p> <hr/> <p>Defines the text directly.</p>
cur=	Defines the currency code applied when type=MONEY .	Currency Code	Enter a reference to a valid currency code.
dec=	Defines the number of decimal places when type=NUMBER .	Valid number	It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.

Mnemonic	Description	Valid Values	Comments
lookup=	Defines the lookup flag whose values appear when type=LOOKUP .	Lookup Field Name	Enter a reference to a valid lookup field name.
table=	Defines the admin table whose values appear when type=TABLE .	Table Name	Enter a reference to a valid control table name.
chartype=	Defines the characteristic type code whose values appear when type=CHARTYPE .	Char Type code	Enter a reference to a valid characteristic type code.
xpath=	This mnemonic is used in conjunction with a Filter Area UI Map. For each filter, you must specify the XPath to the corresponding UI map schema element.	XPath	The type= mnemonic must also be appropriate for the map's input field, otherwise the query's SQL could fail.
likeable=	This mnemonic defines if a likeable search is performed on the entered value when type=STRING .	S	The query will add % to the suffix of the filter value.
		P	The query will add % to the prefix of the filter value.
		PS	The query will add % to the prefix and suffix of the filter value.
divide=	The mnemonic controls if a divider line appears above and/or below the filter. Note, you can specify this parameter twice if you want divider lines placed above and below a filter, e.g., divide=above divide=below .	above	This results in a divider line placed above the filter.
		below	This results in a divider line placed below the filter.
searchField=	This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map.	MD Field Name	Enter the field name that exactly matches the searchField name specified in the oraSearchField HTML element in the UI map.
encrypt=	This mnemonic defines if the user filter is encrypted and needs to be searched by hashed value.	[TBL_NAME,FLD_NAME,WHERE_FLD,WHERE_VALUE] NOTE: The field name referenced here should be the source value of the field. However, the SQL should use the hashed value in its filter.	A valid table name and field name are required. The WHERE_FLD and WHERE_VALUE are optional, but if entered, both are required. Use this to only encrypt the field if another field has a certain value. The following is an example. encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_NBR,'SSN'] . The WHERE_VALUE may also reference another filter. The following is an example. encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_NBR,F1] .

Examples:

- **label=F1_NBR_DAYS type=NUMBER**
- **label=F1_SHOW_ALL_REQ_FLG type=LOOKUP lookup=F1_SHOW_ALL_REQ_FLG**
- Filter value where a Filter UI Map is defined and Description is one of the filters. **type=STRING xpath=description likeable=S**
 - **type=STRING label=DESCR likeable=S divide=below**
 - **label=REQ_TYPE_CD type=TABLE table=F1_REQ_TYPE**

Hidden Filters

Data explorer zones include the ability to define Hidden filters to restrict the rows and / or columns that appear in the zone. The following are the potential sources of a hidden filter's value:

- The global area contains the fields whose values are maintained in [global context](#).
- The portal area contains the fields describing the object currently displayed in a portal.
- Other zones on a portal can broadcast information to the portal area, which can then in turn be used by the zone as a hidden filter.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1-DE**)
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**)
- Info Data Explorer - Single SQL (**F1-DE-SINGLE**)

A hidden filter is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
name=	This mnemonic defines the name of the field that needs to be broadcast from other zones or populated in the portal context	FIELD_NAME	
datasource=	This mnemonic defines the source of the hidden filter's value. If this mnemonic is left blank, the default behavior is as follows: - If the field has been broadcast from another zone, the broadcast value is used. - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). - If still no value, the global context is checked. - If still no value, the zone appears as per the poprule mnemonic.	G P D	Indicates that the zone should look for the filter value in global context. Indicates that the zone should look for the filter value in portal context. Indicates that the zone should look for the filter value in the page data model.
poprule=	This mnemonic controls what happens if the hidden filter is not present.	R O	Indicates that a value for the filter is required. The zone will be set to the "empty state" and the "please broadcast" message will appear in the zone. This is the default value. Indicates that the value is optional. If no value is required, the zone is still built without that value.
type=	Defines the visual metaphor used to capture the filter values.	DATE DATE/TIME STRING MONEY NUMBER LOOKUP TABLE	Filters of this type capture a date. Filters of this type capture a date and time. Filters of this type capture a string Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic. Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic. Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic. Filters of this type capture an administrative table's value (code and description). This type of filter

Mnemonic	Description	Valid Values	Comments
			must also reference the table mnemonic.
		CHARTYPE	Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic.
		ASIS	Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement.
label=	Defines the filter's label that appears in the zone's description bar.	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.
		'text'	Defines the text directly.
cur=	Defines the currency code applied when type=MONEY .	CURRENCY_CD	Enter a reference to a valid currency code.
dec=	Defines the number of decimal places when type=NUMBER .	N	It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.
lookup=	Defines the lookup flag whose values appear when type=LOOKUP .	LOOKUP_FIELD_NAME	Enter a reference to a valid lookup field name.
table=	Defines the admin table whose values appear when type=TABLE .	TABLE_NAME	Enter a reference to a valid admin table name.
chartype=	Defines the characteristic type code whose values appear when type=CHARTYPE .	CHAR_TYPE_CD	Enter a reference to a valid characteristic type code.
searchField=	This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map.	FIELD_NAME	Enter the field name that exactly matches the searchField name specified in the oraSearchField html element in the UI map.

Multi-Select Action

This parameter defines an action to be included in the action area for multi-selection processing. Note that a multi-selection action can only be used if the Multi Select parameter has been set to YES, which causes a checkbox to appear on each row displayed. The action defined here will trigger against all rows selected by the user via the checkbox.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1-DE**)
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**)
- Info Data Explorer - Single SQL (**F1-DE-SINGLE**)

A multi select action has the following mnemonics:

Mnemonic	Description	Valid Values	Comments
script=	This mnemonic defines the script to be invoked when the action is clicked. This is required.	SCR_CD	Enter a reference to a valid BPA script or Service Script.

Mnemonic	Description	Valid Values	Comments
type=	This mnemonic defines how the action should be rendered.	BUTTON	The action is rendered as a button. This is the default.
		LINK	The action is rendered as hypertext.
		ICON	The action is rendered as a graphic icon. For this option, the icon mnemonic is required.
icon=	This mnemonic defines the icon to display when type=ICON .	DISPLAY_ICON_CD	Enter a reference to a valid display icon code.
refresh=	This mnemonic indicates how and if a refresh should occur after the script completes.	NO	Indicates that no refresh is performed. This is the default.
		ZONE	Indicates that a refresh of the zone is performed.
		PORTAL	Indicates that a refresh of the entire portal is performed.
label=	By default, the button label, link text or icon tooltip will come from the script description. Use this mnemonic to override that label.	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.
		'text'	Enter the text directly in single quotes.
list=	When executing the script, the framework builds an XML list containing information from each row selected. This list must be defined in the script's schema and referenced in this mnemonic.	listElementName	Enter a valid list element name from the script schema.
context=[elementName1=rowData1 elementName2=rowData2]	This mnemonic is used to populate the list with the appropriate information from each selected row. The mnemonic supports passing multiple values. In each case the element in the schema list is defined first followed by an equal sign, followed by information about the data used to populate the element defined using one of the valid values defined in the next column. One or more values may be defined. Each context value is defined separated by spaces. The whole set of context values	Cx	Indicates that the element should be populated with a value in the referenced column parameter.
		Px	Indicates that the element should be populated with a value in the referenced post processing parameter.
		COLUMN_NAME	Indicates that the element should be populated with a value from a column in the SQL statement.
		'constant'	Indicates that the value defined in single quotes should be passed.

Mnemonic	Description	Valid Values	Comments
	<p>should be surrounded by square brackets.</p> <p>Example of a schema:</p> <pre><schema> <accountInfo type="list"> <accountId/> <name/> <amount/> <process/> </accountInfo> </schema></pre> <p>Example of list and context mnemonics.</p> <p>list=accountInfo</p> <p>context=[accountId=ACCT_ ID name=C2 amount=P3 process='O']</p>		
class=	Use this mnemonic to override the look and feel of the action using a different CSS style.	'className1' 'className2'	Enter one or more classes in single quotes to be appended to the standard class(es). Multiple class names may be provided.
style=	Use this mnemonic to override the look and feel of the action element using the indicated css style.	Standard style= format.	All allowed css style definitions may be used.

Data Explorer Graph Configuration

For some data explorer zones, it is more effective to display the results in a graphical form such as a pie or line chart. Visualization option parameters enable the graph configuration to be integrated with the data explorer zone that retrieves the data.

The visualization option parameters support three options:

- **Grid** - displays the data in a standard data explorer grid
- **Chart** - displays the data in the form of a chart
- **Map** - provides the ability to invoke a UI Map to display the data

Up to five visualization option parameters may be specified. One of the options must be the standard grid, allowing for a maximum of four graphical options. The zone will display icons corresponding to the visualization types to allow you to switch between the various views. These icons are presented in the same order as they are defined in the parameter list.

NOTE: If the only display option is a standard grid, it is not necessary to specify the grid as a visualization parameter.

Visualization option parameters are provided on the Info Data Explorer - Single SQL (**F1-DE-SINGLE**) and Info Data Explorer - Multiple SQLs (**F1-DE**) zone types.

Visualization Option Parameter Configuration

Mnemonics are used to define the attributes for an option type within the parameter value.

For a **grid**, the mnemonic is 'optiontype=GRID'. No other mnemonics are required.

For a **map**, the mnemonics are 'optiontype=MAP map=MAP_CD schemaPath=xpath', where 'MAP_CD' is the ID of the UI Map and 'xpath' is the schema path of the UI Map. In most use cases the schema elements will match the result set from

the data explorer, in which case no schemaPath mnemonic is needed. If the UI Map schema has additional elements present, the schemaPath attribute will define the group node that the data explorer information will be copied into.

For a **chart**, the option type mnemonics is 'optiontype=CHART'. This is followed by the appropriate chart configuration attributes, which are described in the section below.

Chart Configuration

The following attributes are used to configure a graphical representation of a set of data.

The '**oraChart:**' attribute defines the type of graph to display and its general configuration. The set of configuration parameters available for this attribute are as follows:

Parameter	Values	Description
type:	pie stacked cluster line area combo	Defines the type of chart to display. Required
showLegend:	true false	Defines if the chart should have a legend displayed. Optional (default is true)
legendPosition:	left right bottom top	Defines where the legend should appear. Optional (default is right) Setting position to left or right will automatically render it vertically. Setting position to top or bottom will automatically render it horizontally.
legendBorder:	true false	Defines if the legend should display with a border around it. Optional (default is false)
depth:	true false	A value of true indicates a 3 dimensional depth for the chart. Optional (default false , which is a 2 dimensional chart)
animate:	true false	A value of true indicates that the graph should animate when displayed. Optional (default is true). When using large data sets, consider disabling animation.
dataCursor:	on off	A value of on enables hovering anywhere in the graph. Optional (default is off). It is not applicable to pie charts.
orientation:	horizontal	Defines the chart orientation. This only applies to bar, line, area, combo charts.

Parameter	Values	Description
		E.g., oraChart="type:cluster; orientation:horizontal" , defines horizontal cluster chart. Optional (default is vertical).

The **oraChartSeries** attribute defines the source information for the graph. Most charts support 5 of these attributes, with the following mnemonics:

- **oraChartSeries1**
- **oraChartSeries2**
- **oraChartSeries3**
- **oraChartSeries4**
- **oraChartSeries5**

Stacked charts support an unlimited number of series by continuing to add attributes **oraChartSeries6** and above, but beware of performance implications and memory limits when using an excessively high number of series. All attributes are identical in format and accept the same parameters, as described below.

NOTE: All the charts require **oraChartSeries1**. Stacked, Cluster and Line charts may optionally include the additional series attributes (for multiple bars/lines).

If you define multiple series, then data must be provided for all series defined. The data amounts can be 0 (zero) but they have to be present in order for the chart to display correctly.

The set of configuration parameters available for the **oraChartSeriesN** attribute are:

Parameter	Values	Description
list:	XPath value	Defines the XPath to the list in the XML that contains the data to chart. Required only for HTML definitions in UI Maps. Data explorer values are derived from the columns for the zone.
amount:	Cn Pn XPath value	Defines the element containing the amount to chart. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Required
xaxis:	Cn Pn XPath value	Defines the element containing the x-axis data. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element is specified. Required for Stacked, Cluster, Line, Area and Combo charts.
xaxisFormat:	date dateTime time localDate	Defines the x-axis data format. If it is date , dateTime or time then the value is presented in the format as defined on the user's display profile.

Parameter	Values	Description
	string	In case of localDate or string the data is displayed as is with no special formatting. Optional (Default is date).
label:	Text value	Defines the label for the amount being charted. Either this setting or labelPath: must be defined.
labelPath:	Cn Pn XPath value	Defines the element that provides the label for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Either this setting or label: must be defined.
currency:	A valid Currency code	Defines the currency code for the amount being charted. Optional.
currencyPath:	Cn Pn XPath value	Defines the element that provides the currency code for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Optional.
hoverText:	Text value	Defines the hover text for the chart element. Optional (A default hover text is always available.) Ignored if hoverTextPath: is defined. The following substitution variables are available. <ul style="list-style-type: none"> • \$label This will be replaced with the label text as determined by the label: or labelPath: setting. • \$amount This will be replaced with the amount text as specified by the amount: setting. • \$axis This will be replaced with the x-axis text. • \$% This will be replaced by the percentage "slice" of the pie or bar. • \$newline This will force a line break. <p>If the hover text defined contains any of the above values, they will be replaced by the equivalent text prior to being displayed.</p> <p>Example: "hoverText : \$label \$newline \$amount "</p>

Parameter	Values	Description
hoverTextPath:	Cn Pn XPath value	<p>Defines the element that provides the hover text for the chart element. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>The hover text in the element can utilize all the substitution functionality described above in the hoverText: description.</p> <p>Optional.</p>
type:	bar line area	<p>This attribute is used for the combo chart type only. It defines how each series on the combo chart should be presented.</p> <p>The following example defines a combo chart where one series is rendered as bars and another one as area.</p> <pre>oraChart="type:combo;" oraChartSeries1="xaxis:C3; label:C2; amount:C1;type:bar" oraChartSeries2="xaxis:C3; label:C2; amount:C1;type:area"</pre>
navOpt:	A valid Navigation Option code.	<p>Defines a navigation option to be activated when the chart element is clicked.</p> <p>Optional.</p>
navOptPath:	Cn Pn XPath value	<p>Defines the element that provides the navigation option to be activated when the chart element is clicked. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>Optional</p> <p>Note that both navOpt: and navOptPath: may be configured. The navOptPath: navigation option is processed first. If a value is found it is used, otherwise the value in the navOpt: setting is used. This means that the chart definition can include a default navigation option and a navigation option present in the data will override it.</p>
key:	Cn Pn XPath value	<p>Defines the element that contains the key field data to be used in a navigation option. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>This is required if either navOpt: or navOptPath: is defined.</p> <p>NOTE: Only one key field can be configured for a navigation option.</p>

Parameter	Values	Description
script:	A BPA script name	<p>Defines a BPA script to be activated when the chart element is clicked.</p> <p>Optional</p> <p>When a script is executed, all the elements from the chart data will be made available to the script as temporary variables.</p>
scriptPath:	Cn Pn XPath value	<p>Defines the element that provides the BPA script to be activated when the chart element is clicked. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>Optional</p> <p>Note that both script: and scriptPath: can be configured. The scriptPath: script option is processed first. If a value is found it is used, otherwise the value in the script: setting is used. This means the chart definition can include a default script and a script present in the data will override it.</p>
color:	HTML Color code / RGB value	<p>Optional (default colors applied)</p> <p>Defines the color for the series. The format is a valid HTML color code, e.g. green or blue. All valid color names are defined in this link: http://www.w3schools.com/html/html_colornames.asp.</p> <p>Alternatively an RGB format may be used. (00FF00 is green and 0000FF is blue)</p> <p>NOTE: Refer to Color Contrast for information about the use of the HTML color 'red' and its impact on accessibility.</p>
colorPath:	Cn Pn XPath value	<p>Defines the element containing a color for the series. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>The valid formats as described in the color: setting apply.</p> <p>Optional (default colors applied)</p>
pieColors:	HTML color code / RGB values	<p>Defines the colors for the pie series. Any number of HTML color codes or RGB color values can be specified, separated by spaces.</p> <p>Examples:</p> <pre>pieColors: green blue pieColors: 00FF00 0000FF</pre>

Parameter	Values	Description
		Optional (default colors are applied if the series exceeds the values specified)

The **oraChartBroadcast**: attribute provides the ability to broadcast a value from a chart to the portal context. An unlimited number of fields can be broadcast, configured as name/value pairs; for example: `oraChartBroadcast="FIELD_NAME1:C1;FIELD_NAME2:C2;"` where `FIELD_NAMEn` is the name of the portal context field to be broadcast and `Cn` (or `Pn`) is the element that contains the data value to be broadcast. Broadcast is triggered by clicking on a corresponding section of the chart.

For HTML definitions in UI Maps, the syntax is `oraChartBroadcast="FIELD_NAME1:xpath1;FIELD_NAME2:xpath2;"` where 'xpath_n' is the element in the list schema that contains the data value to be broadcast.

Zone Configuration Examples

Zone with a simple pie chart

In this example, the zone SQL summarizes To Do entries by Role. The column definitions are:

- C1 - role description
- C2 - count of To Do entries by role
- C3 - role ID

Visualization Option 1

This option shows To Do entries by Role as a pie chart. The role ID will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="ROLE_ID:C3"
```

Zone with two chart types

In this example, the zone SQL summarizes To Do entries by Priority and also calculates separate counts by To Do status within priority. The column definitions are:

- C1 - priority description
- C2 - count of To Do entries by priority
- C3 - priority flag value
- C4 - count of Open To Dos by priority
- C5 - count of Being Worked On To Dos by priority
- C6 - Label for the Open To Dos bar in the cluster chart
- C7 - Label for the Being Worked On To Dos bar in the cluster chart

Visualization Option 1

This option shows To Do entries by Priority as a pie chart. The priority value will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie; legendBorder:true;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Visualization Option 2

This option shows To Do entries by Priority as a cluster chart with two data series, one for Open To Dos and another for Being Worked On To Dos . The corresponding priority value will be broadcast to the portal when clicking either the Open or Being Worked on bar of the cluster chart.

```
optiontype=CHART oraChart="type:cluster; showLegend:true;"
oraChartSeries1="axis:C1; axisFormat:string; labelPath:C6; amount:C4;hoverText:$label$newline
$amount;"
oraChartSeries2="axis:C1; axisFormat:string; labelPath:C7; amount:C5;hoverText:$label$newline
$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Pagination Configuration

The various data explorer zones in the product support the ability to configure pagination so that a user can 'page through' a large set of results using "previous" and "next" buttons or links.

There are several zone parameters that are impacted when attempting to configure this functionality. The following steps highlight the configuration.

- The **Enable Pagination** parameter must be configured to define the basic setup for pagination for the zone. This parameter defines whether the "previous" and "next" actions are defined as buttons, links or icons and indicates the location of the actions. It also allows an indication as to whether the additional rows are simply appended, rather than shown in a new "page". Refer to the parameter's embedded help for information about the specific syntax.
- It is recommended that the zone is configured with record count and page information by properly configuring the **Record Count Display** parameter. Refer to the parameter's embedded help for information about the specific syntax.
- Configure the **Number of Rows to Retrieve for SQL** parameter to define the number of records displayed per page. If this parameter is not specified the value in the **Number of Rows to Display** parameter is used.
- Configure the key that will be used for paging so that the system can keep track of the 'page break'. The data must be sorted by the paging key; as a result, the decision for identifying the paging key must take into account the design for the zone and the data being displayed. In addition, the paging key must be unique to ensure that the page breaks occur correctly. See below for configuration examples.
 - The **SQL Statement** must include additional clauses **PAGENEXT** and **PAGEPREV** based on the paging key. In addition, as mentioned above, the paging key must be used in the ORDER BY clause.
 - The **SQL Column** parameters must define the paging key mnemonic to be used in conjunction with the SQL statement paging clauses.
 - It is recommended to configure the **SQL Display Column** parameter to show the data in the same order as the ORDER BY clause.

The following zone types support this capability:

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**).
- Info Data Explorer - Multiple SQLs (**F1-DE**). Note that zones of this type support a union of the results of all the SQL statements. As a result, pagination may only be enabled for zones of this type if a single SQL is used. The system is not able to keep track of the pagination across disparate SQL statements.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**).
- Multi Query Data Explorer (**F1-DE-MULQRY**). Zones of this type do not include configuration for SQL statements or column display. However, they do include configuration for the **Enable Pagination**. This parameter must be configured in order for pagination on the individual zones to work.

NOTE:

Zones used for a Business Service. Note that pagination is ignored when invoking a data explorer zone via a business service. In this scenario, the zone will return the first "chunk" of rows as defined by the Number of Rows parameters.

Zones with data visualization options. Pagination is not supported for zones that define visualization options to show data in a graphical form.

Examples

Simple Paging Key

In this example, the Extendable Lookup Value is defined as Column 1 (C1) and is marked as the paging key. This field is unique for the table and works well as a simple paging key.

```
SELECT A.F1_EXT_LOOKUP_VALUE, A.BUS_OBJ_CD
FROM
  F1_EXT_LOOKUP_VAL A,
  F1_EXT_LOOKUP_VAL_L B
WHERE
  A.BUS_OBJ_CD = :H1
  AND A.BUS_OBJ_CD = B.BUS_OBJ_CD
  AND A.F1_EXT_LOOKUP_VALUE = B.F1_EXT_LOOKUP_VALUE
  AND B.LANGUAGE_CD = :LANGUAGE
  [(F1) AND UPPER(A.F1_EXT_LOOKUP_VALUE) like UPPER(:F1)]
  [(F2) AND ((UPPER(B.DESCR_OVRD) like UPPER(:F2))
  OR (B.DESCR_OVRD = ' ' AND UPPER(B.DESCR) like UPPER(:F2)))]
  [(PAGENEXT) AND A.F1_EXT_LOOKUP_VALUE > :C1]
  [(PAGEPREV) AND A.F1_EXT_LOOKUP_VALUE < :C1]
ORDER BY A.F1_EXT_LOOKUP_VALUE
```

Complex Paging Key

Most queries however do not sort by a unique value. In this case, the paging key needs to be set based on the sorting of the query and should include a unique field, such as the primary key, as the last paging key. In this example, the query is showing results sorted by To Do Type, Role and User. All fields, including the To Do Entry ID (the primary key) are marked as paging keys.

```
SELECT TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, ASSIGNED_DTTM, TD_PRIORITY_FLG, TD_ENTRY_ID
FROM CI_TD_ENTRY
WHERE
  ENTRY_STATUS_FLG IN ('O', 'W')
  [(F1) and TD_TYPE_CD = :F1]
  [(F2) AND ASSIGNED_TO = :F2]
  [(F3) AND ROLE_ID = :F3]
  [(PAGENEXT) and ((TD_TYPE_CD>:C1) or (TD_TYPE_CD=:C1 and ROLE_ID>:C2) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2
  and ASSIGNED_TO>:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3 AND TD_ENTRY_ID>:C4))]
  [(PAGEPREV) and ((TD_TYPE_CD<:C1) or (TD_TYPE_CD=:C1 and ROLE_ID<:C2) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2
  and ASSIGNED_TO<:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3 AND TD_ENTRY_ID<:C4))]
ORDER BY TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, TD_ENTRY_ID
```

Use Data Explorer for Derived Data

There are times when a design warrants displaying data in a data explorer zone that is not accessible via SQL. For example, perhaps the data is from another system and it requires a web service call. The [JMS Message Browser](#) is another example.

The product provides functionality in the data explorer that allows you to call a script after the user filters are populated but before the SQL is executed. The script can retrieve the data as appropriate, store the data in table format so that the SQL can retrieve the data from the table.

The following points provide more detail:

- Create a service script that retrieves the data as needed. This script should store the retrieved data in a temporary table.
 - The product provides a table that may be used. It is called F1_GENERIC_GTT (Generic Global Temporary Table). There is a business service — Create Global Temporary Table Records (**F1-InsertGTTRecords**) that the service script may call to insert the records.

- Note that if the data is accessed via a web service call, it may be appropriate to execute the web service in a separate session using the business service F1-ExecuteScriptInNewSession to trap errors that may be issued by the web service call and provide a better error.
- In the data explorer zone use this service script in the zone's pre-processing script parameter. If any user or hidden filters should be passed into the script, the parameter supports mnemonics for this purpose. Refer to the parameter's embedded help for the supported syntax.
- The SQL for the data explorer should access the temporary table that was populated by the service script.

Configuring Timeline Zones

This topic highlights information related to configuring a [timeline zone](#). The zone type is **F1-TIMELINE**. A timeline zone contains one or more "lines" where each line shows when significant events have occurred. The output of each line is driven by an algorithm configured on a timeline zone. Each algorithm is responsible for retrieving a single type of data. For example, one algorithm may retrieve bills for an account in a given time period whereas another algorithm may retrieve payments for that account for the same time period.

The algorithms to configure for a timeline zone use the **Zone - Timeline** plug-in spot. Please note the following details about the behavior for algorithms for this plug-in spot.

- The timeline algorithm receives all the global context values currently populated. In addition, it receives a start and end date from the zone, based on the time period chosen by the user, along with the maximum number of events that can be reasonably displayed for the chosen time period. The algorithm should use this information to retrieve data for a given type of transaction related to one or more of the input context values for the provided time period.
- For each event found, the algorithm returns information about the event along with many options that assist the user in getting more detail about each event or acting on an event.
 - Event date
 - Primary key of the record (key / value pairs)
 - FK Reference. With this information, the timeline zone will display the appropriate info string to display in the zone's info area when clicking on the event. In addition, the FK reference identifies the appropriate navigation option to use when a user clicks the info string hypertext to view the record on its maintenance page.
 - Background Color and Text Color to use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
 - Icon use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
 - [BPA script](#) to launch when a user clicks on an event. (Optional). The algorithm may return one or more BPA scripts that a user may launch to act on an event. For example, for an event that has a status of **Error**, perhaps a BPA is provided to walk a user through resolving the error.

When a script is initiated from a timeline, the system puts the prime key of the event into a field in the page data model. The name of the field is the column name(s) of the event's prime key. For example, when a script associated with a payment event is kicked off, the system populates a field called PAY_ID with the prime-key of the selected payment.

Note that your specific edge application may supply algorithm types for a timeline zone as part of the base product. Although algorithm types may be provided, typically the product does not deliver algorithms because the parameters for the algorithms are driven by a particular implementation's business rules and preferences. As a result, the product will also not deliver pre-configured timeline zones. Please refer to your edge application's documentation for more information about what timeline algorithm types are delivered, if any and recommendations for configuration.

Defining Context-Sensitive Zones

A context-sensitive zone allows you to associate a zone with a specific user-interface transaction. A context-sensitive zone appears at the top of the Dashboard when a user accesses a page for which the zone is specified as the context. For example, when viewing a business object, additional zones are visible that are specific to the business object page.

CAUTION: Make sure that the zone is appropriate for the transaction on which you are specifying it. For example, if your zone requires a business object ID as one of its keys, it should not be displayed on the To Do entry transaction.

Select **Admin > Context Sensitive Zone** to maintain context-sensitive zones.

Description of Page

The **Navigation Key** is a unique identifier of a tab page within the system. **Owner** indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**).

CAUTION: Important! When introducing a new context sensitive zone, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The grid contains the list of context-sensitive zones and the sequence in which they appear in the dashboard for the selected navigation key. The grid contains the following fields:

- **Zone** is the name of the zone to display in the Dashboard.
- **Sequence** is the sequence in which the zone is displayed (if multiple context-sensitive zones are defined).
- **Owner** indicates if this context sensitive zone is owned by the base product or by your implementation (**Customer Modification**).

Where Used

A context-sensitive zone displays at the top of the Dashboard whenever a user accesses the transaction for with the zone is specified.

Defining Portals

This portal is used to view and maintain the configuration of portals. An implementation may define their own portals or may override some of the settings for base product provided portals.

You can access the portal from the **Admin Menu > System > Portal**. You are brought to a query portal with options for searching for a specific record. Once a portal record has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Understanding Portals and Zones](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Portal.** This zone provides information about the selected portal definition.
- **Options.** This zone lists various configuration options for the selected portal record.
- **Tabs.** This zone lists other tab portals if any are configured for a standalone portal. This zone is only visible when such tabs exist for the current standalone portal.
- **Context Sensitive Zones.** This zone lists context sensitive zones that appear on the dashboard when this portal is displayed . This zone is only visible when such zones exist for the current standalone portal.

Defining Menu Options

This portal is used to define / change any menu in the system. You can access the portal from the **Admin Menu > System > Menu**. You are brought to a query portal with options for searching for a specific menu. Once a menu has been selected you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Updating menus requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience with menus.

NOTE: Security and menus. Refer to [Application Security](#) for a discussion of how application security can prevent menu items (or an entire menu) from appearing.

NOTE: Module configuration and menus. Your [module configuration](#) can prevent menu items (or an entire menu) from appearing.

The following zones may appear as part of the portal's **Main** tab page:

- **Menu.** This zone provides information about the selected menu.
- **Menu Lines.** This zone lists the menu's lines and supports actions to add, edit and delete lines. You may also broadcast a line to review more information about its items configuration.
- **Menu Line Items.** This zone lists item information for a selected menu line.

Application security information for the menu can be reviewed and managed from the **Application Security** tab. The following zones may appear as part of this tab page:

- **Menu Lines.** This zone lists the menu's lines. Broadcast a line to review its application security information.
- **Menu Line Security.** This zone lists application services related to the selected menu line. You may use this zone to review and configure security access for the selected menu line and a specific user group.
- **Menu Line Security Details.** This zone lists the entities secured by a selected application service.

The following zone may appear as part of the portal's **References** tab page:

- **Menu References.** This zone lists entities that reference the selected menu.

The following sections provides more information.

Menu Types

The following types of menus are supported:

- **Admin** is one of the menus that appears in the Application Toolbar. It is a special type of menu because [admin menu](#) items can be grouped alphabetically or by functional group. Refer to the description of Admin Menu Order on [Installation Options - Framework](#) for more information about admin menu options.
- **Main** is another menu that appears in the Application Toolbar that is simply titled [Menu](#).
- **Submenu** defines a menu group that appears when an Application Toolbar menu is selected. for the Admin menu, this is only visible when it's organized functionally.
- **Context** refers to a [context menu](#).
- **Page Action Menu** defines buttons that appear in the [Page Title Area](#).
- **User Menu** refers to the menu items that appear on the [user menu](#); for example, User Preferences.

Extending Product Owned Menus

An implementation may choose to add custom menu lines along with its menu item (or items) to a base product owned menu.

Overriding Menu Lines Sequence

An implementation may override the sequence of a base product owned menu line. Also note that the sequence is defined on the menu line language table, allowing for different orders to be used for different languages (or to let the menu be sorted alphabetically in one language and in a specified order in a different one).

Menu Information is Cached

Use the **Flush Menu** button to flush the cached menu items so you can see any modified or newly created menus. Refer to [Caching Overview](#) for more information.

Defining Navigation Keys

Each location to which a user can navigate (e.g., transactions, tab pages, tab menus, online help links, etc.) is identified by a navigation key. A navigation key is a logical identifier for a URL.

Navigation Key Types

There are three types of navigation keys:

- **System navigation keys** define locations where the target for the navigation is a transaction or portal within the system. The navigation keys define the program component that identifies the page to navigate to.
- **External navigation keys** define a URL that identifies the target location. External URLs can be specified as relative to the product web server or fully qualified. External navigation keys always launch in a new instance of a browser window. Examples of external navigation keys include application viewer links and URLs to external systems.
- **Help navigation keys** define a online help topic that identifies the specific page within the online help to launch. Help navigation keys may be related to a program component when the help is related to a specific page in system.

Navigation Key vs. Navigation Option

The system has two entities that work in conjunction with each other to specify how navigation works:

- **Navigation Key** defines a unique location to which a user can navigate. For example, each page in the system has a unique navigation key. Navigation keys can also define locations that are "outside" of the system. For example, you can create a navigation key that references an external URL. Think of a navigation key as defining "where to go".
- **Navigation Option** defines how a page is opened when a user wants to navigate someplace. For example, you might have a navigation key that identifies a specific page. This navigation key can then be referenced on two navigation options; the first navigation option may allow users to navigate to the page with no context included, while the second navigates to the page with context data provided to automatically display information related to that context.
- Please note that a wide variety of options can be defined on a navigation option. In addition to defining if data is passed to the page, it could also define search options. In addition, there are some navigation options that do not reference a navigation key but rather refer to a BPA script that should be launched.

The Flexibility of Navigation Keys

Navigation keys provide a great deal of functionality to your users. Use navigation keys to:

- Allow users to navigate to new pages or search programs
- Allow users to transfer to an external system or web page. After setting up this data, your users may be able to access this external URL from a menu, a context menu, their favorite links, etc. Refer to [Linking to External Locations](#) for more information.

Refer to the Tool Suite Guide for more information on developing program components.

NOTE: Replacing Base-Package Pages or Searches. If your new page or search has been designed to replace a module in the base-package, the navigation key must indicate that it is [overriding an existing navigation key](#).

Linking to External Locations

If you want to include links to external systems or locations from within the system, you need to:

- Define a [navigation key](#) that specifies the URL of the location. For example, define an external navigation key that as a URL of <http://www.oracle.com/>.
- Define a [navigation option](#) that specifies from where in the system a user can go to your external location. For example, define a navigation option with a usage of **Favorites** or with a usage of **Menu**. Your navigation option points to the navigation key you defined above.
- Add your navigation option to the appropriate location within the system. For example, have users add the navigation option to their [Favorite Links](#) or add the navigation option as an item on a [menu](#).

Overriding Navigation Keys

Your implementation may choose to design a program component (e.g., a maintenance transaction or search page) to replace a component provided by the system. When doing this, the new navigation key must indicate that it is overriding the system navigation key. As a result, any menu entry or navigation options that reference this overridden navigation key automatically navigates to the custom component.

For example, if you have a custom On-line Batch Submission page and would like users to use this page rather than the one provided by the system, setting up an override navigation key ensures that if a user chooses to navigate to the On-line Batch Submission from Menu or a context menu, the user is brought to the custom On-line Batch Submission page.

To create an override navigation key, you need to:

- Define a [navigation key](#) using an appropriate [naming convention](#).
- If the Navigation Key Type of the navigation key being overridden is **External**, specify a Navigation Key Type of **Override (Other)** and define the appropriate URL Component.
- If the Navigation Key Type of navigation key being overridden is **System**, specify a Navigation Key Type of **Override (System)** and populate the Program Component ID with your custom program component ID.
- Specify the navigation key that you are overriding in the **Overridden Navigation Key** field.

Refer to the Tool Suite Guide for more information about developing your own program components.

Maintaining Navigation Keys

Select **Admin > System > Navigation Key** to maintain navigation keys.

Use the **Navigation Key Query** portal to search for an existing navigation key. Once a navigation key is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! When introducing a new navigation key, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

The **Navigation Key** is a unique name of the navigation key for internal use.

Owner indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**). This information is display-only.

Navigation Key Type includes the following possible values:

- **External** indicates that the location is specified in the **URL Component** field.
- **Help** indicates that the navigation key is used to launch online help where the specific help topic is defined in the **URL Component** field.
- **Override (Other)** indicates that the navigation key overrides another navigation key of type **External** or **Help**. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **Override (System)** indicates that the navigation key overrides a system navigation key. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **System** indicates that the navigation key refers to a transaction in the system identified by its program component.

FASTPATH: Refer to [Navigation Key Types](#) for more information about navigation key types.

FASTPATH: Refer to [Overriding Navigation Keys](#) for more information about settings required to override a system navigation key.

Program Component ID is the name of the program component identified by the key (for system navigation keys). The program component ID can also be used to specify the transaction with which an online help link is associated.

Overridden Navigation Key is the name of the navigation key that the current navigation key is overriding (if **Override (Other)** or **Override (System)** is selected for the **Navigation Key Type**). Refer to [Overriding Navigation Keys](#) for more information.

URL Component is the specific URL or portion of the URL for the navigation key (external and help navigation keys only). The URL can be relative to the product web server or fully qualified.

Open Window Options allows you to specify options (e.g., width and height) for opening a browser window for an external navigation key. (External navigation keys always launch in a new browser window.) You can use any valid features available in the `Window.open()` JavaScript method. The string should be formatted the same way that it would be for the features argument (e.g., **height=600,width=800,resizeable=yes,scrollbars=yes,toolbar=no**). Refer to a JavaScript reference book for a complete list of available features.

Application Service is the application service that is used to secure access to transactions associated with **External** navigation keys. If a user has access to the specified application service, the user can navigate to the URL defined on the navigation key. Refer to [The Big Picture of Application Security](#) for more information.

The grid displays menu items that reference the navigation key (actually, it shows menu items that reference navigation options that, in turn, reference the navigation key).

Defining Navigation Options

Every time a user navigates to a transaction, the system retrieves a navigation option to determine which transaction should open. For example:

- A navigation option is associated with every menu item. When a user selects a menu item, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every [favorite link](#). When a user selects a favorite link, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every node in the various trees. When a user clicks a node in a tree, the system retrieves the related navigation option to determine which transaction to open.
- Etc.

Many navigation options are shipped with the base product and cannot be modified as these options support core functionality. As part of your implementation, you may add additional navigation options to support your specific business processes.

Navigation options may also be used to launch a BPA script.

The topics in this section describe how to maintain navigation options.

CAUTION: In order to improve response times, navigation options are cached the first time they are used after a web server is started. If you change a navigation option and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. A special button has been provided on the Main tab of the navigation option transaction that performs this function. Please refer to [Caching Overview](#) for information on the various caches.

Navigation Option - Main

Select **Admin > System > Navigation Option** to maintain a navigation option.

Use the **Navigation Option Query** portal to search for an existing navigation option. Once a navigation option is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Navigation Option** code and **Description**.

CAUTION: When introducing a new navigation option, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The **Flush System Login Info** button is used to flush the cached navigation options so you can use any modified navigation options. Refer to [Caching Overview](#) for more information.

Owner indicates if this navigation option is owned by the base product or by your implementation (**Customer Modification**). This field is display-only. The system sets the owner to **Customer Modification** when you add a navigation option.

NOTE: You may not change navigation options that are owned by the base product.

Use **Navigation Option Type** to define if the navigation option navigates to a **Transaction**, launches a **BPA Script** or opens an **Attachment**.

NOTE: The **Attachment** option type is only applicable to navigation options that are used to launch a file attached to a record in the Attachment maintenance object.

For navigation option types of **script**, indicate the **Script** to launch. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to temporary storage variables available to the script. The script engine creates temporary storage variables with names that match the Context Field names.

For navigation option types of **transaction**, define the **Target Transaction** (navigation key) and optionally a specific **Tab Page** (also a navigation key) if a specific tab on the transaction (other than the Main tab) should be opened when navigating to that transaction.

NOTE: Finding transaction navigation keys. When populating the **Target Transaction** and **Tab Page** you are populating an appropriate navigation key. Because the system has a large number of transactions, we recommend using the "%" metaphor when you search for the transaction identifier. For example, if you want to find the currency maintenance transaction, enter "%currency" in the search criteria.

The additional information depends on whether the target transaction is a fixed page or a portal-based page:

- For portal-based pages:
 - **Navigation Mode** is not applicable and should just be set to **Add Mode**.
 - If navigating to a query portal, by default the query portal will open with the default search option defined. If the navigation should open a different search option, define the **Multi-Query Zone** for that query portal and indicate the **Sub-Query Zone** to open by default. Note that for this configuration, it is common to define **Context Fields** to pre-populate search criteria in the target query zone. When using this configuration, be sure that the target query zone's [user filters](#) are defined to populate data from context.
- For fixed pages:
 - **Navigation Mode** indicates if the **Target Transaction** should be opened in **Add Mode** or **Change Mode**.
 - **Add Mode** should be used if the option is used to navigate to a transaction ready to add a new object. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to the transaction when it opens.
 - **Change Mode** is only applicable for fixed pages and should be used if the option is used to navigate to a transaction ready to update an object. You have two ways to define the object to be changed:
 - Define the name of the fields that make up the unique identifier of the object in the **Context Fields** (and make sure to turn on **Key Field** for each such field).
 - Define the **Search Transaction** (navigation key) if you want to open a search window to retrieve an object before the target transaction opens. Select the appropriate **Search Type** to define which search method should be used. The options in the drop down correspond with the sections in the search (where **Main** is the first section, **Alternate** is the 2nd section, **Alternate 2** is the 3rd section, etc.). You should execute the search window in order to determine what each section does.

When you select a **Search Type**, define appropriate **Context Fields** so that the system will try to pre-populate the search transaction with these field values when the search first opens. Keep in mind that if a search is populated with field values the search is automatically triggered and, if only one object is found that matches the search criteria, it is selected and the search window closes.
 - **Search Group** is only visible if the **Development Tools** module is [not turned off](#). It is used to define the correlation between fields on the search page and the tab page. You can view a tab page's **Search Groups** by viewing the HTML source and scanning for **allFieldPairs**.

The **Go To Tooltip** is used to specify the label associated with the tool tip that appears when hovering over a **Go To** object. Refer to the **Usage** grid below.

The **Usage** grid defines the objects on which this navigation option is used:

- Choose **Favorites** if the navigation option can be used as a [favorite link](#).
- Choose **Menus** if the navigation option can be used as a user's [home page](#) or as a menu or context menu item.
- Choose **Script** if the navigation option can be used in a [script](#).
- Choose **Foreign Key** if the navigation option can be used as a [foreign key reference](#).

- Choose **Go To** if the navigation option can be used as a "go to" destination ("go to" destinations are used on Go To buttons, tree nodes, and hyperlinks).
- If your product supports marketing campaigns, you can choose **Campaign** if the navigation option can be used as a "post completion" transaction on a campaign. For more information refer to that product's documentation for campaigns.

The **Context Fields** grid contains the names of the fields whose contents will be passed to the **Target Transaction** or **Script** or used to launch an **Attachment**. The system retrieves the values of these fields from the "current" page and transfers them to the target transaction or to the script's temporary storage. Turn on **Key Field** for each context field that makes up the unique identifier when navigating to a transaction in **Change Mode**.

NOTE: For an **Attachment**, the grid should contain the Attachment ID.

NOTE: Navigating from a Menu. The standard followed for many base main **menu** navigation options for fixed transactions is that navigation options launched from the Menu dropdown are configured with no context.

Navigation Option - Tree

This page contains a tree that shows how a navigation option is used. Select **Admin > System > Navigation Option** and navigate to the **Tree** tab to view this page.

Description of Page

The tree shows every menu item, favorite link, and tree node that references the navigation option. This information is provided to make you aware of the ramifications of changing a navigation option.

Understanding System Messages

All error, warning and informational messages that are displayed in the system are maintained on the message table. Every message is identified by a combination of two fields:

- **Message category number.** Think of a message category as a library of messages related to a given functional area. For example, there is a message category for billing messages and another one for payment messages.
- **Message number.** A unique number identifies each message within a category.

Every message has two components: a brief text message and a long description.

NOTE: You cannot change the product's text. If the message is "owned" by the product, you cannot change the product's message or detailed description. If you want your users to see a different message or detailed description other than that supplied by the product, enter your desired verbiage in the corresponding override fields (and flush the [cache](#)).

Defining System Messages

This portal is used to search for message categories and messages that appear throughout the system. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a message. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) for more information.

Defining Message Categories

This portal is used to view and maintain a message category and its messages.

CAUTION: Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a specific message. Once a message category has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Message Category.** This zone provides information about the selected message category.
- **Messages.** This zone lists and maintains messages for the selected category.

Defining Messages

This portal is used to view and maintain a specific message. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

CAUTION: Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a specific message. Once a message has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Message.** This zone provides information about the selected message.

Understanding Unified Search

Depending on your product, the toolbar search box may support a product specific search for business entities in addition to the standard search for menu items. For example, the search may support a query of business entities by their name, address, contact details etc. The unified search feature is a simplified version of your product's main search, that allows the user to lookup up records using free form search text or hint codes. For more complex queries, the user may navigate to the corresponding advanced search portal.

The configuration of a unified search option includes the following items:

- A **search service script** that implements the data query and defines the supported **filters**. The application service associated with this script is used to secure the unified search option.

- **Search filter rules** and **hints** for the supported filters. These rules are used to parse the text entered by the user to determine whether it qualifies as a valid filter value.
- The **advanced search** portal to use for more complex queries.

The unified search box interacts with a unified search option implementation as follows:

- As the user types free form text in the search box, the application uses the **search filter rules** and **hints** to parse the entered text and translate it to corresponding query filters.
- The **search service script** is then called to query for entities that match these filters and present the results.
- Selecting a result record navigates to the corresponding portal.
- Selecting the **Advanced Search** link in the search box navigates to the general query portal associated with the unified search option.

If a unified search option is not enabled for your product or the user does not have security access to it then the search box may only be used for searching the menu.

The following sections describe various aspects related to the configuration of a unified search option.

The Search Script Controls Everything

A unified search is implemented as a single service script that controls the following:

- **Filters.** The script determines which filters are supported and how they are applied to return results efficiently. Each filter name must be a valid **Field** record.
- **Results.** The script returns a list of business entities that matches the query filters provided by the user, along with the navigation information needed to drill in to a selected record in the list.
- **Application security.** Only users that have access to the script's application service may use the unified search associated with the search script.
- **Override Advance Search.** The script may override the advanced search portal configured for the search option.

When the search box component initializes, the script is called once in **Prepare Search Details** mode to return the list of supported filter names. In this mode the script does not perform any query.

As the user types in text in the search box, the search box component analyzes the entered text to derive query filters and calls the search script in **Perform Search** mode to return matching results.

The search box component is designed to support any type of unified search implementation and as such, the interaction between the user interface component and the search script is generic. Filters are defined as name / value pairs and results for each matched entity includes details like primary, secondary and tertiary description lines, along with a line that describes the matching text for entry.

NOTE: If your organization needs to implement a custom unified search script, it is strongly recommended that you follow the base product's implementation of such scripts as a reference.

Filter Rules and Hints

A unified search is designed to support a predefined set of filters for querying data. For example, searching customers by their address, name, identifiers; or searching locations by address or name etc. Each filter is uniquely identified by a **Field** name as declared by the search service script.

As the user types in free text in the search box, the application applies parsing rules to determine whether the text may be used as the value of one or more filters supported by the unified search. For example, if the user types in the text "ave", parsing rules may determine that it can be used to filter results by a person's name or address but not their email address.

Each parsing rule, defined in the **Search Filter Rule**[extendable lookup](#), associates a filter's field name with a regular expression. Multiple filter rules defined for the same filter name are processed in execution order sequence and it is enough for one rule to return a match for the search text to be used as the value for the specific filter.

Alternatively, the user may use an explicit hint code to identify the filter they would like to use followed by the filter value. For example, an address filter may be associated with the hint "ad:" allowing the user to enter "ad: main" to look up records by address.

Each hint, defined in the **Search Filter Hint** extendable lookup, associates a filter's field name with a hint code.

Note that filter rules and hints are defined for a specific filter name and not a specific unified search option. The same parsing rules may be shared across searches using the same filter names. For example the parsing rule to identify an "email" filter or the "ad:" hint for an address filter are the same regardless of how these are used by a search query. These rules are automatically associated with any unified search option that uses the same filter names.

NOTE: You may customize the parsing rules and hints associated with a filter by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

Which Unified Search Option is Used?

Each unified search option is defined in the **Unified Search** extendable lookup, referencing the option's search service script and its corresponding advanced search portal. The unified search option is only enabled to users that have access to the search script's application service. When more than one unified search option is configured and enabled for a user, the application chooses the option with the highest sequence as the default option, allowing users to switch to other options they have access to.

Customizing Unified Search

You may customize the parsing rules and hints associated with base product search filters by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

If you need to support a search for different business entities and filters, you need to implement a custom unified search. The configuration of a unified search option involves the following high level steps:

- Design and implement a search script that supports a predefined set of filters and returns the topmost set of matching results while taking into account performance considerations.
- Design hints and filter rules as needed for each of the supported filters. Review existing hints and filter rules associated with same filter names when applicable.
- Register each hint, if any in the **Search Filter Hint** extendable lookup.
- Register each filter rule, if any in the **Search Filter Rule** extendable lookup.
- Register the search script in the **Unified Search** extendable lookup.

Trees

Many edge products and implementations make extensive use of UI tree structures to display hierarchical relationships between records in the system. The framework provides an objects to define a tree structure and the rules on how to populate the nodes in the tree, and processes to interpret the configuration and dynamically render the tree display.

The topics in this section provide information about what is supplied in the framework. Your product may supply UI components with ready built trees for common use cases. Refer to your product documentation for more information.

Common Attributes of Trees

Your organization may have many portals and zones showing data in a hierarchical tree. Most trees in the system follow a similar pattern:

- Trees have a number of levels. There may be different types of tree nodes present in any given level; for instance a list of algorithm types for a script, followed by a list of script steps. Icons may be displayed to further identify the node's object type.

- The most common node types reference an entity within the system such as a schema, script, data area and so on. These nodes usually display the information string from the entity's FK reference and provide the ability to navigate to the entity. They may also allow the node context to be broadcast to other zones in the portal.
- In addition to the ability to navigate to the associated entity, many node types provide a context menu with further navigation paths.
- Some nodes are simply informational and are used to group a set of child nodes below a type or category. For example, the business object Options tree groups the option value nodes below summary nodes that describe the option type.

Each tree defines the nodes that make up the tree and the parent/child relationship between those nodes. A tree node defines which of the common attributes are applicable to the node and the algorithms responsible for retrieving the node data and, optionally, determining the node information to be displayed.

Populate Node Algorithm

A tree node displays a combination of the attributes listed above, typically for an object in context. For a root node, the object will normally be derived from a global or portal context value, such as the current script. For each lower level node, the context is derived from the context fields of its parent row; for instance, algorithms for a specific algorithm type.

The key responsibility of the populate node algorithm is to receive the tree code, node name and the parent context value (or values), determine if there is data that should be shown for this node, and return the a list of the context fields and values applicable to each row in the node. The following highlights additional optional information that may be returned by the algorithm:

- Entity information. If the node is related to a specific entity, the maintenance object code and primary key values may be returned. These are used for determining default information for the node, including navigation details.
- A display icon value. This is used to override the icon defined on the tree node and/or the default icon for the entity as defined on the maintenance object or business object.
- An information string. This may be used to override the default information string for an entity or to display stand-alone text such as a summary or description of the child nodes to follow.

NOTE: The populate node algorithm is responsible for returning all the context values required to populate its child nodes. For an informational or summary node, this may require including the node's parent context fields in its own context. For example, in the script tree, the summary node describing the number of steps is followed by a list of steps for the script. The summary node populate node algorithm needs to include the script code passed in as parent context in its output context list, in order for the steps to be correctly retrieved.

Information Override Algorithm

The information override algorithm has two main purposes:

- Providing alternative information text for a tree node when the information provided isn't suitable for your implementation.
- Retrieving contextual insights related to the tree node entity, to be included in the node's information text. Only badge insight types are currently supported.

The override information algorithm receives the tree code, node name, maintenance object and prime key values for the node. The following highlights the information that may be returned by the algorithm:

- A display icon value.
- An information string. This will be used to override the default information string in the node's formatted string.
- Full node text. This will be used as the full text for the display, overriding the formatting defined on the node.
- A list of badge insight types and their context.

NOTE: If the information override algorithm returns insight types for the entity, it is also responsible for returning all the context values required for those insight types. Refer to [Contextual Insights](#) for more information.

Preparing a Node for Display

The following section highlights key steps in fetching a node's data and formatting it for display.

Determining Node Content

The following steps are performed to retrieve the components making up the tree node display:

- The Populate Node algorithm is called to determine all instance nodes for the tree node along with their related details.
- The Information Override algorithm is called for each node instance to allow for optional override of presentation related details.

The node display contents are determined as follows:

- The icon is determined from the following sources, in order: tree node definition, override information algorithm value, populate node algorithm value, maintenance object / business object default value.
- Broadcast usage is determined by the setting on the tree node definition.
- The information string is determined from the following sources, in order: override information algorithm value, populate node value, maintenance object / business object information algorithm. If the string is derived from the MO/BO algorithm, the short information text is used when available else the standard information is used.
- Context menu usage is determined by the settings on the tree node definition.
- The system supports a different style for header rows, including a larger font. Header style usage is determined by the setting on the tree definition and is only applicable if the node is a root node with only one instance.

Node Text Format

The text for nodes referencing a system entity commonly includes some combination of a label, the entity key and an information string. The node configuration provides a label field and a substitution format string field which may be used to define the node text format. The format string defines which of the three components should be included in the text, the order of those components and any surrounding text and HTML markups. For example, a format string of '%label - %key - %info' will result in a node text like the example below:

▶  Algorithm Type - F1_PROSTINFO - Process Flow Information

If the format string is blank, the default text will include '%info' only. If an override information algorithm is configured that returns the full node text, the text is presented without further formatting.

Auto Expansion

If the tree node definition indicates that the node should be expanded, the system will automatically fetch and display the data for its child node. This processing continues until there are no further child nodes marked for expansion.

Base Delivered Trees

Trees are system data and your product may already deliver several trees out of the box. You may choose to customize a base delivered tree in the following ways:

- You may add your own nodes to an existing tree definition.
- You may override the information string for a node by supplying your own **Information Override** algorithm. If a base override algorithm is configured on the node, your custom algorithm should be plugged in at a higher sequence number, to take precedence over the base algorithm.

Rendering a Tree

To render a tree on the UI, you would include the ou-tree web component in a UI map that references the tree definition.

NOTE: Refer to [Include a Web Component](#) for more information.

Defining Trees

This portal is used to view and maintain information about a tree definition. Trees are commonly used to display hierarchical relationships between objects in the system. Refer to [Trees](#) for background information about defining trees.

You can access the portal from **Admin > System > Tree**. You are brought to a query portal with options for searching for a specific tree definition. Once a tree has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Tree.** This zone provides information about the selected tree.
- **Tree Nodes.** This zone lists the nodes for this tree in hierarchical order. Use the zone actions to add or maintain a node in the tree.
- **Tree Node.** This zone displays the details for a tree node. It is only visible if a tree node name has been broadcast from the Tree Nodes zone.

Contextual Insights

Contextual Insights provide a powerful way to surface focused intelligence and alerts to users in the context of the core screens for any applications built on Oracle Utilities Application Framework. There are multiple options for the visual patterns when surfacing Contextual Insights and the actions that can be performed by users are easily configurable as well. The subsequent topics provide detail about the Insight Type and Insight Group objects that are used to configure the information that may then be displayed in appropriate screens.

Insight Types

The insight type object contains all the detailed configuration for displaying one or more alerts / important information for a record in context. The following sections provide more information about all the configuration managed by the insight type.

Insight Algorithm

Each insight type is used to display some information, typically related to an object in context. It is the responsibility of the insight type algorithm to receive the context value (or values), determine if there is information that should be shown for this context, return the text to display.

The following highlights additional optional information that may be returned by the algorithm:

- A secondary message. This is only applicable to some visual structures where more than one line of information may be displayed.
- A severity value. This is used to override the visual display configuration if different emphasis should be used for different severity values. Refer to [Override Configuration](#) for more information.
- Entity information. If the insight is related to a specific entity, the maintenance object code and primary key values may be returned. This is useful if the insight type configures a BPA or user action algorithms that may perform logic for this entity.
- Navigation and User Action information. This is only applicable to visual structures that support user actions. The algorithm must return the list of all the actions that should be made visible on the insight. If the action includes navigation, the algorithm should return the navigation option and navigation context key and value pairs. Additionally, there is configuration for each action that must be defined. Refer to [User Actions](#) for more information.

Each algorithm can return multiple insights, if applicable. For example, if the insight is about To Do entries related to the object being displayed, you could design your insight algorithm to return a single insight summarizing all the To Do related information. Or you could choose to return separate insights based on To Do information so that you provide more granular information and customize actions or navigation based on the different conditions. For example, if there are To Do Entries that the current user may perform actions on and others that current user cannot update, the algorithm could return two separate insights: one with actions and one without.

NOTE: Preview mode. The insight type maintenance page includes an Insight Preview section that shows the output from the insight algorithm when invoked with an insight mode of "Preview". Every algorithm should include logic that returns appropriate text when called in this mode so that something is displayed in that section.

Visual Structures

Each insight type defines a visual structure which dictates what kind of information may be shown. The system has some fixed layout expectations for each visual structure type. The insight type configuration is used to provide the source for the possible layout.

NOTE: All the insights use color options as part of their configuration. Refer to [Color Option](#) for more information.

Badge Insight

The simplest visual structure is the badge. It is used to display a single line of quick text with a solid background (for visibility) that is meant to alert the user to important summary information or attributes.

A blue rounded rectangular badge with the text "3 Related To Dos" in white.

Inline Insight

The inline insight defines an icon and a single message. This is meant to be more descriptive than a badge. For this type of insight, a default light background is used so the recommendation is to select a color option for both the text and the icon that has only a foreground color defined or has a light background color.

An inline insight consisting of a small calendar icon, a light green background, and the text "3 Related To Dos" in green.

List Insight

The list insight are intended to exist in a list of insights for the object. It defines an icon and can support two lines of text. In addition, this type of insight supports buttons or user actions. Refer to [User Actions](#) for more information. Note that for a list insight, if there is one valid action or 2 valid actions, the action buttons are shown. If there are three or more valid actions, one action is shown and then an 'Other Actions' button is visible. Clicking this shows the other available actions.

Note that the background color for the insight is used as the color for the full insight snippet. The text and the icon are shown on this background. The icon's background color is ignored.

Card

The card insight is the most information rich, with up to two lines of text, [user actions](#), a large icon to call attention and header text. The header text is chosen from a dropdown list of valid options. The product provides out of the box header text of "Information", "Warning" and "Error". Implementations may add additional values to this using the lookup field **HEADER_CAT_FLG**.

Please note the following about the treatment of the various components of the card insight:

- The header text is rendered like a badge insight.

- For the message text displayed in the card, the background color is ignored so a color option with no background color or a light background color should be chosen.
- For the icon, the background color is used to create a square area for display and the icon is rendered in the foreground color.

Override Configuration

Each insight supports default visual setting for the various components of the insight. This includes the color option for the applicable components along with icons and header text, where applicable. In each case, override visual settings may be defined for a given severity number.

For example imagine the algorithm for a badge insight that returns a message with the count of related To Do entries uses a different color option if there are more than 10 related records. To do this, the algorithm can return a severity number and then the configuration user can define the override color option for this severity number.

User Actions

The list and card insights support the definition of user actions that may be presented as buttons when displaying the insight. The actions may do one or more of the following:

- Perform algorithm logic. One or more user action algorithms may be associated with an action button. This should be used to perform server logic that does not require any user interaction. For example, you can provide an action to update the status of a record related to the insight. These algorithms are configured on the Insight Type.
- Navigate to another page. For this type of action, the insight algorithm must provide the navigation context and the navigation option to launch when clicking the button. It's possible to configure navigation and configure user action algorithms. In that case the algorithms are run first and then the navigation occurs.
- Launch a BPA. This is used if there is user interaction needed to perform additional logic and / or if there is conditional navigation such that the logic is needed before navigating. It's possible to configure a BPA and configure user action algorithms. In that case the algorithms are run first and then the BPA is launched. If the insight algorithm also provides navigation for this action, it is ignored in favor of the BPA. The BPA is configured on the Insight Type.

The list of valid actions to display at run time must be returned by the insight algorithm. This allows for the algorithm to have control over which actions to display, in case there are some actions that are conditional. In addition, each possible button requires configuration related to what text should display and the style of the button.

Button Text

The button text to display is chosen from a button text lookup. The lookup name is **INSIGHT_ACT_FLD_FLG**. Implementations may add additional values to this lookup to include new button text. In addition, if you would like to change button text on any product delivered button, you can override the lookup value description.

Action Class

Each action button defines an action class. Any action configured with the action class value of **Positive** value is shown first and is styled differently for emphasis. Other action class values are for information purposes.

Base Delivered Insight Types

Insight types are system data and your product may already deliver several insight types out of the box. You may choose to include one or more insight types in an [Insight Group](#).

Rendering an Insight

To render an insight for an insight type, you would include the ou-insights web component in a UI map that references this insight type. This is how the Insight Preview section of the insight type maintenance page renders the preview.

NOTE: Refer to [Include a Web Component](#) for more information.

Defining Insight Types

The insight type entity is used to define the configuration of a specific type of alert to display extra information related to one or more records in context. Refer to [Insight Types](#) for a detailed description of the supported functionality.

To view or maintain insight types, open **Admin > General > Insight Type**.

This is a standard [All-in-One portal](#).

The information captured on the insight type depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Groups

If there are any insight groups that reference this insight type, the **Related Insight Groups** zone displays the linked insight groups.

Insight Groups

An insight group may be used to include several [insight types](#) together onto a single map. When defining an insight group, you configure the visual structures that the insight group should include. Only insight types for the configured visual structure are available.

Insight Class

Each insight group must reference a unique insight class. The insight class is defined using a lookup. The lookup field is **INSIGHT_CLASS_FLG**. Your product may already deliver base values for insight class. To display insights in a user interface your UI map would include the ou-insights web component. This component includes syntax to reference an insight class and the logic will find the insight group for that class and render all the insight types linked to that group.

Because the insight class is used as the reference in the web component rather than the insight group, it allows your product to supply base logic to show insight group information in a base delivered user interface. The base logic defines an insight class in base and references it on a base UI map. Your implementation can then define the insight group for this insight class and choose the insight types that should be rendered in that map. Refer to your specific product documentation to find out if there are any base delivered insight classes.

If your implementation identifies a new use case where one or more insight types should be displayed, once the insight types are configured, do the following:

- Define a new Insight Class lookup value.
- Define an Insight Group that references this insight class and configure the appropriate insight types.
- Include the appropriate [web component](#) in the map for your user interface where you wish to display this information.

Defining Insight Groups

The insight group entity allows implementations to define multiple related insight types that should be displayed together in a given user interface map or zone. Refer to [Insight Groups](#) for an overview of insight group configuration and functionality.

To view or maintain insight groups, open **Admin > General > Insight Group**.

This is a standard [All-in-One portal](#).

The information captured on the insight group depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Types

The **Related Insight Types** zone displays all the insight types that are currently linked to the group. The Edit link in the zone header allows you to add or remove insight types. Only insight types that reference one of the **Valid Visual Structures** may be selected.

Color Configuration

The topics in this section describe some options for configuring colors to be used in displaying information in the user interface.

Defining Colors

The system provides the [extendable lookup](#) Color (**F1-Color**) to define valid colors to be used in the system. The base colors provided are ones related to the standard color palette used in Oracle products.

At this time, zones and UI maps that define specific colors do not support any syntax to reference a color extendable lookup. In the meantime, colors applied at the zone or map level can still reference HTML colors or reference hex codes directly.

Color Options

The color option entity is used to define a combination of colors to be used in user interface components. The system provides a standard set of color options used for contextual insights.

To view or maintain color options, open **Admin > System > Color Option**.

This is a standard [All-in-One portal](#).

The information captured on the color option depends on the record's business object. Refer to the embedded help text for more information.

Defining Display Icons

Icons are used to assist users in identifying different types of objects or instructions. A limited number of control tables allow administrative users to select an icon when they are configuring the system. Select **Admin > System > Display Icon** to maintain the population of icons available for selection. You are brought to a query portal with options for searching for a specific display icon. Once a display icon has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The latest standard is to use Scalable Vector Graphic (SVG) icons. For these types of icons, the Icon Type is **Variable (SVG)**. The product also supports icons in the .gif or .png format. For these types of icons, the Icon Type defines a pixel size.

URL describes where the icon is located (folder) and the icon name (file name).

Note that there is a standard folder structure for delivered assets such as images. The structure is **{DefaultWebApp}/
{owner}/assets/images|svgs/**

- {Owner} - this is the owner of the icon. The **/cm** folder is used for custom icons.
- svgs - all images that are of type svg are in this folder.
- images - all files that have a file suffix of jpg, gif, png or other types of image formats are in this folder.

When using the above folder structure, then the URL only needs to contain the icon name (file name). The correct full URL is determined automatically at runtime. Images can optionally be placed in other folders under the DefaultWebApp. However, this is not recommended but if used, the URL must contain the full path to the icon (e.g. **/cm/assets/newImages/myIcon.gif**)

Custom Look and Feel Options

The default look and feel of the application can be customized via feature configuration and cascading style sheets. The base product is provided with a **Custom Look And Feel Feature Configuration** type. You may want to set up a feature configuration of this type to define style sheet and UI Map help options.

User Interface

The base product allows for the conditional inclusion of custom style sheets into the system style set. Custom styles may override any style provided by the base product. The style sheet may also include new styles for use in customer zone definitions. Use the **Style Sheet** option on the **Custom Look And Feel Feature Configuration** to define your custom style sheet.

NOTE: Some styles cannot change if they are part of the HTML code.

CAUTION: Implementers must ensure that the customized user interface is stable and scalable. Changing font, alignment padding, border size, and other user interface parameters may cause presentation problems, like scrollbars appearing or disappearing, cursors not working as expected, and unanticipated look and feel alterations of some layouts.

UI Map Help

A **tool tip** can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map zone or UI Map. Refer to the tips context sensitive zone associated with the UI Map page for more information. The **Custom Look And Feel Feature Configuration** provides options to control the following:

- Whether UI Map Help functionality is turned on or off. By default it is turned on.
- Override the default help image with a custom image
- The location of the help image, either before or after the element.

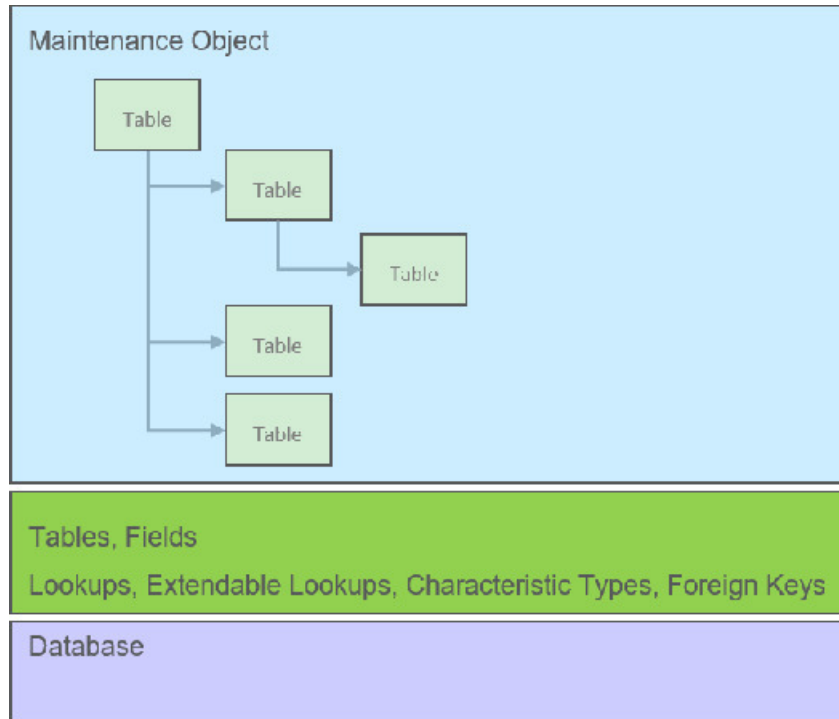

FASTPATH: Refer to the feature configuration for a detailed description of each option.

Database Options

This section describes a variety of database tools that are supplied with the your product.

Understanding The Data Model

The application uses meta-data to describe its data model, from plain description of its tables and fields to more complex hierarchies of maintenance objects.

The following points briefly outline key aspects of application's data model as illustrated in this diagram:

- Table and Field records describe all the tables maintained by the application.
- Valid values for certain fields are defined using corresponding Lookup and Extendable Lookup records.
- Characteristic types may be defined to support an extension of a maintenance object via its characteristics table.
- Maintenance Objects define the physical structure of an entity. Business objects further refine maintenance objects to describe business entities. Refer to [The Big Picture of Business Objects](#) for more information.
- Foreign Key References define ways for searching and navigating to the maintenance portal of an entity.

The following sections further discusses concepts and guidelines related to the data model.

Fields

A Field definition describes the metadata needed by the application to support the capture and display of a piece of information. Fields may correspond to physical columns on database tables or represent any type of element used for calculation or presentation purposes.

The definition includes the following key details:

- Whether the field refers to a physical column on a database table or used as a work field.
- The type of data the field holds.
- The label to use when the field is presented.
- The help text to display when the user clicks on the help icon seeking additional information about this field.

- and more

The following sections further discuss concepts and guidelines related to defining fields.

Physical vs. Work Fields

A Field definition record exists for every physical column on a database table that is used by the application. Refer to [Understanding Tables](#) for more information.

A Field that does not represent a physical column on a database table is considered as work field and needs to be marked as such. Work fields are typically used as labels as well as describe internal elements used in business rules.

Data Type Information

The type of data captured by a field is defined using the following attributes:

- **Data Type** indicates the basic type of value the field holds. Valid values are **Character**, **Character Large Object**, **Date**, **DateTime**, **Number**, **Time**, **Varchar2** and **XML Type**.
- **Extended Data Type** is used to further define the type of data for certain data types. Valid values are **Currency Source**, **Day of Month**, **Duration**, **Money**, **Month of Year**, **Flag**, **Switch** and **URI**.
- **Precision** defines the length of the field. In the case of variable length fields, it is the maximum length possible. For number fields that include decimal values, the precision includes the decimal values.
- **Scale** is only applicable for number fields. It indicates the number of decimal places supported by the field.
- **Sign** is only applicable for numbers. It indicates if the data may contain positive or negative numbers.

Data Type Inheritance

A Field can be defined to inherit its data type attributes from the definition of another field. The field to inherit the attributes from is referenced as the **Base Field**. When using a base field reference, the data type attributes are defined once, on the base field, and all the fields inheriting their data type information from it are kept consistent with that definition as it may change over time. Any change of a field's data type attributes is automatically reflected on all the fields that reference it as their base field.

Data type information may either be specified directly on the field itself or by referencing a base field. The system does not support a way to partially override the base field's data type information.

It is recommended to leverage data type inheritance whenever possible, especially when the reason for creating a new field is to provide an alternate label for the original field in a certain context. In that situation the new field should reference the original field as its base field and provide the new labels and help text as needed.

Labels and Help Text

For fields that appear on a user interface, the description acts as a label to be used for presentation purposes. As per the product's multi-language support, a field is associated with a label for each of the languages enabled in the system.

A field's help text may be used to provide the user with additional information on how the field is used. When populated for a field that is visible on a user interface that supports display of embedded help, a help icon appears for the field, presenting the help text to the user when clicked.

Overriding Labels and Help Text

The label and help text provided for a product owned field may be overridden by your organization using the corresponding override fields.

The field's label and help text can be overridden for a specific table by populating the corresponding override information as part of the table / field definition. However, this override is not used in portal based user interfaces. It is only applicable if the field is displayed on fixed page user interfaces. For fixed pages, if the override label at the table / field level takes precedence over the override at the field level.

Alternate Labels

There are contexts where a separate label may be needed for the "date" and "time" parts of a date/time field. Such an example is when the field is used by the operational analytics product. For example, for a "Completion Date/Time" field you may provide the context label "Creation Date" for the **Date** context and "Creation Time" for the **Time** context. These context labels are optional.

In the same way, date fields, time fields and date/time fields may be associated with a **Date and Time Base** context label, which is a label without a reference to the word "Date", "Time" or "Date / Time". For example, for a "Completion Date/Time" field, the date and time base label may be "Completion". This label that can be used in combination with date or time attributes such as day, month, year, hours, minutes etc.

Overrides labels are available for these additional context labels.

Tables

A Table definition describes the metadata needed by the application to work with and access a database table or view.

The definition includes the following key details:

- The table's description in the application.
- The list of [fields](#) defined on the table and any foreign key constraints they establish with other tables.
- The table's prime key and how it is generated.
- Whether the table holds administrative, master or transactional data.
- Whether the table is released with product owned system data rows or not.
- The table's role in the conversion process.
- How should table content be upgraded.
- and more

The following sections further discusses concepts and guidelines related to defining tables.

System Tables

Tables released with rows that are owned by the base product are referred to as system tables. These tables include the **Owner** (OWNER_FLG) field to capture the owner of each row.

Refer to [System Data](#) for more information about naming conventions and standards around row record ownership.

The **Upgrade** setting on the table definition record controls what happens to the rows in a table when the system is upgraded to a new release. The most common setting allows customer owned rows to be merged with rows owned by the base product. Other settings may keep the content of the table as is, i.e. rows are not touched by the upgrade, or fully refresh the content of the table with base product rows.

Some fields on certain system owned tables are explicitly marked to allow customization. This means implementation are allowed to change these specific fields for a base owned record. Changes to the field value of one of these types of fields by an implementation are maintained when upgrading to a new version of the product.

Designated Table Roles

Some tables are designed to support the following application roles:

- **Key Tables**
 - A key table holds a copy of a table's prime key only and is only applicable to tables with system generated keys.
 - Tables with a system generated keys reference their Key Table as part of their Table definition record.

- Records in the key table remain in the system even when the related entity is archived, preventing the same key from being allocated to a new record. Retaining the key allows the system to keep the integrity of any references that may still exist to the archived entity.
- **Language Tables**
 - To support multi-language implementations, all labels and descriptions that are presented to a user are kept in a designated language table where a row exists for each enabled language.
 - The product is released with the English content provided in the various language tables. An additional row is added to these tables for each enabled language along with the translated content for that language. Refer to [Support For Different Languages](#) for more information.
 - Tables associated with language sensitive fields reference their corresponding Language Table as part of their Table definition record.
- **Characteristics Tables**
 - Many entities in the system support one or more Characteristics tables, which are used to capture additional fields for the object that are not already supported by the entity's provided attributes.
 - A Characteristics table is designed to capture characteristics applicable to its specific entity only. The entity associated with a Characteristics table is referenced on the Table's definition record.
 - Refer to [Setting Up Characteristic Types & Values](#) for more information.
- **Entity Log Tables**
 - Many entities in the system support the ability to capture lifecycle and other important business events on a designated log table.
 - A log table captures the event details in the form of an application message and stores any parameters for the message in a child log parameters table. All log and log parameters tables follow a predefined structure allowing them to be consistently and efficiently implemented.
 - Typically log tables do not participate in the conversion process.

Table Constraints

Foreign key relationships between tables are not enforced at the database level but rather at the application level, providing the application more flexibility around data manipulation and referential integrity.

The following types of constraints may be defined on the Table's definition record:

- **Primary Key** represents the field or set of fields that represent the unique identifier of a record stored in a table.
- **Logical Key** represents an alternate unique identifier of a record based on a different set of fields than the Primary key.
- **Foreign Key** represents a field or set of fields that specifies identifying and non-identifying relationships to other tables in the application. A foreign key constraint references the primary key constraint of another table.
- **Conditional Foreign Key** represents rare relationships between tables where a single field (or set of fields) may reference multiple primary key constraints of other tables within the application as a foreign key.

The system leverages a table's foreign key constraints information to performs referential integrity validation when rows in this table are deleted. These validations can be disabled by checking off the **Enable Referential Integrity** field on the Table definition record.

Table Indexes

The indexes delivered by the base product for a given table are visible in the index metadata. In addition, table index information may be defined as part of the cloud services support for generation of custom tables in certain use cases. Refer to the section [Generating Custom Tables](#) below for more information.

Primary Key Type

A table's primary key may be of the following types:

- **User-defined** means the user specifies the key when a record is added. This type of key is typically used for configuration and administrative tables.
- **System-generated** means a program generates a random numeric key for the record when it is added.
 - This type of table is typically associated with a key table. Refer to the **Designated Table Roles** section for more information.
 - System generated keys may be fully random or partially inherited from a parent table's key for performance reasons. Refer to the **System Generated Keys** for more information.
- **Sequential** means a sequence number is incremented whenever a record is added to the table. The next number in the sequence determines the key value.
- **Database Native Sequential Key** means a unique number is assigned using a database sequence object.
- **Other** means some other business rule allocates the table's prime-key or the prime key is made of multiple parts.

System Generated Keys

In general, randomly generated numeric system keys are used to attempt to evenly distribute records across a full range of possible IDs. Batch programs that use multiple threads will typically divide the threads using ID ranges and evenly distributed keys will help spread out the work across these threads.

If a table using a system generated key is a child of another table, the child table's key may **inherit** a portion of the random number from its parent table's key. Key inheritance for child records further extends the performance benefit. When considering partitioning, the recommendation for DBAs is to range partition data based on the primary key so that different batch threads operate on different partitions which reduces contention for hot blocks. Ideally the number of batch threads will be an exact multiple of the number of partitions. Batch programs that insert child data (for example batch Billing creation) also benefit from this design especially when the child tables are partitioned in the same way. The parent is often the driver of the batch process. If this is multi-threaded, then each thread is processing a set of parent records in a given ID range and all child records are being inserted into the same ID range.

While most entities with system generated keys either use fully random keys or partially inherited keys from a single parent, entities may be designed to implement more specific key generation rules.

When key inheritance is used, the table definition of the child table defines the following information:

- The number of most significant digits from the parent record's primary key to use as the **prefix** for the child record's key value.
- The **parent key field name** to inherit the key from. This information is provided for display and documentation purposes only and is only provided when the inheritance rule implemented by the entity may be documented this way. Typically the child key value is inherited from a single parent key but in some cases the inheritance rule may be more complex. For example, different types of records in the same child table may inherit their key from different parent key fields. In this case, multiple parent field names may be listed to describe the various inheritance options. When the rule is too complex, this information may not be provided on the table definition record.

Conversion Options

The conversion process manages the process by which master and transaction legacy data, loaded into a staging schema, is validated and assigned new system generated keys before it is copied to the production schema. Refer to [Understanding The Conversion Process](#) for more information.

The tool classifies tables into the following roles:

- Administrative tables. These only exist in the production schema. Instead of a table, a view to the production table exists in the staging schema. These views are necessary to enforce foreign key references when data is validated in the staging schema
 - Convertible tables that retain their prime keys. Data conversion is supported for these tables and their prime key values remain unchanged.
 - Convertible tables that require a new system generated key to be assigned. Data conversion is supported for these tables and their prime key is reassigned by the system during conversion.
 - Not convertible tables. Assigning new system generated keys for a record and replacing all foreign key references it might have with the new key is a complicated process that may not be supported for all tables.
- . The **Data Conversion Role** setting on the table definition record controls if / how the table is used by conversion processing.

Date/Time Configuration

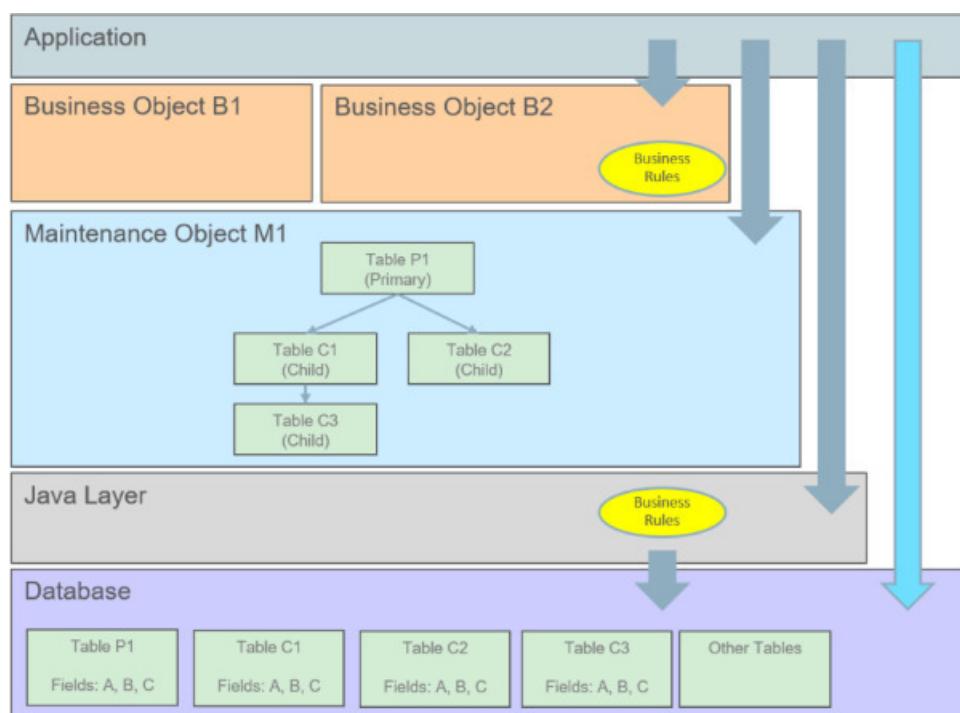

Fields capturing date/time information may be designed to store data in either local legal time or local standard time. Local legal time is captured as entered and displayed as captured in the database. It also assumes the date/time information refers to the time zone defined on the installation options. Refer to [Standard vs. Legal](#) for more information.

Generating Custom Tables

For cloud customers and for certain use cases, the product supports defining table metadata for custom tables and generating the related DDLs for that metadata in the database. For these custom tables, there is a Generation Status visible on the Table metadata that identifies where the Table is in the lifecycle for this supported feature. In addition, the index tab on the table portal is used to define custom indexes that are included in the DDL as part of this feature. If you are a cloud customer and would like more information, refer to the Cloud Services Implementation Guide.

Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes a primary table and any additional child tables that together capture the physical data for the entity. The application reads, adds, updates and deletes an entity as a single object by invoking its maintenance object service.

The following points briefly outline key aspects of application's interaction with maintenance objects as illustrated in this diagram:

- Database tables are maintained solely via the application's Java layer. Direct updates to a table via its Java class is not common and typically reserved to special processes.
- A maintenance object orchestrates the update to an entity's primary table and its child tables as a single object.
- A business object defines a logical representation of an entity, including all or a subset of the maintenance object's tables and fields.
- The more common way to maintain an entity is via its maintenance object, either directly or via one of its business objects. Most entities support the use of business objects and as such their maintenance is typically made via their business objects.
- Direct access to database tables is supported for query purposes only.

The following sections further discusses concepts and guidelines related to defining tables.

Maintaining An Entire Object

A maintenance object includes a single primary table and one or more child tables where each child table can further have nested child tables. The table structure of a maintenance object represents the scope of data that should be maintained together as a single object:

- When an object is added, data is added to each corresponding table.
- When an object is updated, data is updated in each corresponding table.
- When an object is read, data is retrieved from all the tables.
- When an object is deleted, data is deleted from all the tables.

Algorithms

Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Options

The maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system.

Maintenance Objects vs. Business Objects

A maintenance object defines the physical structure of an entity as stored in the database. Different business objects may be defined on top of a maintenance object to represent different types of such entity. A business object includes only the relevant information applicable to the specific type of entity as well as enforces business rules applicable only to that type.

When a maintenance object supports business object configuration, the system uses the **Determine Business Object** maintenance object algorithm to determine the identifying business object that controls a given entity's data structure and rules.

Refer to [The Big Picture of Business Objects](#) for more information.

Defining Valid Values

The product provides several options for defining valid values for a column on a table:

- Lookup
- Extendable Lookup
- Control Table

The following provides more information about the functionality of each of the options available for defining valid values for a column.

Lookup

The simplest mechanism for defining valid values for a column on a table is via the Lookup table. This is sometimes referred to as a “simple” lookup to distinguish it from an extendable lookup (described below). Using the lookup table, you can define valid values and their descriptions. When choosing a valid value that is defined by a lookup, a dropdown UI metaphor is used.

The following highlights functionality related to lookups:

- Lookups are associated with a **Field**. The field is defined as a character data type with an extended data type of **Flag**. The field's label serves as the description for the prompt to select the valid value.
- The lookup code is limited to four characters and must be all uppercase. If there is any functionality where a valid value in the application must match valid values in an external system, the lookup table may not be the appropriate choice.
- The lookup table does not support additional attributes to be defined for each value. This option is only appropriate when a simple code and description pair is needed.
- The product may also use Lookups to define valid values for functionality unrelated to a column on a table. For example, an algorithm plug-in spot may define an input parameter that supports one or more valid values. The plug-in spot may define the valid values using a lookup, allowing for a simple way to validate the value supplied when invoking the algorithm and to document the valid values.

FASTPATH: For more information, refer to [Defining Lookup Options](#).

Extendable Lookup

The extendable lookup provides a way of defining valid values for a column with additional capabilities that are not supported using the Lookup table. When choosing a valid value that is defined by an extendable lookup, a dropdown UI metaphor is used.

The following highlights functionality related to extendable lookups:

- Each Extendable Lookups is defined using a business object.
- A field should be defined for the extendable lookup code. The field defines the label for the lookup code and defines the size of the lookup code. The size is determined based on the business use case. In addition, there are standard fields included in all extendable lookups, including a description, detailed description and an override description (so that implementations can override the description of base delivered values).
- The extendable lookup may define additional information for each value if warranted by the business requirement. See [Additional Attributes](#) for technical information about additional attributes.

FASTPATH: For more information, refer to [Defining Extendable Lookups](#).

Control Table

There may be scenarios where a list of valid values warrants a standalone maintenance object, which is considered an administrative or control table object. When choosing a valid value that is defined by a control, either a dropdown UI metaphor or a search metaphor is used, depending on how it has been designed.

The following points highlight some reasons why this option may be chosen:

- The records require a lifecycle such that BO status is warranted.
- The additional attributes are sophisticated enough that they warrant their own column definition rather than relying on using CLOB or flattened characteristic. For example, if a list of information needs to be captured with several attributes in the list and the information in the list needs to be searchable.

In this situation, if a product has provided a control table for this type of functionality, it will be documented fully in the appropriate functional area. If an implementation determines that a custom control table is warranted, all the standard functionality for a maintenance object is required: database tables, maintenance object metadata, appropriate Java maintenance classes, portals, zones, etc. Refer to the Software Development Kit for more information. No further information is provided in this section for this option.

Characteristic Types

Many maintenance objects in the system support characteristics tables, which are used to capture additional fields for the object that are not already supported by the object's provided attributes. Each characteristic is associated with a characteristic type, which defines attributes of the field you wish to capture.

While each characteristic is stored in a separate row in the characteristic table, the user interface metaphor used to capture and display them differ based on the type of page that is used to maintain the object.

- For portal based pages, the business object drives the display and maintenance of the object. The display and maintenance of each characteristic is determined by the business object's user interface design. For these types of pages, it is recommended that characteristics are defined as flattened elements allowing the user interface to display the characteristic as if it is another field. Refer to [The Flattening Nodes and Attributes](#) for more information about flattening characteristics on a business object schema.
- There are some fixed pages in the system that do not support customization of the user interface. For these objects, the characteristics are displayed / maintained as a generic list.

The topics in this section describe various aspects of a characteristic type definition and usage.

Characteristic Value Types

Every characteristic referenced on an object references a characteristic type. The characteristic type controls the validity of the information entered by a user when they enter the characteristic's values. For example, if you have a characteristic type on user called "skill", the information you setup on this characteristic type controls the valid values that may be specified by a user when defining another user's skill.

When you setup a characteristic type, you must classify it as one of the following categories:

- **Predefined Value.** When you setup a characteristic of this type, you define the individual valid values that may be entered by a user. A good example of such a characteristic type would be one on User to define one or more predefined skills for that user. The valid values for this characteristic type would be defined in a discreet list.
- **Ad hoc Value.** Characteristics of this type do not have their valid values defined in a discreet list because the possible values are infinite. Good examples of such a characteristic type would be ones used to define a user's birth date or their mother's maiden name. Optionally, you can plug-in an algorithm on such a characteristic type to validate the value entered by the user. For example, you can plug-in an algorithm on a characteristic type to ensure the value entered is a date.
- **Foreign Key Value.** Characteristics of this type have their valid values defined in another table. For example perhaps you want to link a user to a table where User is not already a foreign key. Valid values for this type of characteristic would be defined on the user table. Before you can create a characteristic of this type, information about the table that contains the valid values must be defined on the [foreign key reference table](#).
- **File Location.** Characteristics of this type contain a URL. The URL can point to a file or any web site. Characteristics of this type might be useful to hold references to documentation / images associated with a given entity. For example, the image of a letter sent to you by one of your customers could be referenced as a file location characteristic on a customer contact entry. When such a characteristic is defined on an entity, a button can be used to open the URL in a separate browser window.

File location characteristic values must be entered in a "non-relative" format. For example, if you want to define a characteristic value of *www.msn.com*, enter the characteristic value as `http://www.msn.com`. If you omit the `http://` prefix, the system will suffix the characteristic value to the current URL in your browser and attempt to navigate to this location when the launch button is pressed. This may or may not be the desired result.

NOTE:

Due to browser security restrictions, opening URLs using the file protocol ("file://") from pages retrieved using http does not work. If the file protocol is used, the browser either does not return properly or an error is thrown (e.g., "Access Denied", which usually results from cross site scripting features added for security reasons). This issue has no known workaround. To comply with browser security standards, the recommendation is to move the target files to an FTP or HTTP server location to avoid protocols that are subject to browser security restrictions.

Also note that the functionality described in the topics for [Referencing URIs](#) do not apply to this value given that the browser is responsible for connecting to the URI and does not go via server logic.

For references to a file, the recommendation is to use the Attachment functionality to link a file to an object rather than a characteristic type of File Location. Refer to [Attachment Overview](#) for more information. The documentation related to file location remains for upgrade purposes.

Searching By Characteristic Values

For certain entities in the system that have characteristics, you may search for a record linked to a given characteristic value. The search may be done in one of the following ways:

- Some base searches provide an option to search for an object by entering Characteristic Type and Characteristic Value.
- Your implementation may define a customized search for an entity by a characteristic value for a specific characteristic type using a query data explorer.
- Your implementation may require a business service to find a record via a given characteristic value. For example, maybe an upload of user information attempts to find the user via an Employee ID, defined as a characteristic.

Not all entities that support characteristics support searching by characteristics. To confirm if a given characteristic table supports searching, verify that it includes the field **SRCH_CHAR_VAL**.

CAUTION: For ad-hoc characteristics, only the first 50 bytes are searchable. For foreign key characteristics, the search value is populated by concatenating the values of each foreign key column to a maximum of 50 bytes.

For the base searches that provide a generic option to search by characteristic type and value, you can restrict the characteristic types that can be used to search for an entity. For example, imagine you use a characteristic to define a "jurisdiction" associated with a To Do for reporting purposes. If your company operates within a very small number of jurisdictions, you wouldn't want to allow searching for a To Do by jurisdiction, as a large number of To Do entries would be returned.

A flag on the [characteristic type](#) allows an administrator to indicate if searching by this characteristic type is **allowed** or **not allowed**.

Data Typing an Ad-hoc Characteristic Value

An **Ad hoc Value** characteristic type may further restrict the data type of the captured value by referencing a Field. When populated, the system validates that the captured characteristic value complies with the data type definition of the referenced field.

Valid Characteristic Entities

Characteristics are stored in designated tables, each associated with a unique characteristic entity value referenced on the table definition record. A characteristic type record lists all the valid characteristic entities it is allowed to be captured on.

Customizing Base Owned Characteristic Types

Implementations may customize the following aspects of a base owned characteristic type:

- Extend the list of valid values for a base owned **Predefined Value** characteristic type to include additional custom values. Such extension is only supported if the characteristic type is defined with the **Custom** option turned on.
- Provide a custom algorithm to validate an **Ad hoc Value** characteristic type.
- Indicate whether characteristics of this type may be used in searches.
- Extend the list of entities associated with the characteristic type.

Foreign Key References

A Foreign Key Reference defines the necessary information needed to reference an entity in a certain table.

You need to set up this control table if you need to validate a foreign key value against a corresponding table. For example, if a schema element is associated with an FK Reference the system validates the element's value against the corresponding table. Refer to [Configuration Tools](#) to learn more about schema-based objects. Another example is characteristics whose valid values are defined in another table (i.e., you use "foreign key reference" characteristic types). Refer to [Characteristic Types](#) for a description of characteristics of this type.

A FK Reference is used not just for validation purposes. It also used to display the standard information description of the reference entity as well as provide navigation information to its maintenance transaction. Info descriptions appear throughout the UI, for example, whenever an account is displayed on a page, a description of the account appears. The product provides base product FK references for many of its entities as they are used for validation and display of elements in both fixed page user interfaces as well as portal based user interfaces.

An implementation may also see the need to define a foreign key reference. The following points describe what you should know before you can setup a foreign key reference for a table.

- The physical name of the table. Typically this is the primary table of a maintenance object.
- The program used by default to construct the referenced entity's info description.

- The transaction used to maintain the referenced entity. This is where the user navigates to when using the "go to" button or hyperlink associated with the entity.
- The name of the search page or zone used to look for a valid entity.

The topics in this section describe various aspects of a foreign key reference definition and usage.

Information Description Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the standard information associated with a specific referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the [Determine BO](#) maintenance object algorithm system event for more information. If a business object has been determined, the system lets the business object's [Information](#) plug-in, if any, format the description.
- If a business object has not been determined or the business object has no such plug-in, the system lets the maintenance object's [information](#) plug-in, if any, format the description.
- If the maintenance object has no such plug-in, the system uses the info program specified on the FK Reference to format the information.

NOTE: Technical note. The class that returns the information displayed adjacent to the referenced entity is generated specifically for use as an info routine. Please speak to your support group if you need to generate such a class.

NOTE: Generic routine. The system provides a generic information routine that returns the description of control table objects from its associated language table. By "control table" we mean a table with an associated language table that contains a **DESCR** field. Refer to [Defining Table Options](#) for more information on tables and fields. The java class is `com.splwg.base.domain.common.foreignKeyReference.DescriptionRetriever`.

Navigation Information Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the actual transaction to navigate to for a given referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the [Determine BO](#) maintenance object algorithm system event for more information. If a business object has been determined, use the maintenance portal defined as its **Portal Navigation Option** business object option.
- If a business object has not been determined or the business object defines no such option, the system uses the transaction specified on the FK Reference.

Search Options

The product provides two main metaphors for implementing a user interface. For input fields that are foreign keys, search options are dependent on the metaphor used by the page in question.

- A [portal based](#) user interface is a more flexible user interface where an implementation has more options for customizing the look and feel. The base product uses UI maps or automatic UI rendering to display input fields. Elements that are foreign keys may display a search icon if the FK reference defines a Search Zone.

NOTE: Defining search zones directly. It's possible for elements on a UI map to define a specific search zone directly in the HTML, rather than using the search zone defined on an FK reference. Refer to the UI map tips for more information on implementing searches using zones.

- A [fixed maintenance page](#) user interface is a page supplied by the base product where only minor enhancements, if any, can be introduced by implementations. The foreign key reference may be used in one of two ways.

- The based product may use an FK reference to define a base element on one of these pages. If a search is available for such elements, the FK reference's Search Navigation Key is used to implement the search.
- Entities that support characteristics typically include a generic characteristic collection UI metaphor on these types of pages. In this metaphor, a foreign key characteristic displays a search icon if the FK Reference has configured a Search Navigation Key.

NOTE: Not every FK reference provided with the product is configured with a search option. This may be the case if the base delivered pages use a dropdown for this foreign key rather than a search. In addition, base provided FK references that do provide a search may not be configured with both search options. It means that if linking this type of object as a characteristic, the search may not be available if the appropriate search is not configured.

Defining Tables

This portal is used to view and maintain information about an application table.

You can access the portal from the **Admin Menu > Database > Table**. You are brought to a query portal with options for searching for a specific table. Once a table has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Tables](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Table.** This zone provides information about the selected table.
- **Fields.** This zone lists all fields of the selected table and provides various actions to maintain this information.

The following zones may appear as part of the portal's **Relationship** tab page

- **Entity Relationship Diagram.** This zone provides a visual representation of the table's relationship to other tables in the application's data model.

The following zones may appear as part of the portal's **Constraints** tab page

- **Table Constraints.** This zone lists the various key constraints defined for the selected table and provides various actions to maintain this information.
- **Referred By Constraints.** This zone lists all tables referring to the selected table via foreign key constraints.

Refer to [Tables](#) for more information.

The following zones may appear as part of the portal's **Indexes** tab page

- **Table Indexes.** This zone lists the indexes defined for the selected table and provides various actions to maintain this information.

Refer to [Tables](#) for more information.

Defining Fields

This portal is used to view and maintain information about a field. For product owned fields, you may use this portal to override the label of a field on the various pages in the system.

You can access the portal from the **Admin Menu > Database > Field**. You are brought to a query portal with options for searching for a specific field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Fields](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Field.** This zone provides information about the selected field.
- **Tables Using Field.** This zone lists tables referencing the field. It is not visible for work fields.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field. The zone is only visible when the selected field is a lookup field.

The following zone may appear as part of the portal's **References** tab page

- **Field References.** This zone list various configuration entities referencing the current field.

Defining Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes the definition of the tables that together capture the physical data for the entity. In addition, the maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system. Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Many maintenance objects in the system support the use of business objects to further define configuration and business rules for a given record. Refer to [Maintenance Objects](#) for more information.

Maintenance Object - Main

Navigate to **Admin > Database > Maintenance Object** to view information about a maintenance object.

Use the **Maintenance Object Query** portal to search for an existing maintenance object. Once a maintenance object is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Most maintenance objects are provided with the base package. An implementation can introduce custom maintenance objects when needed. Most fields may not be changed if owned by the base package.

Enter a unique **Maintenance Object** name and **Description**. **Owner** indicates if this business object is owned by the base package or by your implementation (**Customer Modification**).

IMPORTANT: If you introduce a new maintenance object, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Service Name is the name of the internal service associated with the maintenance object.

The grid displays the following for each table defined under the maintenance object:

- **Table** is the name of a given table maintained as part of the maintenance object.
- **Table Role** defines the table's place in the maintenance object hierarchy. Only one **Primary** table may be specified within a maintenance object, but the maintenance object may contain many **Child** tables.
- **Parent Constraint ID** specifies the [constraint](#) used to link the table to its parent table within the maintenance object table hierarchy.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

Maintenance Object - Options

Use this page to maintain a maintenance object's options. Open this page using **Admin > Database > Maintenance Object** and then navigate to the **Options** tab.

Description of Page

The options grid allows you to configure the maintenance object to support extensible options.

Select the **Option Type** drop-down to define its **Value**. **Detailed Description** may display additional information on the option type.

Set the **Sequence** to **1** unless the option can have more than one value.

Owner indicates if this is owned by the base package or by your implementation (**Customer Modification**).

NOTE: You can add new option types. Your implementation may want to add additional maintenance option types. For example, your implementation may have plug-in driven logic that would benefit from a new type of option. To do that, add your new values to the customizable lookup field **MAINT_OBJ_OPT_FLG**.

Maintenance Object - Algorithms

Use this page to maintain a maintenance object's algorithms. Open this page using **Admin > Database > Maintenance Object** and then navigate to the **Algorithms** tab.

Description of Page

The **Algorithms** grid contains algorithms that control important functions for instances of this maintenance object. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
- If the algorithm is implemented as a script, a link to the **Script** is provided. Refer to [Plug-in Scripts](#) for more information.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes each **System Event**.

System Event	Optional / Required	Description
Audit	Optional	Algorithms of this type are called to notify of any changes to the maintenance object's set of tables. These algorithms are invoked just before the commit at the end of a logical transaction. The system keeps track of what records are added or changed in the course of a transaction and all MO audit algorithms are executed in order of when each record was first added or updated.
Determine BO	Optional	Algorithm of this type is used to determine the Business Object associated with an instance of the maintenance object. It is necessary to plug in such an algorithm on a Maintenance Object to enable the business object rules functionality. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in

System Event	Optional / Required	Description
		the system invokes the one with the greatest sequence number.
ILM Eligibility	Optional	<p>Algorithms of this type are used for maintenance objects that are enabled for object erasure for Information Lifecycle Management. They are used to review records that have reached the maximum retention days and evaluate if they are ready to be archived.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p>
Information	Optional	<p>We use the term "Maintenance Object Information" to describe the basic information that appears throughout the system to describe an instance of the maintenance object. The data that appears in this information description is constructed using this algorithm.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p>
Manage Erasure Schedule	Optional	<p>Algorithms of this type are used for maintenance objects that are enabled for object erasure, which is a measure to protect Data Privacy. They are triggered when certain system events occur for those objects. The algorithms are used to determine if the record needs to be scheduled for erasure and, if so, create or maintain an entry for the record in the Object Erasure Schedule.</p>
Revision Control	Optional	<p>An algorithm of this type is used to enforce revision control rules when an object is added, changed or deleted. The maintenance object service calls the plug-in once before the object is processed and once more after applying all business object rules. This allows revision rules to take place in proper revision timings.</p>
Transition	Optional	<p>The system calls algorithms of this type upon each successful state transition of a business object as well as when it is first created. These are typically used to record the transition on the maintenance object's log.</p> <p>Note that most base maintenance objects are already shipped with an automatic logging of state transitions. In this case you may use these algorithms to override the base logging functionality with your own. Refer to State Transitions are Audited for more information.</p>
Transition Error	Optional	<p>The system calls this type of algorithm when a state transition fails and the business object should be saved in its latest successful state. The algorithm is responsible for logging the transition error somewhere, typically on the maintenance object's log.</p> <p>Notice that in this case, the caller does NOT get an error back but rather the call ends successfully and the exception is recorded somewhere, as per the plug-in logic.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in</p>

System Event	Optional / Required	Description
		the system invokes the one with the greatest sequence number.

NOTE: You can inactivate algorithms on Maintenance Objects. Your implementation may want to inactivate one or more algorithms plugged into the base maintenance object. To do that, go to the options grid on Maintenance Object - Options and add a new option, setting the option type to **Inactive Algorithm** and setting the option value to the algorithm code.

Maintenance Object - Maintenance Object Tree

You can navigate to the **Maintenance Object Tree** to see an overview of the tables and table relationships associated with the maintenance objects.

Description of Page

This page is dedicated to a [tree](#) that shows the maintenance object's tables as well as [business objects](#), if you have defined any. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Defining Lookups

Lookup fields may be used to define valid values for a column in a table or for other types of values like parameters to an algorithm. This portal is used to view and maintain information about a lookup field and its values. Note that all lookup information is also maintained as part of the corresponding Field portal.

You can access the portal from the **Admin Menu > Database > Lookup**. You are brought to a query portal with options for searching for a specific lookup field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

FASTPATH: Refer to [Defining Valid Values](#) for some background information.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Lookup.** This zone provides information about the selected lookup field.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field.

The base product provides many different lookup fields and their values as part of the product. The following points highlight some functionality related to base-package lookups.

- Fields that are owned by the product will typically provide base lookup values. Implementations are not permitted to remove base delivered lookup values. Implementations may be able to add custom values to base owned lookups. This is controlled with the Custom switch on lookup.
 - When the custom switch is unchecked, it means that there is functionality controlled by the base values and an implementation may not extend or customize this functionality. An example of this type of lookup is the Data Type field on the [Field](#) table. The system supports a distinct list of data types and an implementation may not add additional values.
 - When the custom switch is checked, it means that there is base functionality supplied for the base values but that an implementation can extend the functionality by supplying their own values. An example of this type of lookup is the Access Mode on [Application Service](#). The product provides many values for the access mode lookup, representing

various actions a user may perform. Implementations may add their own values to this lookup. Documentation should indicate when functionality may be extended and should highlight the lookup value that can be extended.

CAUTION: Important! If you introduce new lookup values, you must prefix the lookup value code with **X** or **Y**. If you do not do this, there is a possibility that a future release of the application could introduce a new lookup value with the name you allocated.

- There may be some scenarios where the product supplies a base field and base lookup field with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the lookup values. Typically this type of lookup is for information or categorization purposes. The configuration guide for the functional area associated with the lookup should include a configuration step regarding defining values for this type of lookup.
- The description of base delivered values may be overridden by an implementation.

An implementation may also identify the need for defining a new lookup field with its values.

Defining Extendable Lookups

Extendable lookups are a way of defining valid values that are more sophisticated than simple lookups.

FASTPATH: Refer to [Defining Valid Values](#) for some background information.

The base product provides extendable lookups as part of the product. The following points highlight some functionality related to base-package extendable lookups.

- The base product may supply base extendable lookup values. Implementations are not permitted to remove base delivered extendable lookup values. It is also possible that implementations may be able to add custom values to base owned lookups. If an implementation is not permitted to add lookup values to the base extendable lookup, the extendable lookup's business object will include validation to prevent this. There is no equivalent of the Custom switch that is on the [lookup](#) field.
- There may be some scenarios where the product supplies a base extendable lookup with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the extendable lookup values. The configuration guide for the functional area associated with the extendable lookup should include a configuration step regarding defining values for this type of extendable lookup.
- The description of base delivered values may be overridden by an implementation.

Open this page using **Admin > General > Extendable Lookup**.

You are brought to the **Extendable Lookup Query** where you need to search for the extendable lookup object (i.e., its business object).

Once you have found the appropriate extendable lookup, select the value and you are brought to a standard [All-in-One](#) portal that lists the existing lookup values for the extendable lookup. The standard actions for an All-in-One portal are available here.

Extendable Lookup Advanced Topics

This section provides some additional technical information about extendable lookup attributes

Defining Additional Attributes

The product provides a few different ways to define additional values for an extendable lookup. Some of the methods are only relevant for base delivered lookup values as they may impact whether or not an implementation can update the values.

The following table highlights the options available and some summary information about what the option provides.

Option	Brief Description	Extendable Lookup Value Searchable by this Attribute?	Base Delivered Value Modifiable?
Element mapped to BO_DATA_AREA	The element is mapped to a CLOB field that allows for base delivered values to be modified.	No	Yes
Element mapped to BASE_BO_DATA_AREA	The element is mapped to a CLOB field that does not allow for base delivered values to be modified.	No	No
Flattened characteristic	The element is defined using the flattened characteristic mechanism.	Yes	No

The following points highlight information from the table above:

- The decision of defining an additional attribute using a CLOB mapping or a flattened characteristic will depend on whether the functionality expects that the lookup value is known when the attribute is needed (in which case a CLOB mapping is appropriate) or if the functionality expects to determine the lookup value based on the attribute (in which case, a flattened characteristic is appropriate).
- When the base product defines an extendable lookup with additional attributes and intends to provide base extendable lookup values, it needs to determine whether or not implementations may update the additional attribute or not.
 - If no and the value is mapped to a CLOB, it will map the value to the BASE_BO_DATA_AREA column. This means that implementations will receive an owner mismatch error when attempting to change the value. In addition, upgrading to a new release will replace the value with the base value.
 - If yes and the value is mapped to a CLOB, it will map the value to the BO_DATA_AREA column. This means that implementations will be able to change the value for a base owned record. In addition, upgrading to a new release will not make any changes to the value.
 - For values mapped to a characteristic, the product does not support an implementation changing the value of a base delivered record. If the product would like to support an implementation overriding this type of value, the business object will need to be designed with a corresponding "override" element (also a flattened characteristic), similar to how the product supplies an Override Description field to support an implementation overriding the base product delivered description for a base value. This element will not be delivered with any value and will allow an implementation to populate that value.

NOTE: Note that in this situation, the product functionality that uses this value must cater for the override value.

- All of this detail is only relevant for base provided extendable lookup values. If an implementation adds custom values for a base supplied extendable lookup, all the additional attributes may be populated as appropriate.
- If an implementation defines a custom extendable lookup business object and wants to define an additional attribute using a CLOB, it doesn't matter which CLOB column is used. Both BO_DATA_AREA and BASE_BO_DATA_AREA provide the same functionality for custom business objects.

Capturing a Password

If an extendable lookup includes configuration of a password for some functionality, the system supports automatic encryption of the password value if the schema maps the password to a characteristic using the characteristic type **F1-PWD**.

Defining Characteristic Types

This portal is used to view and maintain characteristic types. An implementation may define their own characteristic types or override some of the settings for base product provided characteristic types.

You can access the portal from the **Admin Menu > General > Characteristic Type**. You are brought to a query portal with options for searching for a specific record. Once a characteristic type record has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOTE: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Characteristic Types](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Characteristic Type.** This zone provides information about the selected characteristic type.
- **Characteristic Values.** This zone is visible for pre-defined characteristic types and shows the existing values (if applicable) with action buttons. It also allows you to add new values. Note that you may only add values to a product owned characteristic type if the Custom switch is checked.

Defining Foreign Key References

The topics in this section describe the transaction that allows you to define foreign key references.

Refer to [Foreign Key References](#) for more information.

To setup a foreign key reference, open **Admin > Database > FK Reference**.

Use the **Foreign Key Reference Query** portal to search for an existing foreign key reference. Once a foreign key reference is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! If you introduce a new foreign key reference, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **FK** (foreign key) **Reference** code and **Description** for the record.

Enter the name of the **Table** whose primary key is referenced. After selecting a **Table**, the columns in the table's primary key are displayed adjacent to **Table PK Sequence**.

Use **Navigation Option** to define the page to which the user will be transferred when they press the go to button or hyperlink associated with the referenced entity. Refer to [Navigation Information Is Dynamically Derived](#) for more information on how this is used.

The **Info Program Type** indicates whether the default program that returns the standard information description is **Java** or **Java (Converted)**, meaning it was converted into Java.

NOTE: **Java (Converted)** program types are not applicable to all products.

Use **Info Program Name** to enter the Java class / program name.

Refer to [Information Description Is Dynamically Derived](#) for more information on the info program is used.

View the source. If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadoc](#) viewer.

Use **Context Menu Name** to specify the context menu that appears to the left of the value.

NOTE: Context Menu Name is not applicable to user interface elements displaying a generic collection using a foreign key characteristic type. It is only applicable for pages utilizing the foreign key compound element type for fixed page user interface and for data displayed in a portal based user interface where the foreign key reference is defined as an attribute for an element. Report parameters that reference foreign key characteristics are an example of a user interface where a context menu is not displayed even if the foreign key reference defines one.

Use **Search Zone** to define the search zone that opens when a user searches for valid values when the foreign key reference is configured as an input field on a portal based page. Refer to [Search Options](#) for more information.

Use **Search Navigation Key** to define the search page that will be opened when a user searches for valid values on a user interface that is a fixed page. Refer to [Search Options](#) for more information.

Use **Search Type** to define the default set of search criteria used by the **Search Navigation Key's** search page.

Use **Search Tooltip** to define a label that describes the **Search Navigation Key's** search page.

NOTE: Search Type and Search Tooltip. These attributes are only applicable to user interface elements utilizing the foreign key compound element type on fixed page user interfaces. Report parameters that reference foreign key characteristics are an example of a user interface where this information is not used even if the foreign key reference defines them.

Audit Trails

The topics in this section describe one way of auditing changes in the system. Note that this technique has limitations and may not be the best option for all situations.

- This functionality is configured at the table and field level. Many base maintenance objects use an XML or CLOB field to capture one or more elements using XML format, configured using a BO schema. This auditing technique is not able to capture changes to individual elements. It can only capture overall changes to the single field. The BO Audit plug-in is a better option for auditing changes to individual elements with the CLOB / XML field.
- The base table provided for supporting audits limits the field size of the before and after values to 254 bytes.
- Auditing is captured for each field. In some cases it is preferred to capture a before and after image for several fields at once. For example, if an address is changed, it's more user friendly to capture the before and after for the full address rather than the individual address components. The BO Audit plug-in allows for capturing a single audit record for multiple elements rather than granular changes for each element.

The subsequent topics highlight how to enable auditing for fields, and describe the auditing queries that you can use to view audit records.

Captured Information

When auditing is enabled for a field, the following information is recorded when the field is changed, added and/or deleted (depending on the actions that you are auditing for that field):

- User ID
- Date and time
- Table name
- Row's prime key value
- Field name
- Before image (blank when a row is added)

- After image (blank when a row is deleted)
- Row action (add, change, delete)

How Auditing Works

You enable auditing on a table in the table's meta-data by specifying the name of the table in which to insert the audit information (the audit table) and the name of the program responsible for inserting the data (the audit trail insert program). Then you define the fields you want to audit by turning on each field's audit switch in the table's field meta-data. You can audit fields for delete, insert and update actions.

Once auditing is enabled for fields in a table, the respective row maintenance program for the table assembles the list of changed fields and calls the audit trail insert program. If any of the changed fields are marked for audit, the audit program inserts audit rows into the audit table.

NOTE: Customizing Audit Information. You may want to maintain audit information other than what is described in [Captured Information](#) or you may want to maintain it in a different format. For example, you may want to maintain audit information for an entire row instead of a field. If so, your implementation team can use the base audit program and base audit tables as examples when creating your own audit trail insert program and audit table structures.

The Audit Trail File

Audit log records are inserted in the audit tables you define. The base product contains a single such table (called **CI_AUDIT**). However, the base audit insert program is designed to allow you to use multiple audit tables.

If you want to segregate audit information into multiple tables, you must create these tables. Use the following guidelines when creating new audit tables (that use the base delivered audit insert program):

- The new audit tables must look identical to the base table (**CI_AUDIT**).
- The new tables must be prefixed with **CM** (e.g., **CM_AUDIT_A**, **CM_AUDIT_B**, etc.). An appropriate java table name must be defined and an *_impl.java program for that java table name must be defined.
- The name of the new table must be referenced on the various tables whose changes should be logged in the new table.

NOTE: It's important to note if you use your own tables (as opposed to using the base package table called **CI_AUDIT**), the SQL used to insert and access audit trail records in the base delivered audit program is dynamic. Otherwise, if the base package's table is used, the SQL is static.

How To Enable Auditing

Enabling audits is a two-step process:

- First, you must turn on auditing for a table by specifying an audit table and an audit trail insert program.
- Second, you must specify the fields and actions to be audited for the table.

The following topics describe this process.

Turn On Auditing For a Table

In order to tell the system which fields to audit, you must know the name of the table on which the field is located. You must specify the audit table and the audit trail insert program for a table in the table's meta-data.

NOTE: Most of the system's table names are fairly intuitive. For example, the user table is called SC_USER, the navigation option table is called CI_NAV_OPT, etc. If you cannot find the table using the search facility on the [Table](#) portal, please contact customer support.

To enable auditing for a table:

- Navigate to the [Table](#) portal and find the table associated with the field(s) for which you want to capture audit information.
- Specify the name of the **Audit Table**.

NOTE: Specifying the Audit Table. You can use the audit table that comes supplied with the base package (**CI_AUDIT**) to audit multiple tables and fields. All the audit logs are combined in a single table (**CI_AUDIT**). However, you can also have a separate audit table for each audited table. Refer to [The Audit Trail File](#) for more information.

- Specify the name of the **Audit Program** . The product provides two programs. **com.splwg.base.domain.common.audit.DefaultTableAuditor** is a standard table audit program. In addition **com.splwg.base.domain.common.audit.ModifiedTableAuditor** is supplied as an alternative. This program does not audit inserts or deletes of empty string data.

CAUTION: By default, none of a table's fields are marked for audit. Even though you have enabled auditing for a table, you must still specify the fields and actions on those fields to be audited (see below).

Specify The Fields and Actions To Be Audited

The system only audits actions (insert, update and delete) made to fields that you want audited.

To specify the fields and actions to be audited:

- Navigate to the [Table](#) portal for a table on which you have enabled auditing.
- For each field you want to audit, specify the actions you want to audit by turning on the **Audit Delete**, **Audit Insert** and **Audit Update** switches as appropriate.

NOTE: You can also turn on the audit switches using the Field zone at the bottom of the [Table](#) portal.

CAUTION: Audit Program Caching! The audit program from the table meta-data is read into a program cache on the application server whenever the date changes or when the server starts. If you implement new auditing on a table, your audit trail does not become effective until this program cache is reloaded. In other words, new audits on tables where the audit program was not previously specified do not become effective until the next day (or the next restart of the application server). However, if you change the fields to be audited for a table where the audit program is already in the cache, your changes are effective immediately.

Audit Queries

There are two queries that can be used to access the audit information.

Audit Query by User

This transaction is used to view changes made by a user that are stored on a given [Audit Trail File](#).

CAUTION: The system only audits changes that you've told it to audit. Refer to [The Big Picture Of Audit Trails](#) for more information.

Navigate to this page by selecting **Admin > Database > Audit Query By User**.

Description of Page

To use this transaction:

- Enter the **User ID** of the user whose changes you wish to view.
- Enter the name of the table on which the audit trail information is stored in **Audit Table**. Refer to [The Audit Trail File](#) for more information about this field.

NOTE: Default Note. If only one audit table is used to store audit trail information, that table is defaulted.

- Specify a date and time range in **Created between** to restrict the records that result from the query.

NOTE: Default Note. The current date is defaulted.

- Click the search button to display all changes recorded on a specific audit table associated with a given user.

Information on this query is initially displayed in reverse chronological order.

The following information is displayed in the grid:

- **Row Creation Date** is the date and time that the change was made.
- **Audited Table Name** contains the name of the table whose contents were changed.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents were changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.
- **Field Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Field Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Audit Query by Table / Field / Key

This transaction is used to view audited changes made to a given table.

CAUTION: The system only audits changes that you've told it to audit. Refer to [The Big Picture Of Audit Trails](#) for more information.

This transaction can be used in several different ways:

- You can view all audited changes to a table. To do this, enter the **Audited Table Name** and leave the other input fields blank.
- You can view all audited changes to a given row in a table (e.g., all changes made to a given user). To do this, enter the **Audited Table Name** and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).
- You can view all audited changes to a given field in a table (e.g., all changes made to all customers' rates). To do this, enter the **Audited Table Name** and the **Audited Field Name**.
- You can view all audited changes to a given field on a specific row. To do this, enter the **Audited Table Name**, the **Audited Field Name**, and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).

Navigate to this page by selecting **Admin > Database > Audit Query By Table/Field/Key**.

Description of Page

To use this transaction:

- Enter the name of the table whose changes you wish to view in **Audited Table Name**.
- If you wish to restrict the audit trail to changes made to a specific field, enter the **Audited Field Name**.
- If you wish to restrict the audit trail to changes made to a given row, enter the row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**). These fields are dynamic based on the **Audited Table Name**.
- Specify a date and time range in **Created between** to restrict the records that result from the query.

NOTE: The current date is defaulted.

- Click the search button to display all changes made to this data.

Information on this query is initially displayed in reverse chronological order by field.

The following information is displayed in the grid:

- **Create Date/Time** is the date / time that the change was made.
- **User Name** is the name of the person who changed the information.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents were changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.
- **Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Bundling

The topics in this section describe the bundling features in the application.

About Bundling

Bundling is the process of grouping entities for export or import from one environment to another.

For example, you might export a set of business objects and service scripts from a development environment and import them into a QA environment for testing. The group of entities is referred to as a bundle. You create export bundles in the source environment; you create import bundles in the target environment.

Working with bundles involves the following tasks:

- Configuring entities for bundling if they are not preconfigured
- Creating an export bundle, which contains a list of entities to be exported from the source environment
- Creating an import bundle to import those entities to the target environment
- Applying the import bundle, which adds or updates the bundled entities to the target environment

Sequencing of Objects in a Bundle

Bundle entities are added or updated to the target environment in the sequence defined in the bundle

Typically, the sequence of entities does not matter. However, sequence is important in the following situations:

- Entities that are referenced as foreign keys should be at the top of the sequence, before the entities that reference them. Specify zones last, as they typically contain numerous foreign key references.
- When importing a business object, specify the business object first, then its plug-in scripts, then the algorithms that reference the scripts, and then the algorithm types that reference the algorithms.
- When importing a portal and its zones, specify the portal first and then its zones.
- When importing a multi-query zone, specify the referenced zones first and then the multi-query zone.
- Always specify algorithms types before algorithms.

You can specify the sequence when you define the export bundle or when you import the bundle to the target environment.

Recursive Key References

Recursive foreign keys result when one object has a foreign key reference to another object that in turn has a foreign key reference to the first object.

For example, a zone has foreign keys to its portals, which have foreign keys to their zones. If the objects you want to bundle have recursive relationships, you must create a 'bundling add' business object that has only the minimal number of elements needed to add the entity. A bundling add business object for a zone contains only the zone code and description, with no references to its portals. In the same way, a bundling add business object for a portal defines only its code and description.

When you apply the bundle, the system initially adds the maintenance object based on the elements defined in the bundling add business object. Before committing the bundle, the system updates the maintenance object with the complete set of elements based on its physical business object.

Note that use of the bundling add BO also benefits records that have optional foreign keys or foreign keys that are part of a child table. That way the person creating the bundle does not have to worry about the sequence of the records. For example, an FK Reference may optionally reference a zone for searching. If a new FK Reference and its search zone are bundled together to copy to another region, the bundling add BO for FK Reference (which doesn't include the Zone) ensures that the FK reference could be added before the zone without getting any validation errors.

Owner Flags on Bundled Entities

The owner flag of the entities in an import bundle must match the owner flag of the target environment.

If you need to import objects that your source environment does not own, you must replace the owner flag in the import bundle with the owner flag of the target environment.

Configuring Maintenance Objects for Bundling

Most base package meta-data objects are pre-configured to support bundling. All other objects must be manually configured.

If a base package maintenance object is pre-configured for bundling, the **Eligible For Bundling** option will be set to "Y" on the Options tab for the maintenance object.

To configure other objects for bundling, review the configuration tasks below and complete all those that apply:

Configuration Task	Scope of Task
Make maintenance objects eligible for bundling	All objects to be included in the bundle.
Add a foreign key reference	All objects to be included in the bundle.
Create a physical business object	All objects to be included in the bundle.

Configuration Task	Scope of Task
Create a bundling add business object	Only needed if there are objects with recursive or optional foreign key references .
Add the Current Bundle zone	Perform this step for any object where you want the Current Bundle zone to appear on the maintenance object's dashboard. This is not required by the bundling process.
Create a custom Entity Search zone and add it to the Bundle Export portal	Perform this step if you would like the object to be listed in the Entity Search zone in the Bundle Export portal. This is not required by the bundling process.

Making Maintenance Objects Eligible for Bundling

The "Eligible For Bundling" maintenance object option must be set to "Y" for all bundled objects. Go to the [Maintenance Object](#) page and search for the maintenance object. On the Options tab, add a new option with the type **Eligible For Bundling**. Set the value to "Y" and click **Save**. This configuration must be in both the source environment and the target environment.

Adding a Foreign Key Reference

Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to [FK Reference](#) and set up a foreign key reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.

Creating a Physical Business Object

If the maintenance object does not already have a Physical BO configured, one must be created to support using it in a bundle. Refer to [Creating a Physical Business Object](#) for more information.

Creating a Bundling Add Business Object

If the objects to be bundled have recursive foreign key references, optional foreign key references or child tables that include foreign key references, create a bundling add business object to avoid problems with referential integrity.

1. Navigate to [Business Object](#) and specify the maintenance object.
2. Click **Generate** in the **BO Schema** dashboard zone to generate a schema that looks like the physical structure of the maintenance object.
3. Remove all child tables and all elements that are not required.
4. Save the business object.
5. Navigate to [Maintenance Object](#) and search for the maintenance object you want to bundle.
6. On the **Option** tab, add a new option with the type **Bundling Add BO**. The value is the name of the bundling add business object you just created.

Adding the Current Bundle Zone

If you want the Current Bundle zone to appear on the maintenance object's dashboard, you must add the Current Bundle zone as a context-sensitive zone for the maintenance object.

1. Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance object.
2. Add the Current Bundle zone F1-BNDLCTXT, to that navigation key.

Adding a Customized Entity Search Query Zone to the Bundle Export Portal

If you want the maintenance object to be searchable in the Bundle Export portal in the Entity Search zone, you must first create an entity-specific query zone to search for the maintenance object. Then you must create a customized entity search

zone that references this new query zone. Finally, you must add the customized entity search zone to the Bundle Export portal.

Note that not all base product entities that are eligible for bundling have a search configured for this zone. There is a limit to the number of searches that may be listed here. The base product has provided searches for only the most common objects that are bundled.

Create an entity-specific query zone to search for the maintenance object:

1. Navigate to [Zone](#) and search for one of the base query zones, such as the Algorithm Search zone F1-BNALGS.
2. Click the **Duplicate** button in the record actions section.
3. Enter a name and description for the new zone.
4. Click **Save**.
5. Customize the details of the parameters for your maintenance object.

Create a customized entity search zone. This step only needs to be done once. If you already have a customized search zone in the Bundle Export portal, skip this step.

1. Navigate to [Zone](#) and search for the F1-BNDLENTQ Entity Search zone.
2. Duplicate this zone.
3. Remove any references to base query zones.

Add the new entity-specific query zone to the customized entity search zone:

1. Locate the customized entity search zone for your Bundle Export portal. This is the zone created in the previous step.
2. Add the name of the query zone you created in the first step to the list of Query Zones.

Add the customized entity search zone to the Bundle Export portal. This step needs to be done only once.

1. Navigate to [Portal](#) and search for the Bundle Export portal, F1BNDLEM.
2. In the zone list, add the entity search zone you created above. (Add the new zone after the base entity search zone).
3. Save the portal.

Working with Bundles

Use the Bundle Export portal to create an export bundle. The export bundle contains a list of entities to be exported from the source environment. When you are ready to import the objects, use the Bundle Import portal to import the objects to the target environment.

Creating Export Bundles

An export bundle contains a list of entities that can be imported into another environment.

To create an export bundle:

1. Log on to the source environment from which objects will be exported.
2. Select **Admin > Implementation Tools > Bundle Export > Add**.
3. Complete the fields in the Main section to define the bundle's basic properties.

NOTE: You can use the Entities section to add bundle entities now, or save the bundle and then add entities as described in step 5.

4. Click **Save** to exit the Edit dialog. The export bundle status is set to Pending.
5. While an export bundle is in Pending state, use any of the following methods to add entities to the bundle:
 - a) Use the **Entity Search** zone on the Bundle Export portal to search for entities and add them to the bundle. If an entity is already in the bundle, you can remove it.
 - b) To import entities from a .CSV file, click **Edit** on the Bundle Export portal, and then click **CSV File to Upload**. Specify the file name and location of the .CSV file containing the list of entities. Click **Submit** to upload the file, and then click **Save** to save the changes.
 - c) Use the **Current Bundle** zone in the dashboard of the entity you want to add. (All entities that are configured to support bundling display a Current Bundle zone). This zone displays a list of all pending export bundles to which you can add the entity.
 - d) When you check an entity into revision control, specify the export bundle on the **Revision Info** dialog.
6. When you have added all entities, click **Bundle** in the Bundle Actions zone on the Bundle Export portal. The export bundle state is set to Bundled and the Bundle Details zone displays the XML representation of every entity in the bundle.

NOTE: The owner flags of the entities in the bundle must match the owner flag of the bundle itself. If the owner flags do not match, the system displays a warning message. Click **OK** to continue or **Cancel** to abort the bundle. If you click OK, you will need to resolve the owner flag discrepancy before you import the bundle to the target environment.

7. Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file). You can now create an import bundle and apply it to the target environment.

NOTE: If you need to make additional changes to the bundle, you must change the bundle state by selecting the **Back to Pending** button in the **Bundle Actions** zone.

Creating and Applying Import Bundles

Import bundles define a group of entities to be added or updated in the target environment.

Before you create an import bundle, you must have already created an export bundle, added entities, and set the bundle's state to Bundled.

To create an import bundle and apply it to the target environment:

1. If you have not already copied the XML from the export bundle, do so now:
 - a) Select **Admin > Implementation Tools > Bundle Export** and search for the bundle.
 - b) Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file).
2. Log on to the target environment.
3. Select **Admin > Implementation Tools > Bundle Import > Add**.
4. In the **Bundle Actions** zone, click **Edit XML**.
5. Paste the contents of the clipboard (or text file if you created one) into the **Bundle Detail** zone.
6. Make any necessary changes to the XML and click **Save**. The status of the import bundle is set to Pending.

NOTE: Use caution when editing the XML to avoid validation errors.

7. To remove entities from the import bundle or change their sequence, click **Edit**. Enter your changes and click **Save** to exit the Edit dialog.
8. When you are ready to apply the bundle, click **Apply**. The import bundle state is set to Applied and the entities are added or updated in the target environment.

Editing Export Bundles

You can add or remove entities from an export bundle when it is in Pending state. You can also change the sequence of entities.

To edit to an export bundle that has already been bundled, you must change the bundle state by selecting the **Back to Pending** button on the Bundle Export portal.

To edit a pending export bundle:

1. Open the bundle in edit mode.
2. Click **Edit** on the Export Bundle portal.
3. Make any necessary changes on the edit dialog and then click **Save**.

Editing Import Bundles

You can remove entities from an import when it is in Pending state. You can also change the sequence of entities and edit the generated XML.

To edit a pending import bundle:

1. Open the bundle in edit mode.
2. To edit the XML snapshot, click **Edit XML**. Edit the XML code as needed, then click **Save**.

NOTE: Use caution when editing the XML to avoid validation errors.

3. To remove entities or change their sequence, click **Edit**. Make any necessary changes and click **Save**.

Revision Control

The topics in this section describe the revision control features in the application.

About Revision Control

Revision control is a tool provided for the development phase of a project to allow a user to check out an object that is being worked on. In addition, it captures the version of the maintenance object when users check in an update, maintaining a history of the changes to the object.

If revision control is enabled for an object you must check out the object to change it. While the object is checked out no one else can work on it. You can revert all changes made since checking out an object, reinstate an older version of an object, recover a deleted object, and force a check in of an object if someone else has it checked out.

NOTE: Revision control does not keep your work separate from the environment. Because the metadata for maintenance objects is in the central database, any changes you make to an object while it is checked out will be visible to others and may impact their work.

Many of the maintenance objects used as configuration tools are already configured for revision control, but it is turned off by default. For example, business objects, algorithms, data areas, UI maps, and scripts are pre-configured for revision control.

Turning On Revision Control

Revision control is turned off by default for maintenance objects that are configured for revision control.

To turn on revision control:

1. Add the base package **Checked Out** zone to the Dashboard portal.
 - a) Navigate to [Portal](#).
 - b) Search for the portal CI_DASHBOARD.
 - c) In the zone list for the **Dashboard** portal, add the zone F1-USRCHKOUT.
2. Set up application security.

For users to have access to revision control, they must belong to a user group that has access to the application service F1-OBJREVBOAS.
3. Add the revision control algorithm to the maintenance object that you want to have revision control.

This step must be repeated for each maintenance object that you want to have revision control.

 - a) Go to the [Maintenance Object](#) page and search for the maintenance object that you want to have revision control.
 - b) On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Configuring Maintenance Objects for Revision Control

Most configuration tool maintenance objects are pre-configured for revision control. You can configure other maintenance objects for revision control, as well.

To configure other objects for revision control:

1. Create a physical business object for the maintenance object. Refer to [Creating a Physical Business Object](#) for more information.
2. Add a foreign key reference to the maintenance object so that the standard information string is displayed. Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to [FK Reference](#) and set up a foreign key reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.
3. Add the **Revision Control** zone to the maintenance object.
 - a) Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance object.
 - b) Add the Revision Control zone, F1-OBJREVCTL, to that navigation key.
4. Add the revision control algorithm to the maintenance object.
 - a) Go to the [Maintenance Object](#) page and search for the maintenance object that you want to have revision control.
 - b) On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Working with the Revision Control Zones

You use two zones in the dashboard to work with revision controlled objects when revision control is turned on.

The **Revision Control** zone gives you several options for managing the revision of the currently displayed object. This zone also shows when the object was last revised and by whom. This information is linked to the **Revision Control Search** portal which lists all of the versions of the object.

Using the Revision Control zone you can:

- Check out an object in order to change it.
- Check in an object so others will be able to work on it.
- Revert the object back to where it was at the last checkout.
- Force a check in of an object that is checked out by someone else. You need special access rights to force a check in.
- Delete an object.

The **Checked Out** zone lists all of the objects that you currently have checked out. Clicking on an object listed in this zone will take you to the page for that object. The zone is collapsed if you have no objects checked out.

See [Revision Control Search](#) for more information about Check In, Force Check In, and Check Out one or more records simultaneously.

Checking Out an Object

You must check out a revision controlled object in order to change it.

An object must have revision control turned on before you can check it out.

NOTE: When you first create or update an object a dialog box informs you that the object is under revision control. You can select **OK** to check out the object and save your changes, or **Cancel** to stop the update.

1. Go to the object that you want to work on.
2. Select **Check Out** in the **Revision Control** dashboard zone.

Checking In an Object

You must check in a revision controlled object in order to create a new version of it. Checking in an object also allows others to check it out.

1. Select a link in the **Checked Out** dashboard zone to go to the object that you want to check in.
2. Select **Check In** in the **Revision Control** dashboard zone.
3. Provide details about the version:
 - In the **External References** field state the bug number, enhancement number, or a reason for the revision.
 - In the **Detailed Description** field provide additional details regarding the revision.
 - In the **Keep Checked Out** box specify if you want to keep the object checked out. If you keep the object checked out then your revision is a new version that you can restore later.
 - In the **Add To Bundle** box specify if the object belongs to a bundle.
4. Select **OK** to check in the object.

Reverting Changes

Reverting changes will undo any changes you made since you checked out an object.

To revert changes:

1. Go to the object that you want to revert.
2. Select **Revert** in the **Revision Control** dashboard zone.
3. In the confirmation dialog box select **OK** to confirm the action or **Cancel** to return to the object page.

Once reverted, the object can be checked out by another user.

Forcing a Check In or Restore

You can force a check in if an object is checked out by another user and that person is not available to check it in.

You must have proper access rights to force a check in or restore.

To force a check in or restore:

1. Go to the object that is checked out by another user.
2. Select **Force Check In** or **Force Restore** in the Revision Control zone.

The **Force Check In** option is the same as a regular check in. The **Force Restore** option checks in the object and restores it to the previously checked in version.

Deleting an Object

If revision control is turned on for an object, you must use the **Revision Control** zone to delete it.

The object must be checked in before it can be deleted.

To delete a revision controlled object:

1. Go to the object that you want to delete.
2. Select **Delete** in the **Revision Control** zone.
3. Provide details regarding the deletion.
4. Select **OK** to delete the object.

The system creates a revision record before the object is deleted so that the deleted object can be restored.

Restoring an Object

You can restore an older version of either a current object or a deleted object.

An object must be checked in before an older version can be restored.

To restore an object:

1. Go to the **Revision History** portal for the object.
If the object was deleted you must search for it by going to **Admin > Implementation Tools > Revision Control**.
2. Select the desired entity by clicking the hyperlink in the **Details** column.
3. Locate the row in the version history that has the version that you want to restore and click **Restore**.
4. In the confirmation dialog box select **OK** to confirm the action or **Cancel** to return to the object page.

Working with the Revision Control Portal

The **Revision Control** portal lists information about each version of a revision controlled object.

You can navigate to the **Revision Control** portal from either a link in the **Revision Control** dashboard zone or by going to **Revision Control** portal through **Admin**.

If you want to find the Revision History entry for an earlier version or deleted object, you must search for the object using the **Revision Control Search** portal. Once you select the desired entry, you can restore a previous version of the object clicking **Restore** in the row for the version that you want to restore. You can also see the details of each version by clicking the broadcast icon for that version.

See [Working with Revision Control Zones](#) for more information about tasks that can be performed through Revision Control.

Revision Control Search

The **Revision Control Search** portal allows users to search for entities that have a revision history. The **Search By** dropdown provides additional functionality so that users can search for revisions that are associated to theirs or other's user ID. Users can also **Check In**, **Force Check In**, or **Check Out** one or more entities through this portal.

Zone Options

- **Revision History Search** allows the user to query for revised entities based on a combination of criteria.
 - In the **User ID** field, enter the user ID that is associated with a revision.
 - In the **External Reference** field, enter an ID from an external system and is associated with a revision.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key 1**, **Key 2**, **Key 3**, **Key 4**, **Key 5** fields, enter the primary identifier(s) for the revised entity. Typically, the entity only requires a single key, but some entities require more than one (for example, Oracle Utilities Customer Care and Billing SA Type require CIS Division and SA Type).
 - In the **Status** dropdown menu, select the entity status for your search.
- **Check In** allows the user to search for entities currently checked out to the logged in user ID and a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them in.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.
- **Force Check In** allows the user to search for entities that are currently checked out by other user IDs (excluding the logged in user ID) based on a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them in.
 - In the **Checked Out By User** field, enter the user ID that has the entity in a Checked Out status.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.
- **Check Out** allows the user to search for entities currently checked in user ID and a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them out.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.

Please see [Working with Revision Control Zones](#) for more information about working with individual entities.

Information Lifecycle Management

Information Lifecycle Management (ILM) is designed to address data management issues, with a combination of processes and policies so that the appropriate solution can be applied to each phase of the data's lifecycle.

Data lifecycle typically refers to the fact that the most recent data is active in the system. As time progresses, the same data becomes old and unused. Older data becomes overhead to the application not only in terms of storage, but also in terms of performance. This older data's impact can be reduced by using advanced compression techniques, and can be put into slower and cheaper storage media. Depending on how often it's accessed, it can be removed from the system to make an overall savings of cost and performance. The target tables for ILM are transactional tables that have the potential to grow and become voluminous over time.

The Approach to Implementing Information Lifecycle Management

This section describes the product approach to implementing ILM for its maintenance objects (MOs).

NOTE: The term archiving is used to cover any of the possible steps an implementation may take in their data management strategy, including compression, moving to cheaper storage, and removing the data altogether.

Age is the starting point of the ILM product implementation for some of its high volume data. In general "old" records are considered eligible to be archived. In the product solution, maintenance objects (MOs) that are enabled for ILM have an ILM Date on the primary table and the date is typically set to the record's creation date. (An MO may have special business rules for setting this date, in which case, a different date may be used to set the initial ILM Date). For implementations that want to use ILM to manage the records in the MO, the ILM date is used for defining partitions for the primary table.

There are cases where a record's age is not the only factor in determining whether or not it is eligible to be archived. There may be some MOs where an old record is still 'in progress' or 'active' and should not be archived. There may be other MOs where certain records should never be archived. To evaluate archive eligibility using information other than the ILM Date, the ILM enabled MOs include an ILM Archive switch that is used to explicitly mark records that have been evaluated and should be archived. This allows DBAs to monitor partitions based on age and the value of this switch to evaluate data that may be ready to be archived.

Evaluating records to determine their archive eligibility should still occur on "old" records. The expectation is that a large percentage of the old records will be eligible for archiving. The small number that may be ineligible could be updated with a more recent ILM date. This may cause the records to move into a different partition and can delay any further evaluation of those records until more time has passed.

For each MO enabled for ILM, the product provides a batch process to review "old" records and an ILM eligibility algorithm that contains business logic to evaluate the record and mark it eligible for archiving or not. The following sections provide more information about the batch process and algorithm functionality.

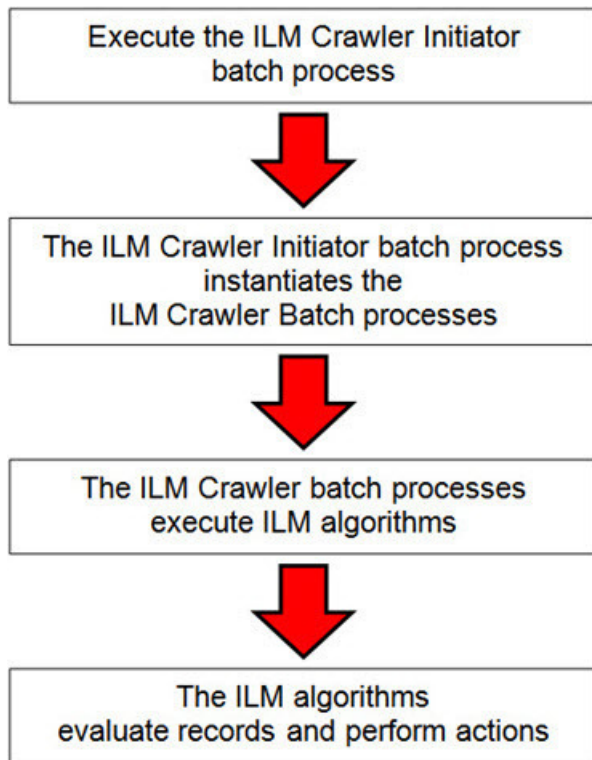

Batch Processes

There are two main types of batch processes that manage data for ILM in the application: ILM Crawler Initiator and individual ILM Crawlers (one for each MO that is configured for ILM).

- **ILM Crawler Initiator: (F1-ILMIN)** - The ILM Crawler Initiator is a *driver* batch process that starts the individual ILM Crawler batch control as defined by the MO's options.

Restartable: In case of server failure, the ILM Crawler Initiator process can be restarted, which will also restart the ILM Crawler processes.

- **ILM Crawler:** Each maintenance object that is configured for ILM defines an ILM Crawler. These are *child* batch processes that can be started either by the ILM Crawler Initiator or by a standalone batch submission.

The ILM Crawler batch process selects records whose retention period has elapsed and invokes the MO's ILM eligibility algorithm to determine if the record is ready to be archived or not. The ILM eligibility algorithm is responsible for setting the record's ILM archive switch to 'Y' and updating the ILM date, if necessary.

The retention period defines the period that records are considered active. It spans the system date and cutoff date (calculated as system date - retention days).

The retention days of an MO is derived as follows:

- If the ILM Retention Days MO option is defined, that is used.
- Otherwise, the Default Retention Days from the ILM Master Configuration record is used.

An error is issued if no retention period is found.

The crawler calculates the cutoff date and selects all records whose ILM archive switch is 'N' and whose ILM date is prior to the cutoff date. Each record returned is subject to ILM eligibility.

If the Override Cutoff Date parameter is supplied, it will be used instead of the calculated cutoff date. An error is issued if the override cutoff date is later than the calculated cutoff date. This parameter is useful if an object has many years of historic data eligible for archiving. Setting this parameter allows for widening the retention period and therefore limiting the process to a shorter period for initial processing

NOTE: ILM Crawler batch processes are designed not to interfere with current online or batch processing. Because of this, these batch processes can run throughout the day.

NOTE: Before passing the cut-off date to the algorithm, the ILM crawler ensures that the number of days calculated (System Date – override cut-off date) is more than the retention period specified in the MO option or the Master Configuration. If the number of days calculated is **less than** the retention period specified on the MO option or the Master Configuration, then it throws an error.

Eligibility Algorithm

Algorithms are triggered by the ILM batch crawler for the maintenance object. The key responsibility of the ILM algorithm is to determine whether a record can be marked as ready to be archived or not. If a record is determined to be ready for archive, the algorithm should set the ILM Archive switch to Y. If not, the algorithm leaves the switch set to N and may decide to update the ILM Date to something more recent (like the System Date) to ensure that the record does not get evaluated again until the future.

This algorithm is plugged into the [Maintenance Object — Algorithm](#) collection.

Oracle Utilities Application Framework provides the algorithm **ILM Eligibility Based on Status (F1-ILMELIG)** to support the ILM batch crawler. Refer to the algorithm type description for details about how this algorithm works. If a maintenance object has special business rules that are evaluated to determine the eligibility for ILM, a custom algorithm can be created and applied by the implementation team.

Enabling ILM for Supported Maintenance Objects

In order to enable ILM for one or more maintenance objects, several steps are needed in both the configuration and in the database. This section describes some configuration enabled by default and some steps that must be taken in order to fully implement ILM.

There is some configuration enabled by default, but it won't be used unless ILM is fully configured. Each maintenance object that the product has configured for ILM has the following provided out of the box:

- **Special Table Columns:** Maintenance objects that support ILM include two specific columns: ILM Archive Switch (**ILM_ARCH_SW**) and ILM Date (**ILM_DT**).
- **Crawler Batch Process:** A "crawler" batch process is provided for each maintenance object that supports ILM and it is plugged into the MO as an option. Refer to [Batch Processes](#) for more information.
- **ILM Eligibility Algorithm:** Each maintenance object that is configured for ILM defines an [eligibility algorithm](#) that executes the logic to set the ILM Archive switch appropriately. This is plugged in to the MO algorithm collection.

If an implementation decides to implement ILM, there are steps that need to be followed, which are highlighted below.

Create the Master Configuration Record

The first step when enabling ILM is to create the **ILM Configuration**[master configuration](#) record.

The master configuration for ILM Configuration defines global parameters for all ILM eligible maintenance objects. For example, the Default Retention Period. In addition, your product may implement additional configuration. Refer to the embedded help for specific details about the information supported for your product's ILM configuration.

In addition, the user interface for this master configuration record displays summary information about all the maintenance objects that are configured to use ILM.

Confirm the Maintenance Objects to Enable

In viewing the list of maintenance objects that support ILM in the ILM master configuration page, your implementation may choose to enable ILM for only a subset of the supported maintenance objects. For example, some of the maintenance objects may not be relevant for your implementation. Or perhaps, the functionality provided by the maintenance object is used, but your implementation does not expect a high volume of data.

For each maintenance object that your implementation has confirmed for ILM, the following steps should be taken:

- Determine if the maintenance object should have a different default retention days than the system wide value defined on the master configuration. If so, use the MO option **ILM Retention Period in Days** to enter an override option for this maintenance object.

- Review the functionality of the ILM Eligibility algorithm provided by the product for this maintenance object. Each algorithm may support additional configuration based on business needs. If your organization has special business rules that aren't satisfied by the algorithm provided by the product, a custom algorithm may be provided to override the base algorithm.

For each maintenance object that your implementation does not want to enable for ILM, inactivate the eligibility algorithm. This will ensure that the ILM Crawler Initiator background process does not submit the crawler batch job for the maintenance object in question.

- Go to the [Maintenance Object - Algorithm](#) tab for each maintenance object and take note of the **ILM Eligibility** algorithm code.
- Go to the [Maintenance Object - Option](#) tab for the same maintenance object and add an option with an option type of **Inactivate Algorithm** and the value set to the ILM eligibility algorithm noted in the previous step.

Database Administrator Tasks

In order to implement ILM for each of the maintenance objects determined above, your database administrator must perform several steps in the database for the tables related to each MO. The following points are a summary of those steps. More detail can be found in the Information Lifecycle Management section of your product's *Database Administration Guide*.

- **Initializing ILM Date:** Your existing tables that are enabled for ILM may not have the ILM Date and ILM Archive switch initialized on all existing records. When choosing to enable ILM, a first step is to initialize this data based on recommendations provided in the DBA guide.
- **Referential Integrity:** The recommended partitioning strategy for child tables in a maintenance object is referential partitioning. In order to implement this, database referential integrity features must be enabled.
- **Partitioning:** This provides a way in which the data can segregate into multiple table partitions and will help in better management of the lifecycle of the data.

Schedule the ILM Crawler Initiator

The final step of enabling the system for ILM is to schedule the ILM crawler initiator **F1-ILMIN** regularly based on your implementation's need. It is recommended to only schedule this batch process once all the required database activities are complete.

Ongoing ILM Tasks

For an environment where ILM is enabled, besides the periodic execution of the ILM crawler batch processes to review and mark records, your database administrator has ongoing tasks.

The DBA reviews and maintains partitions and identifies partitions that may warrant some type of archiving step. The Information Lifecycle Management section of your product's *Database Administration Guide* provides more information for your DBA.

Archived Foreign Keys

If your DBA chooses to archive a partition, there may be records in the system that refer to one of the archived records as a foreign key.

When a user attempts to view a record using a hyperlink or drill down mechanism, if the implementation of the navigation uses FK Reference functionality, the system will first check if the record exists. If not, it will display a message to the user indicating that the record has been archived.

Configuration Tools

This section describes tools to facilitate detailed business configuration. The configuration tools allow you to extend both the front-end user interface as well as create and define specialized back-end services.

Business Objects

A [maintenance object](#) defines the physical tables that are used to capture all the possible details for an entity in the system. A business object is tool provided to further define business rules for a maintenance object.

This section provides an overview of business objects and describes how to maintain them.

The Big Picture of Business Objects

The topics in this section describe background topics relevant to business objects.

What Is A Business Object?

A business object (BO) is a powerful tool used throughout the system. For many maintenance objects, a BO is a key attribute of the record used to define the data it captures, its user interface behavior and its business rules. Some business objects support the definition of a lifecycle, capturing different states that a record may go through, allowing for different business rules to be executed along the way. This type of business object is considered the “identifying” or “governing” business object. We will see later that other types of BOs exist that are different from the “identifying” business object.

The use of business objects allows for extensibility and customization of product delivered maintenance objects. There are many options to adjust the behavior of base delivered business objects. In addition, implementations may introduce their own business objects if the base product delivered objects do not meet their business needs.

NOTE: Not all maintenance objects in the product support business objects as a “identifying” or “governing” tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

A Business Object Has a Schema

A business object has elements. The elements are a logical view of fields and columns in one of the maintenance object’s tables. The structure of a business object is defined using an XML schema. The main purpose of the schema is to identify all the elements from the maintenance object that are included in the business object and map them to the corresponding maintenance object fields. Every element in the BO schema must be stored somewhere in the maintenance object. The BO may not define elements that are derived.

When defining elements for the primary table or the language table (for an administrative object) there is no need to define the name of the physical table in the schema. The system infers this information. The following is a snippet of a schema:

```
<schema>
  <migrationPlan mapField="MIGR_PLAN_CD" suppress="true" isPrimeKey="true"/>
  <bo mapField="BUS_OBJ_CD" fkRef="F1-BUSOB"/>
  <customizationOwner mapField="OWNER_FLG" suppress="input"/>
  <version mapField="VERSION" suppress="true"/>
  <description mapField="DESCR"/>
  <longDescription mapField="DESCRLONG"/>
  ...
```

Many maintenance objects have child table collections (e.g., a collection of names for a person, or a collection of persons on an account). Depending on the requirements, the business object may define the full collection such that the user will

maintain the information in a grid. However, the schema also supports “flattening” records in a child table so that they can be treated as if they were singular elements. The following are examples of each:

Example of a child table. This is a snippet of the Instructions collection on the migration plan business object. You can see that the list attribute defines the child table and all elements within it map to the appropriate column in that table.

```
<migrationPlanInstruction type="list" mapChild="F1_MIGR_PLAN_INSTR">
  <migrationPlan mapField="MIGR_PLAN_CD" suppress="true"/>
  <sequence mapField="PLAN_INSTR_SEQ" suppress="true"/>
  <instructionSequence mapField="INSTR_SEQ"/>
  <instructionType mapField="INSTR_TYPE_FLG"/>
  <parentInstructionSequence mapField="PARENT_INSTR_SEQ"/>
  <businessObject mapField="BUS_OBJ_CD" fkRef="F1-BOMO"/>
...

```

Example of a simple “flattened” field. The business object for Status Reason includes an element called Usage, which maps to a pre-defined characteristic of type **F1-SRUSG**. The “row” defines which child table is being flattened and the attributes of the row in that child that uniquely identify it.

```
<usage mdField="STATUS_RSN_USAGE" mapField="CHAR_VAL">
  <row mapChild="F1_BUS_OBJ_STATUS_RSN_CHAR">
    <CHAR_TYPE_CD is="F1-SRUSG"/>
    <SEQ_NUM is="1"/>
  </row>
</usage>

```

Example of a “flattened row”. This business object for Account includes a single row for the Person collection where only the “financially responsible, main” customer is defined. The “accountPerson” attribute defines one field from that row (the Person Id) and includes the ‘flattening’ criteria in the “row” information. In addition, a second field from that same row (“accountRelType”) is defined. Instead of having to repeat the flattening criteria, the “rowRef” attribute identifies the element that includes the flattening.

```
<accountPerson mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true"/>
    <FIN_RESP_SW default="true"/>
  </row>
</accountPerson>
<accountRelType mapField="ACCT_REL_TYPE_CD" rowRef="accountPerson" dataType="string"/>

```

Example of a “flattened list”. The business object for Tax Bill Type includes an list of valid algorithms for “bill completion”. The Sequence and the Algorithm are presented in a list. The list element identifies the child table and the ‘rowFilter’ identifies the information about the list that is common.

```
<taxBillCompletion type="list" mapChild="C1_TAX_BILL_TYPE_ALG">
  <rowFilter suppress="true" private="true">
    <TAX_BILL_TYPE_SEVT_FLG is="C1BC"/>
  </rowFilter>
  <sequence mapField="SEQ_NUM"/>
  <algorithm mapField="ALG_CD" fkRef="F1-ALG"/>
</taxBillCompletion>

```

In addition, many maintenance objects support an XML structure field within the entity. These fields may be of data type CLOB or XML. One or more business object elements may be mapped to the MO's XML structure field. These elements may be defined in different logical places in the business object schema based on what makes sense for the business rules. When updating the MO, the system builds a type of XML document that includes all the elements mapped to the XML structure and stores it in one column. The following is an example of elements mapped to an XML column:

```
<filePath mdField="F1_FILE_PATH" mapXML="MST_CONFIG_DATA" required="true"/>
<characterEncoding mdField="F1_CHAR_ENCODING" mapXML="MST_CONFIG_DATA"/>

```

NOTE: If the MO's XML structure field is of the data type XML, the database will allow searching for records based on that data, assuming appropriate indexes are defined. If the MO's XML structure field is of the data type CLOB, indexing or joining to elements in this column via an SQL statement is not typically supported. Note that most MOs are currently using the CLOB data type for the XML structure column, if provided.

Some business objects may have child tables that allow data to be stored in an XML structure field. The schema language supports defining elements from those fields in your schema as well.

Besides including information about the physical “mapping” of the element to its appropriate table / field location in the maintenance object, the schema supports additional syntax to provide the ability to define basic validation and data manipulation rules, including:

- Identifying the primary key of the record or the primary key of the a row in a list.
- Identifying which elements are required when adding or changing a record.
- Default values when no data is supplied on an Add.
- For elements that are lookup values, the lookup may be specified to validate that the value of the element is a valid lookup value.
- For elements that are foreign keys to another table, the FK Reference may be specified to validate the data.

The system will check the validity of the data based on the schema definition obviating the need for any special algorithm to check this validation.

In addition, the schema language may include some attributes that are used to auto-render the view of the record on the user interface, such as the **suppress** attribute. Refer to [BO Defines its User Interface](#) for more information.

NOTE: Refer to [Schema Syntax](#) for the complete list of the XML nodes and attributes available to you when you construct a schema.

A business object’s schema may include a subset of the fields and tables defined in the maintenance object. There are two reasons for this:

- The fields or tables may not be applicable to the type of record the business object is governing. For example, a field that is specific to gas may not be included on a Device business object that is specific to electric meters.
- The information is not maintained through the business object, but rather maintained separately. For example, many BO based maintenance objects include a Log table. The records in the log table are typically not included the BO because they are viewed and maintained separately from the business object.

A Business Object May Define Business Rules

A business object may define business rules that govern the behavior of entities of this type.

- Simple element-level validation is supported by schema attributes. Note that element-level validation is executed before any maintenance object processing. For more sophisticated rules you create **Validation** algorithms and associate them with your business object. BO validation algorithms are only executed after "core validation" held in the MO is passed.
- A **Pre-Processing** algorithm may be used to "massage" a business object's elements prior to any maintenance object processing. For example, although simple element-level defaulting is supported by schema attributes. you may use this type of algorithm to default element values that are more sophisticated.
- A **Post-Processing** algorithm may be used to perform additional steps such as creating a To Do Entry or add a log record as part of the business object logical transaction. These plug-ins are executed after all the validation rules are executed.
- An **Audit** algorithm may be used to audit changes made to entities of this type. Any time a business entity is added, changed or deleted, the system detects and summarizes the list of changes that took place in that transaction and hands it over to **Audit** plug-ins associated with the business object. These plug-ins are executed after all the post-processing rules are executed. It is the responsibility of such algorithms to log the changes if and where appropriate, for example as a log entry or an entry in an audit trail table or an entry in the [business event log](#)

By default all elements of the business object are subject to auditing. You can however mark certain elements to be excluded from the auditing process using the **noAudit** schema attribute. Marking an element as not auditable will prevent it from ever appearing as a changed element in the business object's audit plug-in spot. In addition, if the only elements

that changed in a BO are ones marked to not audit, the audit algorithm is not even called. Refer to [Schema Syntax](#) for more information on this attribute.

Refer to [Business Object - Algorithms](#) for more information on the various types of algorithms.

The system applies business object rules (schema based and algorithms) whenever a business object instance is added, changed or deleted. This is only possible when the call is made via the maintenance object service. For example, when made via business object interaction ("invoke BO"), the MO's maintenance page or inbound web services that reference the BO. In addition the system must be able to [determine the identifying business object](#) associated with the actual object being processed. If the business object cannot be determined for a maintenance object instance business object rules are not applied.

NOTE:

Pre-Processing is special. The pre-processing algorithm plug-in spot is unique in that it only applies during a BO interaction. It is executed prior to any maintenance object processing. It means that when performing add, change or delete via the maintenance object service, the pre-processing plug-in is not executed.

CAUTION: Direct entity updates bypass business rules! As mentioned above, it is the maintenance object service layer that applies business object rules. Processes that directly update entities not via the maintenance object service bypass any business object rules you may have configured.

FASTPATH: Refer to [BO Algorithm Execution Order](#) for a summary of when these algorithms are executed with respect to lifecycle algorithms.

The plug-in spots described above are available for all business objects and they are executed by the system when processing adds or updates to the business object. It is possible for a specific maintenance object to define a special plug-in spot for business objects of that MO. When this happens, the maintenance object identifies the special algorithm entity lookup value as an [MO option: Valid BO System Event](#), causing the BO Algorithm collection to include that system event in its list.

A Business Object Defines its User Interface

One of the responsibilities of an identifying business object is to define its user interface rules for viewing and maintenance of its record. The standard implementation for maintaining a business object is that a [maintenance portal](#) is used to display a record. This portal includes a "map" zone that displays the information about the business object. To add or make changes to a record, the user clicks a button that launches a maintenance BPA script which displays a maintenance "map".

The display and maintenance "maps" are driven by the business object. The BO may define a full [UI map](#) where all the information is displayed based on the map's HTML. Note that for a child BO, the maps may be [inherited](#) by a parent BO (or any BO "up the chain").

The standard going forward is to use schema definition and UI Hints to define user interface behavior so that a full UI map is not needed but rather the HTML is derived. The schema language includes some basic display attributes such as **label** and **suppress**. UI hints provide many additional tags and elements that allow dynamic generation of formatted UI Maps. For more complex behavior in the user interface, for example where javascript is needed, UI map fragments may be defined within the schema via UI hints. In this way only complex UI behavior warrants small snippets of javascript and HTML. However the rendering of standard fields can be dynamically rendered. UI map fragments also allow for derived fields to be included in the user interface.

A business object schema may include [data areas](#) for segments of its schema definition to allow for reusable components. In this case the data area would also include schema attributes and UI hints for the elements that it is including.

NOTE: Refer to [UI Hint Syntax](#) for detailed information about the supported syntax.

As mentioned in [Business Object Inheritance](#), schemas are not inherited on a child business object. As such, when using UI hints for automatic UI rendering, the child BO must define the full schema with all the definitions. A good business object hierarchy will be designed for reuse meaning that the child BO will include the parent BO schema or alternatively, the BO schemas will include reusable data areas.

Invoking A Business Object

We have talked about defining a business object. This section describes how business objects are used throughout the system to view, add and update records.

- Various parameters for zones that are used to display data in the system include support for retrieving data by referencing a business object. The zone code will "invoke" the BO, meaning that the record will be retrieved using the referenced BO.
- The system's [scripting](#) language includes a step type to "invoke BO". This allows for BPA scripts, service scripts and plug-in scripts to retrieve information and add or update records using BO interaction.
- [Inbound web services](#) may reference a business object in its operations collection. This allows external systems to add or update records in our product via web service interaction.

Often when configuring a zone or writing a script, the BO to use in the "invoke BO" statement should be the identifying BO of the record. As such, often the script will include steps prior to the "invoke BO" step to "[determine the identifying BO of the record](#)" and once the identifying BO is found, the script step will invoke that BO. Note that zones and inbound web services reference a BO directly. In each case, if the BO to use should be dynamic, then the zone / inbound web service should reference a service script that can perform the steps to identify the BO and then invoke that BO.

It should be noted however that the BO used in an "invoke BO" statement (or referenced in an inbound web service) **does not have to match** the identifying BO for the record. Here are some examples of where this may be true:

- A script may only require a subset of elements for a record and not the entire record. In this case, it is better for performance purposes to define a special BO (sometimes called a "lite" BO or a "mini" BO) that only defines the needed elements. When the system retrieves the data, it will only access the tables that are included in the BO's schema definition. In addition, if there are no elements that map to an XML structure field, the system will skip any parsing of that column. Similarly, if a script is **updating** a subset of elements on a record, it may be beneficial to use a "mini" BO to do the updates.

NOTE: Please note the following with respect to using a mini BO. This BO is only used for its schema. This type of BO would not define algorithms or a lifecycle. Because the BO is special, it often should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to [Determine the Identifying BO](#) for more information.

- The maintenance object to be added or updated in a script may not support business objects as "identifying BOs". For example, Batch Control maintenance object does not have an identifying BO. However, scripts may still wish to retrieve data (or make updates) to these types of records. An easy way to achieve that goal is to define a business object and use "invoke BO" to access the data.

NOTE: Not all maintenance objects support being maintained through a business object interaction. This is true in a small number of older objects where the underlying maintenance service includes additional functionality besides simply updating the database tables. These maintenance objects are identified via the [MO option](#) **BO Maintenance**, set to **N**.

- Some functionality may be trying to add or update records for a maintenance object in a 'physical' manner and do not want or need to use the object's identifying BO. Or the MO may not have an identifying BO. For example, revision control takes a snapshot of a record for audit purpose and to be able to restore a previous version. In this case, the system wants to capture a full "physical" view of the record. To do this, a special "physical" BO may be created that includes all (or most of) the columns and the child tables.

NOTE: Like the mini BO, the physical BO would not define algorithms or a lifecycle and should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to [Determine the Identifying BO](#) for more information.

NOTE: To reiterate, the BO referenced in the "invoke BO" statement or referenced in an inbound web service does not have to match the identifying BO and does not have to be configured to "allow new instances".

Determine the Identifying BO

As mentioned in other topics, the identifying BO is the business object that governs the business rules for a record. This is the business object that the record will be validated against when any additions or changes are made to the record as long as updates are made via the maintenance service. This includes using "invoke BO" for add or update, using inbound web service interaction and for access to the maintenance page service (via an old style fixed page or via a business service).

How does the system determine the identifying BO? An algorithm plugged into the maintenance object (the **Determine BO** plug-in spot) is responsible for this. If the maintenance object is not configured with an algorithm for this plug-in spot, or no BO is found by the algorithm, no BO business rules are applied.

Most maintenance objects in the system capture the record's identifying BO directly on the record. However, it is possible to define the identifying BO somewhere else. For example, there may be some maintenance objects that are master or transaction objects with an associated "type" object where the identifying BO is defined on its "type" object. Note that the standard Determine BO algorithm plugged into most maintenance objects (**F1-STD-DTMBO - Determine Standard Business Object**) checks for these two conditions.

There may also be cases where a single identifying BO is used for all BOs for a given MO. This may be an option used for some older maintenance object created prior to the business object functionality when implementations wish to introduce custom business rules that are common for all records of that MO. The product provides a base algorithm type (**F1-MOBO - Determine Specific Business Object**) that captures the BO as a parameter.

Base Business Objects

For each maintenance object (MO) that supports an "identifying" business object, the type of business object provided by the product depends on the functionality and expected use by implementations. The following are some common patterns.

- There are MOs where the product provides base BOs that implementations may use if applicable for their business rules. In addition, it is expected that implementation will define custom BOs to support their business needs. Good examples of this type of MO are any of the various "rule" MOs. For example, calculation rule in Oracle Utilities Customer Care and Billing or the usage rule in Oracle Utilities Meter Data Management. The product provides business objects for common rules but each implementation could have special rules that they need to implement and will need to create custom business objects.
- There are MOs where the product provides base BOs that supply common behavior for an object. Implementations may find that supplied the business objects match their business requirements and use the BOs as is. It is expected, however that for many implementations, their business rules will require additional elements to be captured or have special rules to apply. In this case the base business objects may be extended. This scenario may apply to 'master' data objects in various products such as the Device or Meter.
- There are MOs where the product may deliver a base BO that is not expected to satisfy most implementations because different jurisdictions or different implementations will typically have their own rules. In this case the base delivered BO can be used as a template or starting point for custom defined BOs. Some examples of this are Rebate Claim in Oracle Utilities Customer Care and Billing.
- There are MOs where the expectation is that every implementation will have different requirements for the type of data to capture and the product will not supply base BOs that can be used as the "identifying" BO. However, it may supply a "parent" BO that defines the lifecycle and many of the business rules that it expects all records to follow. In these

scenarios, the implementations will create "child" BOs that will serve as the "identifying" BOs and refer to the base "parent" BO for many of its rules through [inheritance](#). An example of this is the Activity in Oracle Utilities Mobile Workforce Management.

- There are some scenarios where the base product provides business objects and the expectation is that implementations will use the business objects as delivered with little or no customization. This is a case where the system used business objects to implement product functionality, not because there is an expectation that the implementers will extend the functionality, but because the business object model is the favored development tool even for the product. The objects delivered for Content Migration Assistant are an example.

NOTE: Not all maintenance objects in the product support business objects as a "identifying" or "governing" tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

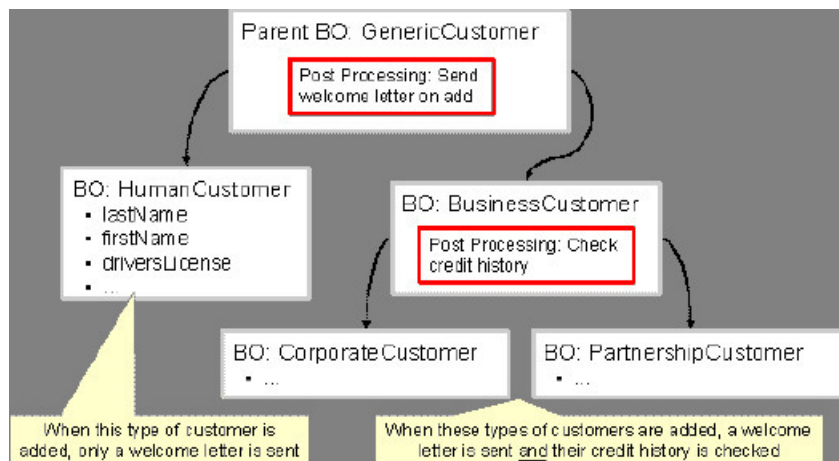

For all maintenance objects, the base product may provide additional BOs that are not meant to be "identifying" BOs, but instead are provided to support functionality to interact with the MO using the BO as a tool as described in [Invoking a BO](#).

- One or more "mini" or "lite" BOs may be supplied for a maintenance object. This may be found when the product has functionality to retrieve a subset of elements for the maintenance object via scripting or via a user interface.
- A "physical" BO may be supplied. This a BO that typically includes all tables and all fields of the maintenance object in there "physical" form. In other words, there is no "flattening" of child tables and any XML structure fields are defined as a single field. Physical BOs are used in system processing where the full record needs to be captured as is. Some functionality that uses a physical BO includes [bundling](#), [revision control](#) and the pre-compare algorithm for CMA to [adjust data prior to comparing](#). If there are any maintenance objects that do not have a base supplied physical BO, refer to [Creating a Physical Business Object](#) for steps on how to provide one.
- A "bundling add" BO may be supplied. Refer to [Recursive Key References](#) for more information as to why this type of BO may be supplied.

Business Object Inheritance

A business object may inherit business rules from another business object by referencing the latter as its parent. A child business object can also have children, and so on. A parent's rules automatically apply to all of its children (no compilation - it's immediate). A child business object can always introduce rules of its own but never remove or bypass an inherited rule.

The following is an illustration of multiple levels of business object inheritance.

Notice how the "Business Customer" business object extends its parent rules to also enforce a credit history check on all types of customers associated with its child business objects.

Most types of business object system events allows for multiple algorithms to be executed. For example, you can have multiple **Validation** algorithms defined for a business object. For these, the system executes all algorithms at all levels in the inheritance chain starting from the highest-level parent business object moving on to lower levels.

Other types of system events allows for a single algorithm to be executed. For example, you can only have one **Information** algorithm to format the standard description of a business object instance. For these, the system executes the one at the level nearest to the business object currently being processed.

NOTE: The parent and its children must reference the same maintenance object.

NOTE: Data structures are not inherited. While you can declare schemas on parent business objects, their children will not inherit them. A good practice is to design child business object schemas to **include** their parent business object's schema.

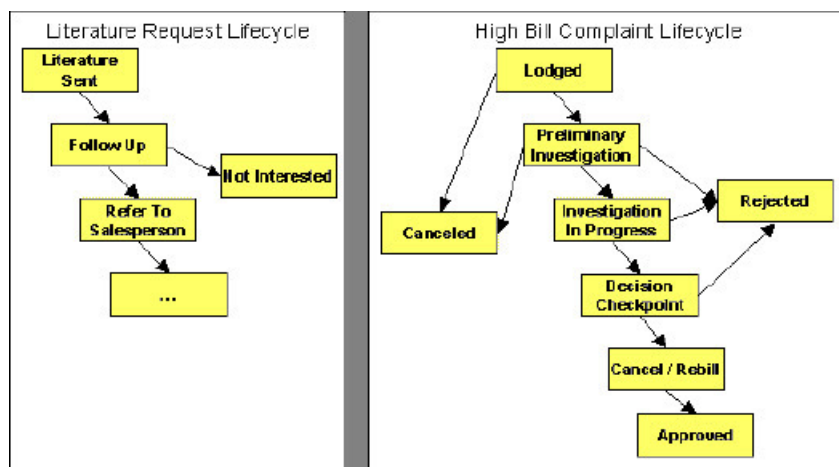

NOTE: User interface maps are inherited. When determining if the business object has a UI map to use for UI rendering, the system looks for display and maintenance maps linked to the BO as options. If the identifying BO does not have maps defined, the system follows “up the chain” of inheritance until it finds a map to use. This allows for a child BO to be used to extend business rules of a parent BO but inherit its user interface behavior. Refer to [Business Object Defines its User Interface](#) for more information.

NOTE: Use Inheritance Wisely. While it is intellectually attractive to abstract behavior into parent BOs to avoid redundant logic and simplify maintenance, before doing this weigh the reuse benefits against the cost in transparency, as it is not easy to maintain a complex hierarchy of business objects.

Each Business Object Can Have A Different Lifecycle

Many maintenance objects have a status column that holds the business entity's current state within its lifecycle. Rules that govern lifecycle state transition (e.g., what is its initial state, when can it transition to another state, etc.) and the behavior associated with each state are referred to as lifecycle rules. Older Maintenance Objects, such as To Do Entry, have predefined lifecycles whose rules are governed by the base-package and cannot be changed. The lifecycle of newer Maintenance Objects exists in business object meta-data and as such considered softly defined. This allows you to have completely different lifecycle rules for business objects belonging to the same maintenance object.

Here are examples of two business objects with different lifecycles that belong to the same maintenance object.

NOTE: A Maintenance Object supports soft lifecycle rules if it is defined with a **Status Field Maintenance Object** option.

The topics that follow describe important lifecycle oriented concepts.

Valid States versus State Transition Rules

The boxes in the above diagram show the potential valid states a business entity of the above business object can be in. The lines between the boxes indicate the state transition rules. These rules govern the states it can move to while in a given state. For example, the above diagram indicates a high bill complaint that's in the **Lodged** state can be either **Canceled** or moved into the **Preliminary Investigation** state.

When you set up a business object, you define both its valid states and the state transition rules.

One Initial State and Multiple Final States

When you set up lifecycle states, you must pick one as the initial state. The initial state is the state assigned to new entities associated with the business object. For example, the above high-bill complaint business object defines an initial state of **Lodged**, whereas the literature request one defines an initial state of **Literature Sent**.

You must also define which statuses are considered to be "final". Typically when an entity reaches a "final" state, its lifecycle is considered complete and no further processing is necessary.

NOTE: Allowing An Entity To Be "Reopened". You can set up your state transition rules to allow a business entity to be "reopened" (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure your business object accordingly.

State-Specific Business Rules

For each state in a business object's lifecycle, you can define the following types of business rules.

FASTPATH: Refer to [BO Algorithm Execution Order](#) for a summary of when these lifecycle algorithms are executed with respect to BO level algorithms.

Logic To Take Place When Entering A State

You can define algorithms that execute before a business entity enters a given state. For example, you could develop an algorithm that requires a cancellation reason before an entity is allowed to enter the **Canceled** state.

You can also incorporate state auto-transitioning logic within this type of algorithms. Refer to [auto-transition](#) for more information.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an enter algorithm to indicate that the other algorithms should be executed by the batch process by setting the "force post processing" indicator to true.

Logic To Take Place When Exiting A State

You can define algorithms that execute when a business entity exists a given state. For example, you could develop an algorithm that clears out error messages when a given entity exits the **Error** state.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an exit algorithm to indicate that the other algorithms should be executed by the batch process by setting the "force post processing" indicator to true.

Monitor Rules

You can define algorithms to monitor a business entity while it is in a given state. This type of logic is typically used to check if the conditions necessary to [transition](#) the entity to another state exist (and, if so, transition it). For example, transition an entity to the **Canceled** state if it's been in the **Error** state too long. Another common use is to perform ancillary work while an entity is in a given state. For example, update statistics held on the object while it's in the **Active** state.

Monitor algorithms are invoked when a business entity first enters a state and periodically after that in [batch](#). You have the option to defer the monitoring of a specific state until a specific monitoring batch job runs. You do so by associating the state with a specific monitoring process. In this case the system will only execute the monitoring rules of this state when that specific batch process runs. This is useful when processing one type of record typically creates another type of record. You may want the processing of the second set of records to be deferred to a later time.

A monitor algorithm can carry out any business logic. In addition it can optionally tell the system to do either of the following:

- Stop monitoring and transition to another state. The system will not call any further monitoring algorithm plugged in on the state and attempt to transition the entity to the requested new state.
- Stop monitoring. Same as above except that no transition takes place. You may want to use this option to prevent transitions while some condition is true.

If none of the above is requested the system keeps executing subsequent monitoring algorithms.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for a monitor algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

FASTPATH: Refer to [Business Object - Lifecycle](#) for more information on how to set up state-specific algorithms.

Inheriting Lifecycle

If a business object references a parent business object, it always [inherits](#) its lifecycle from the highest-level business object in the hierarchy. In other words, only the highest-level parent business object can define the lifecycle and the valid state transitions for each state. Child business objects, in all levels, may still extend the business rules for a given state by introducing their own state-specific algorithms.

The system executes all state-specific algorithms at all levels in the inheritance chain starting from the highest-level parent business object moving on to lower levels.

Auto-Transition

In a single transition from one state to another, the system first executes the **Exit** algorithms of the current state, transitions the entity to the new state, executes the **Enter** algorithms of the new state followed by its **Monitor** algorithms. At this point if a **Monitor** algorithm determines that the entity should be further automatically transitioned to another state the remaining monitoring algorithm defined for the current state are not executed and the system initiates yet another transition cycle.

Notice that an **Enter** algorithm can also tell the system to automatically transition the entity to another state. In this case the remaining **Enter** algorithm as well as all **Monitor** algorithms defined for the current state are not executed.

The following illustration provides an example of an auto-transition chain of events.

In this example a business entity is in a Pending state. While in that state a **Monitor** algorithm determines to auto-transition it to the Denied state. At this point the following takes place:

- No further **Monitor** algorithms of the Pending state are executed
- Pending state **Exit** algorithms are executed
- The system transitions the entity to the Denied state
- Denied state **Enter** algorithms are executed. No further auto-transition is requested.
- Denied state **Monitor** algorithms are executed. No further auto-transition is requested.

Keeping An Entity In Its Last Successful State

By default, any error encountered while transitioning a business entity from one state to another rolls back all changes leaving the entity in its original state.

When applicable, the Maintenance Object can be configured to always keep an entity in its last successful state rather than rolling all the way back to the original state. This practice is often referred to as "taking save-points". In case of an error, the entity is rolled back to the last successfully entered state and the error is logged on the [maintenance object's log](#). Notice that with this approach no error is returned to the calling process, the error is just logged.

The logic to properly log the error is in a **Transition ErrorMaintenance Object plug-in**. The system considers a maintenance object to practice "save-points" when such an algorithm is plugged into it.

Even if the maintenance object practices "save-points", in case of an error the system will not keep an entity in the last successfully entered state if that state is either marked as [transitory](#) or one of its **Enter** algorithms has determined that the entity should proceed to a next state. The system will roll back to the first previous state that does not match these conditions.

Monitoring Batch Processes

A monitor batch process may be used to transition a business object into its next state by executing the monitor algorithms associated with the current state of the entity. The use cases for performing the monitor logic in batch are as follows:

- The record may be waiting for something else to occur before transitioning. The monitor algorithm may be coded to determine if the condition is satisfied and initiate the transition then. For example perhaps when entering a state, a field activity is generated and the record should exit the state when the field activity is complete. The monitor algorithm can check the status of the field activity.
- Perhaps a record is added or updated manually and the next step in the BO lifecycle includes a large amount of processing such that the logic should occur in batch. In this case the BO status is configured with an explicit reference to a batch control (referred to as "deferred"), which indicates to the system that the monitor algorithms should not be performed automatically (but should be deferred to batch). Later when the batch process runs, it selects all the records to process to progress the records.

NOTE: When a status includes a deferred batch control, it may also be configured to allow a user to manually transition the record to the next state rather than waiting for batch. When a user manually transitions a record that includes monitor algorithms, those algorithms are not executed.

- Perhaps a record is added or updated in batch, but a subsequent step in the overall lifecycle should be processed later. This may be accomplished by ensuring that the batch control linked to the state to process later does not match the batch control that added or updated the record.
- Monitor processes may also be used to periodically perform some logic related to the record without actually transitioning the record.

Note that only the parent business object may refer to a deferred monitor batch process. However, any business object in the ["inheritance"](#) chain may be configured with monitor algorithms, which will all be executed.

The base package provides a periodic monitoring batch process for each maintenance object that supports a configurable BO lifecycle. The process periodically executes the monitoring algorithms associated with the current state of an entity, excluding states explicitly referencing a deferred monitoring batch process that is for a different batch control.

A deferred monitoring process selects records whose current state references this particular batch control as their monitor process. Deferred monitor process is only needed when an object has different use cases for monitoring the same type of records with different schedules. In this case only one periodic monitor batch should be configured. Other monitors should be configured to restrict by batch control so that there is no overlap in processing.

NOTE: MO option configuration. The maintenance object includes options to indicate the batch controls delivered for periodic and deferred monitor batch controls.

Your business rules will dictate the execution frequency of each monitoring process and the order in which they should be scheduled. Refer to [Monitor Background Processes](#) in the background process chapter for more information about the parameters supported for this type of batch process.

NOTE: Updates to the business object. When the monitor algorithms indicate that the business object should transition, the monitor batch processes are responsible for ensuring the business object is transitioned appropriately and that the appropriate exit, enter and monitor algorithms are executed. Please note that the business object is not updated using a call to the maintenance object service and therefore by default the [business rules](#) plugged in to the business object are not executed. However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the “force post processing” indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

Transitory States

You can define a state as **Transitory** if you do not wish the business entity to ever exist in that particular state.

The following illustrates a lifecycle with a transitory Validate state.

In this example, the business entity is saved still not validated in the Pending state. At some point, the user is ready to submit the entity for validation and transitions it into a transitory state Validate whose **Enter** rules contain the validation logic. The responsibility of the transitory state's **Enter** algorithms is to decide if the entity is valid or in error and then transitions it into the appropriate final state. In this scenario, you may not ever want the business entity to exist in the Validate state.

Let's also assume that the maintenance object in this example is practicing "[save-points](#)" and requires the entity to be kept in its last successful state. If an error were to occur during the transition from **Validate** to the next state, the system would roll back the entity back to Pending, and not Validate even though the entity has successfully entered the Validate state. Refer to the [Auto Transition](#) section for more information.

State Transitions Are Audited

Most Maintenance Objects that support soft lifecycle definition also have a log to hold significant events throughout a business entity's lifecycle. For example, log entries are created to record:

- When the business entity is created (and who created it)
- When its status changes (and who changed it)

- If a transition error occurred (and the error message)
- References to other objects created throughout the entity's lifecycle. For example, if a To Do entry is created as part of processing the entity, the To Do Entry is referenced in the log.
- Manual entries added by a user (think of these as "diary" entries)

When a business entity is first created and when it transitions into a new state the system calls **Transition** algorithm(s) plugged in on the [Maintenance Object](#) to record these events. If the maintenance object supports a log these events can be captured as log entries.

NOTE: Most base package maintenance objects supporting a log may already provide state transition logging as part of their core logic. In this case you only need to provide a **Transition** plug-in if you wish to override base logging logic with your own.

Required Elements Before Entering A State

You can define additional elements that are required before a business entity can enter a given state. For example, let's assume that a Cancel Reason must be defined before an object can enter the *Canceled* state. You do this by indicating that element as a **Required Element** [state-specific option](#) on the appropriate state on the business object.

Capturing a Reason for Entering a State

Some business objects support configuring certain states to allow or require a status reason when an object enters the state. The product provides a centralized status reason table that may be used to define the valid BO status reasons for various business objects and various states. The status reasons are defined using the [Status Reason](#) portal.

The following sections provide additional information about the BO status reason functionality.

Maintenance Object Must Support Status Reason

In order for a business object to use the centralized status reason table to define reasons, the maintenance object must first support the status reason. MOs that support status reason have the following characteristics:

- The primary table includes a column for Status Reason. This represents the status reason for the record's current status, if applicable.
- The log table includes a column for Status Reason. The standard logic for capturing a log record when entering a state also captures the status reason, if applicable. This allows a user to review the history of the changes in status and the status reason captured for a previous state transition, if applicable.
- The maintenance object option collection includes an option that defines the Status Reason field. This setting is a trigger for business objects of this MO to be able to configure states to allow or require status reason.

Business Object State Indicates if Reasons are Applicable

Once the MO is configured to support status reason, configuration on the business object is required to indicate the states where a reason is applicable. States may be configured to require status reasons, allow status reasons as optional or not allow status reasons. With this configuration, the framework will automatically get the list of valid reasons for a state that allows or requires them and then prompt the user for a status reason when a manual state transition occurs for that state. It also automatically triggers an error if the state requires a status reason and no reason is provided.

NOTE: The status reason configuration on the business object state is customizable. That means that for a product owned business object, an implementation may opt to change the delivered configuration.

Status reasons are defined for the parent (or "lifecycle") business object. All business objects in the hierarchy of the parent business object have the same valid reasons for their states.

The status reason code must be unique for the centralized status reason table. Business object and status are required fields, so it is not possible to share a common reason `code` (like “Not applicable”) across multiple business objects or states. If multiple BOs / states want to support a reason “Not applicable” then each must define a unique record for it. This point should be considered when planning for your status reasons.

Selectable vs. Not Selectable

When defining a status reason, you may indicate whether it’s **Selectable** or **Not Selectable**. When a manual transition is performed and a user is prompted for a status reason, only the **Selectable** reasons are presented. The **Not Selectable** reasons may be defined to support transitions that occur via algorithm processing.

NOTE: The Selectable setting is customizable. That means that if a product provides a base owned status reason for a business object state, an implementation may opt to change whether it is selectable or not. Careful consideration should be made before changing a base delivered status reason from **Not Selectable** to **Selectable** as this may affect base provided algorithm functionality that could be relying on the setting of **Not Selectable**.

Status Reason Business Object

The status reason maintenance object, as with many maintenance objects in the product, references a business object used to define attributes and behavior related to defining status reasons. The framework provides a business object for status reason (**F1-BOStatusReason**). For the business objects that have states that require a status reason (let’s call these “transactional BOs”), if there is some special logic required for defining the status reasons, it is possible to define a different status reason BO. In this situation, the override status reason BO to use for capturing status reasons should be defined as a BO option on the transactional BO using the **Status Reason Business Object** option type. If a transactional BO does not define any status reason BO option, then the **F1-BOStatusReason** is used when adding a status reason.

Defining a Usage

The base product status reason BO provides the ability to define a “usage” value. This is useful for algorithms that perform state transitions where a status reason is needed and where the algorithm is usable by more than one business object. In this case, the status reason to use cannot be provided as a parameter because each business object must define its own set of status reasons for each state. The Usage value can be used instead. Each business object can configure the status reason to use in the algorithm and set the appropriate usage value. The algorithm can reference the usage value and retrieve the correct status reason to use based on the record’s transactional BO.

The status reason business object provided with the framework product (**F1-BOStatusReason**) supports capturing a usage. The valid usage values are defined in the **Status Reason Usage** characteristic type.

Alternatives for Defining Reasons

There may be business objects in the system that capture reasons that are defined somewhere besides the BO status reason table. For example, some objects may have an explicit administrative table for status reasons. Some objects may use a Lookup or an Extendable Lookup to capture reasons. Refer to the business object description for information about how valid reasons are defined, if applicable.

If a business object supports a reason that is not related to a state transition (such as a creation reason), the BO status reason would not be used. One of the alternate methods for defining a reason, described above, would be used.

Opening UI Maps Before Entering A State

You can define a UI Map to capture additional elements before a business entity can enter a given state. You do this by configuring the **State Transition UI Map** [state-specific option](#) on the appropriate state on the business object.

There may be circumstances in which the status pre-processing logic can determine the value of the elements, in which case it is not necessary to invoke the map. The system provides a data area (**F1-StateTransitionCommon**) which contains a boolean element to indicate if the state transition map can be skipped. This data area can be included in your pre-processing

script to allow the element to be set according to your business logic. The base maintenance script (**F1-MainProc**) references this element to determine whether to open the state transition map.

BO Algorithm Execution Summary

This table highlights the processing steps that occur when adding or changing a record that is governed by a business object.

Invoke BO	
Event	Comments
BO Pre-processing algorithms executed	These algorithms are only executed when Invoke BO is used. The business object in the Invoke BO is the one whose rules are executed.
MO Processing	
Event	Comments
Determine if status has changed.	The system keeps a note of the new status value but initially proceeds with the old value.
MO Processing.	Standard MO processing, including MO validation is executed.
Determine BO algorithm executed.	The MO level algorithm is executed to determine the identifying BO .
BO Validation algorithms executed.	
State transition rules are performed if the status has changed.	BO Status Exit algorithms for the “old” status executed. Status updated to the new value. BO Status Enter algorithms for the “new” status executed. If no error — MO Transition algorithms are executed. FASTPATH: Refer to State Transitions are Audited for more information. If error and there are “save points” the MO Transition Error algorithms are executed. FASTPATH: Refer to Keeping An Entity In Its Last Successful State for more information. Otherwise, the error is reported.
BO Status Monitor algorithms are executed.	If the record transitions again, the prior step (State transition rule step) is repeated for the new transition.
BO Post-processing algorithms are executed.	
BO Audit algorithms are executed.	These algorithms are only executed if the system detects a change in elements that are not marked with “no audit”.

NOTE: To emphasize, the steps in the MO Processing table are only executed when the maintenance object service is invoked. Any add or update initiated by an “invoke BO” statement will invoke the MO service. This is also true for web service that invoke the business object. The [Monitor Batch Process](#) does not invoke the maintenance service. By default the monitor batch process only executes the monitor algorithms and the state transition rules (if the monitor algorithms indicate that a status change should occur). However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the “force post processing” indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

NOTE: For records that do not have a status, the state transition rules and the monitor rules are not applicable.

Granting Access To Business Objects

Every business object must reference an [application service](#). When you link a business object to an application service, you are granting all users in the group access to its instances. You can prevent users from transitioning a business object into

specific states by correlating each business object status with each application service action (and then don't give the user group rights to the related action).

FASTPATH: Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

The system checks if a user has access rights each time the application is invoked to add, change, delete, read, or transition a business object. However, if a business object invokes another business object, we assume that access was controlled by the initial business object invocation and we do not check access for other business objects that it invokes. In other words, access rights are only checked for the initial business object invoked in a service call.

In order to apply business object security the system must be able to determine the business object associated with the actual object being processed. To do that the Maintenance Object itself has to have a **Determine BO** algorithm [plugged in](#). If this algorithm is not plugged in or it cannot determine the BO on the MO, the system will not invoke any BO rules. If the business object cannot be determined for a maintenance object instance, business object security is not checked. In this case the system checks the user's access rights using standard maintenance object security.

NOTE: Parent business objects are ignored. If a child business object exists, a user need only have access to the child business object's application service (not to every application service in the business object hierarchy).

Defining Business Objects

The topics in this section describe how to maintain business objects.

Note that several context sensitive dashboard zones appear on this page and are visible on all tabs.

- **Schema Tips.** This zone provides several links to launch help topics related to valid schema syntax and UI Hint syntax in one click.
- **View UI Rendering.** This zone provides buttons to view the automatic rendering of the Display map or Input map based on the attributes defined in the schema, including UI hints.
- **Generate Schema.** This zone includes a button that can be used to generate a “physical” schema based on the maintenance object definition. The element names are taken from the Java field name for each column. Once generated, adjust the schema as desired.
- **Create a BO Algorithm.** This zone includes a button to create a script based algorithm related to this business object. You are then prompted for information regarding the plug-in spot (BO or BO Status) and the system event, the name, description, etc. Once all the information is provided, the system creates an algorithm type, algorithm, links the algorithm to the business object, creates the script and brings you to the script step to start defining the logic for the plug-in script.
- **BOs Linked to the MO.** This zone displays other business objects for the same maintenance object as the BO currently displayed. You may drill into any of the other BOs by clicking its description.

Business Object - Main

Use this page to define basic information about a business object. Open this page using **Admin > System > Business Object**

Use the **Business Object Query** portal to search for an existing business object. Once a business object is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Business Object** name and **Description**. Use the **Detailed Description** to describe the purpose of this business object in detail. **Owner** indicates if this business object is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new business object, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Enter the **Maintenance Object** that is used to maintain objects of this type.

Enter a **Parent Business Object** from which to [inherit](#) business rules.

Lifecycle Business Object is only displayed for child business objects, i.e. those that reference a parent business object. It displays the highest-level business object in the inheritance hierarchy. Refer to [Inheriting Lifecycle](#) for more information.

Application Service is the application service that is used to provide security for the business object. Refer to [Granting Access To Business Objects](#) for more information. The application service on the child business object must have the same valid actions as the application service on the parent business object.

Use **Instance Control** to allow or prevent new entities from referencing the business object. Typically only the [identifying BOs](#) are marked to allow new instances.

Click the **View Schema** hyperlink to view the business object's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

The options grid allows you to configure the business object to support extensible options. Select the **Option Type** dropdown to define its **Value**. **Detailed Description** may display additional information on the option type. Set the **Sequence** to **1** unless the option can have more than one value. **Owner** indicates if this option is owned by the base package or by your implementation (**Customer Modification**).

NOTE: You can add new options types. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do that, add your new values to the customizable lookup field **BUS_OBJ_OPT_FLG**. If you add a new option type for a business option, you must update its maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Option Type**[maintenance object option](#).

Business Object - Schema

Use this page to maintain a business object's schema. Open this page using **Admin > System > Business Object** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the business object.

Click the **View Schema** hyperlink to view the business object's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

The [Schema Designer](#) zone allows you to edit the business object's schema. The purpose of the schema is to describe the business object's properties and map them to corresponding maintenance object fields.

FASTPATH: Refer to [Schema Syntax](#) and [UI Hint syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **Schema Tips** zone in the dashboard provides links to launch these help topics directly.

NOTE: Generating a Schema A context sensitive "Generate Schema" zone is associated with this page. The zone provides a button that allows the user to generate a basic schema that includes all the fields for all the tables for the BO's maintenance object. Note that each maintenance object has an underlying service and it's possible that some of the child

tables in the maintenance object are not included in the service definition. If that is the case, a message is issued and the generated schema would need to be adjusted to remove that child table.

NOTE: View UI Rendering. A context sensitive "View UI Rendering" zone is associated with this page. The zone is useful for [business objects that define the user interface detail](#) using schema attributes and UI Hints. The buttons allow you to view the automatically rendered display and input maps.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Business Object - Algorithms

Use this page to maintain a business object's algorithms. Open this page using **Admin > System > Business Object** and then navigate to the **Algorithms** tab.

Description of Page

The **Algorithms** grid contains algorithms that control important functions for entities defined by this business object. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
- If the algorithm is implemented as a script, a link to the **Script** is provided. Refer to [Plug-In Scripts](#) for more information.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes each **System Event**. Refer to [A Business Object May Define Business Rules](#) for more information about these system events.

System Event	Optional / Required	Description
Audit	Optional	<p>Algorithms of this type may be used to audit certain changes made to business object instances.</p> <p>The system hands over to the algorithms a summary of all the elements that were changed throughout a specific call to update an object. Excluded from this processing are elements explicitly marked on the schema as requiring no audit. For each element its original value before the change as well as its new value are provided.</p> <p>It is the responsibility of the algorithms to record corresponding audit information.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p>
Information	Optional	<p>We use the term "Business Object Information" to describe the basic information that appears throughout the system to describe an entity defined by the business object. The data that appears in this</p>

System Event	Optional / Required	Description
		<p>information description is constructed using this algorithm.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number found on the business object closest to the current business object in the inheritance hierarchy. Refer to Business Object inheritance for more information.</p>
Post-Processing	Optional	<p>Algorithms of this type may be used to perform additional business logic after a business object instance has been processed.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p>
Pre-Processing	Optional	<p>Algorithms of this type further populates a request to maintain a business object instance right before it is processed.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p>
Validation	Optional	<p>Algorithms of this type may be used to validate a business object instance when added, updated or deleted.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p>

FASTPATH: Refer to [BO Algorithm Execution Summary](#) for more information about how these algorithms fit within the business object processing.

NOTE: Generate Algorithm. A context sensitive "Generate a BO Algorithm" zone is associated with this page. Refer to [Defining Business Objects](#) for more information about this zone.

NOTE: You can add new system events. Your implementation may want to add additional business object oriented system events. For example, your implementation may have plug-in driven logic that would benefit from a new system event. To do that, add your new values to the customizable lookup field **BO_SEVT_FLG**. If you add a new business object system event, you must update the maintenance object to declare this new system event. Otherwise, it won't appear on the system event dropdown. You do that by referencing the new system event as a **Valid BO System Event maintenance object option**.

NOTE: You can inactivate algorithms on base Business Objects. Your implementation may want to use a business object provided by the base product, but may want to inactivate one or more algorithms provided by the base business object. To do that, on the business object where this algorithm is referenced, go to the options grid on Business Object - Main and add a new option, setting the option type to **Inactive Algorithm** and setting the option value to the algorithm code.

Business Object - Lifecycle

Use this page to maintain a business object's lifecycle oriented business rules and options. Open this page using **Admin > System > Business Object** and then navigate to the **Lifecycle** tab.

Description of Page

The **Status** accordion contains an entry for every status in the object's [lifecycle](#). The entry appears differently for a child business object as it can only extend its inherited lifecycle by introducing algorithms and options of its own.

Use **Status** to define the unique identifier of the status. This is not the status's description, it is simply the unique identifier used by the system. Only the highest-level business object can define lifecycle statuses. For a child business object the inherited status description is displayed allowing navigation to the corresponding entry on the business object defining the lifecycle.

Use **Description** to define the label of the status. This field is hidden for a child business object.

Use **Access Mode** to define the action associated with this status. Refer to [Access Rights](#) for the details of how to use this field to restrict which users can transition a business entity into this state. This field is hidden for a child business object.

Enter a **Monitor Process** to defer the monitoring of entities in this state until the specific batch process runs. Refer to [Monitor Rules](#) for more information. This field is hidden for a child business object.

The **Status Reason** dropdown indicates if users should be prompted to provide a specific reason when the business object enters this state. This field appears only if the Status Reason Field is configured as an option on the business object's maintenance object. Valid values are blank, **Optional**, and **Required**. The default value is blank (users are not prompted to provide a status reason). See [Configuring Status Reasons](#) for more information about status reasons.

Use **Status Condition** to define if this status is an **Initial**, **Interim** or **Final** state. Refer to [One Initial State and Multiple Final States](#) for more information about how this field is used. This field is hidden for a child business object.

Use **Transitory State** to indicate whether a business entity should ever exist in this state. Only **Initial** or **Interim** states can have a transitory state value of **Yes**. Refer to [transitory states](#) for more information. This field is hidden for a child business object.

Use **Alert** to indicate that being in this state warrants an application alert. This may be used by custom logic to provide an alert to a user that entities exist in this state. This field is hidden for a child business object.

Use **Display Sequence** to define the relative order of this status for display purposes. For example when displayed on the status accordion and on the summary tab page. This field is hidden for a child business object.

Algorithms

The **Algorithms** grid contains algorithms that control important functions for a given status. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
- If the algorithm is implemented as a script, a link to the **Script** is provided. Refer to [Plug-In Scripts](#) for more information.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes each **System Event**.

System Event	Optional / Required	Description
Enter	Optional	Algorithms of this type apply business rules when a business object instance enters a given state. The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object Inheritance for more information.
Exit	Optional	Algorithms of this type apply business rules when a business object instance exits a given state.

System Event	Optional / Required	Description
Monitor	Optional	<p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object Inheritance for more information.</p> <p>Algorithms of this type monitor a business object instance while in a given state. Typically these are used to auto-transition it to another state.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object Inheritance for more information.</p>

FASTPATH: Refer to [BO Algorithm Execution Summary](#) for more information about how these algorithms fit within other business object algorithms.

NOTE: Generate Algorithm. A context sensitive "Generate a BO Algorithm" zone is associated with this page. Refer to [Defining Business Objects](#) for more information about this zone.

NOTE: You can inactivate status level algorithms on base Business Objects. Your implementation may want to use a business object provided by the base product, but may want to inactivate one or more of the status oriented algorithms provided by the base business object. To do that, on the business object and status where this algorithm is referenced, go to the options grid and add a new option, setting the option type to **Inactive Algorithm** and setting the option value to the algorithm code.

Next Statuses

Use the **Next Statuses** grid to define the valid statuses a business entity can transition into while it's in this state. This section is hidden for a child business object. Refer to [Valid States versus State Transition Rules](#) for more information. Please note the following about this grid:

- **Status** shows the statuses for the top-level business object, the **Status Code**, the **Lifecycle BO description**, and the **Status description** for each status.
- Use **Action Label** to indicate the verbiage to display on the button used to transition to this status.
- **Sequence** controls the relative order of one status compared to others for display purposes. This information may be used to control the order in which buttons are presented on a user interface.
- **Default** controls which next state (if any) is the default one. This information may be used by an **Enter** or **Monitor** algorithm to determine an auto-transition to the default state. It may also be used to also mark the associated button as the default one on a user interface.
- **Transition Condition** may be configured to identify a common transition path from the current state. By associating a given "next status" with a transition condition value, you can design your auto-transition rules to utilize those flag values without specifying a status particular to a given business object. Thus, similar logic may be used across a range of business objects to transition a business entity into, for example, the next **Ok** state for its current state. You'll need to add your values to the customizable lookup field **BO_TR_COND_FLG**.
- **Transition Role** controls whether only the **System** or both **System and User** have the ability to transition a business entity into a given "next status".
- When you initially set up a business object lifecycle, none of the statuses will reside on the database and therefore you can't use the search to define a "next status". We recommend working as follows to facilitate the definition of this information:
 - Leave the Next Statuses grid blank when you initially define a business object's statuses
 - After all statuses have been saved on the database, update each status to define its Next Statuses (this way, you can use the search to select the status).

Options

The options grid allows you to configure the business object status to support extensible options. Select the **Option Type** drop-down to define its **Value**. **Detailed Description** may display additional information on the option type. Set the **Sequence** to **1** unless the option can have more than one value. **Owner** indicates if this option is owned by the base package or by your implementation (**Customer Modification**).

NOTE: You can add new options types. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do that, add your new values to the customizable lookup field **BO_OPT_FLG**. If you add a new option type for a status, you must update the business object's maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Status Option Type** [maintenance object option](#).

Business Object - Summary

This page summarizes business object information in a high level. Open this page using **Admin > System > Business Object > Search** and then navigate to the **Summary** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the business object.

Click the **View Schema** hyperlink to view the business object's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

The **Business Object Hierarchy** zone displays in a tree view format the [hierarchy](#) of child business object associated with the current business object. It also shows the current business object's immediate parent business object.

For business objects with a lifecycle, the **Lifecycle Display** zone shows a graphical depiction of the lifecycle. Refer to the embedded help of that zone for more information.

The **Options** zone summarizes business object and state specific options throughout the [inheritance](#) chain.

The **Rules** zone summarizes business object and state specific rules throughout the [inheritance](#) chain.

Advanced BO Tips and Techniques

The topics in this section describe some advanced tips and techniques for configuring business objects.

Creating a Physical Business Object

The physical business object's schema represents the complete physical structure of the maintenance object, and includes elements for all fields in the maintenance object's tables. There are several processes in the system that may use a maintenance object's physical BO.

To create a physical business object for the maintenance object:

1. Navigate to [Business Object](#) and specify the maintenance object.
2. Click **Generate** in the **BO Schema** dashboard zone to generate a schema that looks like the physical structure of the maintenance object.
3. Save the physical business object.
4. Navigate to [Maintenance Object](#) and search for the maintenance object.

5. On the **Option** tab, add a new option with the type **Physical Business Object**. The value is the name of the physical business you just created.

Managing To Do Entries

The product provides several base algorithm types that may be used to manage To Do entries through status changes for a given record via BO lifecycle plug-ins.

Create To Do Entry

The product supplies a BO status Enter algorithm type **Generic To Do Creation (F1-TDCREATE)** that creates a To Do entry based on parameter configuration. Refer to the algorithm type description for more information about how it determines the To Do type or To Do role and how to populate the appropriate message text onto the To Do. This algorithm may be used in conjunction with the Retry Logic (below).

If your implementation has a business rule that requires a To Do entry to be created when entering a given BO status and the logic provided by the algorithm type meets the needs of the business rule, this algorithm type may be used. Create an algorithm for the algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Retry Logic

The algorithm type **Retry for To Dos (F1-TODORETRY)** is supplied for a special use case. It is a BO status monitor plug-in and may be used for a state that is a type of ‘error’ or ‘waiting’ state. It relies on the To Do entry creation logic to set a Retry Frequency. The algorithm transitions to the originating state to retry the logic. The idea is that the condition that caused the record to enter the ‘error’ or ‘waiting’ state may be resolved after some period of time has passed, allowing the record to progress in its lifecycle. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as a Monitor algorithm. The state should also have an algorithm for the **Generic To Do Creation** algorithm type plugged in as an Enter algorithm (or something equivalent) that sets the appropriate Retry Frequency.

To Do Completion

It is common that one or more To Do entries associate with a given record should be completed when exiting a state (if it is not already completed). The system supplies the algorithm type **Generic To Do Completion (F1-TODOCOMPL)** that may be used for this purpose. Note that the algorithm type functionality is not tied to any To Do creation logic. It may be used for any use case where To Do entries should be completed on exiting a state. Refer to the algorithm type description for more information about its functionality and how to prevent certain To Do entries from being automatically completed.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Exit algorithm.

Submitting a Batch Job

The product provides a base algorithm type that submits a batch job when entering a BO state. This functionality allows for “event driven” batch submission where the event is the lifecycle transition for a certain record.

The algorithm type is **Create Batch Job Submission Entry for Batch Control (F1-SCHEDJOB)**. The batch control code is a parameter for the algorithm. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameter with the batch control that should be submitted and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Defining Status Reasons

Status Reasons are used to provide more information about why a business object transitioned to a given state. The status reason table provides a centralized place where status reasons can be defined across many different business objects and states.

NOTE: Refer to [Defining Reasons for Entering a State](#) for overview information.

If a business object has one or more states that are configured to capture a status reason, you may configure the valid reasons by navigating to the status reason portal using **Admin > System > Status Reason**.

The topics in this section describe the base-package zones that appear on the Status Reason portal.

Business Objects with Status Reason List

This zone displays the business objects that have one or more status values that allow status reasons to be defined.

Click the broadcast icon to open other zones that contain more information about the business object's status reasons.

Status Reasons

The **Status Reasons** zone contains a list of the existing status reasons for the broadcasted business object.

Data Areas

The data area has no business purpose other than to provide a common schema location for re-used schema structures. It exists solely to help eliminate redundant element declaration. For example, if you have multiple schemas that share a common structure, you can set up a stand-alone data area schema for the common elements and then include it in each of the other schemas.

Be aware that a stand-alone data area can hold elements that are mapped to true fields. For example, you might have 50 different types of field activities and all might share a common set of elements to identify where and when the activity should take place. It would be wise to declare the elements that are common for all in a stand-alone data area and then include it in the 50 field activity business objects.

It's strongly recommended that you take advantage of stand-alone data areas to avoid redundant data definition!

CAUTION: Dynamic inclusion! When the system renders a schema, all schemas included within it are expanded real-time. This means that any change you make to a data area will take effect immediately within all schemas it is referenced within.

NOTE:

Schema Tips. The data area page includes a special Schema Tips zone that provides a link to launch help topics related to the [Advanced Schema Topics](#) help in one click.

Data areas may be included in a business object that does not define a full UI map for display or input. Rather, it is using auto-rendering by defining UI attributes in its schema and via UI hints.

NOTE: View UI Rendering. A context sensitive "View UI Rendering" zone appears on this page. It may be used for a data area that is part of a business object that is using auto-rendering for the display and input maps. The buttons allow you to view the rendered UI for the segment of the schema that is defined by the data area.

Defining Data Areas

The topics in this section describe how to maintain Data Areas.

Data Area - Main

Use this page to define basic information about a data area. Open this page using **Admin > System > Data Area**.

Use the **Data Area Query** portal to search for an existing data area. Once a data area is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Data Area** name and **Description**. Use the **Detailed Description** to describe what this data area defines in detail. **Owner** indicates if the data area is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new data area, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Click the **View Schema** to view the data area's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

To extend another data area, reference that data area in the **Extended Data Area** field. By extending a data area you can add additional elements to a base product data area.

Here's an example of an extended data area:

- The product releases with data area A, which contains elements a, b, and c.
- Your implementation creates data area CM-A, which contains element z, and references data area A as the extended data area.
- At run time, everywhere data area A is included it will contain elements a, b, c, and z.

Data Area - Schema

Use this page to maintain a Data Area's schema and to see where the data area is used in the system. Open this page using **Admin > System > Data Area** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays the main attributes of the data area.

The [Schema Designer](#) zone allows you to edit the data area's schema. The purpose of the schema is to describe the structure and elements of the data area.

FASTPATH: Refer to [Schema Syntax](#) and [UI Hint syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **Schema Tips** zone in the dashboard provides links to launch these help topics directly.

NOTE: View UI Rendering. A context sensitive "View UI Rendering" zone is associated with this page. The zone is useful for data areas that are to be included in [business objects that define the user interface detail](#) using schema attributes and UI Hints. The buttons allow you to view the automatically rendered display and input maps.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Business Services

A business service is used to expose a back-end service so that it may be invoked by a script or a zone or a map to retrieve information or perform functions, depending on the related service.

As with the business object, the business service's interface to the internal service is defined using its schema. The schema maps the business service's elements to the corresponding elements in the internal service program's XML document. Just as a business object can simplify the schema of its maintenance object by only defining elements that it needs and “flattening” entries in a child collection to be defined as a singular element, a business service schema may simplify its service XML in a similar way.

FASTPATH: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

[Inbound web services](#) and [scripts](#) support interaction with business services. You can also invoke a business service from a Java class.

Service Program

This transaction defines services available in the system. These include user interface services as well as stand-alone services that perform a specific function. A service may be referenced by a business service. Use this transaction to view existing service and introduce a new stand-alone service to be made available to a Business Service.

Select **Admin > System > Service Program** to maintain service programs.

Description of Page

Service Name is the unique identifier of the service.

CAUTION: Important! When adding new service programs, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Owner indicates if this service is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a service. This information is display-only.

Description describes the service.

Application Service is the application service that is used to provide [security](#) for the service. If the service is related to a maintenance object, the access modes for the application service should be the standard **Add**, **Change**, **Delete** and **Inquire**. For other services, the application service should have the **Execute** access mode.

Service Type indicates whether the service is a **Java Based Service** or a **Java (Converted) Service**. Note that services generated to support a portal in the system will not have a service type populated.

This **Program Component** grid shows the list of program user interface components associated with the service. For a stand-alone service, this list is typically not applicable.

Defining Business Services

The topics in this section describe how to maintain business services.

Note that several context sensitive dashboard zones appear on this page and are visible on all tabs.

- **Schema Tips.** This zone provides several links to launch help topics related to valid schema syntax.
- **Generate Schema.** This zone includes a button that can be used to generate the schema based on the XML of its related Service. Once generated, adjust the schema as desired.

Business Service - Main

Use this page to define basic information about a Business Service. Open this page using **Admin > System > Business Service**

Use the **Business Service Query** portal to search for an existing business service. Once a business service is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Business Service** name and **Description**. Use the **Detailed Description** to describe the purpose of this business service in detail. **Owner** indicates if the business service is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new business service, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Enter the internal **Service Name** being called when this business service is invoked.

Enter the **Application Service** that is used to provide security for the business service. The application service must have an Access Mode of Execute.

Click the **View Schema** to view the business service's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

Business Service - Schema

Use this page to maintain a Business Service's schema and to see where the Business Service is used in the system. Open this page using **Admin > System > Business Service** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the business service.

The [Schema Designer](#) zone allows you to edit the business service's schema. The purpose of the schema is to map the business service's elements to the corresponding fields of the back-end service program it rides on.

NOTE: Generating a Schema A context sensitive "Generate Schema" zone is associated with this page. The zone provides a button that allows the user to generate a basic schema that includes all the elements that are found in the XML of the BS's service.

FASTPATH: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **Schema Tips** zone in the dashboard provides a link to launch this help topic directly.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Useful Services and Business Services

The following section highlights some business services and services provided by the product that may be useful for implementations to use.

Data Explorer Service

The system provides a mechanism for performing an SQL select statement for use in scripting, Java plug-ins, or via a web service call. This is done by creating a zone using one of the data explorer zone types where the SQL is defined. Then, create a business service using the Data Explorer service (**FWLZDEXP**).

NOTE: There are numerous business services delivered with the base product that reference this service that may be used as a template.

The following points highlight how to create your own business service for this service. Note that typically a separate business service exists for each zone.

- Enter a **Business Service** code and a **Description**. It is recommended to define the business service code to match the zone code so that it's easier to manage which business service invokes which zone.
- Select the **Service Name**FWLZDEXP.
- On the **Schema** tab, under the *<schema>* node, enter mapping for the fields that are required for the Data Explorer service:
 - The **Zone** should be mapped into service field **ZONE_CD** . Define the zone code as the default value.
 - For every **user filter** defined on the zone, create a schema mapping into the service field **Fx_VALUE**, where "x" is the filter number (from the zone parameters).
 - For every **hidden filter** defined on the zone, create a mapping into the service field **Hx_VALUE**, where "x" is the filter number (from the zone parameters).
 - The search results are returned as a list by the data explorer service. Each column value is in the service field **COL_VALUE** with an appropriate sequence number (**SEQNO**). The results can be **flattened** based on sequence number allowing for a logical element name to be defined.
 - Another useful field is **ROW_CNT**, which provides the number of rows retrieved by your search.

The following is an example of the schema for a BS that receives a business object code and returns a list of status values and their descriptions that allow status reasons to be defined.

```
<schema>
  <zone mapField="ZONE_CD" default="F1-BOSTSLST" />
  <bo mapField="H1_VALUE" />>
  <rowCount mapField="ROW_CNT" />>
  <results type="list" mapList="DE">>
    <status dataType="string" mapField="COL_VALUE">
      <row mapList="DE_VAL">>
        <SEQNO is="1" />>
      </row>>
    </status>>
    <description dataType="string" mapField="COL_VALUE">
      <row mapList="DE_VAL">>
        <SEQNO is="2" />>
      </row>>
    </description>>
  </results>>
</schema>
```

Maintenance Object Log Service

Many maintenance objects support a log table that follows a pattern of column names and behavior. The system provides a service called Generic MO Log Service (**F1MOLOGP**) that may be used to perform common functions related to log entries:

- Read log entries. If you pass a certain MO, primary key and log sequence number, the service will return the details of that log entry. The product provides a generic business service that may be used for this purpose — Generic MO - Retrieve Log Details (**F1-ReadMOLog**). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.
- Add log. The service may be used to add a log entry. If a user log is added, then the comments from the user are populated in the detailed description. System generated log entries typically supply a message category / message number along with other information such as the status, a specific log type and optionally a related object reference (via a characteristic). The product provides a generic business service that may be used for this purpose — Add Generic MO Log (**F1-AddMOLog**). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.

Base Business Services

The following table highlights some business services provided by the product that may be useful for custom logic for an implementation.

CAUTION: This is not intended to be a complete reference of Business Services. Refer to the business service page to find all the supported business services.

Business Object Related Services

Business Service Name	Description
F1-AutoTransitionBO	Performs monitoring algorithms associated with the current state of a given business object instance (which may result in subsequent state transitioning).
F1-CompareBusinessObjectData	Compares two versions of a given business object instance.
F1-DetermineBo	Determines the business object of a given instance of a maintenance object by executing the MO's Determine BO logic.
F1-GetRequiredFieldsForBOState	Returns the required fields for a given business object status.
F1-RetrieveBOOption	Returns BO option values for a given BO and option type.
F1-RetrieveBOStatusOption	Returns BO option values for a given BO, status and option type.
F1-RetrieveBOStatusOption	Retrieves a list of BOs for a given MO that are accessible for the current user.
F1-RetrieveBoStatusDescription	Return the description of a given BO status.
F1-RetrieveBusinessObjectLabel	Return the label appropriate for a given path (e.g. element) within a BO schema.
F1-RetrieveNextStates	Return a list of next possible states based on the input of a MO and its prime key, or a BO and one of its statuses.

Email Related Services

Business Service Name	Description
F1-EmailService	Sends an email message in real time.
F1-RetrieveEmailAddress	Retrieves the email addresses of users belonging to a To Do Role.
F1-RetrieveEnvironmentURL	Retrieves the current environment URL information for the installation.

Tools for Maps and Scripting

Business Service Name	Description
F1-AddWarning	This business service may be used to log a warning by providing the message details. The system gathers all the warning and displays them to the user all at once.
F1-CheckOnlineConnection	Check if Connection is Online or Batch.
F1-CheckWarning	Used to check if any warnings have been accumulated. If warnings have been accumulated, any logic that cannot be rolled back (when the warnings are shown) should not be performed.
F1-DateMath	Performs various date and time math calculations. Refer to the BS description for more details.
F1-DateTimeFormattingService	Formats a given date / time based on the user's display profile settings.
F1-ExecuteScriptInNewSession	Executes a Service Script in a new processing session/transaction.
F1-GetFieldLabel	Retrieves the label for a given field.
F1-GetForeignKeyReference	Returns foreign key reference information for a given FK Reference and primary key, including info description, navigation option, and context menu.
F1-GetFKReferenceDetails	Returns foreign key reference information for a given MO and primary key, including FK reference code, info description, navigation option, search zone and context menu.
F1-GetLookupDescription	Returns lookup description for a lookup field value given the lookup field name.
F1-GetExtLookUpVal	Returns the list of values for a given extendable lookup BO.
F1-GetMonthInYearAbbreviation	Returns a 3-character month abbreviation for an input date in system format.
F1-NumberAmountFormatter	Formats a given amount or number based on the user's display profile settings. It also may receive input to adjust the scale and optionally apply currency settings.
F1-OutmsgDispatcher	Dispatches a real-time message giving the user the option of whether to persist the message on the database, and whether to trap errors that may take place during the call. Refer to Real Time Messages for more information.
F1-OutmsgMediator	Alternative to F1-OutmsgDispatcher and may be a better option if the sender does not require an outbound message record to be instantiated. Refer to Real Time Messages for more information.

Business Service Name	Description
F1-RethrowError	Issues an application error using the input message category / number / parameters.
F1-RetrieveMODescription	Retrieves the description for a maintenance object.
F1-ReturnMessage	Returns the expanded message given a message category, number, parameters, and parameter types.
F1-SavePointDispatcher	Allows for a service script to be executed where exceptions are trapped and the transaction is rolled back to a save point set before the service script execution.

User Related Services

Business Service Name	Comments
F1-CheckApplicationSecurity	Checks a user's security for a given application service / access mode
F1-CheckUserAuthorization	Determine whether a given user is authorized for access based on the input application service, security code, and authorization level.
F1-DeterminelfUserCanApproveTD	Determine if the current user can approve a given To Do.

User Interface (UI) Maps

The User Interface (UI) map holds HTML to be rendered within [portal zones](#) and [Business Process Assistant \(BPA\) scripts](#). UI maps allow your implementation to create input forms and output maps that closely match your customer's business practices. In other words, the UI Map is designed to facilitate the capture and display of your [business objects](#) and [business services](#).

The UI map is a repository for a single HTML document paired with an XML schema where the schema defines the data that the HTML document displays and/or modifies. The UI Map HTML gives you the ability to craft the display by any method that an html document can support, including JavaScript and full CSS functionality.

Configuration tool support for UI Maps hinges around the ability to inject and extract an XML document from the HTML. For more information on the specialized support for HTML and JavaScript functionality refer to [UI Map Attributes and Functions](#).

```

<html>
<head>
<title>Output Personal Information</title>
<link rel="stylesheet" type="text/css" href="cm_templates/cmStyles.css"/>
</head>
<body>

<table width="100%" border="0" cellpadding="2" style="margin-top:15px;" >

  <tr>
    <td/>
    <td/> <!-- locate the edit button on the bottom of the third column -->
    <td rowspan="99" style="vertical-align:bottom; margin-left:5px">

Figure 3: HTML Input Form Rendered (for BPA Script)

Portal zones can reference a UI map for the zone header. They may also utilize a UI map to define their filter area. This type of UI map is not a complete HTML document, but is instead configured as a UI Map "fragment".

NOTE: UI Map Tips. A context sensitive "UI Map Tips" zone is visible on the UI map maintenance page. This zone provides several links to launch help topics related to valid schema syntax and UI Hint syntax in one click.

NOTE: Editing HTML. You can use a variety of HTML editors to compose your HTML, which you can then cut, and paste into your UI map. In addition, the zone provides a complete list of the XML schema nodes and attributes available to you when you construct the map's data schema.

Defining UI Maps

The topics in this section describe how to maintain UI Maps.

UI Map - Main

Use this page to define basic information about a user interface (UI) Map. Open this page using **Admin > System > UI Map**

Use the **UI Map Query** portal to search for an existing UI Map. Once a map is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Map** name. **Owner** indicates if the UI map is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new UI map, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Use **UI Map Type** to indicate whether the map is a **Complete XHTML Document**, **Complete HTML Document**, **XHTML Fragment** or an **HTML Fragment**. The default value is **Complete XHTML Document**.

Enter a **Description**. Use the **Detailed Description** to describe how this map is used in detail.

Click on the **View Schema** to view the UI map's expanded schema definition. Doing this opens the [schema viewer](#) window.

Use the **Test UI Map** hyperlink to render your HTML in a test window.

NOTE: The **Test UI Map** hyperlink also exercises the proprietary functionality that binds an XML element with an HTML element so you can get immediate feedback on your HTML syntax.

UI Map - Schema

Use this page to maintain a UI Map's HTML and schema and to see where the UI Map is used in the system. Open this page using **Admin > System > UI Map** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the UI Map.

The **HTML Editor** zone allows you to edit the HTML document of the map.

NOTE: Refer to [UI Map Attributes and Functions](#) and [UI Map Standards](#) for more information about HTML definition syntax. These topics describe good ways to produce simple HTML, however, they are not an HTML reference. Note that you can use a variety of HTML editors to compose your HTML, which you can then cut and paste into your UI map.

NOTE: Providing Help. A [tool tip](#) can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map. Refer to [UI Map Attributes and Functions](#) for more information on how to enable and provide UI map help.

The [Schema Designer](#) zone allows you to edit the data schema part of the map. The purpose of the schema is to describe the data elements being displayed by the map.

FASTPATH: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **UI Map Tips** zone in the dashboard provides a link to launch this help topic directly.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

UI Map Attributes and Functions

NOTE: This topic uses the term "field" to refer to both the generic concept of displaying and capturing data in a 'field' as well as referring to the meta-data object supplied in the product to define [Fields](#). When referring to the latter, the term "MD Field" (meta-data Field) is used and a hyperlink to the Field documentation is provided.

Contents

Bind XML to HTML

Only two different attributes are required to bind a UI Map's XML to its HTML. Both of these attributes require an XML document embedded within the HTML, where the XML is bounded by <xml> nodes.

WARNING: You must embed a pair of <xml></xml> tags within your HTML document for binding to occur.

Linking a Field

Syntax	Values	Description
oraField=" "	Field element XPath	This attribute is used to link an HTML element directly with an XML element, where the XML element is defined within the UI Map's XML schema. The attribute can be used with any <i>rendering</i> HTML element, such as: , <div>, and <input>.

- HTML for input element:

```
<html>
<body>
<table>
  <tr>
    <td>Address:</td>
    <td><input type="text" oraField="address"/></td>
  </tr>
  <tr>
    <td>City:</td>
    <td><input type="text" oraField="city"/></td>
  </tr>
  <tr>
    <td>State:</td>
```

```

        <td><input type="text" oraField="state"/></td>
      </tr>
      <tr>
        <td>Zip:</td>
        <td><input type="text" oraField="zip"/></td>
      </tr>
    </table>
  </body>
</xml>
<root>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>

```

Rendered HTML

Address:

City:

State:

Zip:

- HTML for span and div elements:

```

<html>
<body>

<div oraField="address"></div>
<span oraField="city"></span>
<span>,</span>
<span oraField="state"></span>
<span oraField="zip"></span>
<span oraField="country"></span>

</body>
<xml>
  <root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
  </root>
</xml>
</html>

```

HTML rendered:

123 Main St
Alameda, CA 94770

Linking a List

This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the framework to replicate the table's HTML for each occurrence of the list.

Syntax	Values	Description
oraList=" "	List element XPath	This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the

Syntax	Values	Description
		framework to replicate the table's HTML for each occurrence of the list.

NOTE: The oraField attributes embedded within the list must contain XPath navigation relative to the list. See below for an example.

```

<html>
<head><title>Bind xml list element</title></head>
<body>
<table oraList="payment">
  <thead>
    <tr>
      <th><span>Pay Date</span></th>
      <th><span>Amount</span></th>
    </tr>
  </thead>
  <tr>
    <td>
      <span oraField="date" oraType="date"></span>
    </td>
    <td align="right">
      <span oraField="amount" oraType="money"></span>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <payment>
    <date>2008-01-01</date>
    <amount>44.28</amount>
  </payment>
  <payment>
    <date>2008-02-01</date>
    <amount>32.87</amount>
  </payment>
  <payment>
    <date>2008-03-01</date>
    <amount>21.76</amount>
  </payment>
</root>
</xml>
</html>

```

HTML rendered:

```

Pay Date Amount
01-01-2008 $44.28
02-01-2008 $32.87
03-01-2008 $21.76

```

Build a Dropdown List

The following attributes are provided to build an HTML 'select' element, also called a dropdown, based on various sources.

Source	Syntax	Values	Examples
Lookup	oraSelect="lookup: ;"	Lookup field	<pre> ... <td>House Type:</td> <td> <select oraField="houseType" oraSelect="lookup:HOUSE_TYPE;"> </select> </pre>

Source	Syntax	Values	Examples
			</td>
Extendable Lookup	oraSelect="lookupBO: ;"	BO code	<pre> ... <td>UI Device Display Type:</ td> <td> <select oraField="uiDeviceType" oraSelect="lookupBO: Fl- DeviceDisplayTypes;"></ select> </td> </pre>
Characteristic Type (pre-defined)	oraSelect="charType: ;"	Characteristic Type code	<pre> ... <td>Usage:</td> <td> <select oraField="statusReasonUsage" oraSelect="charType:Fl- SRUSG;"></select> </td> ... </pre>
Control Table	<p>oraSelect="table: ;"</p> <p>NOTE: This attribute only works with tables that follow the standard control table structure where there is a related language table that includes that includes the column DESCR as its description column. Use the Application Viewer data dictionary to identify tables that qualify for this functionality.</p> <p>WARNING: The oraSelect function will only work if less than 500 values are displayed.</p>	Table name	<pre> ... <td>Currency: </td> <td> <select oraField="currency" oraSelect="table:CI_CURRENCY_CD;" </select> </td> ... </pre>
Page Service	oraSelect="service: ;"	Page Service name	<pre> ... <td>Country:</td> <td> <select oraField="country" oraSelect="service:CIPTCNTW;" </select> </td> ... </pre>
Embedded List	<p>Used to build a select dropdown based on a list within the map's XML.</p> <p>oraSelect="valuePath: ;descPath: ;"</p>	<p>After the valuePath, indicate the XPath of the element that holds the values. After the descPath, indicate the XPath of the element that holds the descriptions.</p>	<pre> <html> <body> <table summary="" border="0" cellpadding="1" cellspacing="1"> <tr> <td>Select: </td> <td><select oraSelect= "valuePath:list/value; descPath:list/desc" oraField="target"></ select></td> </tr> </table> </body> <xml> <root> <target>10</target> <list> <value>10</value> <desc>Ten</desc> </list> </root> </xml> </pre>

Source	Syntax	Values	Examples
			<pre> </list> <list> <value>20</value> <desc>Twenty</ desc> </list> <list> <value>40</value> <desc>Forty</desc> </list> </root> </xml> </html> </pre>
Service Script	oraSelect="ss: ;"	Service Script code	See below for additional syntax needed when using this function.
Business Service	oraSelect="bs: ;"	Business Service code	See below for additional syntax needed when using this function.

When specifying a service script or a business service, extra mapping information is needed to pass data to and from the service.

Syntax	Values	Description
oraSelectIn=" ;"	serviceXPath:element;	Used to pass the value of another element into the service (mapping to the service's XPath).
	serviceXPath:'Literal';	Used to pass a constant or literal to the service (mapping to the service's XPath).
oraSelectOut="valuePath: ; descPath: "	See examples below	Used to indicate which element in the service's output holds the values and which one holds the descriptions.

Example using a business service:

```

...
<td>External System: </td>
<td>
  <select oraField="externalSystem"
    oraSelect="bs:F1-RetrieveExternalSystems"
    oraSelectIn="outboundMsgType:boGroup/parameters/outboundMsgType;"
    oraSelectOut="valuePath:results/externalSystem;
    descPath:results/description">
  </select>
</td>
...

```

This method for building dropdowns is often used when there is a dependency between elements and the list of valid values in a dropdown (for the child element) is based on another element in the map (the parent element). When the parent element is changed, it may be required to refresh the child element. This behavior can be implemented using the function called within an **onChange** event in the map. The syntax is **oraHandleDependentElements('dependent element');**. Multiple target elements (dependents) can be named.

The following example is related to the above business service example where the list of external systems is specific for a given outbound message type, which is passed in as input. The snippet below shows the configuration for the outbound message type element to trigger a refresh of the external system's dropdown list.

```

...
<div>
  <label oraLabel="boGroup/parameters/outboundMsgType"></label>
  <span>
    <select oraSelect="table:F1_OUTMSG_TYPE"
      oraField="boGroup/parameters/outboundMsgType"

```

```

        onChange="oraHandleDependentElements('boGroup/parameters/externalSystem');" >
        </select>
    </span>
</div>
...

```

Format Input and Output Fields

The following attributes are designed to apply data type formatting for input and output fields.

Automatic Formatting

Syntax

oraSchemaDataTypes="false"

This attribute is used to trigger automatic formatting in the rendered HTML document. The automated formatting will occur according to the data type attributes defined in the UI map's schema. For details on specific data type formatting, please refer to the oraType attribute descriptions below.

WARNING: The attribute **oraSchemaDataTypes="true"** will be automatically injected into the UI map's HTML! If you do not wish to apply the schema's data types to the rendered HTML then you must specify this attribute in the body node with a value of false. The attribute **<body oraSchemaDataTypes="false">** is required to avoid automatic formatting!

- UI Map schema:

```

<schema>
  <schemaDate dataType="date" />
  <schemaDateTime dataType="dateTime" />
  <schemaFKRef fkRef="CI_USER" />
  <schemaLookup dataType="lookup" lookup="ACCESS_MODE" />
  <schemaMoney dataType="money" />
  <schemaNumber dataType="number" />
  <schemaTime dataType="time" />
</schema>

```

- UI Map HTML:

```

<html>
<body oraSchemaDataTypes="true">
<table border="1" cellpadding="1" cellspacing="1">
  <tr><th>dataType</th><th>result type</th><th>input result</th><th>display-only result</th></tr>
  <tr>
    <td rowspan="2">date (from schema)</td>
    <td>raw</td>
    <td><input oraField="schemaDate" oraType="string" /></td>
    <td><span oraField="schemaDate" oraType="string"></span></td>
  </tr>
  <tr>
    <td>rendered</td>
    <td><input oraField="schemaDate"></td>
    <td><span oraField="schemaDate"></span></td>
  </tr>
  <tr>
    <td rowspan="2">dateTime (from schema)</td>
    <td>raw</td>
    <td><input oraField="schemaDateTime" oraType="string"></td>
    <td><span oraField="schemaDateTime" oraType="string"></span></td>

Date Formatting

This function is used to display a date according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.

Syntax

oraType="date"

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date: </td>
    <td><span oraField="date" oraType="date"></span></td>
  </tr>
  <tr>
    <td>Date: </td>
    <td><input oraField="date" oraType="date" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <date>2008-12-28</date>
</root>
</xml>
</html>

```

HTML rendered.

Date: 12-28-2008

Date:

Time Formatting

This function is used to display a time according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.

Syntax

oraType="time"

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Time: </td>
    <td><span oraField="time" oraType="time"></span></td>
  </tr>
  <tr>
    <td>Time: </td>
    <td><input oraField="time" oraType="time" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <time>00.28.54.389</time>
</root>
</xml>
</html>
```

HTML rendered.

Time: 12:28AM

Time:

Date and Time Formatting

This function is used to display a timestamp according to the user's display profile. If this function is used for an input element, it is broken into two pieces, one for [date](#) and one for [time](#). Optionally, the time portion of the date time element can be suppressed using the attribute value 'time:suppress'.

Syntax

oraType="dateTime; time:suppress"

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date time: </td>
    <td><span oraField="dateTime" oraType="dateTime"></span></td>
  </tr>
  <tr>
    <td>Date only: </td>
    <td><span oraField="dateTime" oraType="dateTime; time:suppress"></span></td>
  </tr>
  <tr>
    <td>Date time: </td>
    <td><input oraField="dateTime" oraType="dateTime" /></td>
  </tr>
</table>
```

```

<tr>
  <td>Date only: </td>
  <td><input oraField="dateTime" oraType="dateTime; time:suppress"/></td>
</tr>
</table>
</body>
</xml>
<root>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>

```

HTML rendered.

Date time: 11-01-2009 12:28AM

Date only: 11-01-2009

Date time:

Date only:

Date / Time Formatting with Standard Time

This true function is used to render a date / time element according to the daylight savings time schedule of the 'base' time zone. The 'base' time zone is specified on the Installation table and represents the database time zone. For input elements with this setting, all time entered is assumed to correspond with the daylight savings time schedule of the base time zone. If a time is entered that cannot be unambiguously translated to standard time, then the user will be required to provide a time zone label to indicate whether daylight savings time, or standard time, has been entered.

Syntax

oraType="dateTime; stdTime:true;"

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date time: </td>
    <td><span oraField="dateTime" oraType="dateTime; stdTime:true;"></span></td>
  </tr>
  <tr>
    <td>Date time: </td>
    <td><input oraField="dateTime" oraType="dateTime; stdTime:true;" /></td>
  </tr>
</table>
</body>
</xml>
<root>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>

```

HTML rendered.

NOTE: The time zone label is displayed because 1:28 is ambiguous otherwise. Legally, November 1, 2009 1:28 AM occurs twice because daylight savings time (DST) is removed at 2:00 AM. With the stdTime function time zone labels are only displayed when required to clarify time overlaps.

Date time: 11-01-2009 01:28AM PDT

Date time:

HTML rendered for the following day.

Date time: 11-02-2009 12:28AM

Date time:

Date and Time Formatting with Time Zone Reference

Syntax	Valid Values	Description
<code>oraType="dateTime; stdTimeRef: ;"</code>	Reference an XPath after the colon.	This function is used to render a date / time element according to the daylight savings time schedule of a time zone whose XPath is referenced. Note that the time processed is assumed to have been stored in the standard time of the referenced time zone - so only daylight savings time shifting will execute - not time zone shifting.
<code>oraType="dateTime; displayRef: ;"</code>	Reference an XPath after the colon.	This function is similar to the <code>stdTimeRef</code> function, except that this function will execute time zone shifting in addition to daylight savings time shifting. To use <code>displayRef</code> correctly, only associate it with time zone elements that have been stored in the base time zone.

For input elements, all time entered is assumed to correspond with the daylight savings time schedule of the referenced time zone. If a time is entered that cannot be unambiguously translated to standard time, then the user will be required to provide a time zone label to indicate whether daylight savings time, or standard time, has been entered.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date time: </td>
    <td><span oraField="dateTime" oraType="dateTime; stdTimeRef:timeZone;"></span></td>
  </tr>
  <tr>
    <td>Date time: </td>
    <td><input oraField="dateTime" oraType="dateTime; stdTimeRef:timeZone;" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <timeZone>US-EAST</timeZone>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>
```

HTML rendered.

NOTE: The time zone label is always displayed for a referenced time zone.

Date time: 11-01-2009 01:28AM EDT

Date time:

HTML rendered for the following day.

Date time: 11-02-2009 12:28AM EST

Date time:

Duration Formatting

Syntax

oraType="duration"

This function is used to display time duration. For an input element, the value entered by the user is translated from minutes to hour and minutes as appropriate. For example, an entered value of '90', is converted to '00:01:30' when tabbing out of the input field.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Duration: </td>
    <td><span oraField="duration" oraType="duration"></span></td>
  </tr>
  <tr>
    <td>Duration: </td>
    <td><input oraField="duration" oraType="duration" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <duration>90</duration>
</root>
</xml>
</html>
```

HTML rendered.

Duration: 00:01:30

Duration:

Day in Month Formatting

Syntax

oraType="dayInMonth"

This function is used to display a concatenated day and month.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Day In Month: </td>
    <td><span oraField="dayMonth" oraType="dayInMonth"></span></td>
  </tr>
  <tr>
    <td>Day In Month: </td>
    <td><input oraField="dayMonth" oraType="dayInMonth" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <dayMonth>0228</dayMonth>
</root>
</xml>
</html>
```

HTML rendered.

Day In Month: 02-28

Day In Month:

Month In Year Formatting

Syntax

oraType="monthInYear"

This function is used to display a concatenated month and year.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Month In Year: </td>
    <td><span oraField="month" oraType="monthInYear"></span></td>
  </tr>
  <tr>
    <td>Month In Year: </td>
    <td><input oraField="month" oraType="monthInYear" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <month>200811</month>
</root>
</xml>
</html>
```

HTML rendered.

Month In Year: 11-2008

Month In Year:

Monetary Formatting

This function is used to display a number as a monetary amount. See the table for configuration options with respect to the currency. For input elements, an error is issued if a non-numeric value is entered.

Syntax	Description
oraType="money: "	Directly specify a currency code after the colon.
oraType="money;currencyRef: "	Reference an XPath (after the colon) for an element that references a currency code.
oraType="money"	If no currency or currency reference is specified, the installation currency is used.

NOTE: You must specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the `oraMoney` style.

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css" />
  <link rel="stylesheet" type="text/css" href="cisEnabled.css" />
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
```

```

<tr>
  <td>Amount, currency specified:</td>
  <td><span oraType="money:EUR" oraField="totalAmt"></span></td>
</tr>
<tr>
  <td>Amount, default currency:</td>
  <td><span oraType="money" oraField="totalAmt"></span></td>
</tr>
<tr>
  <td>Amount, default input:</td>
  <td><input oraType="money" oraField="totalAmt" /></td>
</tr>
<tr>
  <td>Amount, currency reference:</td>
  <td><input oraType="money;currencyRef:cur" oraField="totalAmt" /></td>
</tr>
</table>
</body>
<xml>
<root>
  <totalAmt>50500.09</totalAmt>
  <cur>EUR</cur>
</root>
</xml>
</html>

```

HTML rendered

```

Amount, currency specified: €50500.09
Amount, default currency: $50500.09
Amount, default input: 
Amount, currency reference: 

```

Number Formatting

This function is used to display a number or validate an input value. For input elements, the system will return an error if a non-numeric value is entered.

Syntax

oraType="number"

NOTE: You must specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the `oraNumber` style.

```

<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css" />
  <link rel="stylesheet" type="text/css" href="cisEnabled.css" />
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Count:</td>
    <td><span oraType="number" oraField="count"></span></td>
  </tr>
  <tr>
    <td>Count, input:</td>
    <td><input oraType="number" oraField="count" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <count>989</count>

```

```
</root>
</xml>
</html>
```

HTML rendered.

Count: 989
Count, input:

FK Reference Formatting

By default, when an element with an **fkRef** oraType is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

Note that you can enable the foreign key hyperlink separately as well, refer to [Embed Framework Navigation](#) for more information. The various attributes used to control foreign key reference functionality are as follows. Note that in every case, the default value is **true**. A value of **false** should be used to disable the feature.

Syntax

oraType="fkRef:true|false; info:true|false; context:true|false; navigation:true|false; search:true|false"

- **fkRef.** A value of 'true' enables all of the following foreign key reference processing. Use a value of 'false' to disable automatic FK Reference processing.
- **info.** A value of 'true' renders an [information string](#) on the UI map, if applicable.
- **context.** A value of 'true' renders a context menu to appear before the foreign key reference element, if applicable.
- **navigation.** A value of 'true' causes the information string to be rendered as a hyperlink, if applicable. Clicking the hyperlink [navigates](#) to the appropriate page.
- **search.** A value of 'true' displays a search icon that launches the [search zone](#) if applicable.

NOTE: Foreign key navigation and context menu functionality is only available for UI maps presented in a portal zone. UI Maps presented during BPA script processing cannot support navigation options. Search functionality is only available for input HTML elements.

- UI Map schema:

```
<schema>
  <bo fkRef="F1-BOMO" />
</schema>
```

- UI Map HTML:

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Business Object</td>
    <td><span oraField="bo" oraType="fkRef:true; info:true; context:true; navigation:true;"></span></td>
  </tr>
</table>
</body>
</html>
<root>
  <bo>F1-COUNTRY</bo>
</root>
</xml>
```

```
</html>
```

- HTML rendered.

BUSINESS OBJECT

▼ Country

Lookup Formatting

This function is used to display the description of a lookup value.

Syntax	Valid Values
<code>oraType="lookup: "</code>	Lookup field name after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Status:</td>
    <td><span oraField="status" oraType="lookup: BATCH_JOB_STAT_FLG"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <status>PD</status>
</root>
</xml>
</html>
```

HTML rendered.

Status: Pending

Extendable Lookup Formatting

This function is used to display the description of an extendable lookup value.

Syntax	Valid Values
<code>oraType="lookupBO: "</code>	Business Object code name after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Value:</td>
    <td><span oraField="status" oraType="lookupBO: Fl-DeviceDisplayTypes"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <status>oraTablet</status>
</root>
</xml>
</html>
```

HTML rendered.

Value: Tablet size

Characteristic Type Formatting

This function is used to display the description of a predefined characteristic value.

Syntax	Valid Values
<code>oraType="charType: "</code>	Characteristic Type code after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Skill:</td>
    <td><span oraType="charType:CM-SKILL" oraField="skill"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <skill>10</skill>
</root>
</xml>
</html>
```

HTML rendered.

Skill: Quality assurance

Control Table Formatting

This function is used to display the description of a control table that has an associated language table.

Syntax	Valid Values
<code>oraType="table: "</code>	Table code after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Currency:</td>
    <td><span oraType="table:CI_CURRENCY_CD" oraField="curr"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <curr>USD</curr>
</root>
</xml>
</html>
```

HTML rendered.

Currency: United States Dollars

Add / Remove Grid Formatting

Syntax	Description
<code>oraType="addGridRow"</code>	The addGridRow function is used to build "insert row" dialog into the UI map.

Syntax**Description****oraType="deleteGridRow"**

The deleteGridRow function is used to build "delete row" dialog into the UI map.

- A 'delete' image is displayed.
- Clicking the image removes the adjacent row from the grid.

NOTE: Because add and delete dialogs are relevant only inside a table, these attributes must be specified within a <td> element.

WARNING: These attributes are designed to work with the business object action of 'replace' rather than 'update'. Therefore, if the map contains a grid, the business object action of 'replace' must be used to update the business object. Refer to [BO Replace Action](#) for more information.

Example:

```

<html>
<head>
<title>Demonstrate Grid Add and Grid Delete OraTypes</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table oraList="listEntry">
  <thead>
    <tr>
      <th/>
      <th/>
      <th><span>Date</span></th>
      <th><span>Amount</span></th>
    </tr>
  </thead>
  <tr>
    <td oraType="addGridRow"></td>
    <td oraType="deleteGridRow"></td>
    <td>
      <input oraField="date" oraType="date"></input>
    </td>
    <td align="right">
      <input oraField="amount" oraType="money"></input>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <listEntry>
    <date>2008-01-01</date>
    <amount>44.28</amount>
  </listEntry>
  <listEntry>
    <date>2008-02-01</date>
    <amount>32.87</amount>
  </listEntry>
  <listEntry>
    <date>2008-03-01</date>
  </listEntry>
</root>

```

```

    <amount>21.76</amount>
  </listEntry>
</root>
</xml>
</html>

```

HTML rendered.

	DATE		AMOUNT
+ 	01-01-2008	 	\$44.28
+ 	02-01-2008	 	\$32.87
+ 	03-01-2008	 	\$21.76

Unformatted Elements

This function is used to display the contents of an element that contains 'raw' data as defined for the schema element being rendered.

Syntax

oraType="raw"

- UI Map schema:

```

<schema>
  <rawStuff type="raw"/>
</schema>

```

- UI Map HTML:

```

<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Raw Stuff:</td>
    <td><span oraType="raw" oraField="rawStuff"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <rawStuff>
    <ele1>text in element 1</ele1>
    <group1>
      <ele2>text inside element 2, group 1</ele2>
      <ele3>text inside element 3, group 1</ele3>
    </group1>
  </rawStuff>
</root>
</xml>
</html>

```

HTML rendered.

Raw Stuff:	<pre><ele1>text in element 1</ele1> <group1> <ele2>text inside element 2, group 1</ele2> <ele3>text inside element 3, group 1</ele3> </group1></pre>
------------	--

String Formatting

This function is used to display the contents of an element, as XML pretty-print, when the element contains escaped XML.

Syntax

`oraType="xmlString"`

NOTE: It is not required, but the pretty print of the rendered XML is enhanced if you specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header.

Example:

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>XML Stuff:</td>
    <td><span oraType="xmlString" oraField="xmlStuff"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <xmlStuff>
    <ele1>text in element 1</ele1>
    <group1>
      <ele2>text inside element 2, group 1</ele2>
      <ele3>text inside element 3, group 1</ele3>
    </group1>
  </xmlStuff>
</root>
</xml>
</html>
```

HTML rendered.

XML Stuff:	<pre><ele1>text in element 1</ele1> <group1> <ele2>text inside element 2, group 1</ele2> <ele3>text inside element 3, group 1</ele3> </group1></pre>
------------	--

HTML rendered without `oraType="xmlString"`

XML Stuff:	<pre><ele1>text in element 1</ele1><group1><ele2>text inside element 2, group 1</ele2><ele3>text inside element 3, group 1</ele3></group1></pre>
------------	--

HTML Formatting

This function is used to display the contents of an element as HTML as opposed to plain text. An element defined as `oraType="fkref"` is automatically rendered as HTML.

Syntax

`oraType="html"`

WARNING:

To avoid execution of malicious HTML not all HTML tags are supported. The list of supported tags is defined in the "F1-HTMLWhiteList" managed content definition.

If unsupported HTML is detected the entire element is escaped and rendered as plain text. It is therefore recommended to properly escape any source string that contributes to the final HTML element if it is not expected to contain valid HTML. This way only the offending string is escaped and not the entire element.

If the HTML element is composed in scripting refer to the 'escape' function described in the [Edit Data Syntax](#) for more information. Use the `WebStringUtilities.asHTML` java API for escaping text composed in Java.

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Info :</td>
    <td><span oraType="html" oraField="info"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <info><b>text in bold</b></info>
</root>
</xml>
</html>
```

HTML rendered.

Info : **text in bold**

HTML rendered without `oraType="html"`

Info : text in bold

Display Labels

Derive Label from an Element

This attribute is used to obtain a language sensitive label for a ``, `<td>`, or `<input>` HTML element.

Syntax

`oraLabel=" "`

Valid Values

XPath of an element in the UI map schema. The element must reference either the `mapField=`, `mdField=`, or `label=` attribute.

NOTE: You can also define a field directly in your HTML for label definition, refer to [Deriving Label from a Field](#) for more information.

NOTE: If the schema contains multiple attributes, the oraLabel attribute will pick the label to render according to the following hierarchy: The label attribute overrides the mdField attribute, which in turn will override the mapField attribute.

- UI Map schema:

```
<schema>
  <user mapField="USER_ID" />
  <info type="group" mapXML="CLOB">
    <city label="Metro Area" />
    <age mdField="AGE_LBL" />
  </info>
</schema>
```

- HTML:

```
<html>
<head><title oraMdLabel="BUS_LBL"></title></head>
<body>
<table>
  <tr>
    <td oraLabel="user"></td>
    <td><input oraField="user" /></td>
  </tr>
  <tr>
    <td oraLabel="info/city"></td>
    <td><input oraField="info/city" /></td>
  </tr>
  <tr>
    <td oraLabel="info/age"></td>
    <td><input oraField="info/age" /></td>
  </tr>
  <tr>
    <td />
    <td><input type="button" oraMdLabel="ACCEPT_LBL" /></td>
  </tr>
</table>
</body>
<xml>
<root>
  <user>RWINSTON</user>
  <info>
    <city>Alameda</city>
    <age>32</age>
  </info>
</root>
</xml>
</html>
```

HTML rendered:

User	<input type="text" value="RWINSTON"/>
Metro Area	<input type="text" value="Alameda"/>
Age	<input type="text" value="32"/>
	<input type="button" value="Accept"/>

Deriving Label from a Field

This attribute is used to obtain a language sensitive label for a , <td>, <input>, or <title> HTML element. The label text is derived from the field referenced.

Syntax**Valid Values**

oraMdLabel=" "MD Field code.

NOTE: You can also define labels derived from the map's schema definition, refer to [Derive Label from an Element](#) for more information.

- **HTML:**

```
<html>
<head><title oraMdLabel="Fl_DETAILS_LBL"></title></head>
<body>
<table>
  <tr>
    <td oraLabel="user"></td>
    <td><input oraField="user"/></td>
  </tr>
  <tr>
    <td oraLabel="info/city"></td>
    <td><input oraField="info/city"/></td>
  </tr>
  <tr>
    <td oraLabel="info/age"></td>
    <td><input oraField="info/age"/></td>
  </tr>
  <tr>
    <td/>
    <td><input type="button" oraMdLabel="ACCEPT_LBL"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <user>RWINSTON</user>
  <info>
    <city>Alameda</city>
    <age>32</age>
  </info>
</root>
</xml>
</html>
```

HTML rendered:

The screenshot shows a web browser window titled "Details - Google Chrome". The address bar displays "Not secure | slcao351.us.oracle.com:20000/spl/usermap". Below the address bar, there is a section titled "Details" containing a form. The form has three input fields: "User" with the value "RWINSTON", "Metro Area" with the value "Alameda", and "Age" with the value "32". Below these fields is an "Accept" button.

Enable UI Map Help

The [Display Labels](#) section describes ways to derive the label for an element using an underlying [MD Field](#). In addition, if the same MD field contains help text, the system will automatically generate a tool tip adjacent to the element label. Clicking the tool tip allows the user to view the help text.

It is possible to change the rendering of the tool tip. Refer to [Custom Look And Feel Options](#) for more information

Search Using a Pop-Up Explorer Zone

Search Option

This attribute is used to enable search zone functionality for input HTML elements.

Syntax	Valid Values
<code>oraSearch=" "</code>	Zone code.

NOTE: The `oraSearch` attribute is similar to the `oraType` attribute, because it will be 'automatically' included into HTML via the `oraSchemaDataTypes` attribute. This means that coding the `oraSearch` attribute into UI Map HTML is only required if a search zone has not been specified in the schema, or in the schema element's FK reference.

- Example of defining the search in the HTML. UI Map's Schema:

```
<schema>
  <uiMap/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap" oraSearch="F1-UISRCH"></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

- Example of defining the search in the schema. UI Map's Schema:

```
<schema>
  <uiMap search="F1-UISRCH" />
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap"></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

- Example where the FK reference defines the search zone. UI Map's Schema:

```
<schema>
  <uiMap fkRef="F1-UISRC" />
```

```
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

In all cases, the HTML rendered is the same.

Initializing Search Fields

This optional attribute is used to initialize search zone filters. Multiple filters may be initialized. This attribute can only be used in conjunction with the oraSearch attribute.

Syntax	Valid Values	Field Value Options	Comments
<code>oraSearchField=""</code>	One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon.	No value	If you do not specify a field value, then the value of the input element containing the oraSearchField attribute will be used.
<code>oraSearchField="fieldName:fieldValue: ..."</code>	The field name is used to identify the zone filter to initialize when the search is launched. The field name must match the value of the searchField mnemonic specified on a search zone user filter or hidden filter parameter.	XPath 'literal'	Indicate the XPath to the schema element that contains the value to use. Indicate a literal value to supply.

NOTE: If you do not specify an oraSearchField attribute and the schema element has a search enabled fkRef specified, the framework automatically builds an oraSearchField where the field name is equal to the FK reference's key (MD) [fields](#).

WARNING: The pop-up explorer zone can be invoked one of two ways: By clicking on the search button, or by hitting the enter key from the field to the left of the button. If you click on the button then no search field information will be passed to the zone. Search field information is only used to initialize zone filter values when enter is pressed.

Two filter values are initialized as shown in the following example:

```
<schema>
  <bo/>
  <uiMap/>
</schema>

<html>
<body>
```

```

<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap" oraSearch="F1-
UISRCH" oraSearchField="MAP_CD; BUS_OBJ_CD:bo;"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <bo/>
  <uiMap/>
</root>
</xml>
</html>

```

Mapping Returned Search Fields

This optional attribute is used to direct values returned by the search zone. Multiple fields may be specified. This attribute can only be used in conjunction with the oraSearch attribute.

Syntax	Valid Values	Field Value Options	Comments
oraSearchOut=" "	One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon.	No value	If you do not specify a field value, then the input element containing the oraSearchField attribute receives the returned value.
oraSearchOut="field name:xpath target; ..."	The field name is used to identify the search result returned from the query zone. The field name must match the ELEMENT_NAME mnemonic defined within the explorer zone's search results parameter.	XPath	Indicate the XPath to the schema element that should receive the returned value.

NOTE: If you do not specify an oraSearchOut attribute, the framework will build a default where the field name will be set equal to the oraSearchField's field name.

Two values are returned in the following example:

```

<schema>
  <bo/>
  <mo/>
</schema>

```

```

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>BO Search </td>
    <td><input oraField="bo" oraSearch="Z1-BOSRCH" oraSearchOut="BUS_OBJ_CD; MO_CD:mo;"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <bo/>
  <mo/>
</root>
</xml>
</html>

```

Display Errors

Display Error Variables

One of the following error variables may be displayed.

Syntax

`oraErrorVar="ERRMSG-TEXT"`

`oraErrorVar="ERRMSG-LONG"`

`oraErrorVar="ERRMSG-CATEGORY"`

`oraErrorVar="ERRMSG-NUMBER"`

```
...  
<table width="100%" cellpadding="12">  
  <tr class="oraErrorText">  
    <td>  
      <a href="" onclick="oraShowErrorAlert(); return false;">  
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>  
      </a>  
    </td>  
  </tr>  
</table>  
...
```

HTML rendered

Last name required

User Id BOND007

First Name

Last Name

Highlight a Field in Error

NOTE: For more information on throwing an error, refer to the [Terminate Statement](#) in the Edit Data Syntax.

Syntax

`oraError="automate:true|false; prefix: "`

Comments

Specifying **automate:true** automatically enables highlighting of the element in error when issuing an error. Note that **true** is the default and doesn't need to be specified. Specify **automate:false** to turn off field highlighting.

The system uses a match on the element name referenced in the error to the element names in the UI map. If the elements in the schema are within an XPath that may not match what is referenced by the error, use **prefix:XPath** to specify that.

NOTE: A pair of stylesheet references, `cisEnabled` and `cisDisabled`, must be specified for reference of the `oraError` style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the `oraError` style.

The following HTML example shows that the elements in the map are defined within a group called **boGroup**. The element name returned by the error will not include this group so in order for the field highlighting to work properly the **prefix:** attribute must indicate the group name.

```
<html>
<head>
  <title>User Zone Input</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body oraError="automate:true; prefix:boGroup">
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
<table width="100%" border="0" cellpadding="4">
  <tr style="padding-top:30px;">
    <td align="right" class="label">User Id</td>
    <td>
      <span oraField="boGroup/userId" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">First Name</td>
    <td>
      <input oraField="boGroup/firstName" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">Last Name</td>
    <td>
      <input oraField="boGroup/lastName" class="normal"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <boGroup>
    <userId>BOND007</userId>
    <firstName>James</firstName>
    <lastName></lastName>
  </boGroup>
</root>
</xml>
</html>
```

HTML rendered, where the error element thrown is equal to 'lastName':

Overriding the Error Element Name

In the rare occasion where the element name returned by the error doesn't match the element name in the map, you can add an explicit attribute to indicate the error element name.

Syntax	Valid Values	Comments
<code>oraErrorElement=</code>	"element name"	The element name referenced here must exactly match the name of the error element assigned when the error was thrown. More than one HTML field can be referenced by the same error element name.

NOTE: A pair of stylesheet references, `cisEnabled` and `cisDisabled`, must be specified for reference of the `oraError` style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the `oraError` style.

This illustrates a scenario where the element name associated with the error differs from the element name on the map.

```
<html>
<head>
  <title>User Zone Input</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
<table width="100%" border="0" cellpadding="4">
  <tr style="padding-top:30px;">
    <td align="right" class="label">User Id</td>
    <td>
      <span oraField="userId" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">First Name</td>
    <td>
      <input oraField="firstName" class="normal" oraErrorElement="firstName"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">Last Name</td>
    <td>
      <input oraField="familyName" class="normal" oraErrorElement="lastName"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId>BOND007</userId>
  <firstName>James</firstName>
  <familyName></familyName>
</root>
</xml>
</html>
```

HTML rendered.

Display Error Pop-Up

When the error text is displayed, this function may be used to pop-up the standard error dialog (which displays more information) when a user clicks the error message.

Syntax

oraShowErrorAlert(); return false;

```

<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
<table>
  <tr>
    <td >Address:</td>
    <td><input type="text" oraField="address"/></td>
  </tr>
  <tr>
    <td>City:</td>
    <td><input type="text" oraField="city"/></td>
  </tr>
  <tr>
    <td>State:</td>
    <td><input type="text" oraField="state"/></td>
  </tr>
  <tr>
    <td>Zip:</td>
    <td><input type="text" oraField="zip"/></td>
  </tr>
  <tr>
    <td/>
    <td style="padding-top:15px;">
      <oraInclude map="F1-SaveCancelButton"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>

```

Fire JavaScript for Browser Events

Working with the JavaScript Framework

There are many JavaScript events that can be used within the HTML/Javascript environment. These include events such as onLoad, onBlur, onChange, etc. The UI Map Framework also makes use of some of these events. It is important that any UI Map you develop works with the framework in order to obtain consistent results (events may not always be executed in the same order at all times!).

WARNING:

The following describes the recommended approach for safely handling loading and processing field updates in your UI Maps.

If JavaScript is required within an XHTML UI Map or fragment, it will be necessary to bound it within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/*  */

//
// javascript
//

/* ]]&gt; */
&lt;/script&gt;</pre></div><div data-bbox="467 942 912 959" data-label="Page-Footer"><hr/><p>Oracle Utilities Customer to Meter Administrative User Guide • 221</p></div>
```

Element Change Event

Syntax	Valid Values
<code>oraChange=" "</code>	A JavaScript function.

At the time of UI Map load, if there is an event handler already attached to an HTML element, the framework removes it and attaches a combined event handler. The combined handler calls any **framework handler first** and then calls the other (custom) handlers.

WARNING: Note that the function must not be used to execute logic that will modify the associated field data value again - or an endless loop will occur.

In the following example the **oraInvokeBS** function is executed when the button is clicked.

```
<html>
  <head>
    <title>oraInvokeBS test</title>
  </head>
  <body>
    <table>
      <tr>
        <td>User Id:</td>
        <td>
          <input oraField= "xmlGroup/userId"/>
          <input type="button" value="Search" oraChange="oraInvokeBS('UserSearch', 'xmlGroup');"/>
        </td>
      </tr>
      <tr>
        <td/>
        <td>Search Results</td>
      </tr>
      <tr>
        <td/>
        <td>
          <table oraList="xmlGroup/searchList">
            <tr>
              <td><span oraField="userId"></span>
            </td>
            </tr>
          </table>
        </td>
      </tr>
    </table>
  </body>
  <xml>
    <root>
      <xmlGroup>
        <userId/>
        <searchList>
          <userId></userId>
        </searchList>
      </xmlGroup>
    </root>
  </xml>
</html>
```

Page Load Event

Syntax	Valid Values
<code>oraLoad=" "</code>	A JavaScript function.

WARNING: When executing oraLoad within a fragment UI map, and you need to execute a JavaScript function during page load (where the function invokes a business object, business service, or service script) you can use the special syntax "**oraLoad[\$SEQUENCEID]**". For other special syntax used for map fragments, refer to the [Construct a Portal Zone Header](#) section.

- In the following example, the `oraDisplayNone` function is executed during page load:

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td oraLoad="oraDisplayNone(item,'userId','')">User Id: </td>
    <td><span oraField="userId"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId>SPLAXT</userId>
</root>
</xml>
</html>
```

- HTML rendered

User Id: SPLAXT

After Page Load Event

Syntax	Valid Values
<code>oraAfterLoad=""</code>	A JavaScript function.

In the following example the `oraGetValueFromScript` function is executed after page load.

```
<div>
  <label for="boGroup_parameters_externalSystem" oraLabel="boGroup/parameters/externalSystem">
  </label>
  <span>
    <select oraSelect="bs:F1-RetrieveExternalSystems" class="oraInput"
      id="boGroup_parameters_externalSystem" oraField="boGroup/parameters/externalSystem"
      oraSelectOut="valuePath:results/externalSystem; descPath:results/description"
      oraSelectIn="outboundMsgType:boGroup/parameters/outboundMsgType"
      oraAfterLoad
      ="oraGetValueFromScript(document.getElementById('boGroup_parameters_externalSystem'));">
    </select>
  </span>
</div>
```

Hide Elements

Hide Using a Function

The system provides multiple techniques for hiding an HTML element.

Syntax	Valid Values	Comments
<code>oraDisplayNone(item);</code>	(item, 'XPath', 'value', 'operator')	Used to hide an element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This

Syntax	Valid Values	Comments
		may be set instead to another operator such as '!=', '>', or '<'.
	(item, function name, true false)	Used to indicate a JavaScript function, which must return a Boolean.
oralsSuppress="true"		Use this option for fields that need to be hidden always and not dependent on something else. Set this attribute on the HTML element (div element).

- Example where the User Id label is hidden when no User Id value exists.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td oraLoad="oraDisplayNone(item,'userId','')>User Id: </td>
    <td><span oraField="userId"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId></userId>
</root>
</xml>
</html>
```

- Example where the Save button is hidden when the user does not have security access to the action of change ('C') for the application service 'F1-DFLTS'.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td oraLoad="oraDisplayNone(item, oraHasSecurity('F1-DFLTS', 'C'), false );">
      <input name="Save" type="button" onclick="oraInvokeBO('CM-
IndividualTaxpayer', null, 'replace')"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId></userId>
</root>
</xml>
</html>
```

Check User's Security Access

The system provides two functions to check a user's security access to a given application service and access mode. These are commonly used for hiding elements.

Syntax	Parameters
oraHasSecurity()	'Application Service code'
	'Access Mode'
oraHasSecurityPath('x','y')	'Application Service XPath'
	'Access Mode XPath'

See the previous section for an example of the **oraHasSecurity** function. The following shows an example where the status button is hidden when the user does not have security access to the access mode 'ACT' of the application service 'FORMTST'.

```
<html>
<body>
<table>
  <tr>
    <td oraLoad="oraDisplayNone(item, oraHasSecurityPath('appService', 'accessMode'), false );">
      <input oraField="statusLabel" type="button" onclick="oraRunScript('UpdateState','status');"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <status>ACTIVATE</status>
<statusLabel>Activate</statusLabel>
<appService>FORMTST</appService>
  <accessMode>ACT</accessMode>
</root>
</xml>
</html>
```

Invoke Schema Based Services

The system provides functions for invoking a business object, business service or service script.

Invoke BO Function

This function is used to perform a BO interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Syntax	Parameters	Comments
oralInvokeBO()	'BO Name'	
	'XPath' or null	Identifies a group element via XPath. If you specify the word null , then the entire embedded XML object will be passed.
	'action'	Indicate the action to use. Valid values are add, delete, read, update, replace, fastAdd and fastUpdate . FASTPATH: Refer to BO Actions for more information about the various BO actions.

Example with the statement invoked in a JavaScript function.

```
function invokeBO {
  if (!oraInvokeBO('F1-User', 'xmlGroup', 'read')) {
    oraShowErrorAlert();
    return;
  }
}
```

Example with the statement invoked within onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeBO('F1-User');"/>
```

Invoke BS Function

This function is used to perform a business service interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Syntax	Parameters	Comments
<code>oraInvokeBS()</code>	'BS Name' 'XPath' or null	Identifies a group element via XPath. If you specify the word null , then the entire embedded XML object will be passed.

Example with the statement coded within a JavaScript function.

```
function invokeBS {
    if (!oraInvokeBS('F1-UserSearch', 'xmlGroup')) {
        oraShowErrorAlert();
        return;
    }
}
```

Example with the statement invoked via onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeBS('F1-RetrieveInfo');"/>
```

Invoke SS Function

This function is used to perform a service script interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Syntax	Parameters	Comments
<code>oraInvokeSS()</code>	'Service Script Name' 'XPath' or null	Identifies a group element via XPath. If you specify the word null , then the document belonging to the parent node will be passed. If the parent node is not enough, then the entire document can always be passed using the following syntax: <code>oraInvokeSS('service script', null, null, {\$SEQUENCEID})</code>

Example with the statement invoked within a JavaScript function:

```
function invokeSS {
    if (!oraInvokeSS('F1-GetUsers', 'xmlGroup')) {
        oraShowErrorAlert();
        return;
    }
}
```

Example with the statement invoked within onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeSS('F1-GetUserInfo');"/>
```

Refresh a Rendered Map or Portal Page

Refresh Map

This function is used to 'Refresh' only the map zone issuing the command.

Syntax

oraRefreshMap;

```
...
  <tr>
    <td/>
    <td><input type="button" onclick="oraRefreshMap();" value="Refresh"/></td>
  </tr>
...
```

Refresh Page

This function is used to refresh all zones in the portal.

Syntax

oraRefreshPage;

```
...
  <tr>
    <td/>
    <td><input type="button" onclick="oraRefreshPage();" value="Refresh"/></td>
  </tr>
...
```

Embed Framework Navigation

Navigate using Navigation Option

This function is used to navigate to another page using the information defined on a navigation option.

Syntax

oraNavigate();

Parameters

'Navigation Option code'

'Key XPath'

WARNING: This function is only intended for a UI map defined within a portal zone. It should not be used within a UI map launched by a BPA script.

The following example exhibits two possible uses of this function: as a URL and as a button. Note that the UI Map schema must contain a fkRef attribute. Refer to [FK Reference Formatting](#) for more information.

```
<schema>
  <userId fkRef="CI_USER"/>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>User Link: </td>
    <td><a href="" onclick="oraNavigate('userMaint','userId'); return false;">
      <span oraField="userId" oraType="fkRef:CI_USER"></span></a>
    </td>
  </tr>
</table>
<tr>
  <td>User Button: </td>
  <td><input type="submit" onclick="oraNavigate('userMaint','userId')"
    value="Go to User"/></td>
</tr>
</table>
</body>
<xml>
```

```

<root>
  <userId>SPLAXT</userId>
</root>
</xml>
</html>

```

HTML rendered.

Launch BPA Script

Launch BPA Script

Syntax	Parameters	Comments
<code>oraRunScript();</code>	'BPA script code'. 'XPath Element'	One or more element values may be passed into the BPA where it may be referenced as temporary variables.

WARNING: This function is only applicable to UI maps displayed in portal zones. UI maps launched within a running BPA script cannot directly launch another BPA script from the UI map's HTML. Instead, return a value from the UI map and execute a Perform Script or Transfer Control step type.

NOTE: It is incumbent on the script author to pull information out of temporary storage in the initial steps of the script.

In the following example, a temporary variable named 'personId' is created with value '1234567890' and the BPA script named 'Edit Address' is launched.

```

<html>
<body>
<table>
  <tr>
    <td>
      <div oraField="address"></div>
      <span oraField="city"></span>
      <span>,</span>
      <span oraField="state"></span>
      <span oraField="zip"></span>
      <span oraField="country"></span>
      <a href="" onClick="oraRunScript('Edit Address','personId');">edit</a>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <personId>1234567890</personId>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>

```

HTML rendered.

123 Main St
Alameda, CA 94770 [edit](#)

Launch BPA Script With Values

This function is used to launch a BPA, providing name/value pairs to push into temporary storage. Multiple values can be passed. The BPA script can then reference the temporary variables by name.

Syntax	Parameters	Comments
<code>oraRunScriptWithValues();</code>	'BPA script code'. 'XPath Element Name':value	One or more pairs of element names and values.

NOTE: You would use this JavaScript function, instead of `oraRunScript`, if you need to push values to the BPA script that are not located in the UI Map's XML structure.

In the example below, a JavaScript function named 'editUser()' is responsible for launching the BPA script named 'UserEdit'. The temporary variable named 'userId' will be created with value 'CMURRAY'.

```
<html>
<head>
<script type="text/javascript">

function editUser() {
    var values = {'userId': 'CMURRAY'};
    oraRunScriptWithValues('UserEdit', values);
    return;
}

</script>
</head>
<body>
...
</body>
</html>
```

Exit UI Map with Bound Values

This function is used to exit a UI Map. When you quit the map you can specify a value to return to the script and, in addition, whether to return updated XML.

Syntax	Parameters	Comments
<code>oraSubmitMap();</code>	'Return Value' Boolean value	Indicates if the updated XML should be returned. Default is true .

In the following example, the Save button will return updated information, the Cancel button will not.

```
<html>
<body>
<table>
  <tr>
    <td/>
    <td style="padding-bottom:15px;">
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span oraErrorVar="ERRMSG-TEXT"></span></a>
    </td>
  </tr>
  <tr>
    <td >Address:</td>
    <td><input type="text" oraField="address"/></td>
  </tr>
  <tr>
    <td>City:</td>
```

```

        <td><input type="text" oraField="city"/></td>
      </tr>
    <tr>
      <td>State:</td>
      <td><input type="text" oraField="state"/></td>
    </tr>
    <tr>
      <td>Zip:</td>
      <td><input type="text" oraField="zip"/></td>
    </tr>
    <tr>
      <td/>
      <td style="padding-top:15px;">
        <input type="button" value="Save" onClick="oraSubmitMap('SAVE');"/>
        <input type="button" value="Cancel" onClick="oraSubmitMap('CANCEL',false);"/>
      </td>
    </tr>
  </table>
</body>
</xml>
<root>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>

```

Save and Cancel buttons rendered:

Include a Map Fragment

This function is used to embed a map fragment within another UI map. Note that it is possible to use the include node within a map or a map fragment.

Syntax	Parameters	Comments
<code><oralInclude map=' ' prefixPath=' '/></code>	map='UI Map Code' prefixPath='Xpath'	Optionally specify an xpath prefix to be appended onto every included oraField, oraLabel, oraList, oraSelect valuePath and descPath, oraDownloadData, and oraUploadData attribute value defined within the included UI map fragment's HTML. NOTE: This functionality only applies to XPath attribute values when those values do not appear beneath an oraList attribute. Any XPath value within a table containing

Syntax	Parameters	Comments
		an oraList attribute will not be affected by a prefixPath.

- An example of a map fragment with two buttons, named 'F1-SaveCancelButtons'.

```
<input onClick = "oraSubmitMap('SAVE');" oraMdLabel="SAVE_BTN_LBL" class="oraButton" type="button"/>
<input onClick = "oraSubmitMap('CANCEL',false);" oraMdLabel="CANCEL_LBL" class="oraButton" type="button"/>
```

- An example of a map that includes the map fragment named 'F1-SaveCancelButtons'.

```
...
<tr>
  <td colspan="2" align="center">
<oraInclude map="F1-SaveCancelButtons"/>
  </td>
</tr>
...
```

Include a Web Component

A web component is a custom HTML element that produces a specific user interface feature. Each supported web component typically has one or more defined HTML attributes that affect how the web component functions and how it appears. The more complex web components may have a corresponding system configuration object that defines the behavior and information displayed by the resulting user interface element. For example the web component that produces a "tree" of information has a Tree configuration table, which defines the details about how to retrieve information for the tree and how to display each node.

Common Attributes

Some common attributes that may be used for each web component are:

- A reference to the specific instance of the configuration object that governs the details to produce.
- The ability to pass in context data as name and value pairs.
- A 'mode' that support showing a preview of the feature

Some attributes support a **single value** that is referenced. For these types of attributes, the value may be provided using one of the following references:

- Literal value. The value can be referenced directly. Example:

```
treename="F1-Tree"
```

- XPath Reference. XPath references must use the explicit syntax **x[value]**. Example:

```
treename="x[migrationTree]"
```

- Global or Portal context reference. These references must use the explicit syntax **c[value]**.

```
treename="c[TREE_NAME]"
```

- Field label reference. These references must use the explicit syntax **md[value]**.

```
text=md[F1_ADD_LBL]"
```

- Field help text reference. These references must use the explicit syntax **mdh[value]**.

```
text=mdh[F1_OPERATIONS_LBL]"
```

For **complex attributes** that support one or more name / value pairs, the syntax for defining the names and values follows the same rules as above for literal values, XPath references and context. Colons (":") should be used to separate the name from the value and semi-colons (";") separate each pair.

```
context="FIELD_NAME1:x[value1];FIELD_NAME2:F1AB;x[fieldName3]:c[FIELD_NAME3];"
```

A given web component may have additional HTML attributes specific to its functionality.

NOTE: Any UI map that defines a web component must include the F1-OJETLIBSR map fragment within the "body" tag.

```
<body>
<oraInclude map="F1-OJETLIBSR" />
. .
</body>
```

NOTE: Standard HTML attributes may also be provided (e.g ID=".." and style=".."). These are defined as normal. It should be noted that the web components themselves may control some styling aspects directly and thus override any style settings provided on the HTML web component. For example, the Contextual Insights configuration provides settings for text color that would override any color defined in the HTML.

The following sections describe each supported web component.

Trees

Refer to [Trees](#) for more information about tree configuration.

Syntax	Parameters	Comments
<code><ou-tree...></ou-tree></code>	<code>treename="singleValue"</code>	You must supply a reference to the name of the tree object that defines the configuration of the tree to display. This attribute expects a single value that follows the syntax described in the single value section above.
	<code>context="..."</code>	Optionally pass in one or more name / value pairs. The syntax follows the example shown in the complex attributes information above.

The following example uses an explicit reference to a tree and does not pass any context. The particular tree relies on global context, which the tree node algorithm has access to.

```
<ou-tree treename="C1-PremiseTree"></ou-tree>
```

Contextual Insight

Refer to [Contextual Insights](#) for information about the configuration related to defining contextual insights.

Syntax	Parameters	Comments
<code><ou-insights ...></ou-insights></code>	<code>insightType="singleValue"</code>	Use this attribute to specify an insight type to display. Either this attribute or the insight class attribute must be supplied. This attribute expects a single value that follows the syntax described in the single value section above.
	<code>insightClass="singleValue"</code>	Use an insight class to display all the insight types for the insight group related to this class. This attribute expects a single value that follows the syntax described in the single value section above.

Syntax	Parameters	Comments
	context="..."	Optionally pass in one or more name / value pairs. The syntax follows the example shown in the complex attributes information above.
	mode="preview"	Optionally pass in a mode of preview to indicate to the underlying insight algorithm that prepares the data that the insight is being called in preview mode, with no context available. Ideally the algorithm returns sample information.
	class=" "	Optionally provide a CSS helper class to control aspects of the rendered insight. Supported values: class="card-full-width" - Applicable to card insights. Use this option class to ensure that the width for a card insight adjusts to the width of the zone that contains it. Card insights that don't set this parameter use a fixed width.

The following example is from the insight preview map where the insight type is the one in context. No context data is needed and the mode is 'preview'.

```
<ou-insights insightType="x[insightType]" mode="preview"></ou-insights>
```

The following example uses an insight class and passes in context values from XPath elements with explicitly defined context names.

```
<ou-insights insightClass="ClCI" context="PER_ID:x[personId];ACCT_ID:x[accountId];PREM_ID:x[promiseId];"></ou-insights>
```

Button

The button web component provides support for the standard set of button formats used within the system.

Syntax	Parameters	Comments
<ou-button...></ou-button>	type="singleValue"	You must define the type of button to display. This attribute expects a single value that follows the syntax described in the single value section above. The valid type values are: <ul style="list-style-type: none"> image - image only text - text only imageText - image followed by text menu - text plus a dropdown caret to open the menu imageMenu - image plus a dropdown caret to open the menu If no type attribute is supplied, a 'broken button' image will be displayed.
	img="singleValue"	Define the path of the image to display. Either this attribute or the image reference attribute

Syntax**Parameters****Comments**

		<p>must be supplied for a button type that includes an image. This attribute expects a single value that follows the syntax described in the single value section above.</p> <p>Note that for SVG images, if the reference includes only the SVG file name with no path, the path is assumed to be the Framework SVG repository.</p>
imgRef="singleValue"		<p>Define the display icon reference of the image to be used. Either this attribute or the image attribute must be supplied for a button type that includes an image. This attribute expects a single value that follows the syntax described in the single value section above.</p>
text="..."		<p>Define the various text elements needed by the button. The syntax follows the example shown in the complex attributes information above. The valid text element name values are:</p> <ul style="list-style-type: none">• label - the label text to be used for the button• tooltip - the hover text to be used for the button• aria-label - the ARIA label for the button
menu="singleValue"		<p>Define the menu to be used with the button. This attribute must be supplied for a button type that includes a menu control. This attribute expects a single value that follows the syntax described in the single value section above.</p>
disabled="singleValue"		<p>This is a standard HTML attribute. A value of "true" or just the presence of the text "disabled" will result in an initially disabled button.</p>
security="..."		<p>Optionally define the security settings for the button. The button will be hidden if the user does not have the appropriate security access. The syntax follows the example shown in the complex attributes information above. The valid security element name values are:</p> <ul style="list-style-type: none">• service - the application service whose security access governs access to the button• accessMode - the specific access mode for the service that determines a more granular level of access to the button

Syntax

Parameters

Comments

`clickAction="..."`

Optionally define the action to be taken when the button is 'clicked'. The syntax follows the example shown in the complex attributes information above. There are specific 'name' values for the attribute as follows:

- **action** - the action to be taken. Valid values are 'BPA' and 'NAVIGATE'
- **script** - the script to be performed when the action is 'BPA'
- **navopt** - the navigation option to be used when the action is 'NAVIGATE'

The attribute may also include other name/value pairs that define information to be passed into the script or used as navigation context fields.

In addition to the security attribute settings, the system will check that the user has access to the script or navigation path before performing the action.

The standard HTML 'onClick' attribute may still be used. If the HTML includes an 'onClick' attribute as well as the 'clickAction', the 'onClick' attribute will take precedence

The following is an example of a simple button with text.

```
<ou-button type="text" text="label:md[F1_BOOKMARK_LBL];"></ou-button>
```

The following is an example of an icon button using a display icon reference.

```
<ou-button type="image" imgRef="F1CMNT"></ou-button>
```

The following is an example of an image menu button.

```
<ou-button type="imageMenu" imgRef="F1STTGS" menu="CI_CONTEXTSCRIPT" text="tooltip:md[F1INSTY_VIS_LBL];"></ou-button>
```

The following is an example of text button that navigates to another page.

```
<ou-button type="text" text="label:md[ALG_CD];tooltip:md[GOTO_ALG]" clickAction="action:NAVIGATE; navopt:flalgqTa"></ou-button>
```

Show Schema Default on Add

Default values within in the UI map's schema will be displayed on a UI map's input fields if an embedded <action> node has a value of 'ADD' or blank.

Syntax

```
<action>ADD</action>
```

```
<action> </action>
```

The schema default for the <description> element will be displayed:

```
<schema>
  <action/>
  <boGroup type="group">
    <key/>
    <description default="enter description here"/>
  </boGroup>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Description </td>
    <td><input oraField="boGroup/description"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <action>ADD</action>
  <boGroup>
    <key/>
    <description/>
  </boGroup>
</root>
</xml>
</html>
```

HTML rendered.

Description	<input type="text" value="enter description here"/>
-------------	---

Configure a Chart

In addition to integrating charts with zones, the system supports using the same attributes within the UI Map HTML to configure a graphical representation of an XML list. The designer can control the type, size, position, and contents of the chart using these attributes. For details of the attributes and syntax, refer to [Data Explorer Graph Configuration](#).

Graph Examples

- Sample of a pie chart configuration:

```
<html>
<head>
<title>Pie Chart</title>
</head>
<body>

<div style="width:100%; height:290px;"
  oraChart="type:pie;"
  oraChartSeries1="list:set; labelPath:date; amount:amount; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

</body>

<xml>
<root>
  <set>
<date>05-02-2003</date>
<amount>163.24</amount>
<billId>592211649441</billId>
  </set>
  <set>
<date>06-02-2003</date>
<amount>97.29</amount>
<billId>592211649442</billId>
```

```

    </set>
    <set>
<date>07-02-2003</date>
<amount>54.38</amount>
<billId>592211649443</billId>
    </set>
</root>
</xml>
</html>

```

- A pie chart rendered for a single series:

- Sample of a line, cluster, or stacked graph configuration - each with two series:

```

<html>
<head>
<title>Stacked Chart</title>
</head>
<body>

<div style="width:100%; height:300px;"
  oraChart="type:line;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

<div style="width:100%; height:300px;"
  oraChart="type:cluster;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

<div style="width:100%; height:300px;"
  oraChart="type:stacked;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

</body>

<xml>
<root>
  <set>
<date>05-02-2003</date>
<amount>163.24</amount>
<balance>163.24</balance>
<billId>592211649441</billId>
  </set>
  <set>
<date>06-02-2003</date>

```

```
<amount>97.29</amount>
<balance>260.53</balance>
<billId>592211649442</billId>
  </set>
  <set>
<date>07-02-2003</date>
<amount>54.38</amount>
<balance>314.91</balance>
<billId>592211649443</billId>
  </set>
</root>
</xml>
</html>
```

- Three types of chart rendered for two series each: line, cluster, and stacked.

Upload and Download a CSV File

The following HTML attributes can be used to manage both an upload and a download between a list defined within the map's schema and a CSV (comma separated value) file. Note that this technique is only recommended for a small to medium volume of data, for example no more than several hundred rows. For higher volumes, it is recommended to use batch upload / download functionality instead.

The syntax is `oraUploadData="type:embed;path:list xpath;useLabels:true;showCount:true"`

Upload configuration requires you to name a CSV file to be uploaded, and an XML list as target. By convention, each CSV row will create a separate list instance. Each comma-separated field in the file will be uploaded as a separate element in the list. To embed an upload dialog within a map, the **oraUploadData** attribute must be associated with a container element such as a div, td, or span.

The optional **useLabels:true** value indicates that while parsing the upload CSV file, the headers are expected to be labels

NOTE: If you do not specify the **useLabels:true** value and the XML target element name is "camelCase" then the corresponding spreadsheet header should be title case with a space between words, e.g.;"Camel Case". Letters and special characters are not considered a different word, for example Address1 must be uploaded into the target XML element address1.

Specifying the optional **showCount:true** value will display the number of records uploaded.

CAUTION: If you are using a grid in conjunction with the **oraUploadData** function, then you must maintain the grid's list with a 'replace' business object action. Refer to [BO Replace Action](#) for more information.

Sample of **oraUploadData="embed"** within a div element.

```
<html>
<head>
  <title>File Upload</title>
</head>
<body>

  <div oraUploadData="type:embed;path:myList" > </div>

</body>

<xml>
<root>
  <myList>
<id>838383930</id>
  <name>Janice Smith</name>
  </myList>
  <myList>
<id>737773730</id>
  <name>Bill McCollum</name>
  </myList>
</root>
</xml>
</html>
```

This file upload dialog will be embedded into the body of the page where the oraUploadData is defined.

oraUploadData="type:popup;path:list xpath;useLabels:true;showOk:true;showCount:true"

Upload configuration requires you to name a CSV file to be uploaded, and an XML list as target. By convention, each CSV row will create a separate list instance. Each comma-separated field in the file will be uploaded as a separate element in the list. To upload a CSV file using a pop-up dialog, the oraUploadData attribute must be associated with an input element such as a button, text link, or image.

The optional useLabels:true value is used to indicate that while parsing the upload CSV file, the headers are expected to be labels

NOTE: If you do not specify the useLabels:true value and the XML target element name is "camelCase" then the corresponding spreadsheet header should be title case with a space between words, e.g., "Camel Case". Letters and special characters are not considered a different word, for example Address1 must be uploaded into the target XML element address1.

Specifying the optional showOk:true value will display an "Ok" button once the upload finishes. The popup will stay open until the button is pressed. Additionally, specifying the showCount:true value will display number of records uploaded.

CAUTION: If you are using a grid in conjunction with the **oraUploadData** function, then you must maintain the grid's list with a 'replace' business object action. Refer to [BO Replace Action](#) for more information.

Sample of oraUploadData="popup" associated with a button:

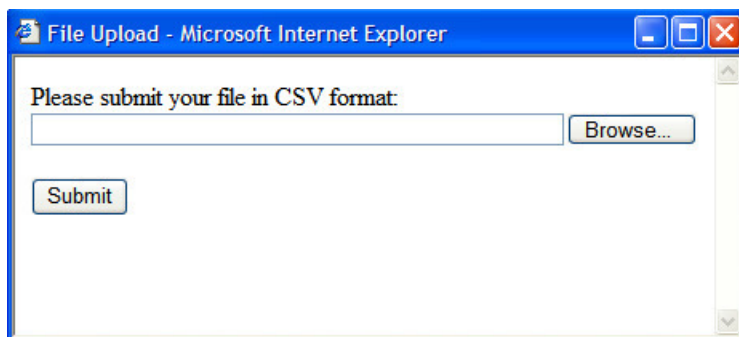

```
<html>
<head>
  <title>File Upload</title>
</head>
<body>
  <input type="button" name="submitButton" oraUploadData="type:popup;path:myList;" value='Get Data'>
  <table oraList="myList">
    <tr/>
    <tr>
      <td><span oraField="id" /></td>
      <td><span oraField="name" /></td>
    </tr>
  </table>
</body>
<xml>
<root>
  <myList>
    <id>838383930</id>
    <name>Janice Smith</name>
  </myList>
  <myList>
    <id>737773730</id>
    <name>Bill McCollum</name>
  </myList>
</root>
</xml>
</html>
```

HTML Rendered:

838383930 Janice Smith

737773730 Bill McCollum

Pressing the "Get Data" button will launch a standard file upload dialogue (provided by Framework) as shown below.

oraDownloadData="list xpath"

Download configuration requires you to name an XML list to be downloaded. By convention, each list instance will represent a separate row in the created file. By default every element of the list will be comma separated in the file.

NOTE: The number formatting is based on the user profile setting. For localities where the decimal symbol is a comma, an implementation may configure a property setting (`spl.csv.delimiter.useFromDisplayProfile=true`) to cause the system to use a semicolon as the delimiter that separates the elements rather than a comma.

Sample of oraDownloadData.

```
<html>
<head>
<title>File Download</title></head>
<body>
<input type="button" name="downloadButton" oraDownloadData="myList" value="Download" />
</body>
<xml>
<root>
  <myList>
    <id>881-990987</id>
    <name>John Mayweather</name>
  </myList>
  <myList>
    <id>229-765467</id>
    <name>Anna Mayweather</name>
  </myList>
  <myList>
    <id>943-890432</id>
    <name>Andrew Brewster</name>
  </myList>
</root>
</xml>
</html>
```

HTML Rendered:

Download

Pressing the "Download" button will launch a standard file download dialogue (provided by Framework) as shown below.

A successful download will result in a CSV file:

	A	B	C
1			
2	Id	Name	
3	881-99098	John Mayweather	
4	229-76546	Anna Mayweather	
5	943-89043	Andrew Brewster	
6			

To download data from a sub list use the attribute `oraDownloadDataInList` instead of `oraDownloadData`. The attribute `oraDownloadDataInList` will have the sub list name. The XPath of the sub list is used to pick data of the specific row from the parent list. Thus only the specific sub list is downloaded.

`oraDownloadDataUseLabels="true"`

The `oraDownloadDataUseLabels` attribute can be used in conjunction with the `oraDownloadData` attribute described above. Specify `oraDownloadDataUseLabels` if you want the generated CSV file to use the element labels for columns headers rather than element names.

Construct Portal Zone Map Fragments

Portal zones can reference a UI map for the zone header and filter area. This UI map is not a complete HTML document, but is instead configured as a UI Map fragment. When constructing a zone map fragment you can reference the following substitution variables. Note that these variables will be dynamically populated at run time with information particular to the map's zone within the portal:

Variable	Replacement Logic
[\$ZONEDESCRIPTION]	Zone's description text.
[\$SEQUENCEID]	Zone's sequence ID.
[\$ZONENAME]	Zone's name.
[\$HELPTEXT]	Zone's help text.
[\$ZONEPARAMNAME]	Zone parameter's value (or blank if it has not been specified).

WARNING:

- Refer to one of the following maps as examples: F1-UIMapHeader and F1-ExplorerHeader.
- These maps make use of the [oraInclude](#) tag to incorporate HTML fragments for the header menu and framework actions. Refer to the zone type parameters for the UI Map fragments you should include in your HTML.
- If you wish to have the "help text" icon appear next to your zone description, you should have `id="title_[$SEQUENCEID]"` on the `<td>` that contains your description.
- If it is necessary to encapsulate JavaScript within a UI Map fragment, it will be necessary to bound the JavaScript within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
  /* */
  //
  //javascript
  //
  /*]]&gt; */
&lt;/script&gt;</pre>
</div>
<div data-bbox="467 942 913 959" data-label="Page-Footer">
<p>Oracle Utilities Customer to Meter Administrative User Guide • 243</p>
</div>
```

NOTE: If you wish to preserve the values of a filter input field, within a filter map fragment, for the framework 'Go Back' and 'Go Forward' functionality, you must associate the input field (text box, select, etc.) with a unique HTML id. Input field values associated with a unique id will be captured in the framework's 'memento'. The 'memento' is used to rebuild the input map when the portal zone is navigated to using the 'Go Back' or 'Go Forward' functionality.

NOTE: Many specialized functions exist to manipulate zone behavior, for example:

- **oraGetZoneSequence(zoneName).** Uses the zone's code to retrieve its sequence number.
- **oraIsZoneCollapsed(sequenceId).** Uses the zone's sequence to determine if collapsed.
- **oraHandleCollapse(seq).** Collapse a zone.
- **oraHandleExpand(seq,refresh).** Expand and/or refresh a zone.

All of these, and many more functions, are located within the JavaScript library [userMapSupport.js](#) described below.

NOTE: When executing oraLoad within a fragment UI map, and you need to execute a JavaScript function during page load (where the function invokes a business object, business service, or service script) you can use the special syntax "oraLoad[\$SEQUENCEID]". Refer to the [Load Page Event](#) section for more information.

Example of oraLoad[\$SEQUENCEID] used within a function:

```
<script type="text/javascript">
function oraLoad[$SEQUENCEID]() {
checkRebateClaimStatus();
}

function checkRebateClaimStatus() {
    var work = id('analyticsFilterText[$SEQUENCEID]',
document).cells[0].innerText.split(' ');
    var rebateClaimId = work[work.length - 3];
    id('rebateClaimId', document).value = rebateClaimId;
oraInvokeSS('C1-CheckRCSt','checkRebateClaimStatus', false);
    var statusIndicator = id('statusInd', document).value;
    if (statusIndicator == 'C1PE' || statusIndicator == 'C1ID') {
        id('addRebateClaimLine', document).style.display = '';
    } else {
id('addRebateClaimLine', document).style.display = 'none';
    }
}
</script>
```

F1-ExplorerHeader rendered:

 [\$ZONEDESCRIPTION]

Invoking a Business Object

The oraInvokeBO function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke BO Function](#) which allows for a business object to be invoked within the UI map's HTML. Refer to that section for a description of the first three parameters.

Syntax	Parameters	Comments
oraInvokeBO()	'BO Name'	
	'XPath' or null	
	'action'	
	null	This must be specified as the fourth argument.

Syntax	Parameters	Comments
	[\$SEQUENCEID]	This must be specified as the fifth argument.
	true false	Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map.

Example in a portal zone header:

```
oraInvokeBO('CM-User','xmlGroup','read', null, [$SEQUENCEID], true)
```

Invoking a Business Service

The oraInvokeBS function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke BS Function](#) which allows for a business service to be invoked within the UI map's HTML. Refer to that section for a description of the first two parameters.

Syntax	Parameters	Comments
oraInvokeBS()	'BO Name'	
	'XPath' or null	
	null	This must be specified as the fourth argument.
	[\$SEQUENCEID]	This must be specified as the fifth argument.
	true false	Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map.

Example in a portal zone header:

```
oraInvokeBS('CM-UserSearch','xmlGroup', null, [$SEQUENCEID], true)
```

Invoking a Service Script

The oraInvokeSS function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke SS Function](#) which allows for a service script to be invoked within the UI map's HTML. Refer to that section for a description of the first two parameters.

Syntax	Parameters	Comments
oraInvokeSS()	'Service Script Name'	
	'XPath' or null	
	null	This must be specified as the fourth argument.
	[\$SEQUENCEID]	This must be specified as the fifth argument.
	true false	Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map.

Example in a portal zone header:

```
oraInvokeSS('UserSearch','xmlGroup', null, [$SEQUENCEID], true)
```

Detecting Unsaved Changes

Use this function to return a Boolean set to true if there are unsaved changes. The system will interrogate the function when the user attempts to navigate and issue a warning accordingly. This function is only needed if a UI map is using custom javascript to manage elements such that the system is not able to detect whether changes have been made. Also note that it's the responsibility of the UI map javascript to manage the values in the Boolean used for this function.

```
function hasUnsavedChanges(){
    return isDirtyFlag;
}
```

Hiding Portal Tabs

The product provides the ability to use JavaScript to hide a tab on the current portal based on some condition using the oraAuthorizeTab JavaScript API. This API accepts a function as a parameter and turns off the tab index indicated.

For example, the UI Map may have a function to turn off one or more tab indexes.:

```
function overrideTabIndex(index){
    if (index == 2) return false;
    if (index == 3) return false;
}
```

The JavaScript is referenced "on load":

```
<body class="oraZoneMap"
onLoad="oraAuthorizeTabs(overrideTabIndex);">
```

Required JavaScript Libraries

All of the functionality described in this document depends on a pair of JavaScript libraries. If you are writing and executing your maps entirely within the UI map rendering framework - you do not need to manually insert the following libraries - the framework will insert them for you when the UI Map is rendered.

WARNING: When executing HTML outside of the framework you must include the following references explicitly within your HTML. In addition, the tool you use to render the HTML must have access to a physical copy of privateUserMapSupport.js for bind support.

```
src="privateUserMapSupport.js"
```

Your HTML document must reference this library to execute binding in a stand-alone environment.

WARNING: Referencing functions within this JavaScript library is dangerous - because these functions are owned by framework and they may be changed during version upgrade or via the normal patch process.

```
<script type="text/javascript" src="privateUserMapSupport.js"></script>
```

```
src="userMapSupport.js"
```

To take advantage of optional toolset features, you must reference this library.

NOTE: You can reference the functions within this JavaScript library to write custom functions within the UI map..

```
<script type="text/javascript" src="userMapSupport.js"></script>
```

```
onload="oraInitializeUserMap();"
```

To execute binding in a stand-alone environment, you must embed the following onload function into the <body> node.

```
<body onload="oraInitializeUserMap();">
```

UI Map Standards

- [Using OJET](#)

Basic UI Map Templates

All UI Maps share the same basic structure regardless of placement (page area, zone, pop-up) or usage (display only, input).

Sample XML

All information in this document is based upon the following XML structure.

```
<xml>
  <root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
      <type>Home Phone</type>
      <number>510-555-2287</number>
    </contactInformation>
    <contactInformation>
      <type>Cell Phone</type>
      <number>510-555-4285</number>
    </contactInformation>
  </root>
</xml>
```

Display Only UI Map

```
<html>
<head>
  <title oraMdLabel="ADDRESS_LBL"></title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body class="oraZoneMap">
<table cellpadding="4" width="100%">
  <colgroup>
    <col class="oraLabel oraTableLabel" />
    <col class="oraNormal oraTableData" />
  </colgroup>
  <tr>
    <td oraLabel="address"></td>
    <td oraField="address"></td>
  </tr>
  <tr>
    <td oraLabel="city"></td>
    <td oraField="city"></td>
  </tr>
  <tr>
    <td oraLabel="state"></td>
    <td oraField="state"></td>
  </tr>
  <tr>
    <td class="oraSectionEnd" oraLabel="zip"></td>
    <td class="oraSectionEnd" oraField="zip"></td>
  </tr>
</table>
```

```

        <td colspan="2" class="oraSectionHeader" oraMdLabel="CONTACT_LBL"></td>
</tr>
<tr>
    <td colspan="2" class="oraSectionStart oraEmbeddedTable">
        <table oraList="contactInformation" cellspacing="2">
            <thead >
                <tr>
                    <th class="oraGridColumnHeader" nowrap="nowrap">
                        <span oraLabel="contactInformation/type"></span>
                    </th>
                    <th class="oraGridColumnHeader" nowrap="nowrap">
                        <span oraLabel="contactInformation/number"></span>
                    </th>
                </tr>
            </thead >
            <tbody>
                <tr>
                    <td class="oraNormalAlt oraDisplayCell">
                        <span oraField="type"></span>
                    </td>
                    <td class="oraNormal oraDisplayCell">
                        <span oraField="number"></span>
                    </td>
                </tr>
            </tbody>
        </table>
    </td>
</tr>
</table>
</body>
<xml>
    <root>
        <address>123 Main St</address>
        <city>Alameda</city>
        <state>CA</state>
        <zip>94770</zip>
        <contactInformation>
            <type>Home Phone</type>
            <number>510-555-2287</number>
        </contactInformation>
        <contactInformation>
            <type>Cell Phone</type>
            <number>510-555-4285</number>
        </contactInformation>
    </root>
</xml>
</html>

```

Input UI Map

```

<html>
<head>
    <title oraMdLabel="ADDRESS_LBL"></title>
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
    <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
    <tr class="oraErrorText">
        <td><a href="" onclick="oraShowErrorAlert(); return false;">
            <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span></a>
        </td>
    </tr>
</table>
<table cellspacing="4" width="100%">
    <colgroup>
        <col class="oraLabel oraTableLabel" />
        <col class="oraNormal oraTableData" />

    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
      <type>Home Phone</type>
    </contactInformation>
  </root>

```

```
        <number>510-555-2287</number>
    </contactInformation>
</contactInformation>
    <type>Cell Phone</type>
    <number>510-555-4285</number>
</contactInformation>
</root>
</xml>
</html>
```

Basic HTML and Styles

The basic templates introduced the standard HTML and styles used for UI Maps. These standards are described individually in the following sections.

Stylesheets

The styles to apply the standard look to the maps are all contained in stylesheets. These stylesheets should be included in all UI Maps.

```
...
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
    <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
...
```

Title

Each UI Map should have a <title> tag.

```
...
    <title oraMdLabel="ADDRESS_LBL"></title>
...
```

This will give the UI Map a descriptive title.

- If the UI Map is presented in a "pop-up", the title will be in the window title bar.
- If the UI Map is presented in the page area, the title will be added as a tag to the UI Map and will appear at the top of the UI Map.
- If the UI Map is presented as a zone map, it will be ignored. The <title> tag should still be included in the HTML as standard.

Zone Maps

When the map is presented in a zone as part of a portal, the UI Map should have a border so that the information is "contained" within the zone.

```
...
    <body class="oraZoneMap">
...
```

Page Area Maps vs Pop-Up Maps

The presentation of the UI Maps can vary from design to design. The following standards have been applied to decide when to use a Page Area UI Map and when to use a Pop-Up Map:

- If there are multiple UI Maps in the sequence, always use the Page Area.
- If the UI Map has many input fields, always use a Page Area.
- If the UI Map is a "confirmation" type dialog or only has one or two input fields, use a Pop-Up.

NOTE: The difference between "just a few input fields" and "many input fields" can be discretionary. The final decision should rest with the dialog designer.

Error Messages

Input maps have a ability to present error messages to the User.

```
...
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td><a href="" onclick="oraShowErrorAlert(); return false;">
      <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span></a></td>
  </tr>
</table>
...
```

This HTML structure provides the necessary elements and functions to display errors to the User. It should be directly after the <body> tag. When there is no error, nothing will be visible on the UI Map. It will be made visible if an error occurs and the UI Map is re-presented to the User. Clicking on the link (when visible) will result in a pop-up alert appearing with the long error message text.

Standard Layout and Styles

The information is presented on the UI Map by using a <table> to organize the information in rows and columns.

```
...
<table cellspacing="4" width="100%">
<colgroup>
<col class="oraLabel oraTableLabel" />
  <col class="oraNormal oraTableData" />
</colgroup>
...
```

The <colgroup> and <col> tags allow for the application of classes to the columns (the label is in the first column and the data is in the second column.). Using these tags mean that the class attribute (to apply styles) does not need to be defined on every <td>.

Grids (Tables of Data)

A UI Map could contain information that is best presented as a grid. These are referred to as "Embedded Tables". The embedded table can be used to display information or input information.

Example Embedded Table HTML

The embedded table will be included within a row (<tr>) of the basic layout:

```
...
<tr>
  <td colspan="2" class="oraEmbeddedTable">
    <table oraList="contactInformation" cellspacing="2">
      <thead >
        <tr>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/type"></span>
          </th>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/number"></span>
          </th>
        </tr>
      </thead >
      <tbody>
        <tr>
          <td class="oraNormalAlt oraDisplayCell">
            <span oraField="type"></span>
          </td>
          <td class="oraNormal oraDisplayCell">
            <span oraField="number"></span>
          </td>
        </tr>
      </tbody>
    </table>
  </td>
</tr>
```

```

    </td>
</tr>
...
<xml>
  <root>
    <address> 123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
      <type>Home Phone</type>
      <number>510-555-2287</number>
    </contactInformation>
    <contactInformation>
      <type>Cell Phone</type>
      <number>510-555-4285</number>
    </contactInformation>
  </root>
</xml>

```

Embedding the Table

The embedded table is included within the overall table structure. The `colspan` attribute ensures that the embedded table can span the standard two columns of the overall layout table.

```

...
<tr>
  <td colspan="2" class="oraEmbeddedTable">
    ...
    ...
    ...
  </td>
</tr>
...

```

Embedded Table Structure

The embedded table is very similar to the basic layout table.

```

...
<table oraList="contactInformation" cellpadding="2">
<thead>
  ...
  ...
</thead>
<tbody>
  ...
  ...
</tbody>
</table>
...

```

- The `<table>` tag has a slightly smaller cellpadding and it defines the "list" element contained in the XML that will be used to provide the data.
- The `<thead>` element is used to give the embedded table headings for the columns.
- The `<tbody>` element is the element that will be repeated for each referenced "list" element in the XML. In the previous example, there are two "contactInformation" list elements, so the displayed embedded table will have two rows.

Column Headings

Embedded tables should have headings for the displayed columns. The `<thead>` tag defines these.

```

...
<thead>
  <tr>
    <th class="oraGridColumnHeader" nowrap="nowrap">
      <span oraLabel="contactInformation/type"></span>
    </th>

```

```

        <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/number"></span>
        </th>
    </tr>
</thead>
...

```

The "nowrap" attribute prevent the column heading from taking multiples lines. If multiples lines are required, the "nowrap" may be removed.

Input Fields

Embedded tables may be used for input as well as display only. The framework provides a convenient control to assist in the creation of editable embedded tables.

```

...
<tr>
    <td colspan="2" class="oraEmbeddedTable">
        <table oraList="contactInformation" cellspacing="2">
            <thead >
                <tr>
                    <th class="oraGridColumnHeaderButton"></th>
                    <th class="oraGridColumnHeaderButton"></th>
                    <th class="oraGridColumnHeader" nowrap="nowrap">
                        <span oraLabel="contactInformation/type"></span>
                    </th>
                    <th class="oraGridColumnHeader" nowrap="nowrap">
                        <span oraLabel="contactInformation/number"></span>
                    </th>
                </tr>
            </thead >
            <tbody>
                <tr>
                    <td oraType="addGridRow"></td>
                    <td oraType="deleteGridRow"></td>
                    <td>
                        <input type="text" oraField="type" />
                    </td>
                    <td>
                        <input type="text" oraField="number" />
                    </td>
                </tr>
            </tbody>
        </table>
    </td>
</tr>
...

```

There are two new columns added to the input embedded table.

- oraType="addGridRow" will add a "+" button to the row. This will allow the User to add an additional row to the existing grid.
- oraType="deleteGridRow" will add a "-" button to the row. This will allow the User to delete an existing row from the grid.

NOTE: The <thead> tag also requires these two new columns to be added.

These controls are, as standard, placed at the beginning of the row in the order shown. Either of the controls may be omitted if required (if, for example, Users are not permitted to delete information).

The presence of either of these controls will activate the "empty list" process. This means that if the XML has no data for the "list" specified, the input grid will display with an empty row ready for the input of new information.

Action Buttons

Example Action Button HTML

Action buttons are used to perform some specified function from the UI Map. The actions are as varied as the information being displayed/updated. Below are two common examples:

- Save. Normally used on an Input UI Map to allow a User to save any changes they have made.
- Cancel. Normally used on an Input UI Map to allow a User to cancel changes in progress.

```
...
<tr>
  <td colspan="2" class=" oraEmbeddedTable">
    <table cellspacing="2">
      <tr>
        <td>
          <input class="oraButton" oraMdLabel="C1_SAVE_LBL" type="button"
            onClick="oraSubmitMap( 'OK' );"/>
        </td>
        <td>
          <input class="oraButton" oraMdLabel="CANCEL_LBL" type="button"
            onClick="oraSubmitMap( 'CANCEL' ,false);"/>
        </td>
      </tr>
    </table>
  </td>
</tr>
...
```

Button Standards

The following points highlight some standards related to buttons.

- Buttons are included as an embedded table.
- Buttons should be grouped together. They should not be placed in different areas of the UI Map.
- The location of the buttons depends mainly on the type of UI Map.
 - Display Only UI Maps should have a Record Actions section in the upper right section of the UI map.
 - Input UI Maps should have the buttons at the foot of the UI Map (after all input fields).

Available Styles

Styles are all contained in the referenced CSS stylesheets. They are applied by the HTML "class" attribute. The actual style settings used are not documented here as they may be adjusted. This section only specifies when a particular style should be used.

NOTE: The "class" attribute may reference more than one style (class="oraLabel oraSectionEnd")

Style	Comments	Example
oraButton	Applied to <input> elements where the type is button.	... <input class="oraButton" oraMdLabel="CANCEL_LBL" type="button" onClick="oraSubmitMap('CANCEL' ,false);"/> ...
oraDisplayCell	Applied to the <td> tag of an embedded table. It defines how the table cell looks (not the data contained inside the cell).	... <td class="oraDisplayCell"> </td>

Style	Comments	Example
oraEmbeddedTable	Applied to the <td> tag that will contain the embedded table.	<pre> ... <tr> <td colspan="2" class=" oraEmbeddedTable"> <table cellpadding="2"> </table> </td> </tr> ... </pre>
oraError	<p>This style is applied to elements that are identified as "error elements". Refer to Display Errors for more information.</p> <p>NOTE: This style is not normally applied directly in the UI Map HTML</p>	
oraErrorText	This style is applied to the elements concerned with error messages.	<pre> ... <table width="100%" cellpadding="12"> <tr class="oraErrorText"> <td> </td> </tr> </table> ... </pre>
oraGridColumnHeader	This style is applied to the <td> tags that define column headers within embedded table.	<pre> ... <thead > <tr> <th class="oraGridColumnHeaderButton"></th> <th class="oraGridColumnHeaderButton"></th> <th class="oraGridColumnHeader" nowrap="nowrap"> </th> <th class="oraGridColumnHeader" nowrap="nowrap"> </th> </tr> </thead > ... </pre>
oraGridColumnHeaderButton	This style is applied to the <td> tags that define the column headers for the "+" and "-" buttons used on editable embedded tables.	<pre> ... <thead > <tr> <th class="oraGridColumnHeaderButton"> </th> <th class="oraGridColumnHeaderButton"> </th> <th class="oraGridColumnHeader" nowrap="nowrap"> </th> <th class="oraGridColumnHeader" nowrap="nowrap"> </th> </tr> </thead > ... </pre>
oraInput	<p>This style is applied to input fields:</p> <ul style="list-style-type: none"> <input type="text"> 	<pre> ... <input type="text" class="oraInput" oraField="address" /> ... </pre>

Style	Comments	Example
	<ul style="list-style-type: none"> • <input type="checkbox"> • <select> • <textarea> <p>NOTE: This can normally be omitted as input styles are applied automatically when oraSchemaDataTypes="true".</p>	
oraInputMoney	<p>This style is applied to input fields:</p> <ul style="list-style-type: none"> • <input type="text"> • <select> (rare) • <textarea> (not recommended) <p>NOTE: This can normally be omitted as input styles are applied automatically when oraSchemaDataTypes="true".</p>	<pre>... <input type="text" class="oraInputMoney" oraField="amount" /> ...</pre>
oraInputNumber	<p>This style is applied to input fields:</p> <ul style="list-style-type: none"> • <input type="text"> • <select> (rare) • <textarea> (not recommended) <p>NOTE: This can normally be omitted as input styles are applied automatically when oraSchemaDataTypes="true".</p>	<pre>... <input type="text" class="oraInputNumber" oraField="count" /> ...</pre>
oraLabel	<p>This style is applied to standard label fields that are right aligned.</p> <p>NOTE: This can normally be omitted as it is applied by the <col> tag.</p>	<pre>... <td class="oraLabel" oraLabel="address"></td> ...</pre>
oraLabelAlt	<p>This style is applied to standard label fields only if it is desired to have the label aligned to the left.</p>	<pre>... <td class="oraLabelAlt" oraLabel="address"></td> ...</pre>
oraLabelCenter	<p>This style is applied to standard label fields only if it is desired to have the label aligned in the center of the cell.</p>	<pre>... <td class="oraLabelCenter" oraLabel="address"></td> ...</pre>
oraLink	<p>This style is applied to foreign key references (links). This is automatically added by the UI Map framework but can also be used manually if desired.</p>	<pre>... <td class="oraLabel"> Google</td> ...</pre>
oraNormal	<p>This style is applied to standard data fields (display only) that are left aligned.</p>	<pre>... <td class="oraNormal" oraField="address"></td> ...</pre>

Style	Comments	Example
	<p>NOTE: This can normally be omitted as it is applied by the <col> tag.</p>	
oraNormalAlt	This style is applied to standard data fields (display only) only if it is desired to have the data aligned to the right.	<pre>... <td class=" oraNormalAlt" oraField="address"></td> ...</pre>
oraNormalCenter	This style is applied to standard data fields (display only) only if it is desired to have the data aligned in the center of the cell.	<pre>... <td class=" oraNormalCenter" oraField="address"></td> ...</pre>
oraPageTitle	<p>This style is applied to the element that contains the page title.</p> <p>NOTE: This style is not normally applied directly in the UI Map HTML. The is created by the UI Map framework when the UI Map is displayed in the page area.</p>	<pre>... ...</pre>
oraSectionEnd	<p>This style is applied to the <td> tags at the end of a "section" (group of elements). It provides some space to separate the section from the following information.</p> <p>NOTE: The style must be applied to both <td> tags or the label may be misaligned with the data/input.</p>	<pre>... <tr> <td class="oraSectionEnd" oraLabel="zip"> </td> <td class="oraSectionEnd" oraField="zip"> </td> </tr> ...</pre>
oraSectionHeader	<p>This style is applied to the <td> tag used to give a heading for a section within the information being displayed. It does not provide spacing before or after itself. The oraSectionStart and oraSectionEnd classes are used for this.</p> <p>NOTE: The section header should span both the label column and the data column.</p>	<pre>... <tr> <td class="oraSectionHeader" colspan="2" oraMdField="DATA_SECTION_LBL"></td> </tr> ...</pre>
oraSectionStart	<p>This style is applied to the <td> tags at the start of a "section" (group of elements). It provides some space to separate the section from the previous information (often a section header).</p> <p>NOTE: The style must be applied to both <td> tags or the label may be misaligned with the data/input.</p>	<pre>... <tr> <td class="oraSectionStart" oraLabel="zip"></td> <td class="oraSectionStart" oraField="zip"></td> </tr> ...</pre>
oraTableData	This style is applied to the <col> tag for the data column of the main table (second column). It is used to provide a percentage width for the horizontal space to be used for the information.	<pre>... <colgroup> <col class="oraLabel" oraTableLabel"/> <col class="oraNormal" oraTableData"/> </colgroup> ...</pre>
oraTableLabel	This style is applied to the <col> tag for the label column of the main table (first column). It is used	<pre>... <colgroup> <col class="oraLabel" oraTableLabel" /> ...</pre>

Style	Comments	Example
	to provide a percentage width for the horizontal space to be used for the labels.	<pre><col class="oraNormal oraTableData" /> </colgroup> ...</pre>
oraTinyText	This style is typically applied directly beneath an <input> tag to provide information or a hint to the user concerning information relevant to the input. For example, name or address format.	<pre>... <tr> <td oraLabel="address"></td> <td> <input type="text" oraField="address" /> <div class="oraTinyText" oraField="addressFormatHint"></div> </td> </tr> ...</pre>
oraZoneMap	This style is used applied when the UI Map is to be displayed as a zone on a portal.	<pre>... <body class="oraZoneMap"> ...</pre>

Using OJET

There are some UI maps delivered by the product that use UI widgets provided by Oracle JavaScript Extension Toolkit (OJET). Releases for OJET do not always align with releases of the framework. In addition, there are times when OJET adjusts APIs that the product uses. The framework will attempt to ensure that each release of the product has the latest and greatest version of the OJET libraries. Implementations are discouraged from attempting to use features in OJET that are not used by the product because the product is not necessarily testing those features and is not ensuring that upgrades to the APIs for those features are backward compatible.

Note that the product isolates the references to OJET into a UI map fragment that is included in the maps that use OJET widgets. This is so that changes to future versions of OJET are minimized to a single place. The map is called F1-OJETLIBS. If your implementation wants to use OJET, the recommendation is to use this UI map fragment.

Ensuring Unique Element IDs for UI Maps

The following describes how to modify JavaScript code to ensure the proper rendering of unique element IDs for UI Maps.

The modification is required only for code that renders HTML using a `getElementById()` (or similar) function to generate list IDs and avoid account verification or related errors.

The following sample snippet contains the necessary modifications:

```
...
function getElementsFromList(namePrefix) {
  var ret = [];
  var elements = document.getElementsByTagName("INPUT");
  for(var i=0;i<elements.length;i++) {
    var elemID = elements[i].id;
    if((id) && (id.startsWith(namePrefix + '_'))) {
      ret.push(elements[i]);
    }
  }
  ...
  return ret;
}
```

Since IDs aren't necessarily unique in generated UI Map IDs, the code shown above ensures uniqueness at runtime by appending an underscore and row number (e.g., `myField_1`, `myField_2`) for proper handling by Framework in the rendered HTML, while still allowing you to reference the unmodified IDs contained in the generated UI Map.

A switch in the `spl.properties` file also permits you to disable the generation of unique IDs for elements in a grid (as described below), though, for standards compliance reasons, it is highly recommended that this switch be left at its default value.

```
Property Name: spl.runtime.compatibility.uiMapDisableGenerateUniqueHtmlIDs
File Name: spl.properties (under web project in FW)
Default Value: false
Accepted Values: true or false
Description: This property controls the generation of unique IDs for all input elements inside
a list. When this value is set to true it disables the generation of unique IDs, thus
replicating the old behavior. When this property is set to false or this property is missing
it enables the generation of unique IDs, thus enabling the list to be standards-compliant.
```

Process Flows

This section describes concepts and provides guidelines related to the configuration of various type of process flows.

Understanding Process Flows

A process flow is a user interface guiding a user through a series of actions in order to accomplish a specific task. The task can be as simple as the collection of information in order to update business data or involve more complex logic such as submitting and tracking batch processes, exchanging messages with an external system, etc.

This section describes topics related to designing and working with process flows.

A Process Flow Is Made Of Panels

Each process flow consist of a number of sequential "steps" needed to accomplish a certain task. Each step is represented by a stop on a progress bar and an associated panel.

Progress is linear in that each step may only lead to a single next step. A process flow always starts at a single initial step but allows for one or more final steps at which the user may choose to complete the process.

At any step the user may take the following actions:

- Enter data or take action as prompted by the step's panel.
- Continue to a next step, if any.
- Navigate back to any step they have previously visited.
- Finish the process flow if the current step is a final step.
- Save off their work on the process flow and either continue their work or navigate away. At a later time the user may resume their work on the process flow from where they have left off.
- Cancel the process flow.

A process flow type defines the entire metadata needed to control the behavior of process flows of a given type. This includes the sequence of steps, the panel and rules associated with each step and more.

Panel Presentation

The panel presented on each step of the process flow is rendered based on the panel type selected on the step configuration.

For a **Data Area** type of panel, the panel is rendered using UI Hints built into the schema of a specified data area.

For a **UI Map** type of panel, the panel is rendered using a specified UI map fragment.

For a **Panel Set** type of panel, the panel is rendered as a set of tabs, one for each panel that references the current panel as its parent panel. Clicking on each tab renders the UI based on the selected panel's type. The behavior of a panel set is analogous to or can be thought of as a nested process flow within a single panel. A panel set may not include another panel set.

A Single UI Map

While the user enters data one panel at a time, data is collected and captured at the entire process flow level. All the elements edited and displayed on the various panels of the process flow must be included in the overall process schema and referenced by their appropriate XPath location in that schema. Each type of process flow defines its unique schema on a designated UI map.

The UI map's HTML should simply include the **Process Flow Controller (F1-ProcessController)** UI map fragment and nothing else. The latter is designed to render the user interface for a process flow based on the metadata defined on its process flow type.

Panel Scripts

A single **Pre-Processing** service script may be associated with a panel for the purpose of preparing the data before the panel is presented to the user. The system calls the script each time the user navigates to this panel on a non-finalized process flow.

A single **Post-Processing** service script may be associated with a panel for the purpose of validating the data entered by the user on that panel. The system calls the script each time the user exits the panel on a non-finalized process flow.

Process Flow Scripts

A single **Process Start** service script may be associated with a process flow for the purpose of preparing the data before a newly initiated process flow is presented to the user.

A single **Process End** service script is executed when the user clicks on the **Finish** or **Cancel Process** buttons to complete the process flow. The entire set of data collected by the process flow UI map schema is provided to this service script for final processing.

NOTE: The schema of these scripts should be the same as the **Process Flow UI map** schema. This would ensure that business rules have access to the entire data captured by the user.

Summary Panel

By default, when a user finishes a process flow, as well as when they view an already closed process, the process flow portal displays the last panel the user was working on. For more complex process flows, you may provide a panel that summarizes information from the entire process. When specified on the process flow type, the system displays that summary panel instead of the default view of a closed process. The user may toggle between the summary view and the detailed view at any time.

The summary panel may be implemented as a UI map fragment or a data area like other panels but may not be associated with any panel script.

Launching A New Process Flow

Each process flow must be initiated and executed by a designated BPA script that has the following simple steps:

- Set BPA area height to zero.
- Populate the temporary variable **\$processCode** with the code of the specific process flow type.
- Transfer control to the **Process Flow Navigation (F1-PROCEXEC)** common BPA script.

Launching a process flow of a specific type is assumed to be made from a designated menu option or within a specific context applicable to that type of work. As such, this item needs to be configured specifically for each type of process flow. The navigation option associated with that launching option should reference the BPA script associated with the corresponding type of process flow.

Saving Off Work

The user may save off their work on a process flow at any time. If enabled on the process flow type, the system would also automatically save the data when the user navigates to another panel or away from the process flow portal.

On either manual or automatic save operations, the **Process Manager** script defined on the process flow type is called to save off the entire process flow data on a designated record in the database.

The base product provides a generic **Process Flow** maintenance object that is designed to support the storage of any type of process flow as well a corresponding process manager script. Should process flows of a specific type be stored elsewhere, then a dedicated process manager script should be implemented and used instead.

Review Process Flow Records

A process flow record is created when a user saved off their work or the process flow type enables automatic saving. When the user finishes a process flow, depending on the process flow type configuration the record may be deleted or retained for audit purposes.

Reviewing process flow records of a specific type is assumed to be made from a designated menu option or within a specific context applicable to that type of work. As such this item needs to be configured specifically for each type of process flow. The navigation option associated with that item should reference a query portal designed to query and manage the specific type of process flow records.

In addition to standard query features, the query portal should allow the user to resume their work on a non-finalized process flow as well as review the data captured on a completed record. When implementing such a query portal, refer to the sample **Process Flow Query (F1PRSTRQ)** portal for key features. Your specific product may already include such query portals for process flow types it supports. Refer to your specific product documentation for additional information.

Designing Process Flows

A wide range of process flows may be designed to implement online tasks business users may need to perform. Refer to [Understanding Process Flows](#) for more information.

Below is a high-level summary of the steps required to design and configure various types of process flows.

Analyze The Task

The following provides a the high-level guidance in analyzing the necessary data and rules needed to support an implementation of a new type of process flow:

- Identify the data and business rules that are needed to complete the entire task.
 - When possible, organize data into logical groups of details defined as data areas.
 - Design logic for the final processing script that accepts the entire data entered along with the user's action to either complete or cancel the task.
 - If data needs to be initially prepared for a newly initiated process flow, design logic for a corresponding initial processing script.
 - Determine whether a summary panel may be useful for the user to review the outcome of a completed process.
- Design the sequence of panels the user should follow to complete the task. Identify the initial and final panels.
- Review each panel and determine the following:
 - Is it a single panel or a nested process flow (i.e. a panel set)?
 - What is the title of the panel and its label on the progress bar?
 - How should the layout be rendered? Use a data area that leverages UI Hints to describe the panel layout when possible. For more complex HTML requirements you may use a UI map fragment.

- Should details on this panel be defaulted with some initial values when the user enters this panel? If so, design logic for a corresponding pre-processing script.
- If data entered on this panel should be validated before the user exits the panel, design logic for a corresponding post-processing script.
- Design the summary panel if needed.
- Determine whether this type of process flow should be automatically saved by the system or solely rely on the user to control when data is saved.
- Determine whether a record of a completed process flow should be retained for audit purposes or deleted upon completion.
- Determine whether a user may delete in progress records of such process flow.
- Determine whether process flows of this type are saved and stored in a dedicated table in the database or are saved in the generic table provided by the base product. The assumption is that introducing new designated storage maintenance objects is not common. Refer to your edge product documentation for additional maintenance objects that may have been provided to support specific types of process flows shipped with the product.
- Determine the context in which a user can initiate, resume work on, and review process flows of that type.
 - The process flow may be launched from a menu or a favorite script etc.
 - Design the query portal a user would use to find and resume a saved off process flow of this type as well as review completed process flow records. Depending on the context of this task, the query may be associated with the same menu line that initiates the process flow.

Using UI Map Panels

Typically a map fragment is rendered as part of a complete UI map but when used as a process flow panel the system renders the panel assuming the fragment contains a complete map.

Therefore, such fragment should include the following items:

- The standard error message section used for reporting errors.
- This line `<xml style="display:none"></xml>` at the end of the HTML content for proper binding of data to their HTML elements.

A UI map based panel allows for more control over some of the buttons available to the user. For example, the panel may prevent the user from proceeding to the next panel unless required information is entered. Refer to the explicit APIs listed in the process controller UI Map (F1-ProcessController) for more information.

Configure The Process Flow Type

The following describes the high-level steps needed to configure a new type of process flow:

- Create the UI map for the process flow. Its schema should contain all the details needed to complete the task. Its HTML should only include the process controller UI map fragment.
- Create a start processing service script if needed.
- Create a final processing service script such that it applies all the rules needed to complete or cancel the task.
- For each panel perform the following:
 - Create a UI map fragment for it unless it corresponds to a data area already included in the process flow schema. Make sure the XPath of each element references in the data area or UI map is the same XPath of that element in the process flow's UI map schema.
 - Create a pre-processing service script if needed. Not applicable to the summary panel.
 - Create a post-processing service script if needed. Not applicable to the summary panel.

- Set up a label and title MD fields if existing ones cannot be used.
- Create a BPA script for the process flow.
- Configure the [process flow type](#) record.
- Set up a navigation option and reference the BPA script on it. Associate the navigation option with a menu or provide other means for the user to initiate the process flow.
- Create a query portal for the specific type of process flow records. Add the new query portal to a menu or provide other means for the user to resume work on a process flow they have saved off or review completed records.

Control Visibility of Standard Buttons

You may leverage the following JavaScript functions to control the visibility of standard process flow buttons:

- Next: **enableNext()**, **disableNext()**, **hideNext()** , **showNext()**
- Finish: **enableFinish()**, **disableFinish()**, **hideFinish()** , **showFinish()**
- Save: **enableSave()**, **disableSave()**, **hideSave()** , **showSave()**.

Defining Process Flow Types

This portal is used to maintain process flow types.

Refer to [Understanding Process Flows](#) for more information.

You can access the portal from the **Admin Menu > System > Process Flow Type**.

The following zones may appear as part of the portal's **Main** tab page

- **Process Flow Type List.** This zone lists all process flow types. Broadcast a record to display the details of the selected process flow type.
- **Process Flow Type.** This zone provides information about the selected process flow type.

Action Method

Action method is an object that may be used to define configuration based on some criteria. For example, when initiating a Start Service scenario, the service request type may differ based on the CIS division and the customer class. When a user initiates a Start Service process, the system can prompt the user for information about the customer that can determine the CIS division and the customer class. The system can then call an algorithm passing this information to retrieve the appropriate service request type to use as defined in the action method. Throughout this section, the term 'criteria' is used to identify the information used to determine the desired configuration and the term 'details' or 'results' is used to identify the configuration information being determined.

If you were to design a use case to use this functionality consider the following:

- What information needs to be identified (the 'details'/'results')? The example above uses a configuration object as its example (service request type). However, the information you are determining could be anything that can differ by some combination of attributes. You could use this to determine which collection algorithm to execute based on criteria. Or the number of days to wait to continue with some process for some use case.
- When and where do I need to determine this information and what do I do with it once I receive it?
 - Is this needed as part of a user interaction?
 - Or is this needed for internal processing?

- What is the criteria needed to determine the desired information? Do I have this information at the time that I need it? Or do I need to prompt a user for the information?

The framework product supplies the generic objects needed to support this type of functionality. The individual edge products or implementations can build their use cases with the tools provided. The topics in this section further describes the provided features.

Action Method Role

The action method functionality is driven by the Action Method Role, which represents a given use case. Some examples of action method roles that may be relevant in an enterprise product are 'Start Service', 'Stop Service' and 'Transfer Service'. The valid action method roles are defined using an extendable lookup and referenced on the Action Method. One and only one action method may be defined for one action method role.

The action method role record may reference an action method role BPA script, if the use case for this Action Method Role involves user interaction. The responsibility of this script, if needed is to take the action method role value, determine the action method that references the role and identify the more specific Action Processing BPA script (defined on the business object) and transferring control to that script. This reference may be used for audit or information purposes, depending on how you have implemented the user experience. The action method role BPA is ideally configured on an appropriate menu entry or an action button on a specific user interface related to this use case.

If your business use case does not require user interaction, then an action method role BPA script is not necessary.

Action Method Business Object

The action method's business object is used to define the information that needs to be configured for both the criteria and the results. Continuing to use the above example, the business object for a Start Service use case defines a list that captures the CIS division and customer class along with the service request type to use. The information is configured in the XML data area for the action method and the schema design is dictated by the business requirements. For example, it may be that your use case dictates a default value for the results (in our case, the service request type) plus override values based on a division and customer class combination.

Get Action Method Details Plug-in

Besides defining the schema information for capturing the criteria and results, the business object defines the algorithm that should be invoked to retrieve the results based on the criteria.

The plug-in spot is **Get Action Method Details**. Its API is flexible in the information it receives and returns so that each action method use case can design the algorithm based on its business requirements.

The algorithm receives a list of 'Criteria Data' using a 'name' and up to 5 values (to handle multi-part primary keys). Typically only 'value 1' is needed for each entry. The algorithm type designed for a given action method business object can determine what information is receives. It could be that it expects the criteria elements defined on the action method. In our example, the algorithm type could expect to receive the CIS division and customer class. Alternatively, the algorithm type could be designed to receive a value that can be used to determine the criteria needed. For example, it could receive the account ID and use that information to determine the CIS division and customer class.

The algorithm returns one or more results as 'Details'. The information returned is based on the use case. In our example, the service request type is returned. Your business requirements may use the action method role to return multiple results, for example a service request type and a process flow type to invoke to capture all the information needed to start service.

The product provides a business service **F1-RetrieveActionMethodDetails** to call the algorithms for a given action method value.

Action Processing BPA

If your business requirement requires user interaction either to determine the criteria to pass to the Get Action Method Details algorithm or to use the resulting information to continue with an online action, an Action Processing BPA is needed. This BPA should be designed and linked to your action method business object as an option using the **Action Processing BPA Script** option type.

The design of this BPA depends on your business requirements. But at a high level, it may need to prompt the user for information needed to determine the criteria associated with the action method details, then call the **F1-RetrieveActionMethodDetails** business service to execute the algorithms for your action method. Once the results are returned, the script would proceed with the next step in the business use case.

NOTE: If any additional information needs to be gathered by the server before or after the call to the business service that executes the algorithms, then the recommendation is that the BPA should call a service script that does all the server level logic at one time.

Action Method Role vs. Action Method Business Object

The action method role defines the use case. The business object is used to design the schema for the criteria and the results and identifies the action processing BPA and the Get Action Method Details plug-in. It may warrant a unique business object for each action method role. However, there may be cases where more than one action method role and its action method can reuse the same business object. For example, imagine there are different service request types for Start Service, Stop Service and Transfer Service, however in all cases the valid value is driven by the CIS division and customer class. These three separate action method roles and action methods can reuse a common business object defining the criteria of CIS division and customer class determining the appropriate service request type.

Defining Action Methods

Refer to [Action Method](#) for an overview of action method functionality.

To maintain the action methods applicable to your implementation, open **Admin > System > Action Method**.

This is a standard [All-in-One portal](#) and includes the standard List and display zones for an action method.

The information captured on the action method depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Algorithms

In this section, we describe how to set up the user-defined algorithms that perform many important functions including:

- Validating the format of a phone number entered by a user.
- Validating the format of a latitude/longitude geographic code entered by a user.
- In products that support payment and billing:
 - Calculating late payment charges.
 - Calculating the recommended deposit amount.
 - Constructing your GL account during the interface of financial transactions to your GL
- And many other functions...

The Big Picture Of Algorithms

Many functions in the system are performed using an algorithm. Algorithms are called at strategic points (often referred to as a "plug-in spot") within system processing to perform specific code. The plug-in spots are preconfigured with the product and vary from object to object. Algorithms are used by the base product to provide out of the box functionality. The algorithm framework provides a means for implementations to insert their own custom code, which can be instead of the base delivered code or in addition to it.

NOTE: Algorithm = Plug-in. We use the terms plug-in and algorithm interchangeably throughout this documentation.

Algorithm Type Versus Algorithm

Often the system will just talk about algorithms but in actuality there are two important objects that provide this plug-in functionality.

- An **Algorithm Type** defines the plug-in spot. In addition, it defines program to execute. The program may be defined using Java or using a [plug-in script](#). The algorithm type also defines any parameters that must be supplied to algorithms of this type.
- An **Algorithm** is an instance of an **Algorithm Type**. If the algorithm type does not define any parameters, then there will be only one algorithm for the algorithm type. If the algorithm defines parameters, then there could be several algorithms for a given algorithm type, one for each unique set of parameter values for a given use case. The algorithm is the object that gets referenced on a given control table when configuring your system.

Algorithm Plug-in Spot

The plug-in spot, also called Algorithm Entity and System Event, defines several aspects of the functionality for algorithms that are executed.

- When in system processing are algorithms of this plug-in spot executed? For example, algorithms for the Installation Option - To Do Pre-creation are called when a To Do is getting added, before any insert to the database is performed.
- The API for the plug-in spot. This is often referred to as the "hard parameters" for the plug-in spot. What information is every algorithm provided when called? Additionally, if the algorithm is expected to return information to the caller, this is also part of the hard parameters. For example, the Installation Option - To Do Pre-creation plug-in spot receives all the information about the To Do that is about to be added. It may add or update values. It may also return an indication to not create the To Do, if desired.

NOTE: The hard parameters are different from the parameters defined on the algorithm type. Those are referred to as the "soft parameters". Those parameters are used to configure settings that the algorithm type code uses per its specific functionality.

- What is the responsibility of algorithms for the plug-in spot? When defining a plug-in spot, the product defines the responsibility of the code for the algorithm types created for that spot. For example, is the algorithm determining information and returning it? Or is it supposed to perform an update? Algorithms for the Installation Option - To Do Pre-creation plug-in spot should not do any updates. Rather they should adjust the To Do information (if desired) in the hard parameters and return them. The calling logic will use that adjusted information when inserting the To Do record.
- Where do you configure the algorithm? We have been using the Installation Option - To Do Pre-creation plug-in spot as an example. As the description suggests, these algorithms are configured on the Installation Option - Algorithm collection. Each plug-in spot defines where (on which control table) the algorithms are plugged in. The system standard for the description of the Algorithm Entity flag value that defines the available plug-in spots is "Control Table Name - Event". For example the To Do Type - Calculate Priority algorithm plug-in spot means that algorithms are configured on the To Do Type. This information also indicates the granularity of the algorithm. Installation Option algorithms are system wide. But an algorithm plugged in on To Do Type, for example, indicates that only To Do Entries for that To Do Type will have that algorithm executed.
- Are multiple algorithms allowed? There are some plug-in spots where it doesn't make sense to support multiple algorithms. An example of this is the Batch Control - Select Records plug-in. This plug-in is used by the plug-in driven batch process and is responsible for selecting the records to process. Only one algorithm of this type is allowed on a given Batch Control. An example of a plug-in spot that would support multiple algorithms is a validation plug-in spot. Note that when a plug-in spot supports multiple algorithms, there can be yet additional aspects of the plug-in spot design.
 - In some cases, this type of plug-in spot simply executes each algorithm. A validation plug-in spot is an example of this.
 - In some cases, the algorithm could return an indication to the plug-in spot 'driver' to not execute any subsequent algorithms. Business Object Status - Enter is an example of a plug-in spot that supports this capability.

- In some cases, the plug-in spot may support sharing information from one algorithm to the next. Migration Plan - Pre-Compare is an example of a plug-in spot that supports this capability.

Each plug-in spot is defined in the Algorithm Entity lookup (**ALG_ENTITY_FLG**). When defining an algorithm type or defining a plug-in script, once you select the algorithm entity value, a help icon should appear. Clicking this icon will show you the description of the plug-in spot. It may be that online help provides more information about a given plug-in spot as well. Note that to see the hard parameters defined for a given plug-in spot, go to the [Script](#) page in add mode and select the script type of plug-in and the desired algorithm entity lookup value. Then navigate to the Data Area tab. The **View Plug-In Script Data Area** link will display the hard parameters.

Base Product Algorithms

The base product provides many, many algorithm types and algorithms out of the box. Sometimes algorithms are delivered to provide support for common use cases that we know our clients will need. Many algorithms, however, are provided because we are implementing system functionality using the same infrastructure and capabilities that our implementation use for their own custom code.

When an algorithm type is delivered, the decision as to whether an algorithm is also provided depends on some factors related to whether soft parameters are defined for the algorithm type.

- If no parameters are defined for the algorithm type, a corresponding algorithm is typically also provided.
- If parameters are defined and the values are on configuration data that is normally owned by the implementation, a base algorithm will probably not be defined.
- If parameters are defined and the values are not dependent on configuration data, it's possible that one or more algorithms are provided.

To review the algorithm types that are delivered with the product, go to the Algorithm Type query. The query provides several search options, including searching by the algorithm entity lookup value.

How To Add A New Algorithm

Before you can add a new algorithm, you must determine if you can use one of the [algorithm types](#) supplied with the system by using the algorithm type query.

If you can use one of the algorithm types, simply add the algorithm and then reference it on the respective control table. Refer to [Defining Algorithms](#) for how to do this.

If you have to add a new algorithm type, you may have to involve a programmer. Let's use an example to help clarify what you can do versus what a programmer must do. Assume that you require an additional geographic type validation algorithm. To create your own algorithm type you must:

- Write a new program to validate geographic type in the appropriate manner. Alternatively, you may configure a plug-in script to implement the validation rules. The advantage of the latter is that it does not require programming. Refer to [plug-in script](#) for more information.
- Create an Algorithm Type called **Our Geographic Format** (or something appropriate). On this algorithm type, you'd define the name of the program (or the plug-in script) that performs the function. You'd also define the various parameters required by this type of algorithm.
- After creating the new Algorithm Type, you can reference it on an Algorithm.
- And finally, you'd reference the new Algorithm on the Geographic Type that requires this validation.

Minimizing The Impact Of Future Upgrades

The system has been designed to use algorithms so an implementation can introduce their own logic in a way that's 100% upgradeable (without the need to retrofit logic). The following points describe strong recommendations about how to construct new algorithm type programs so that you won't have to make program changes during future upgrades:

- Do not alter an algorithm type's hard parameters. For example, you might be tempted to redefine or initialize parameters defined in an algorithm type's linkage section. Do not do this.
- Follow the naming conventions for the new algorithm type code and your source code, i.e., both the source code and the algorithm type should be prefixed with "CM". The reason for this naming convention is to make it impossible for a new, base-package algorithm type from overwriting your source code or algorithm type meta-data (we will never develop a program or introduce meta-data beginning with CM).
- Avoid using embedded SQL to perform insert/update/delete. Rather, invoke the base-package's object routines or common routines.
- Avoid using base messages (outside of common messages, i.e., those with a message number < 1000) as we may deprecate or change these messages in future releases. The most common problem is caused when an implementation clones a base package algorithm type program because they need to change a few lines of logic. Technically, to be 100% upgradeable, you should add new messages in the "90000" or greater category (i.e., the category reserved for implementation-specific messages) for every message in your new program even though these messages may be duplicates of those in the base package.

Defining Algorithm Types

The system provides many algorithm types to support base product functionality. If you need to introduce a new type of algorithm, open **Admin > System > Algorithm Type**.

Use the **Algorithm Type Query** portal to search for an existing algorithm type. Once an algorithm type is selected, you are brought to the maintenance portal to view and maintain the selected record.

FASTPATH: Refer to [The Big Picture Of Algorithms](#) for more information.

CAUTION: Important! If you introduce a new algorithm type, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **Algorithm Type** and **Description**.

Owner indicates if this algorithm type is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add an algorithm type. This information is display-only.

Enter a **Detailed Description** that describes, in detail, what algorithms of this type do.

Use **Algorithm Entity** to define where algorithms of this type can be "plugged in". If a detailed description about an algorithm entity is available, a small help icon is visible adjacent to the dropdown. Click the icon to view the information.

NOTE: The values for this field are customizable using the [lookup](#) table. This field name is **ALG_ENTITY_FLG**.

Use **Program Type** to define if the algorithm's program is written using **Java**, a **Plug-In Script**, or **Java (Converted)**, meaning the program has been converted to Java.

NOTE: **Java (Converted)** program types are not applicable to all products.

Use **Program Name** to define the program to be invoked when algorithms of this type are executed:

- If the Program Type is **Java (Converted)**, enter the name of the converted program.
- If the Program Type is **Java**, enter the Java class name.
- If the Program Type is **Plug-In Script**, enter the plug-in [script](#) name. Only plug-in scripts defined for the algorithm entity may be used.

NOTE: View the source. If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadocs](#) viewer. For plug-in scripts, drill into the plug-in script to view the details.

Use the **Parameter Types** grid to define the types of parameters that algorithms of this type use. The following fields should be defined for each parameter:

- Use **Sequence** to define the relative position of the **Parameter**.
- Use **Parameter** to describe the verbiage that appears adjacent to the parameter on the Algorithm page.
- Indicate whether the parameter is **Required**. This indicator is used when parameters are defined on algorithms that reference this algorithm type.
- **Owner** indicates if the parameter for this algorithm type is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add an algorithm type with parameters. This information is display-only.

NOTE: When adding a new algorithm type that is for a Java program, the parameters are automatically generated based on the Java code. Once an algorithm type exists, any additional parameters defined in the Java code should be manually added to the algorithm type. For other program types, algorithm type parameters must be manually defined.

NOTE: When a new algorithm type parameter is added for any program type, existing algorithms for the algorithm type do not automatically get updated with the new parameter. The algorithms must be manually updated.

Defining Algorithms

This portal is used to view and maintain information about an algorithm.

You can access the portal from the **Admin Menu > System > Algorithm**. You are brought to a query portal with options for searching for a specific algorithm. Once an algorithm has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [The Big Picture Of Algorithms](#) for more information.

CAUTION: Important! If you introduce a new algorithm, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Algorithm.** This zone provides information about the selected algorithm.
- **Other Algorithms.** This zone lists other algorithms of the same algorithm type. The zone is only visible when such algorithms exist.

The following zones may appear as part of the portal's **References** tab page

- **Algorithm References.** This zone list various configuration entities referencing the current algorithm.

NOTE: If the product delivers an algorithm with parameter values defined, an implementation may override the base provided parameter values by adding an additional effective dated collection of parameters.

NOTE: If an algorithm is defined and subsequently a new parameter is added to the algorithm type, existing algorithms for the algorithm type should be updated to add a new effective dated entry to the parameter collection. At this point the latest list of parameters for the algorithm type are visible. Configure the parameters accordingly.

Advanced Algorithm Tips

Initiating Actions that Cannot be Rolled Back

If you have an algorithm that creates a sync request or performs some other logic that could cause a message to be sent and cannot be rolled back, you should be sure to cater for warnings in the design.

- The algorithm should be performed after all validations that could accumulate warnings.
- The algorithm should include a step to call the Business Service **F1-CheckWarning** and see if any warnings have been accumulated. If so, don't perform the action. It means that the user will get a warning and if they click "OK", all the processing will happen again, but this time without accumulating any warnings. Refer to the plug-in script **F1-GnChgDCap** for an example.

Script Options

We use the term "script" to define processing rules that your implementation sets up to control both front-end and back-end processing:

- Rules that control front-end processing are defined using [Business Process Assistant \(BPA\)](#) scripts. For example, your implementation could set up a BPA script to guide a user through your organization's payment cancellation process.
- Rules that control back-end processing are defined using [Server-based](#) scripts. For example, your implementation could set up a server-based script to control the processing that executes whenever a given type of adjustment is canceled.

The topics in this section describe how to configure your scripts.

The Big Picture Of Scripts

This section describes features and functions that are shared by both BPA scripts and server-based scripts.

Scripts Are Business Process-Oriented

To create a script, you must analyze the steps used to implement a given business process. For example, you could create a "stop auto pay" BPA script that:

- Asks the user to select the customer / taxpayer using an appropriate search page
- Asks the user to define the date on which the person would like to stop making automatic payments
- Invokes a server-based script that populates the end-date on the account's latest automatic payment instructions.

After you understand the business process, you can set up a script to mimic these steps. If the business process is straightforward (e.g., users always perform the same steps), the script configuration will be straightforward. If the business process has several logic branches, the composition of the script may be more challenging.

A Script Is Composed Of Steps

A script contains one or more steps. For example, a "stop auto pay" BPA script might have three steps:

- Ask the user to select the customer / taxpayer using an appropriate search page
- Ask the customer the date on which they'd like to stop making automatic payments (and default the current date)
- Invoke a server-based script that, in turn, updates the account's auto pay options.

Each step references a step type. The step type controls what happens when a step executes. It might be helpful to think of a script as a macro and each step as a "line of code" in the macro. Each step's step type controls the function that is executed when the step is performed.

FASTPATH: Refer to [How To Set Up Each Step Type](#) for a detailed description of all available step types and how to set them up.

A Script May Declare Data Areas

Both BPA and server-based scripts may have one or more [data areas](#):

- If the script contains steps that exchange XML documents, you must declare a data area for each type of XML document. For example, if a BPA script has a step that invokes a service script, the BPA script must declare a data area that holds the XML document that is used to pass information to and from the service script.
- You can use a data area as a more definitive way to declare your temporary storage. For example, you can describe your script's temporary storage variables using a [stand-alone data area](#) schema and associate it with your script.

Various step types involve referencing the script's data areas as well as support the ability to compare and move data to and from field elements residing in the data areas.

An Edit Data step supports the syntax to dynamically declare data areas as part of the step itself. This technique eliminates the need to statically declare a data area. Refer to [Edit Data Syntax](#) for more information on edit data commands and examples of the use of dynamic data areas.

NOTE: Some server based scripts may not use data areas as means of defining or exchanging data, depending on script type and the chosen scripting technique. Refer to [The Big Picture Of Server Based Scripts](#) for an overview of server scripts and their applicable scripting options.

Securing Script Execution

The system supports the ability to secure the execution of scripts by associating the script with an Application Service. Refer to [The Big Picture of Application Security](#) for more information. Application security is optional for user-invocable BPA scripts. If a script is not associated with an application service, all users may execute the script. Otherwise, only users that have **Execute** access to the application service may execute the script. For service scripts, the application service is required.

The Big Picture Of BPA Scripts

FASTPATH: Refer to [The Big Picture Of Scripts](#) to better understand the basic concept of scripts.

Users may require instructions in order to perform certain tasks. The business process assistant allows you to set up scripts that step a user through your business processes. For example, you might want to create scripts to help users do the following:

- Add a new person to an existing account
- Set up a customer to pay automatically
- Modify a customer who no longer wants to receive marketing information
- Modify a customer's web password
- Record a trouble order
- Merge two accounts into one account
- Fix a bill with an invalid rate

- ... (the list is only limited by your time and imagination)

Users execute these scripts via the [business process assistant](#) (BPA). Users can also define their favorite BPA scripts in their [user preferences](#). By doing this, a user can execute a script by pressing an accelerator key (Ctrl + Shift + a number).

Don't think of these scripts as merely a training tool. BPA scripts can also reduce the time it takes to perform common tasks. For example, you can write a script that reduces the "number of clicks" required to add a new person to an existing account.

CAUTION: Future upgrade issues. Although we make every effort not to remove fields or tab pages between releases, there may be times when changes made by the base-package will necessitate changes to your scripts. Please refer to the release notes for a list of any removed fields or tab pages.

CAUTION: Scripts are not a substitute for end-user training. Scripts minimize the steps required to perform common tasks. Unusual problems (e.g., a missing meter exchange) may be difficult to script as there are many different ways to resolve such a problem. However, scripts can point a user in the right direction and reduce the need to memorize obscure business processes.

The topics in this section describe background topics relevant to BPA scripts.

How To Invoke Scripts

Refer to [Initiating Scripts](#) for a description of how end-users initiate scripts.

Developing and Debugging Your BPA Scripts

We recommend considering the approaches outlined below when you construct scripts.

While designing your scripts, determine the most maintainable way to set them up. Rather than creating complex, monolithic scripts, we recommend dividing scripts into smaller sections. For example

- Determine if several scripts have similar steps. If so, set up a script that contains these common steps and invoke it from the main scripts using a **Perform script** step.
- Determine if a large script can be divided into logical sections. If so, set up a small script for each section and create a "master script" to invoke each sub script via a **Transfer control** step.

For debugging purposes, you may find it helpful to categorize the step types into two groups: those that involve some type of activity in the [script area](#), and those that don't. The following step types cause activity in the script area: **Height, Display text, Prompt user, Input data, Input Map, Set focus to a field.**

The rest of the step types are procedural and involve no user interaction. There are two techniques you can use to assist in debugging these step types.

- You can instruct the system to display text in the script area.
- You can display an entire data area (or a portion thereof) in the script area by entering `%+...+%` where ... is the name of the node whose element(s) should be displayed.

NOTE: Time saver. When you develop a new BPA script, change your [user preferences](#) to include the script as your first "favorite". This way, you can press Ctrl+Shift+1 to invoke the script (eliminating the need to select it from the [script menu](#)).

Launching A Script From A Menu

You can create menu items that launch BPA scripts rather than open a page. To do this, create a [navigation option](#) that references your script and then add a menu item that references the navigation option.

If the navigation option is referenced on a [context menu](#) and the navigation option has a "context field", a temporary storage variable will be created and populated with the unique identifier of the object in context. For example, if you add a "script" navigation option to the bill context menu and this navigation option has a context field of BILL_ID, the system will create a temporary storage variable called BILL_ID and populate it with the respective bill id when the menu item is selected.

Launching A Script When Starting The System

You can set the system to launch a script upon startup. This may be used for integrations from an external system or for use cases within the application where a link has been configured to launch the application in a new browser tab, allowing the original page to remain open. Refer to [Creating Application Links in External Applications](#) for details of what is supported.

Executing A Script When A To Do Entry Is Selected

The system creates [To Do entries](#) to highlight tasks that require attention (e.g., records in error). Users can complete many of these tasks without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a bill that's in error due to an invalid mailing address. You can set up the system to execute a script when this To Do entry is selected by a user. This script might prompt the user to first correct the customer's default mailing address and then re-complete the bill.

The following points provide background information to help you understand how to implement this functionality:

- Every To Do entry references a [To Do type](#) and a [message category and number](#). The To Do type defines the category of the task (e.g., bill errors). The message number defines the specific issue (e.g., a valid address can't be found.). Refer to [The Big Picture of System Messages](#) for more information about message categories and numbers.
- When a user drills down on a To Do entry, either a script launches OR the user is transferred to the transaction associated with the entry's To Do type. You control what happens by configuring the To Do type accordingly:
 - If you want to launch a script when a user drills down on an entry, you link the script to the [To Do type and message number](#). Keep in mind that you can define a different script for every message (and some To Do types have many different messages).
 - If the system doesn't find a script for an entry's To Do type and message number, it transfers the user to the To Do type's default transaction.

NOTE: How do you find the message numbers? We do not supply documentation of every To Do type's message numbers (this list would be impossible to maintain and therefore untrustworthy). The best way to determine which message numbers warrant a script is during pre-production when you're testing the system. During this period, To Do entries will be generated. For those entries that warrant a script, simply display the entry on [To Do maintenance](#). On this page, you will find the entry's message number adjacent to the description.

- These types of scripts invariably need to access data that resides on the selected To Do entry. Refer to [How To Use To Do Fields](#) for the details.

The Big Picture Of Script Eligibility Rules

You can configure [eligibility criteria](#) on the scripts to limit the scripts that a user sees in the [script search](#). For example, you could indicate a script should only appear on the script menu if the user belongs to the level 1 customer service representative group. You may also indicate that a script should only appear if the data a user is viewing has certain criteria. For example, if you are using Oracle Utilities Customer Care and Billing, you can indicate that a script should only appear if the current account's customer class is residential. By doing this, you avoid presenting the user with scripts that aren't applicable to the current data in context or the user's role.

The topics in this section describe eligibility rules.

Script Eligibility Rules Are Not Strictly Enforced

The [script search](#) gives a user a choice of seeing all scripts or only scripts that are eligible (given the current data in context and their user profile). This means that it's possible for a script that isn't eligible for the given context data / user to be executed via this search. In other words, the system does not strictly enforce a script's eligibility rules.

It might be more helpful to think of eligibility rules as "highlight conditions". These "highlight conditions" simply control whether the script appears in the [script search](#) when a user indicates they only want to see eligible scripts.

You Can Mark A Script As Always Eligible

If you don't want to configure eligibility rules, you don't have to. Simply indicate that the script is always eligible.

You Can Mark A Script As Never Eligible

If you have scripts that you do not want a user to select from the script menu, indicate that it is never eligible. An example of a script that you wouldn't want a user to select from the menu is one that is [launched when a To Do entry is selected](#). These types of scripts most likely rely on data linked to the selected To Do entry. As a result, a user should only launch scripts of this type from the To Do entry and not from the script menu.

Criteria Groups versus Eligibility Criteria

Before we provide concrete examples of eligibility criteria, we need to explain two concepts: Criteria Groups and Eligibility Criteria. A script's criteria groups control whether a user is eligible to choose a script. At a high level, it works like this:

- A criteria group has one or more eligibility criteria. A group's criteria control whether the group is considered true or false.
- When you create a group, you define what should happen if the group is true or false. You have the following choices:
 - The user is eligible to choose the script
 - The user is not eligible to choose the script
 - The next group should be checked

We'll use the following example from Oracle Utilities Customer Care and Billing to help illustrate these points. Assume a script is only eligible if:

- The customer has electric service and the user belongs to user group A, B or C
- OR, the customer has gas service and the user belongs to user group X, Y or A

This script requires two eligibility groups because it has two distinct conditions:

- IF (Customer has electric service AND (User belongs to user group A, B or C))
- IF (Customer has gas service AND (User belongs to user group X, Y or A))

If either condition is true, the script is eligible.

You would need to set the following criteria groups in order to support this requirement:

Group No.	Group Description	If Group is True	If Group is False
1	Customer has electric service and the user belongs to user group A, B or C	Eligible	Check next group
2	Customer has gas service and the user belongs to user group X, Y or A	Eligible	Ineligible

The following criteria are required for each of the above groups:

Group 1: Customer has electric service and the user belongs to user group A, B or C				
Seq	Logical Criteria	If Eligibility Criteria is True	If Eligibility Criteria is False	If Insufficient Data
10	Customer has electric service	Check next condition	Group is false	Group is false
20	User belongs to user group A, B or C	Group is true	Group is false	Group is false

Group 2: Customer has gas service and the user belongs to user group X, Y or A				
Seq	Logical Criteria	If Eligibility Criteria is True	If Eligibility Criteria is False	If Insufficient Data
10	Customer has gas service	Check next condition	Group is false	Group is false
20	User belongs to user group X, Y or A	Group is true	Group is false	Group is false

The next section describes how you might configure the specific logical criteria in each of the groups.

Defining Logical Criteria

When you set up an eligibility criterion, you must define two things:

- The field to be compared
- The comparison method

You have the following choices in respect of identifying the *field to be compared* :

- You can execute an algorithm to retrieve a field value from somewhere else in the system.
- Some products may support choosing a characteristic linked to an appropriate object in the system (such as an account or person).

You have the following choices in respect of identifying the *comparison method*:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value.
- You can execute an algorithm that performs the comparison (and returns True, False or Insufficient Data). This is also a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

The [Examples Of Script Eligibility Rules](#) provide examples to help you understand this design.

Examples Of Script Eligibility Rules

The topics in this section provide examples about how to set up script eligibility rules.

A Script With A Time Span Comparison

A script that is only eligible for senior citizens has the following eligibility rules:

- Customer class = Residential
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the script. It would look as follows:

Group No.	Group Description	If Group is True	If Group is False
1	Residential and Senior Citizen	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Residential, Calif, Senior					
Seq	Field to Compare	Comparison Method	If True	If False	If Insufficient Data
10	Algorithm: retrieve account's customer class	= R	Check next condition	Group is false	Group is false
30	Person characteristic: Date of Birth	Algorithm: True if senior	Group is true	Group is false	Group is false

The first criterion is easy; it calls an algorithm that retrieves a field on the current account. This value, in turn, is compared to a given value. If the comparison results in a True value, the next condition is checked. If the comparison doesn't result in a True value, the **Group is false** (and, the group indicates that if the group is false, the script isn't eligible).

The last criterion contains a time span comparison. Time span comparisons are used to compare a date to something. In our example, we have to determine the age of the customer based on their birth date. If the resultant age is > 65, they are considered a senior citizen. To pull this off, you can take advantage of a comparison algorithm supplied with the base script as described below.

- Field to Compare. The person characteristic in which the customer's birth date is held is selected.
- Comparison Method. We chose a comparison algorithm that returns a value of **True** if the related field value (the customer's date of birth) is greater than 65 years (refer to **SECC-TIMESPN** for an example of this type of algorithm). Note that this time span algorithm can be used to compare days, weeks and months as well.

You'll notice that if a value of **True** is returned by the **True if senior** algorithm, the group is true (and we've set up the group to indicate a true group means the script is eligible).

A Script With Service Type Comparison

Imagine a script that is only eligible if the current customer has gas service and the user belongs to user groups A, B or C. This script would need the following eligibility rules:

- Customer has gas service
- User belongs to user group A, B, or C

These rules require only one eligibility group on the script. It would look as follows:

Group No.	Group Description	If Group is True	If Group is False
1	Has gas service and user is part of user group A, B or C	Eligible	Ineligible

The following criteria are required for this group:

Group 1: Has gas service and user is part of user group A, B, or C					
Seq	Field to Compare	Comparison Method	If True	If False	If Insufficient Data

10	Algorithm: check if customer has gas service	= True	Check next condition	Group is false	Group is false
20	Algorithm: check if user belongs to user group A, B or C	= True	Group is true	Group is false	Group is false

Both criteria are similar - they call an algorithm that performs a logical comparison. These algorithms are a bit counter intuitive (but understanding them provides you with another way to implement complex eligibility criteria):

The first criterion works as follows:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the current account has service agreements that belong to a given set of service types. It returns a value of **True** if the customer has an active service agreement that matches one of the service types in the algorithm. In our example, the "check if customer has gas service" algorithm returns a value of **True** if the customer has at least one active service agreement whose SA type references the gas service type. The "check if customer has electric service" algorithm is almost identical, only the service type differs.
- **Comparison Method.** We simply compare the value returned by the algorithm to True and indicate the appropriate response.

The second criterion works similarly:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the user belongs to any user group in a set of user groups. It returns a value of **True** if the user belongs to at least one user group defined in parameters of the algorithm. Refer to algorithm type **SECF-USRNGRP** for an example of this type of logic.
- **Comparison Method.** We simply compare the value returned by the algorithm to True and indicate the appropriate response.

NOTE: Bottom line. The "field to compare" algorithm isn't actually returning a specific field's value. Rather, it's returning a value of **True** or **False**. This value is in turn, compared by the "comparison method" and the group is set to true, false or check next accordingly.

The Big Picture Of Server-Based Scripts

FASTPATH: Refer to [The Big Picture Of Scripts](#) to better understand the basic concept of scripts.

Server-based scripts allow an implementation to configure backend business processes. The system supports three types of server-based scripts, **Plug-In** scripts, **Service** scripts and **Groovy Library** scripts.

- **Plug-in scripts** allow an implementation to develop routines that are executed from the system's various plug-in spots. For example, an implementation could configure a plug-in script that is executed every time an adjustment of a given type is frozen.
- **Service scripts** allow an implementation to develop common routines that are invoked from both front-end and back-end services. For example, an implementation could create a service script that terminates an account's automatic payment preferences. This service script could be invoked from a BPA script initiated by an end-user when a customer asks to stop paying automatically, and it could also be executed from a plug-in script if a customer fails to pay their debt on time. Service scripts are typically written using xpath scripting.
- **Groovy Library scripts** allow an implementation to develop groups of common routines written in the Groovy language which may be invoked from **Groovy Member** step types.

The topics in this section describe background topics relevant to server-based scripts.

Additional Coding Options For Server Scripts

Server based scripts often perform complex functions best supported by coding in languages with more comprehensive command sets than the base script steps. The system supports two common third-party languages for this purpose.

XML Path Language (XPath) is a language for querying and evaluating elements or nodes in an XML document. XPath commands and expressions can be used directly within [edit data](#) step types. The script engine version is used to define the applicable XPath version.

Groovy is an object-oriented, dynamic language for the Java platform. The framework supports the use of Groovy within server-based scripts to provide restricted and controlled access to Java-like code, particularly for cloud based implementations. The following topic provides more information on how to incorporate Groovy code into scripts.

Using Groovy Within Scripts

Groovy code can be incorporated in scripts using the step type **Groovy Members**. For each script with Groovy code, there will be a single Groovy class created by concatenating all **Groovy Members** steps.

For security, the product and third party Java classes available for scripting in Groovy are restricted. The allowable base classes may be viewed in the [Groovy Javadocs](#) viewer via the 'View Groovy Javadocs' link in the context sensitive Script Tips zone. The list of allowable third party classes can be viewed via the 'View third party Groovy allowlist' link in the Script Tips zone.

NOTE: This system supports the use of Groovy for back end processing purposes. It is not intended for user interfaces. Groovy is also not applicable to BPA scripts.

Groovy Script Engine

For scripts invoked from within Java and entirely written in Groovy should use a script engine version of **Groovy**. The system processes this type of script in a similar way to code written in Java. This avoids the need to convert the script to and from XML format and allows the use of code that acts directly on the system objects with consequent performance benefits.

The following script types support the Groovy engine version:

Plug In Scripts

Plug-in Scripts can be configured to use the Groovy engine if they contain only Groovy oriented step types. The system provides an automatically generated superclass that defines the plug-in spot API. Internally, the Groovy code must conform to the system conventions for Java based algorithm types, including the inclusion of an 'invoke' method that is the plug-in entry point, and the definition of 'soft' parameters using annotations.

Groovy Library Scripts

Groovy Library Scripts provide the ability to create groups of common routines written in Groovy that can be called from within other scripts. Scripts of this type must include a single step type of **Groovy Library Interface** in which the publicly available methods in the library are listed. The supporting code for those methods is defined in one or more **Groovy Members** step types within the library script. The methods defined in the library can accept arguments and return values of any type. Scripts of this type use the Groovy engine by default and cannot include scripting step types.

Scripts that need to invoke methods from a Groovy library can use the `createLibraryScript` method provided by the system to instantiate the library interface. Ensure that the class being instantiated includes the `.class` filename extension.

Invoking Groovy within the Scripting Engine

If a plug-in script or a service script is configured to use a scripting engine version, it can include a mixture of regular and **Groovy Members** step types. The script step types will define the process to be executed. The **Groovy Members** steps contain code that can be called from **Edit Data** step types within the script using the `invokeGroovy` command. Only

Groovy methods that receive no arguments and return void are supported using this command. Refer to the section on [edit data](#) steps for more details.

For scripts using this option, the framework provides a superclass containing methods that support common scripting actions such as move commands, string evaluation, and methods to invoke business objects, business services and service scripts. Refer to the Groovy specific Javadocs for details of the supported methods.

Importing Groovy Classes

All the Groovy classes used by your script should be explicitly declared in a **Groovy Imports** step type. When saving a script, if the system finds classes referenced in the script that are not explicitly declared, the system issues a warning and automatically adds import statements for the classes. Script writers should review the imports to confirm that they are the correct classes (in case there is a class with the same name in two different packages).

Backward Compatibility

In previous releases, the system did not require explicit imports and had logic to automatically import all callable classes available to Groovy at run-time. For any existing script that does not explicitly declare its imports, the system continues to fall back on importing all callable classes at runtime. However, the recommendation is to identify and update any such script as this is not the recommended practice.

The system provides a batch program **F1-CAGVY** that reports all scripts that required the automatic import step to successfully compile. In addition, this batch program is useful when the version of Groovy is upgrade to proactively detect possible issues in compilation of existing scripts that may occur due to changes in Groovy. Implementations are encouraged to run this batch program in the short term to identify and fix any scripts missing explicit imports and also for any Groovy version upgrade to review any implementation owned scripts that may be reported.

Plug-In Scripts

NOTE: This section assumes you are familiar with the notion of plug-in spots (algorithm entities) and plug-ins. See [The Big Picture Of Algorithms](#) for more information.

As an alternative to writing a java program for a plug-in spot, the framework supports creating plug-ins using the defined script steps, Xpath commands, Groovy code or a combination of these three options.

The following topics describe basic concepts related to plug-in scripts.

A Plug-In Script's API

Like program-based plug-ins, plug-in scripts:

- Run on the application server
- Have their API (input / output interface) defined by the plug-in spot (i.e., plug-in scripts don't get to declare their own API)
- Can only be invoked by the "plug-in spot driver"

For plug-ins configured to use a script engine version, the best way to understand the script's API is to use the **View Script Schema** hyperlink to view its parameters data area schema.

```

<schema>
  <parm type="group">
    <soft type="list">
      <value/>
    </soft>
    <hard type="group">
      <action use="input"/>
      <businessObject type="group" use="input">
        <id/>
      </businessObject>
    </hard>
  </parm>
</schema>

```

Notice the two groups: soft and hard. If you are familiar with plug-in spots, you'll recognize these as the classic soft and hard parameters:

- The **soft** parameters are the values of the parameters defined on the algorithm. Notice they are not named - if you want to reference them in your plug-in script, you must do it by position.
- The **hard** parameters are controlled by the plug-in spot (i.e., the algorithm entity). Notice that this plug-in spot has a single input parameter called "**businessObject/id**". Also notice the **use=** attribute - this shows that this parameter is input-only (i.e., you can't change it in the plug-in script).

NOTE: XPath. You can click on an element name to see the XPath used to reference the element in your script.

Plug-ins configured to use the **Groovy** engine version do not use an XML interface for the API and instead are processed in the same way as Java algorithms. The framework supplies a dynamically generated superclass that implements the plug-in spot for Groovy objects. Use the **View Script Superclass** hyperlink to view this superclass and the methods to set and get the hard parameters.

NOTE: For plug-in scripts using the **Groovy** engine version, soft parameters do not appear in the plug-in spot API as defined by the superclass. Plug-ins using only Groovy code define their soft parameters using annotations, in a similar way to Java algorithms, and fetch those values using methods defined in the algorithm code.

Setting Up Plug-In Scripts

The following points describe how to implement a plug-in script:

- Compose your plug-in [script](#), associating it with the appropriate algorithm entity (plug-in spot).
- Create a new algorithm type for the respective algorithm entity, referencing your plug-in script as the program to carry out the algorithm type's function. Only plug-in scripts associated with the algorithm entity may be referenced on the algorithm type.
- Set up an algorithm for the respective algorithm type and plug it in where applicable. Refer to [Setting Up Algorithm Types](#) for more information.

Service Scripts

BPA scripts run on the client's browser and guide the end-users through business processes. Service scripts run on the application server and perform server-based processing for [BPA scripts](#), [zones](#) and more. You may want to think of a service script as a common routine that is set up via scripting (rather than programming).

The following topics describe basic concepts related to service scripts.

A Service Script's API

As with any common routine, a service script must declare its input / output parameters (i.e., its API). A service script's API is defined on its [schema](#).

NOTE: Refer to [Schema Nodes and Attributes](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

Invoking Service Scripts

Any type of script configured to use a scripting engine version may [invoke a service script](#):

- A BPA script may invoke a service script to perform server-based processing.
- Plug-in scripts may invoke a service script (like a "common routine").
- A service script may call another service script (like a "common routine").

Map zones may be configured to invoke service scripts to obtain the data to be displayed. Refer to [Map Zones](#) for more information.

[Inbound web services](#) support interaction with service scripts allowing the outside world to interact directly with a service script.

You can also invoke a service script from a Java class.

Groovy Library Scripts

Just as service scripts can define common routines written in scripting language, Groovy library scripts are used to define groups of common components or methods written in Groovy. Groovy library code runs on the application server and performs server-based processing for scripts that utilize Groovy code.

The following topics describe basic concepts related to Groovy library scripts.

A Groovy Library Script's API

A Groovy library script's API is composed of one or more public methods whose code is defined in the script's steps. Those methods are defined in a step type of **Groovy Library Interface**. A Groovy library script must have one (and only one) step of this type.

Invoking Groovy Library Methods

Any type of script that supports the **Groovy Members** step type may invoke common methods defined in Groovy library scripts.

Code within a **Groovy Members** step must create an instance of the Groovy library interface definition to enable the interface methods to be invoked. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Debugging Server-Based Scripts

The server can create log entries to help you debug your server scripts.

The logs contain a great deal of information including the contents of the referenced data area for **Move data**, **Invoke business object**, **Invoke business service** and **Invoke service script** steps.

Refer to the [Debug Mode](#) topic in the Configuration Tools chapter for details of how to execute the application in debug mode.

Maintaining Scripts

The script maintenance transaction is used to maintain your scripts. The topics in this section describe how to use this transaction.

FASTPATH: Refer to [The Big Picture Of Scripts](#) for more information about scripts.

Script - Main

Use this page to define basic information about a script. Open this page using **Admin > System > Script**.

Use the **Script Query** portal to search for an existing script. Once a script is selected, you are brought to the maintenance portal to view and maintain the selected record.

NOTE: Script Tips. A context sensitive "Script Tips" zone is associated with this page. The zone provides links to [Edit Data Syntax](#) and [Advanced Schema Topics](#) so that users can quickly access those online help topics to aid in constructing scripts. In addition, the zone provides links to view the [Groovy Javadocs](#) viewer and the allowlist of third party Groovy classes so that users can verify the restricted list of classes available for Groovy coding in the script.

Description of Page

Enter a unique **Script** code and **Description** for the script. Use the **Detailed Description** to describe the purpose of this script in detail. **Owner** indicates if the script is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new script, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Script Type indicates if this is a **BPA Script**, **Plug-In Script**, **Groovy Library Script** or **Service Script**. Refer to [The Big Picture Of BPA Scripts](#) and [The Big Picture Of Server Based Scripts](#) for more information.

Accessibility Option appears only for BPA scripts. Set this value to **Accessible from Script Menu** for any script that may be launched as a stand-alone script. Scripts with this configuration may be linked to a navigation option so that they may be invoked from a menu and may be configured by a user as a favorite script. Set this value to **Not Accessible from Script Menu** for any script that cannot be launched on its own. For example, any script that is invoked as a sub-script from another script should have this setting. In addition, any script that is designed to be launched from within a specific portal where certain data is provided to the script should include this setting.

Enter an **Application Service** if the execution of the script should be secured. The application service should include **Execute** as one of its access modes. Refer to [Securing Script Execution](#) for more information. This field does not appear if the script type is **Groovy Library Script**.

Algorithm Entity appears only for [plug-in scripts](#). Use this field to define the [algorithm entity](#) into which this script can be plugged in.

Business Object appears only for business object related plug-in scripts. Enter the [Business Object](#) whose elements are to be referenced by the plug-in script.

Script Engine Version defines key information affecting the context and execution of the script.

- Script engine version values of 1, 2 and 3 define the version of the XML Path Language (XPath) to be used for the script. Versions 2 and 3 use the XPath 2 engine supplied by the XQuery team. This is the same engine used inside the Oracle database. The current script engine version 3 is a modified version that offers performance improvements without impacting existing version 2 scripts.

The default script engine version is 3.0 for plug-in and service scripts. The default version for BPA scripts is 1.0 as higher level versions are not applicable.

There are some additional details to note about script engine version 1.0:

- The XPath library used is Jaxen
- For BPA scripts, it uses the browser's xpath and XML support except for Internet Explorer where the XSD parser is used.
- XPath 1 (and even JavaScript) uses floating point arithmetic, which means that adding a collection of numbers with two decimal places might end up with a value of 10779.079999999998 instead of 10779.08
- A Script Engine Version value of **Groovy** is only applicable to plug-in scripts. It is used to indicate that only Groovy related step types are used in the script and signals to the system that there is no need to convert the data to and from an XML interface. This allows for greater efficiency in script execution.
- The value **Framework Version 2.1 Compatibility Mode** remains for upgrade purposes. This value should only be applicable to early versions of BPA scripts using syntax that is incompatible with XPath syntax.

NOTE: The **Script Engine Version** field does not appear for **Groovy Library** scripts. The script engine version for these scripts is set to **Groovy** by default and cannot be changed.

Click the **View Script Schema** to view the [script's data areas](#) on the [schema viewer](#) window. This link does not appear if the script engine version is **Groovy**.

Click the **View XSD** hyperlink to view a script's schema definition in XSD format. This link only appears if the script type is **BPA Script** or **Service Script**.

The **View Script Superclass** hyperlink appears only for plug-in scripts using an engine version of **Groovy**. Click this link to view the code of the runtime generated superclass for the related plug-in spot's implementation.

The **View Script As Text** hyperlink appears for server-based scripts only. Click this link to view the internal scripting commands in a separate window.

The [tree](#) summarizes the script's steps. You can use the hyperlink to transfer to the **Step** tab with the corresponding step displayed.

Script - Step

Use this page to add or update a script's steps. Open this page using **Admin > System > Script** and then navigate to the **Step** tab.

NOTE: Time saver. You can navigate to a step by clicking on the respective node in the tree on the Main tab.

Description of Page

The **Steps** accordion contains an entry for every step linked to the script. When a script is initially displayed, its steps are collapsed. To see a step's details, simply click on the step's summary bar. You can re-click the bar to collapse the step's details. Please see [accordions](#) for the details of other features you can use to save time.

Select the **Step Type** that corresponds with the step. Refer to [How To Set Up Each Step Type](#) for an overview of the step types.

CAUTION: The Step Type affects what you can enter on other parts of this page. The remainder of this section is devoted to those fields that can be entered regardless of Step Type. The subtopics that follow describe those fields whose entry is contingent on the Step Type.

Step Sequence defines the relative position of this step in respect of the other steps. The position is important because it defines the order in which the step is executed. You should only change a Step Sequence if you need to reposition this step.

But take care; if you change the Step Sequence and the step is referenced on other steps, you'll have to change all of the referencing steps.

NOTE: Leave gaps in the sequence numbers. Make sure you leave space between sequence numbers so that you can add new steps between existing ones in the future. If you run out of space, you can use the **Renumber** button to renumber all of the steps. This will renumber the script's steps by 10 and change all related references accordingly.

Display Step is only enabled on BPA scripts for step types that typically don't cause information to be displayed in the [script area](#) (i.e., step types like **Conditional Branch**, **Go to a step**, **Height**, etc). If you turn on this switch, information about the step is displayed in the script area to help you debug the script.

CAUTION: Remember to turn this switch off when you're ready to let users use this script.

NOTE: If **Display Step** is turned on and the step has **Text**, this information will be displayed in the script area. If **Display Step** is turned on and the step does not have **Text**, a system-generated messages describing what the step does is displayed in the script area.

Display Icon controls the [icon](#) that prefixes the **Text** that's displayed in the script area. Using an icon on a step is optional. This field is only applicable to BPA scripts.

Text is the information that displays in the [script area](#) when the step executes. You need only define text for steps that cause something to display in the script area.

FASTPATH: Refer to [How To Substitute Variables In Text](#) for a discussion about how to substitute variables in a text string.

FASTPATH: Refer to [How To Use HTML Tags And Spans In Text](#) for a discussion about how to format (with colors and fonts) the text that appears in the script area.

The other fields on this page are dependent on the **Step Type**. The topics that follow briefly describe each step type's fields and provide additional information about steps.

Click on the **View Script Schema** hyperlink to view the script's data areas. Doing this opens the [schema viewer](#) window.

The **View Script As Text** hyperlink appears for server-based scripts only. Click this link to view the internal scripting commands in a separate window. The presented script syntax is valid within [edit data](#) steps.

How To Set Up Each Step Type

The contents of this section describe how to set up each type of step. Note that some step types are only applicable for BPA scripts and some step types are only supported for server based scripts. Each section indicates whether there are any script type limitations.

Conditional Branch Steps

Conditional branch steps allow you to conditionally jump to a different step based on logical criteria. For example, you could jump to a different step in a script if the customer is residential as opposed to commercial. In addition, several fields are required for **Conditional Branch** steps:

Compare Field Type and **Compare Field Name** define the first operand in the comparison. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Current To Do Information.** Use this field type when the field being compared resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.

- **Data Area.** Use this field type when the field being compared is one that you put into one of the scripts data areas in an earlier step. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the field being compared resides on one of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the field being compared is a [global variable](#).
- **Temporary Storage.** Use this field type when the field being compared is one that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the field being compared resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Condition defines the comparison criteria:

- Use >, <, =, >=, <=, <> (not equal) to compare the field using standard logical operators. Enter the comparison value using the following fields.
- Use **In** to compare the first field to a list of values. Each value is separated by a comma. For example, if a field value must equal **1, 3** or **9**, you would enter a comparison value of **1,3,9**.
- Use **Between** to compare the field to a range of values. For example, if a field value must be between **1** and **9**, you would enter a comparison value of **1,9**. Note, the comparison is inclusive of the low and high values.

Comparison Field Type, Comparison Field Name and **Comparison Value** define what you're comparing the first operand to. The following points describe each field type:

- **Current To Do Information.** Use this field type when the comparison value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.
- **Data Area.** Use this field type when the comparison value resides in one of the scripts data areas. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the comparison value resides on one of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the field being compared is a constant value defined in the script. When this field type is used, use **Comparison Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for instructions on how to use constants.
- **Temporary Storage.** Use this field type when the comparison value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the comparison value resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

NOTE: Conditional field types. The field types **Current To Do Information, Page Data Model** and **User Interface Field** are only applicable to BPA scripts. Only the field types **Temporary Storage** and **Predefined Value** are applicable when the Condition is **In** or **Between**.

The above fields allow you to perform a comparison that results in a value of **TRUE** or **FALSE**. The remaining fields control the step to which control is passed given the value:

- **If True, Go to** defines the step that is executed if the comparison results in a **TRUE** value.
- **If False, Go to** defines the step that is executed if the comparison results in a **FALSE** value.

NOTE: Numeric Comparison. Comparison of two values may be numeric or textual (left-to-right). Numeric comparison takes place only when values on both side of the comparison are recognized as numeric by the system. Otherwise, textual comparison is used. Fields for **Current To Do Information**, **Data Area**, **Page Data Model**, and **User Interface Field** types are explicitly associated with a data type and therefore can be recognized as numeric or not. This is not the case for fields residing in **Temporary Storage** or those set as **Predefined Values**. A **Temporary Storage** field is considered numeric if it either holds a numeric value moved to it from an explicitly defined numeric value (see above) or it is a resultant field of mathematical operation. A **Predefined Value** field is considered numeric if the other field it is compared to is numeric. For example, if a numeric field is compared to a **Predefined Value** the latter is considered numeric as well resulting in numeric value comparison. However, if the two fields are defined as **Predefined Values** the system assumes their values are text strings and therefore applies textual comparison.

Display Text Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Display text steps cause a text string to be displayed in the script area. Steps of this type can be used to provide the user with guidance when manual actions are necessary. In addition, they can be used to provide confirmation of the completion of tasks.

The information you enter in the **Text** field is displayed in the [script area](#) when the step is executed.

The text string can contain [substitution variables](#) and [HTML formatting commands](#). Also note that for debugging purposes, you can display an entire data area (or a portion thereof) by entering `%+...+%` where `...` is the name of the node whose element(s) should be displayed.

Edit Data Steps

Edit data steps provide a free format region where you can specify commands to control your script processing.

Enter your scripting commands in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for defining the edit data step.

In general, the syntax available within edit data mimics the commands available within the explicit step types. However, there are a few commands that are available only within edit data. For example, the two structured commands: **For**, and **If**.

NOTE: Not all BPA step types are supported using the edit data syntax. Refer to the details below for more information on edit data commands and examples.

The topics in this section provide detail of the syntax supported in the edit data step type.

Comments

You can place comments into your script using the double slash notation `//` in the first two characters of the edit data step.

Example:

```
//  
// quit with error  
//  
if ("not(customer/securityEnabled)")  
terminate with error (8000, 1001 %1="customer/id" %2='not allowed');  
end-if;
```

Temporary Variables

Temporary variables can be declared within all types of scripts. They should be referenced by a leading single dollar sign (`$`). However, temporary variables behave differently in the various script types:

- In BPA Scripts temporary variables remain persistent from one BPA script to another (refer to the [Perform Script and Transfer Control statements](#)), which means that you can use temporary variables to communicate between BPA scripts.
- Temporary variables cannot be passed from a BPA script to a service or plug-in script. Only data area elements can be passed between these types of scripts.
- Within service and plug-in scripts, temporary variables remain persistent only for the life of the particular script that declared the variable. This means that temporary variables cannot be passed between plug-in scripts and service scripts, only [global variables](#), [context variables](#) and data area elements can be passed between these types of scripts.

Declaring / Initializing / Defaulting Temporary Variables

When using a temporary variable, it should be declared or initialized with an appropriate value before using it. A typical method for declaring a variable is to simply move data to it in a move statement, for example.

```
move "0" to $index;
```

FASTPATH: Refer to [Move to a Temporary Variable](#) for more information on implicit declaration of a temporary variable within a move statement.

For BPA scripts, as mentioned above, temporary variables may be passed from one BPA script to another. As such, it is common to reference a temporary variable in a BPA that should have been initialized by a previous BPA. However, if there is any reason that a temporary variable did not get initialized by a previous BPA, a reference to it will cause an error. It is good practice, therefore, to use the **default** statement that will initialize temporary variables that are not already created / initialized.

- The following statement will initialize the temporary variable \$InputAction – but only if the temporary variable has not yet been initialized:

```
default $InputAction;
```

- The following statement will set the value of the temporary variable \$InputAction to 'read' – but only if the variable has not yet been initialized:

```
default $InputAction as 'read';
```

NOTE: Scripts should take care not to define variables using a reserved keyword. The following table lists the reserved keywords.

Context Variables

Context variables are only available within service scripts. The context variable will be available for the duration of the service script and all that it invokes. Therefore, you can use a context variable within a service script to communicate information to a lower level service script or schema. They should be referenced by leading double dollar signs ('\$\$').

NOTE: Because context variables are available for lower level scripts, they may sometimes be referred to as global variables or global context variables. But they should not be confused with [global variables](#).

Declaring / Initializing / Defaulting Context Variables

When using a context variable, it should be declared or initialized with an appropriate value before using it. A typical method for declaring a variable is to simply move data to it in a move statement, for example.

```
move 'context variable' to $$contextVariable;
```

FASTPATH: Refer to [Move using a Context Variable](#) for more information.

Move Statement

The **move** statement copies a source value to a target. The following table highlights various options supported in the move statement.

Statement	Example Description	Example Syntax
Move to Element move "xpath" to "xpath";	Move statement with simple XPath reference.	<pre>move "acct/totalBalance" to "parm/formattedValue";</pre>
NOTE: An XPath expression is surrounded by double quotes.	Move statement with XPath concatenate function.	<pre>move "concat(person/ firstName, ', ', person/lastName)" to "parm/fullName";</pre>
	Move statement with XPath substring-before function.	<pre>move "substring-before(parm/ fullName, ', ')" to "person/firstName";</pre>
	Move statement with XPath substring-after function.	<pre>move "substring-after(parm/ fullName, ', ')" to "person/lastName";</pre>
	Move statement with XPath substring function.	<pre>move "substring(parm/date,1,4)" to "parm/year";</pre>
Move to Element move 'literal' to "xpath";	Move statement using a literal string.	<pre>move 'okay for mailing' to "account/ preferences[type="mail"]/text";</pre>
Move to Element move 'Boolean' to "xpath";	Move statement with Boolean as literal string.	<pre>if ("account/balance > 0") move 'true' to "account/hasDebitBalance"; end-if;</pre>
	Moving an expression, which results in a Boolean. Note that the filter in the example below is located on a group node.	<pre><schema> <account> <hasDebitBalance type="boolean"/ > <balance/> </account> </schema></pre> <pre>move "boolean(account[balance>0])" to "account/hasDebitBalance";</pre>
Move to Group move "xpath" to "xpath";	Move a set of elements from one group with another. The system matches the initial level of element names and the group / list names from the source schema to the target schema. For lists and groups, the default behavior is to move all elements within the source group / list to the target group / list (even if they are not defined in the target group / list). The business service F1-MoveByName may be used for more granular control of the move	<pre>move "account/ custInfo" to "person";</pre> <p>This statement is equivalent to the following statement:</p> <pre>move "account/custInfo/ *" to "person/*";</pre>

Statement	Example Description	Example Syntax
	(without having to define each individual move statement).	
Move using a Temporary Variable	When moving to a temporary local variable, it is not surrounded by double quotes. move "xpath" to \$variable;	<pre>move "count(Person/names/ personName) + count(Person/ids/personId) " to \$PersonChildCount;</pre>
	When moving from a temporary variable, the variable is surrounded by double quotes. move "\$variable" to "xpath";	<pre>move "\$AccountBalance" to "parm/formattedValue";</pre>
Move using a Context Variable move "xpath" to \$\$variable; move \$\$variable to "xpath";	Context variables, source or target, are referenced without any double quotes.	<pre>move 'context value' to \$\$contextVariable; // // here, we move from a context variable. move \$\$contextVariable to "MarketMessage/sender";</pre>
Move using a Dynamic Location move "xpath" 'literal' to evaluate("xpath" \$variable); move evaluate("xpath" \$variable) to "xpath" \$variable;	The evaluate statement allows your move source or target location to be dynamically derived from a variable or schema element location.	<pre>move 'literal' to evaluate("schemaLocation"); // move "schemaLocation" to evaluate(\$Variable); move evaluate("schemaLocation") to \$Variable; // move evaluate(\$Variable) to "schemaLocation";</pre>
Move escape move escape("xpath" \$variable) to "xpath" \$variable;	Move escape is only available for service scripts and plug-in scripts. The escape statement scans your source text value for HTML content and escapes it, i.e. replaces any HTML-like characters with special characters that are escaped from HTML rendering. By doing so the text would be displayed as plain text when displayed as part of an HTML element. NOTE: You should only use this function if the text is to be displayed as part of an HTML element and is suspected to contain HTML-like characters or even malicious HTML that should not be rendered as HTML. If incorrectly displayed using a non HTML element, the special escape characters, if any would be visible as part of your text. Refer to the UI Map Attributes and Functions for more information on how to define an element to display HTML content.	<pre>move escape("schemaLocation") to \$Variable; // move escape(\$Variable) to "schemaLocation";</pre>
Move null move null to "xpath";	You can remove information from the XML instance document through the special syntax of move 'null'. Note that you can specify either a node name in the XPath expression or a group name. If you specify a group then the group and all child elements will be eliminated from processing.	Remove a node and all of its child nodes: <pre>if ("boolean(customer/ securityEnabled)") goto updateInfo; else move null to "customer"; end-if;</pre>

Statement	Example Description	Example Syntax
		Remove all child nodes of a group node with the suffix '/*'. <pre>if ("boolean(customer/ securityEnabled)") move null to "customer/*"; end-if;</pre>

Go To Statement

The edit data step supports functionality analogous to the [Go To](#) step type. The syntax is **goto label;** where the label represents another location within the edit data text field (identified by this label) or represents another step in the script.

The following is an example of going to another location in the same step identified by the label **addSpouse**.

```
if ( "string(parm/spouse/name) != $BLANK" )
  goto addSpouse;
end-if;
addSpouse: invokeBO 'Person' using "parm/spouse" for add;
```

The following is an example of going to a different step within the same script. The step sequence is the reference used as the label.

```
if ( "string(parm/spouse/name) != $BLANK" )
  goto 110;
end-if;
.
.
.
110: invokeBO 'Person' using "parm/spouse" for add;
```

Conditional Branch Statement

The edit data step supports functionality analogous to the [Conditional Branch](#) step type. The syntax is **branch (“xpath”) goto label else label;** where:

- The XPath condition in the **branch** statement must evaluate to a Boolean value of True or False.
- The targets for the **goto** and **else** statements are labels that represent another location within the edit data text field (identified by this label) or represent another step in the script.

The following example uses labels for **addSpouse** and **addAccount**

```
branch ( "string(parm/spouse/name) != $BLANK" ) goto addSpouse else addAccount;
```

If Statement

The **if** statement is similar to the conditional branch statement. Either can be used to structure the logic of your script. This statement may optionally include an **else** statement but it should always end with an **end-if** statement.

NOTE: This is an example of a statement that is not represented as a separate step type. It is only available within the edit data text.

The syntax is **if (“xpath”) else end-if;**. The XPath condition must evaluate to a Boolean value of True or False. The following are some examples.

Example where the XPath contains a simple logical condition.

```
if ( "string(parm/spouse/name) != $BLANK" )
  //
  // Create spouse since spouse name present
  goto addSpouse;
else
  //
  // Create account without spouse
```

```
goto addAccount;
end-if;
```

Example where the XPath contains a complex condition.

```
if ("string(parm/spouse/name) != $BLANK and string(parm/hasSpouse) = true or boolean(parm/requireSpouse)")
//
// Create spouse since spouse name present
goto addSpouse;
end-if;
```

Example of a stacked set of statements used to evaluate multiple possible values of a field.

```
if ("parm/rowCount = 0")
//
// no rows found
goto quit;
end-if;
if ("parm/rowCount = 1")
//
// one row found
goto process;
end-if;
if ("parm/rowCount > 1")
//
// more than one row found
goto quit;
end-if;
quit: terminate;
```

The following XPath shows Boolean based on the existence of the node. In this example, if the node exists in the XML instance document being processed, the statement will evaluate to True. If no element is found, the statement evaluates to false.

NOTE: When treating XPath nodes as Boolean variables be aware that an empty node evaluates to True. Only a missing node return False.

```
if ("boolean(parm/spouse/name)")
goto addSpouse;
else
//
// Create account without spouse
goto addAccount;
end-if;

if ("not(parm/spouse/name)")
//
// Create account without spouse
goto addAccount;
else
goto addSpouse;
end-if;
```

For Statement

The **for** statement creates a list of nodes or values depending on your XPath expression. If you specify a list node then every child node of the list, along with its contents, will be available within the loop. If you specify a child node directly, then a list of values only will be available within the loop.

NOTE: For more information on creating new entries in a list, please refer to the [creating a new list instance](#) example.

NOTE: This is an example of a statement that is not represented as a separate step type. It is only available within the edit data text.

The syntax is **for (\$variable in "xpathList") end-for**; The XPath condition must evaluate to a Boolean value of True or False.

The following examples are based on this sample schema:

```
<schema>
  <SAList type="list">
    <id/>
    <balance/>
  </SAList>
  <SAContributor type="list">
    <id/>
  </SAContributor>
</schema>
```

Example that specifies the list node in the XPath expression where all child nodes are available for processing.

```
move "0" to $AccountBalance;
move "0" to $index;
for ($SAList in "SAList")
  move "$SAList/balance + $AccountBalance" to $AccountBalance;
  //
  // keep track of each SA contributing to the balance in the SA Contributor list
  move "1 + $index" to $index;
  move "$SAList/id" to "SAContributor[$index]/id";
end-for;
```

Example that specifies a child node within the list node in the XPath expression. Only values of that node are available for processing.

```
move "0" to $AccountBalance;
for ($SABalance in "SAList/balance")
  move "$SABalance + $AccountBalance" to $AccountBalance;
end-for;
```

Example that shows that a filter can be used to limit the rows selected by the **for** loop.

```
move "0" to $AccountDebitBalance;
for ($SAList in "SAList[Balance>0]")
  move "$SAList/balance + $AccountDebitBalance" to $AccountDebitBalance;
end-for;
```

Example that shows the use of a filter when specifying child nodes.

```
move "0" to $AccountCreditBalance;
for ($SABalance in "SAList[Balance<0]/balance")
  move "$SABalance + $AccountCreditBalance" to $AccountCreditBalance;
end-for;
```

List Processing

This section provides details about processing lists. The examples in this section reference the following schema:

```
<schema>
  <parm type="group">
    <name/>
  </parm>
  <Person type="group">
    <names type="list">
      <type/>
      <name/>
    </names>
  </Person>
</schema>
```

Referencing a List Element. You can move a value to a particular list instance by referencing an identifying node in the list within a filter. The syntax is **move "xpath" to "xpathList[filter]/element"**; Example:

```
move "parm/name" to "Person/names[type='main']/name";
```

Creating a New List Instance. A special notation can be used within a move target statement to indicate a new list instance should be created. The "+" indicates to the script processor that a new instance of a list should be initiated for the target element. The syntax is **move "xpath" to "+xpathList"**; Example:

```
move "parm/name" to "Person/+names/name";
```

Deleting a List Instance. An XML list entry can be deleted from the database by moving an action attribute of 'delete' to the element name. To cause a database delete of a list entry requires an attribute of action="delete" in the target node and a subsequent update BO interaction. The syntax is **move 'delete' to 'xpathList@action'**); Example:

```
if ("parm/action = 'd'")
  move "0" to $index;
  for ($CCList in "CCList")
    move "1 + $index" to $index;
    if ("CCList/id = parm/id")
      move 'delete' to "CCList[$index]@action";
      goto update;
    end-if;
  end-for;
end-if;
```

The following shows the resulting XML.

```
<root>
  <CCList>
    <id>9876538976</id>
    <balance>309.98</balance>
  </CCList>
  <CCList action="delete">
    <id>4321125899</id>
    <balance>87.45</balance>
  </CCList>
</root>
```

NOTE: Deleting a list instance through use of the action attribute is risky if iterative BO interactions are required. The XML document that contains the list instance to be deleted will not be altered after a successful BO interaction, which means the document will still contain the list instance even though it no longer exists. To solve this problem, it is essential to re-read the BO after any BO update where the action attribute of 'delete' has been used.

NOTE: An alternative to the delete attribute described here, is to use the BO action of [replace](#). Manipulating a list to use the replace action avoids the problem described above concerning stale information in request documents post BO update.

Functions for Processing a List

XPath provides several functions that are useful to process elements of a list including **count**, **sum** and **last**.

The following examples are based on this sample XML document:

```
<xml>
  <ft>
    <type>bill</type>
    <date>20100101</date>
    <amt>30.30</amt>
    <cat>tax</cat>
  </ft>
  <ft>
    <type>adj</type>
    <date>20100301</date>
    <amt>20.20</amt>
    <cat>int</cat>
  </ft>
  <ft>
    <type>bill</type>
    <date>20100201</date>
    <amt>10.10</amt>
    <cat>tax</cat>
```

```
</ft>
</xml>
```

The following is an example of a sum. The syntax is **move "sum(xpathList/element)" to \$variable**; The example sums the total balance.

```
move "sum(ft/amt)" to $TotalBalance;
```

The following is an example of a sum using a filter to get a subtotal. The example sums the balance of the entries that have the 'tax' category.

```
move "sum(ft[cat='tax']/amt)" to $TaxBalance;
```

The following is an example of a count. The syntax is **move "count(xpathList)" to \$variable**; The example finds the count of the number of FT entries in the list.

```
move "count(ft)" to $TranCount;
```

The following is an example of 'last', which is used to locate the last entry. The syntax is **move "last(xpathList)" to \$variable**; The example finds the last amount in the FT list.

```
move "ft[last()]/amt" to $LastAmount;
```

Declare and Invoke Schema Based Objects

You can invoke a business object, business service or service script within the edit data step. To support the dynamic invoke, a dynamic data area name can be declared.

The schema being declared may be a business object (BO) schema, a business service (BS) schema, a service script (SS) schema, data area (DA) schema or a UI map schema. The declare statement will differ based on the type of schema, but the syntax is analogous.

- **declareBO 'BO Name' | \$variable | "xpath" as 'DynamicDataArea';**
- **declareBS 'BS Name' | \$variable | "xpath" as 'DynamicDataArea';**
- **declareSS 'SS Name' | \$variable | "xpath" as 'DynamicDataArea';**
- **declareDA 'DA Name' | \$variable | "xpath" as 'DynamicDataArea';**
- **declareMap 'Map Name' | \$variable | "xpath" as 'DynamicDataArea';**

When invoking a BO, BS or SS, the name of the object can be specified as a literal or it can be a value contained within an element or a variable. For every Invoke, you must supply an XPath reference to a group name.

When invoking a business object, an action must be supplied. The syntax is **invokeBO 'BO Name' | \$variable | "xpath" using "xpath" for action**; The valid actions are as follows:

- **read.** This action reads the current view of the BO data.
- **add.** This action will add the object and read and return the resulting view of the BO.
- **fastAdd.** This action will add the object but does not perform a subsequent 'read' to return the resulting view of the BO. This option is better than add for performance purposes if there is no reason to re-read the record.
- **update.** This action will update the object and read and return the resulting view of the BO. This action executes a 'merge' of the information specified in the invoke statement's request XML document with existing BO data. Using this action allows the script to only indicate the elements that are changing.
- **fastUpdate.** This action will update the object but does not perform a subsequent 'read' to return the resulting view of the BO. This option is better than update for performance purposes if there is no reason to re-read the record.
- **delete.** This action deletes the object.
- **replace.** This action is an alternate to the update action. The replace action completely replaces existing BO data with the information in the request document. Typically, the replace action is used when a BO contains a list because it is easier to simply replace all instances of a list rather than attempt a list merge, which requires special logic to [delete a list instance](#) explicitly.

NOTE: The replace action must be used when using the UI map functionality to [Upload a CSV File](#).

NOTE: The replace action is currently not supported for any maintenance object that is maintained in a 'fixed' page that uses a list metaphor to show all the records in the page at once. Currency is an example of this type of page.

Examples:

```
invokeBO 'BusinessObject' using "dataArea" for fastAdd;
invokeBO $variableBO using "dataArea" for fastUpdate;
invokeBO "daName/boElement" using "dataArea" for replace;
```

The syntax of the invoke statements for both a business service and service script are similar. The BS / SS is specified along with the XPath reference to the group name:

- **invokeBS 'BS Name' | \$variable | "xpath" using "xpath";**
- **invokeSS 'SS Name' | \$variable | "xpath" using "xpath";**

The examples use the **invokeBS** statement but the statements are similar for the **invokeSS** statement.

```
invokeBS 'BusinessService' using "dataArea";
invokeBS $variableBS using "dataArea";
invokeBS "daName/bsElement" using "dataArea";
```

BO Warnings. Note that for BPA scripting, the **invoke** statements may also indicate how to handle warnings.

Syntax	Description	Examples
with warn asError	Indicates that a warning should be treated as an error displayed in the UI map. The text asError is optional.	<pre>invokeBO 'BusinessObject' using "dataArea" for add; invokeSS 'ServiceScript' using "dataArea" with warn asError;</pre>
with warn popup	Indicates that a warning should be presented in the standard framework popup. In this scenario, the user is presented with standard OK and Cancel buttons. If the user clicks OK, it means that the process should continue. If the user clicks Cancel, the processing should discontinue. This is the recommended setting.	<pre>invokeBS "daName/bsElement" using "dataArea" with warn popup;</pre>
with warn suppress	Indicates that a warning should be suppressed. This is the default if no warning syntax is added to the invoke statement.	<pre>invokeBS "daName/bsElement" using "dataArea" with warn suppress; invokeSS 'ServiceScript' using "dataArea";</pre>

NOTE: For service scripts, all objects invoked from the service script will inherit their warning level. Therefore, if the service script is invoked **with warn**, all nested invoke statements will also be invoked **with warn**.

For BPA scripts, there should also be logic following the invocation to handle errors and warnings (if **with warn as popup** is used). The system variable **\$WARNING** is set to **true** if the user has clicked the Cancel button in the warning popup. If a map was shown, the logic should redisplay the map (where the warning message will be redisplayed.) This allows the user to potentially make changes and save again. If no map was shown prior to the warning, then the logic should terminate.

The system variable **\$ERROR** indicates that an error was received. If a map was shown prior to the error, then the logic should redisplay the map where the error will be shown. If no map was shown, then the product provides a BPA Script **F1-HandleErr** that should be used to display the error. The following is an example of typical error handling logic.

```
invokeBO "F1-DetermineBo/output/bo" using "boSchema" for update with warn popup;
```

```

if ("WARNING")
  if ("map_schema/action = 'DEL'")
    terminate;
  else
    goto maintMap;
  end-if;
end-if;
if ("ERROR")
  if ("map_schema/action != 'DEL'")
    goto maintMap;
  else
    transferControl 'F1-HandleErr';
  end-if;
end-if;

```

System and Global Variables

The following tables highlight system and global variables available for script writing.

System Variables - All Script Types

The following system variables are available for all script types (service scripts, plug-in scripts, and BPA scripts).

Variable	Description	Example
\$BLANK	Represents an empty node.	<pre> if ("string(parm/spouse/name) != \$BLANK") goto addSpouse; end-if; </pre>
\$CURRENT-DATE	<p>Represents the current date.</p> <p>For BPA scripts, this is the browser date.</p> <p>For server scripts this is the server date (and is affected by the system date override logic).</p>	<pre> move "\$CURRENT-DATE" to \$tempDate; </pre>
\$CURRENT-STD-DTTM	Represents the current date-time expressed in standard time (meaning without any adjustments for summer time / daylight savings time).	<pre> move "\$CURRENT-STD-DTTM" to \$tempDateTime; </pre>
\$DEVICE-OS	Represents the user's device operating system.	<pre> move "\$DEVICE-OS" to \$tempDeviceOs; </pre>
\$DEVICE-BROWSER	Represents the user's device browser.	<pre> move "\$DEVICE-BROWSER" to \$tempDeviceBrowser; </pre>
\$DEVICE-DISPLAY-TYPE	Represents the user's device screen display type whether it is Desktop size or Medium or Small size. Returned values may be like oraDesktop, oraTablet and oraPhone.	<pre> move "\$DEVICE-DISPLAY-TYPE" to \$tempDeviceDisplayType; </pre>
\$DEVICE-INFO	Provides the combination of all three device properties (DEVICE-OS, DEVICE-BROWSER and DEVICE-DISPLAY-TYPE) and each property value is separated by semi-colon.	<pre> move "\$DEVICE-INFO" to \$tempDeviceInfo; </pre>

System Variables - BPA Scripts Only

The following system variables are only available / applicable for BPA script types.

Variable	Description	Example
\$DOUBLE_QUOTE	Represents a double quote.	<code>move "\$DOUBLE_QUOTE" to \$tempField;</code>
\$SINGLE_QUOTE	Represents an apostrophe.	<code>move "\$SINGLE_QUOTE" to \$tempField;</code>
\$SPACE	Contains a single space value.	<code>move "\$SPACE" to \$tempField;</code>
\$SYSTEM-DATE	Represents the server date. Note that this date is affected by the system date override logic)	<code>move "\$SYSTEM-DATE" to \$tempDate;</code>

System Variables - Server Scripts Only

The following system variables are only available / applicable for service script and plug-in script types.

Variable	Description	Example
\$ADDITIONAL-IP-INFO	An HTTP request includes an "additional IP address" header field. This may be populated by an implementation if there is some information available on the proxy server or load balancer, such as the originating IP address.	<code>move "\$ADDITIONAL-IP-INFO" to "parm/request/headerIpAddress";</code>
\$CURRENT-DTTM	Represents the current date-time.	<code>move "\$CURRENT-DTTM" to \$tempDateTime;</code>
\$F1-INSTALLATION-TIMEZONE	Represents the time zone code defined on the installation options .	<code>move "\$F1-INSTALLATION-TIMEZONE" to \$timeZone;</code>
\$LANGUAGE	Represents the language code the script is using. Typically this is the user's default language.	<code>move "\$LANGUAGE" to \$tempLanguage;</code>
\$PROCESS-DATE	Represents the process date. The process date differs from the current date because the process date will remain consistent throughout the duration of the process being executed. For example, if a service script stores several business objects – the process date is initialized at the start of the service script execution and each business object will have the same process date defaulted. The current date, especially the current date time, will reflect the actual time of processing.	<code>move "\$PROCESS-DATE" to \$tempDate;</code>
\$PROCESS-DTTM	Represents the process date-time. Note that the process date and time is initialized at the start of a particular process and will not reflect the exact date and time of an update.	<code>move "\$PROCESS-DTTM" to \$tempDateTime;</code>
\$REQUESTING-IP-ADDRESS	Represents the IP address from the HTTP request. Note that if the request is routed through a proxy server or load balancer, this IP address is be the IP address of the proxy or load balancer, not the IP address of the end user. Refer to the \$ADDITIONAL-IP-INFO variable for information.	<code>move "\$REQUESTING-IP-ADDRESS" to "parm/request/systemIpAddress";</code>
\$USER	Represents the user ID of the user executing the script.	<code>move "\$USER" to \$tempUser;</code>

Variable	Description	Example
		For BPA scripts that need to know the user ID of the current user, refer to Useful Tips and Tricks .

Global Variables

BPA scripts and service scripts have access to the values defined in [Global Context](#).

When a BPA script is launched from the user interface, these variables will be automatically initialized. They may be referenced with a single dollar sign in front of the field name. For example if PER_ID is a supported global variable, then \$PER_ID can be referenced within the BPA script:

```
move "$PER_ID" to "schema/customerId";
```

For service scripts, global variables may only be referenced if the service script has been invoked directly from a BPA script or a zone on a portal. When a service script is invoked from a BPA script or portal zone, it will have access to the suite of global context variables populated in the UI session. For service scripting, the global fields must be prefixed by two dollar signs (instead of one like in BPA scripting). For example if PER_ID is a supported global context variable, then \$\$PER_ID can be referenced within the service script.

```
move $$PER_ID to "schema/customerId";
```

NOTE: As described in [Context Variables](#), a service script may declare context variables that use the same two dollar sign syntax.

Perform Script and Transfer Control Statements

The edit data step supports functionality analogous to the [Perform script](#) step type and the [Transfer Control](#) step type. These are both applicable only to BPA scripts.

Syntax	Valid Values	Comments
performScript	'BPA Script Name'	Script to perform is explicitly provided.
	\$Variable	Script to perform is found in a variable.
	"XPath"	Script to perform is found in an element, referenced by its XPath.
transferControl	Analogous to the performScript statement	

NOTE: When the script named in the **performScript** statement has finished, control will be returned to the calling BPA script. When the script named in the **transferControl** statement has finished, you will not be returned to the calling script, complete control will be granted to the transferred to script.

Navigate Statement

The edit data step supports functionality analogous to the [Navigate to a page](#) step type. This is applicable only to BPA scripts.

Syntax	Valid Values	Comments
navigate	'Navigation Code'	Navigation option is explicitly provided.
	\$Variable	Navigation option is found in a variable.
	"XPath"	Navigation option is found in an element, referenced by its XPath.

In addition, the edit data step supports the ability to indicate that the dashboard should be refreshed when navigating. This is only applicable to BPA scripts.

Syntax	Valid Values
navigateAndReloadDashboard	Analogous to the navigate statement

Declare BO with BO Group

This statement is specific to BPA scripts that plan to use the base script Main BO Maintenance Processing (**F1–MainProc**) for its Generate Edit Map statements. This script expects that the data used to display in the map is within a **boGroup** tag.

Syntax	Valid Values	Comments
declareBOWithBOGroup	'BO Name'	BO is explicitly provided.
	\$Variable	BO is found in a variable.
	"XPath"	BO is found in an element, referenced by its XPath.

The following table highlights additional syntax for this statement.

Syntax	Valid Values
as	'Dynamic Schema Name'

Examples:

```
declareBOWithBOGroup 'BusinessObject' as 'newMapSchema';
declareBOWithBOGroup $variableBO as 'newMapSchema';
declareBOWithBOGroup "daName/boElement" as 'newMapSchema';
```

Invoke Map Statement

The edit data step supports functionality analogous to the [Invoke map](#) step type. This is applicable only to BPA scripts.

Syntax	Valid Values	Comments
invokeMap	'Map Name'	UI Map is explicitly provided.
	\$Variable	UI Map is found in a variable.
	"XPath"	UI Map is found in an element, referenced by its XPath.

The following table highlights additional syntax for this statement.

Syntax	Valid Values	Comments
using	"Data Area group name"	Indicates the data area to be passed to and from the server when rendering the HTML form associated with the map.
target	bpa	
	page	
	popup	

Refer to the [Invoke map](#) step type for more information about the **target** values.

If the UI map is configured to return a value, then it can be evaluated using the **\$MAP-VALUE** variable.

```
invokeMap 'UI Map' using "dataArea";  
  
invokeMap $variableMap using "dataArea";  
  
invokeMap "daName/mapElement" using "dataArea" target bpa;  
  
// $MAP-VALUE is a variable returned by the invoked map.  
if ("$MAP-VALUE='continue' ")  
    goto 300;  
else  
    terminate;  
end if;
```

Generate Edit Map Statements

The 'generate edit map' statements are used to dynamically generate and launch a UI edit map based on a schema definition. The schema used may be a BO schema, a BS schema, an SS schema or a DA schema. This is applicable only to BPA scripts. The generate statement will differ based on the type of schema, but the syntax is analogous.

Syntax

generateBOEditMap

generateBSEditMap

generateSSEditMap

generateDAEditMap

The BO code / BS code / SS code / DA code may be specified using a literal (surrounded by single quotes), as a temporary variable or by referencing an XPath schema location (surrounded by double quotes).

The following table highlights additional syntax for this statement.

Syntax	Valid Values	Comments
using	"Data Area group name"	Indicates the data area to be passed to and from the server when rendering the HTML form associated with the map.
target	bpa page popup	

The target values indicate where the generated map should be displayed as described in the [Invoke map](#) step type. If the UI map is configured to return a value, then it can be evaluated using the **\$MAP-VALUE** variable.

The examples use the **generateBOEditMap** but the statements are similar for the other schema types.

```
generateBOEditMap 'BO Name' using "dataArea";  
  
generateBOEditMap $variableMap using "dataArea";  
  
generateBOEditMap "daName/mapElement" using "dataArea" target bpa;  
  
// $MAP-VALUE is a variable returned by the invoked map.  
if ("$MAP-VALUE='continue' ")  
    goto 300;  
else  
    terminate;  
end if;
```

Terminate Statement

The edit data step supports functionality analogous to the [Terminate](#) step type.

The following is an example of a simple **terminate** step that will stop the script.

```
if ( "not (parm/spouse/name) " )
  terminate;
else
  goto addSpouse;
end-if;
```

The **terminate with error** statement is only available in a service script.

NOTE: For issuing an error from a BPA script refer to [Useful Tips and Tricks](#).

Syntax	Attributes	Comments
terminate with error (x, y %n= element=)	'x' represents the message category	Required.
	'y' represents the message number	Required.
	%n="Element XPath" or %n='literal'	Specify the substitution parameters supported by the message using either literal values or XPath references. When the value to substitute is an element within a list, use the XPath of the element within the list qualified by the list occurrence.
	element='Element XPath' or element=\$variable	Optionally specify an element name within a UI map to highlight as part of the error. When the element in error is within a list, use the XPath of the element within the list qualified by the list occurrence.

Example of a simple field:

```
if ( "string(customer/lastName) = $BLANK" )
  terminate with error (8000, 1001 %1="customer/
lastName" %2='Last name required' element='customer/lastName');
end-if;
```

Example of terminate where the element to mark is in a list:

```
for ($list in "parm/hard/newBusinessObject/listName")
  if /** check some condition for elementName
    terminate with error (11000, 11000 %1="$list/elementName" element='$list/elementName');
  end-if;
end-for;
```

FASTPATH: For more information on presenting errors in a UI map, please refer to [Display Errors](#).

Invoking Groovy Code

If you have a plug-in script or a service script that mixes XPath scripting and Groovy scripting, the edit data step supports the ability to invoke Groovy code using the syntax **invokeGroovy 'method'**; where 'method' is the name of a method defined in a **Groovy Members** step within the script. Only methods that do not receive arguments and return void can be invoked in this way. However, the method invoked from the edit data step can be supported by additional Groovy code in other **Groovy Members** step types.

Example Edit Data step:

```
invokeGroovy 'invoke';
```

Example Groovy Members step:

```
void invoke() {
    initParms()
    readBO()
    initConfig()
    retrieve()
    updateBO()
}
```

NOTE: As mentioned in [Using Groovy Within Scripts](#), if this is a plug-in script and the code is only Groovy, you should use the **Groovy** script engine version rather than the above technique. This is considered more efficient as it avoids the conversion of the data to and from the XML interface.

Debugging a BPA Script

If a BPA script has height greater than zero, then selected nodes of the script's data area can be displayed at runtime. The XML data is displayed during script execution within the BPA script's display area. Specify the XPath of an XML node from any of the BPA script's data areas, between the paired characters: '%+' and '+%'.

For example, the entire contents of the schema group node named 'input', and the specific contents of the schema element named 'output/status' will be displayed in the BPA script's display area. The debug text must be entered into the BPA script's text area and not within the script's edit data field. Debug text can be declared for any explicit step of the script.

```
display input: %+input+% , and output status: %+output/status+%
```

Useful Tips and Tricks

This section provides some suggestions about how to implement some common logic.

Finding the Logged In User in a BPA

For server based scripts, the **\$USER** variable is populated with the current logged in user. This variable is not available for BPA scripts. The BPA can call the service script **F1-GetUser** if this information is needed.

Issuing an Error from a BPA script

For server based scripts, you use the **terminate with error** statement to return an error message to display to the user. The BPA can display that error by transferring control to **F1-HandleErr** as described in the [Declare and Invoke Schema Based Objects](#). This is not supported in a BPA script. A technique that is available to a BPA for issuing an error is to call the business service **F1-RethrowError** passing the error details. This business service populates the appropriate system error fields needed to issue the error. Then transfer control to **F1-HandleErr**.

```
if ("string($assignedToUser) != string(F1-GetUser/user)")
    declareBS 'F1-RethrowError' as 'errorMsg';
    move '11010' to "errorMsg/messageCategory";
    move '11511' to "errorMsg/messageNumber";
    move "$toDoEntryId" to "errorMsg/messageParameters/+parameters/parameterValue";
    invokeBS 'F1-RethrowError' using "errorMsg";
    transferControl 'F1-HandleErr';
end-if;
```

Go To Steps

Go to steps allow you to jump to a step other than the next step. Additional fields required for **Go To** steps:

Next Step defines the step to which the script should jump.

Height Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Height steps are used to change the height of the script area to be larger or smaller than the standard size.

The following additional fields are required for **Height** steps:

Script Window Height defines the number of **Pixels** or the **Percentage** (according to the **Height Unit**) that the script window height should be adjusted. The percentage indicates the percentage of the visible screen area that the script area uses. For example, a percentage value of **100** means that the script area will use the entire area.

NOTE: Standard Number of Pixels. The default number of pixels used by the script area is **75**.

NOTE: Adjust script height in the first step. If you want to adjust the height of the script area, it is recommendation to define the **height** step type as your first step. Otherwise, the script area will open using the standard height and then readjust, causing the screen to redisplay.

NOTE: Hide script area. You could use this type of step to set the height to **0** to hide the script area altogether. This is useful if the script does not require any prompting to the user. For example, perhaps you define a script to take a user to a page and with certain data pre-populated and that is all.

NOTE: Automatically close script area. If you want the script area to close when a script is completed, you could define the final step type with a height of 0.

Input Data Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Input data steps cause the user to be prompted to populate an input field in the script area. The input value can be saved in a field on a page or in temporary storage. A **Continue** button always appears adjacent to the input field. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Input Data** steps:

Destination Field Type and **Destination Field Name** define where the input field will be saved. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Page Data Model.** Use this field type to put the input field into a field that resides on any of the tab pages in the [object display area](#) (i.e., the field populated doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Temporary Storage.** Use this field type to put the input field into temporary storage. Use **Field Name** to name the field in temporary storage. Refer to [How To Name Temporary Storage Fields](#) for more information.
- **User Interface Field.** Use this field type to put the input field into a field that resides on the currently displayed tab page. Note, if you want to execute underlying default logic, you must populate a **User Interface Field**. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

The **Prompt Values** grid may be used to define additional buttons. A separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.
- **Sequence** controls the order of the buttons.
- **Next Script Step** defines the step to execute if the user clicks the button.

Invoke Business Object Steps

Invoke business object steps allow you to interact with a [business object](#) in order to obtain or maintain its information.

The following additional fields are required for **Invoke business object** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts. Refer to [BO warnings](#) for more information about handling warnings when invoking a BO.

Group Name references the [data area](#) to be passed to and from the server when communicating with the **Business Object**. Indicate the **Action** to be performed on the object when invoked. Valid values are **Add, Delete, Fast Add (No Read), Fast Update (No Read), Read, Replace, Update**.

FASTPATH: Refer to [BO Actions](#) for more information about the various actions.

The business object call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script, to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in [global variables](#). This field is only applicable to BPA scripts.

NOTE: Error technique. Let's assume a scenario where a business object is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Invoke Business Service Steps

Invoke business service steps allow you to interact with a [business service](#).

The following additional fields are required for **Invoke business service** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts.

Group Name references the [data area](#) to be passed to and from the server when the **Business Service** is invoked.

The business service call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script, to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in [global variables](#). This field is only applicable to BPA scripts.

NOTE: Error technique. Let's assume a scenario where a business service is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful

to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Invoke Function Steps

NOTE: Functions were implemented prior to the introduction of business services (BS), service scripts (SS) and business objects (BO). The functionality is still supported, but the recommendation for implementations going forward is to use a step that invokes one of the above configuration tool objects in a script rather than defining a function.

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Invoke function steps may be used to retrieve or update data independent of the page currently being displayed. For example, if you design a script that takes different paths based on the customer's customer class, you could invoke a function to retrieve the customer's customer class.

FASTPATH: You must set up a function before it can be referenced in a script. Refer to [Maintaining Functions](#) for the details.

The following additional fields are required for **Invoke Function** steps:

Function defines the name of the function. The function's **Long Description** is displayed below.

When a function is invoked, it will either be successful or return an error. The next two fields control the step to which control is passed given the outcome of the function call:

- **If Success, Go to** defines the step that is executed if the function is successful.
 - **If Error, Go to** defines the step that is executed if the function returns on error. Refer to [How To Use Constants In Scripts](#) for a list of the global variables that are populated when a function returns an error.
-

NOTE: Error technique. If a function returns an error, we recommend that you invoke a step that transfers control to a script that displays the error message information and stops (note, the error information is held in [global variables](#)). You would invoke this script via a **Transfer Control**.

The **Send Fields** grid defines the fields whose values are sent to the function and whose field value source is not **Defined On The Function**. For example, if the function receives an account ID, you must define the name of the field in the script that holds the account ID.

- **Field** contains a brief description of the field sent to the function.
- **Source Field Type** and **Mapped Field / Value** define the field sent to the function. Refer to the description of Source Field under [How To Set Up Move Data Steps](#) for a description of each field type.
- **Comments** contain information about the field (this is defined on the function).

The **Receive Fields** grid defines the fields that hold the values returned from the function. For example, if the function returns an account's customer class and credit rating, you must set up two fields in this grid.

- **Field** contains a brief description of the field returned from the function.
- **Destination Field Type** and **Mapped Field** define the field returned from the function. Refer to the description of Destination Field under [How To Set Up Move Data Steps](#) for a description of each field type.
- **Comments** contain information about how the field (this is defined on the function).

Invoke Map Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Invoke map steps are used to invoke a **UI Map** to display, capture and update data using an HTML form. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Invoke map** steps:

Group Name references the **data area** to be passed to and from the server when rendering the HTML form associated with the **Map**.

Use **Target Area** to designate where the map will be presented.

- Select **BPA Zone** if the map should be presented within the **script area**.
- Select **Page Area** if the map should be presented in the **object display area**, i.e. the frame typically used to house a maintenance page.
- Select **Pop-up Window** if the map should be launched in a separate window.

The **Returned Values** grid contains a row for every button defined on the map.

- **Returned Value** is the value returned when the user clicks the button.
- **Use as Default** can only be turned on for one entry in the grid. If this is turned on, this value's Next Script Step will be executed if the returned value does not match any other entry in the grid. For example, if the user closes a pop-up (rather than clicking a button), the default value will be used.
- **Next Script Step** defines the step to execute if the user clicks the button.

Invoke Service Script Steps

Invoke service script steps allow you to execute a **service script**.

The following additional fields are required for **Invoke service script** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts.

Group Name references the **data area** to be passed to and from the server when the **Service Script** is invoked.

The service script call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in **global variables**. This field is only applicable to BPA scripts.

NOTE: Error technique. Let's assume a scenario where a service script is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Groovy Imports Steps

NOTE: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Imports step types provide a free format text area where you list the Groovy classes to be imported for use by the code in **Groovy Member** steps within the script.

Enter a description of the imports step in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter the list of classes to import in the **Edit Data Text** field using the syntax **import 'class'**; where 'class' is the fully qualified package name of the Groovy class. Click the adjacent icon to open a window providing more space for editing the text.

When saving a script, if the system has been configured accordingly, when the system detects references to a Groovy class that is not explicitly listed in this step, the system warns the user and adds an explicit import for that class. (If no Groovy Import step type exists for the script, one will be added.) Users should review the imported class to ensure it is the expected class, in the case of multiple classes with a similar name.

NOTE: For security, the classes that may be imported are restricted to those allowed by the Framework. The warning and automatic update to the script is controlled by a property setting. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Groovy Library Interface Steps

NOTE: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Library Interface steps are only applicable to **Groovy Library Scripts**. They provide a free format text area where you can list the Groovy methods defined within the script that are available for use by other scripts.

Enter a description of the interface step in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter the list of interface methods in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for editing the list.

NOTE: Every **Groovy Library Script** must have one and only one step of type **Groovy Library Interface**. The supporting code for the available methods is defined using one or more **Groovy Member** steps in the same script. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Groovy Member Steps

NOTE: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Member steps provide a free format text area where you can enter Groovy code.

Enter a description of the code block in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter your code in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for editing the code.

NOTE: While it is possible to set up multiple steps of type **Groovy Member** the system treats these steps as a single class for compilation and execution purposes. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Label Steps

Label steps allow you to describe what the next step(s) are doing. Steps of this type are helpful to the script administrators when reviewing or modifying the steps in a script, especially when a script has many steps. When designing a script, the label steps enable you to provide a heading for common steps that belong together. The script tree displays steps of this type in a different color (green) so that they stand out from other steps.

There are no additional fields for **Label** steps.

Mathematical Operation Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Mathematical operation steps allow you to perform arithmetic on fields. You can also use this type of step to add and subtract days from dates. For example, you could calculate a date 7 days in the future and then use this value as the customer's next credit review date. The following additional fields are required for **Mathematical Operation** steps:

Base Field Type and **Base Field Name** define the field on which the mathematical operation will be performed. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Page Data Model.** Use this field type when the field resides on any of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Temporary Storage.** Use this field type when the field resides in temporary storage. You must initialize the temporary storage field with a Move Data step before performing mathematical operations on the field. Refer to [How To Set Up Move Data Steps](#) for more information.
- **User Interface Field.** Use this field type when the field resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Math Operation controls the math function to be applied to the **Base Field**. You can specify +, -, /, and *. Note, if the base field is a date, you can only use + or -.

Math Field Type, **Math Field Name** and **Math Field Value** define the field that contains the value to be added, subtracted, divided, or multiplied. The following points describe each field type:

- **Current To Do Information.** Use this field type when the value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the value resides on any of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the value is a constant. When this field type is used, use **Source Field Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for more information. Note, if you are performing arithmetic on a date, the field value must contain the number and type of **days/ months/ years**. For example, if you want to add 2 years to a date, the source field value would be **2 years**.
- **Temporary Storage.** Use this field type when the value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the value resides in a field on the current tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Move Data Steps

Move data steps allow you to move data (from a source to a destination). The following additional fields are required for **Move data** steps:

Source Field Type, **Source Field Name** and **Source Field Value** define what you're moving. The following points describe each field type:

- **Context Variable.** Use this field type in a plug-in or service script if the source value is a variable initiated in a higher level script. This is only applicable to Service Scripts and Plug-in Scripts.
- **Current To Do Information.** Use this field type when the source value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Data Area.** Use this field type when the field being compared is one that you put into one of the script's data areas in an earlier step. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Global Context.** Use this field type when the source value is a [global context variable](#). This is only applicable to BPA Scripts.
- **Page Data Model.** Use this field type when the source value resides on any of the tab pages in the [object display area](#) (i.e., the source field doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Portal Context.** Use this field type when the source value is a variable in the portal context. This is only applicable to BPA Scripts.
- **Predefined Value.** Use this field type when the source value is a constant value defined in the script. When this field type is used, use **Source Field Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for instructions on how to use constants.

NOTE: Concatenating fields together. You can also use **Predefined Value** if you want to concatenate two fields together. For example, let's say you have a script that merges two persons into a single person. You might want this script to change the name of the person being merged out of existence to include the ID of the person remaining. In this example, you could enter a **Source Field Value** of **%ONAMEmerged into person %PERID** (where **ONAME** is a field in temporary storage that contains the name of the person being merged out of existence and **PERID** contains the ID of the person being kept). Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values to compose the field value.

- **Temporary Storage.** Use this field type when the source value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the source value resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.

Destination Field Type and **Destination Field Name** define where the source field will be moved. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Context Variable.** Use this field type in your plug-in or service script if you use a variable to communicate information to a lower level service script or schema. This is not applicable to BPA Scripts.
- **Data Area.** Use this field type when the destination field resides on one of the scripts data areas. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.

- **Page Data Model.** Use this field type when the destination field resides on any of the tab pages in the [object display area](#) (i.e., the field populated doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Portal Context.** Use this field type when the destination to be updated is in the current portal context. This is only applicable to BPA Scripts.
- **Temporary Storage.** Use this field type when the destination field resides in temporary storage. Use **Field Name** to name the field in temporary storage. Use **Field Name** to name the field in temporary storage. Refer to [How To Name Temporary Storage Fields](#) for more information.
- **User Interface Field.** Use this field type when the destination field resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.

NOTE: Conditional field types. The field types **Current To Do Information**, **Page Data Model** and **User Interface Field** are only applicable to BPA scripts.

Navigate To A Page Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Navigate to a page steps cause a new page (or tab within the existing page) to be displayed in the object display area. Steps of this type are a precursor to doing anything on the page. The following additional field is required for **Navigate to a page** steps:

Navigation Option defines the transaction, tab, access mode (add or change) and any context fields that are passed to the transaction in change mode. For example, if you want a script to navigate to Person - Characteristics for the current person being displayed in the dashboard, you must set up an appropriate navigation option. Refer to [Defining Navigation Options](#) for more information.

NOTE: Navigating to a page in update mode. Before you can navigate to a page in change mode, the page data model must contain the values to use for the navigation option's context fields. If necessary, you can move values into the page data model using a [Move Data step](#) first. For example, before you can navigate to a page in change mode with an account ID in context, you may need to move the desired account ID into the ACCT_ID field in the page data model. The actual field name(s) to use are listed as context fields on the [navigation option](#).

Perform Script Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Perform script steps cause another BPA script to be performed. After the performed script completes, control is returned to the next step in the original script. You might want to think of the scripts referred to on steps of this type as "subroutines". This functionality allows you to encapsulate common logic in reusable BPA scripts that can be called from other BPA scripts. This simplifies maintenance over the long term.

The following additional field is required for **Perform script** steps:

Script is the name of the script that is performed.

Press A Button Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Press a button steps cause a button or link text to be ‘pressed’ in the [object display area](#), the [application toolbar](#) or the [page title area](#). For example, you could use this type of step to add a new row to a person's characteristic (and then you could use a **Move Data** step to populate the newly added row with a given char type and value). The following additional fields are required for **Press a button** steps:

Button Name is the name of the button to be pressed. This button must reside on the currently displayed tab page (or in the application toolbar or page actions toolbar). Refer to [How To Find The Name Of A Button](#) for more information.

Prompt User Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Prompt user steps cause the user to be presented with a menu of options. The options can be presented using either buttons or in the contents of a drop down. You can also use steps of this type to pause a script while the user checks something out (and when the user is ready to continue with the script, they are instructed to click a prompt button). The following additional fields are required for **Prompt User** steps:

Prompt Type controls if the prompt shown in the script area is in the form of **Button(s)** or a **Dropdown**. Note, if you use a **Dropdown**, a Continue button appears adjacent to the dropdown in the script area when the step executes. The user clicks the Continue button when they are ready for the script to continue.

The **Prompt Values** grid contains a row for every value that can be selected by a user. Note, if you use a **Prompt Type of Button(s)**, a separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button or in the dropdown entry. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.
- **Sequence** controls the order of the buttons or dropdown entries.
- **Use As Default** can only be turned on for one entry in the grid. If this is turned on for a dropdown entry, this value is defaulted in the grid. If this is turned on for a button, this button becomes the default (and the user should just have to press **Enter** (or **space**) rather than click on it).
- **Next Script Step** defines the step to execute if the user clicks the button or selects the dropdown value.

Set Focus To A Field Steps

NOTE: BPA scripts only. This step type is only applicable to BPA scripts.

Set focus to a field steps cause the cursor to be placed in a specific field on a page. A **Continue** button always appears in the script area when this type of step executes. The user may click the **Continue** button when they are ready for the script to continue. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Set focus to a field** steps:

Destination Field Name defines the field on which focus should be placed. This field must reside on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

The **Prompt Values** grid may be used to define additional buttons. A separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.
- **Sequence** controls the order of the buttons.
- **Next Script Step** defines the step to execute if the user clicks the button.

Terminate Steps

Terminate steps cause a server-based script to end processing successfully or issue an error.

The following additional fields are required for **Terminate** steps:

Error indicates whether an error should be thrown or not. If error, **Error Data Text** must be specified, indicating the error message and any message substitution parameters. Refer to [Edit Data Syntax](#) the actual syntax of initiating an error message.

NOTE: The ability to terminate a step in error is only supported for server-based scripts.

Transfer Control Steps

NOTE: **BPA scripts only.** This step type is only applicable to BPA scripts.

Transfer control steps cause the current BPA script to terminate and the control to pass to another BPA script. You might want to construct a BPA script with steps of this type when the script has several potential logic paths and you want to segregate each logic path into a separate BPA script (for ease of maintenance).

The following additional fields are required for **Transfer control** steps:

Subscript is the name of the script to which control is transferred.

Additional Topics

The contents of this section provide additional information about steps.

How To Find The Name Of User Interface Fields

This section is only relevant if you are using the legacy capability of BPA scripts to bring a user to a base fixed page and populate information into fields on that page. Follow these steps to find the name of a field that resides on a fixed page:

- Navigate to the page in question.
- Right click in the body of the page.
- Select **Inspect** from the pop-up menu to display the HTML.
- In the search look for the text "Widget Info". Note that if there are multiple sections on the page, you will find multiple "Widget Info" results. Based on the details shown, you are able to confirm which section you are looking for. For example, the following is an example from the Algorithm - Main page:

```

* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_CD, IT - CI_ALG$ALG_CD - Algorithm Code
*   IM_ALG_CD, IM - $SEARCH_FOR_ALG_LBL - Search for Algorithm
*   OWNER_FLG, IS - $OWNER_FLG - Owner
*   DESCR50, IT - $DESCR50 - Description
*   IM_Main_algtypCont, IM - $F1_SHOW_ALG_CTX - Show Algorithm Context Menu
*   ALG_TYPE_CD, IT - $ALG_TYPE_CD - Algorithm Type
*   IM_ALG_TYPE_CD, IM - $SEARCH_ALGTYPE_LBL - Search for Algorithm Type
*   ALG_TYPE_DESCR50, PL - $DESCR50 - Description
*   ALG_TYPE_LONG_DESC, IA - $DESCRLONG - Detailed Description
*   IM_VerScroll_lftArrow, IM - $PREVIOUS_ALG_LBL - Previous Version
*   ALG_VER$recordCount, SN - $OF_LBL - Of
*   IM_VerScroll_rtArrow, IM - $NEXT_ALG_LBL - Next Version
*   IM_ADD, IM - $ADD_ALG_LBL - Add Version
*   IM_DEL, IM - $DELETE_ALG_LBL - Delete Version
*   ALG_VER$EFFDT, IT - $EFFDT - Effective Date
*   L_OWNER_LBL, LP - $OWNER_FLG - Owner
*   ALG_VER$OWNER_FLG, IS - $OWNER_FLG - Owner
*   resultGrid, GD

```

The field names that you'll reference in your scripts are defined on the left side of the HTML (e.g., ALG_CD, DESCR50, ALG_TYPE_CD, etc.).

The names of fields that reside in scrolls are in a slightly different format. The following is an example of the HTML for the version scroll that appears on Algorithm - Main. Notice that the fields in the scroll are prefixed with the name of the scroll plus a \$ sign. For example, the effective date is called **ALG_VER\$EFFDT**.

```

*   IM_VerScroll_lftArrow, IM - $PREVIOUS_ALG_LBL - Previous Version
*   ALG_VER$recordCount, SN - $OF_LBL - Of
*   IM_VerScroll_rtArrow, IM - $NEXT_ALG_LBL - Next Version
*   IM_ADD, IM - $ADD_ALG_LBL - Add Version
*   IM_DEL, IM - $DELETE_ALG_LBL - Delete Version
*   ALG_VER$EFFDT, IT - $EFFDT - Effective Date
*   L_OWNER_LBL, LP - $OWNER_FLG - Owner
*   ALG_VER$OWNER_FLG, IS - $OWNER_FLG - Owner

```

The names of fields that reside in grids are in a slightly different format. The following is an example of the HTML for the algorithm parameters grid that appears on Algorithm - Main. Notice that the fields in the grid are prefixed with the name of the grid plus a :x\$. For example, the algorithm parameter label is called **ALG_PARM:x\$ALG_PARM_LBL**. When you reference such a field in your script, you have the following choices:

- Substitute **x** with the row in the grid (and keep in mind, the first row in a grid is row **0** (zero); this means the second row is row **1**).
- If you want to reference the "current row" (e.g., the row in which the cursor will be placed), you can keep the **x** notation (**x** means the "current row").

```

* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_PARM:x$ALG_PARM_LBL, IL - CI_ALG_TYPE_PRM_L$ALG_PARM_LBL - Parameter
*   ALG_PARM:x$SEQNO, IL - $SEQNO - Sequence
*   ALG_PARM:x$ALG_PARM_VAL, IA - $ALG_PARM_VAL - Value
*

```

How To Find The Name Of Page Data Model Fields

You find the name of a **Page Data Model** field in the same way described under [How To Find The Name Of User Interface Fields](#). The only restriction is that you cannot refer to hidden / derived fields. However, you can refer to any of the object's fields regardless of the tab page on which they appear. For example, if you position the object display area to the Main tab of the Account transaction, you can reference fields that reside on all of the tab pages.

CAUTION: If you populate a **Page Data Model** field, none of the underlying default logic takes place. For example, if you populate a customer contact's contact type, none of the characteristics associated with the customer contact type are defaulted onto the customer contact. If you want the underlying defaulting to take place, you must populate a **User Interface Field**.

How To Find The Name Of A Button

This section is only relevant if you are using the legacy capability of BPA scripts to bring a user to a base fixed page and perform functionality by executing existing buttons on that page.

If you want a **Press a button** step to press a button or click a link in the application toolbar, use one of the following names:

Button Name

IM_GOBACK

IM_HISTORY

IM_GOFORWARD

IM_menuButton

IM_USER_HOME

IM_MY_PREF

IM_helpButton

If you want a **Press a button** step to press a button in the page actions toolbar, use one of the following names:

Button Name

IM_SAVE

IM_REFRESH

IM_CLEAR

IM_COPY

IM_DELETE

IM_ScrollBack

IM_ScrollForward

The following buttons are also supported:

Button Name

IM_TO_DO

IM_CurrentTo Do

Comments

This navigates to the [To Do Entry](#) page for the user's current To Do. Refer to [A User's Current To Do](#) for more information.

Button Name	Comments
IM_MINIMIZE_DASHBOARD	Pressing this will collapse the dashboard. Note that when a script is finished, it will return the dashboard to the state it was when the script was launched.
IM_MAXIMIZE_DASHBOARD	Pressing this will expand the dashboard. Note that when a script is finished, it will return the dashboard to the state it was when the script was launched.

Follow these steps to find the name of other buttons that reside in the object display area of a fixed page:

- Navigate to the page in question.
- Right click in the body of the page
- Select **Inspect** from the pop-up menu.
- In the search look for the text "Widget Info". Note that if there are multiple sections on the page, you will find multiple "Widget Info" results. Based on the details shown, you are able to confirm which section you are looking for.
- Iconized buttons (e.g., search buttons) are represented as HTML images and their field names are prefixed with **IM**. The following is an example of the HTML on the Algorithm - Main page (notice the **IM** fields for the iconized buttons).

```
* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_CD, IT - CI_ALG$ALG_CD - Algorithm Code
*   IM_ALG_CD, IM - $SEARCH_FOR_ALG_LBL - Search for Algorithm
*   OWNER_FLG, IS - $OWNER_FLG - Owner
*   DESCR50, IT - $DESCR50 - Description
*   IM_Main_algtypCont, IM - $F1_SHOW_ALG_CTX - Show Algorithm Context Menu
*   ALG_TYPE_CD, IT - $ALG_TYPE_CD - Algorithm Type
*   IM_ALG_TYPE_CD, IM - $SEARCH_ALGTYPE_LBL - Search for Algorithm Type
```

- Transaction-specific actions buttons are represented as switches. The following is an example of the HTML on the Batch Job Submission - Main page (notice the **SW** fields for the buttons). Note, if you want to **Set focus** to such a field, you would move a **Predefined Value** of **TRUE** to the switch.

```
*   ACTION_Q_SW, BU - $ACTION_Q_SW - Duplicate & Queue
*   ACTION_CANCEL_SW, BU - $CANCEL_SW - Cancel
```

How To Substitute Variables In Text

You can substitute field values into a step's text string. You do this by prefixing the field name whose value should be substituted in the string with a **%**. For example, the message, "On **%COMPLETION_DTTM** this bill was completed, it's ending balance was **%ENDING_BALANCE**" contains two substitution variables (the bill's completion date / time and the bill's ending balance).

To substitute the value of an element from a data area you need to reference its XPath location as follows: **%=XPath=**%. If you want to substitute the whole XML node, not just the value, you need to reference it as follows **%+XPath+%**.

Only fields linked to the [current To Do](#) and fields that reside in [temporary storage](#) and [global variables](#) can be substituted into a text string.

NOTE: You can substitute fields that reside in the User Interface or Page Data Model by first moving them into temporary storage (using a **Move data** step).

You can also substitute field values into the verbiage displayed in [prompts](#) using the same technique.

How To Use HTML Tags And Spans In Text Strings and Prompts

You can use HTML tags in a step's text string. For example, the word "Continue" will be italicized in the following text string "Press<i>Continue</i> after you've selected the customer" (the **<i>** and **</i>** are the HTML tags used to indicate that the surrounded text should be italicized).

The following are other useful HTML tags:

- `
` causes a line break in a text string. If you use `

` a blank line will appear.
- ` text ` causes the surrounded text to be colored as specified (in this case, red). You can also use hex codes rather than the color name.

Please refer to an HTML reference manual or website for more examples.

NOTE: Refer to [Color Contrast](#) for information about the use of the HTML color 'red' and its impact on accessibility.

How To Use Constants In Scripts

Some steps can reference fields called **Predefined Values**. For example, if you want to compare an input value to the letter "Y", the letter **Y** would be defined as a Predefined Value's field value.

Special constants are used for fields defined as switches. When you move **TRUE** to a switch, it turns it on. When you move **FALSE** to a switch, it turns it off.

You can use a [global variable](#) as a Predefined Value. For example, if you wanted to move the current date to a field, you'd indicate you wanted to move a Predefined Value named **%CURRENT_DATE**.

How To Use Global Variables

Some explicit steps can reference fields called **Predefined Values**. In addition to referencing an ad hoc constant value (e.g., the letter **Y**), you can also reference a global variable in such a field value. A global variable is used when you want to reference system data.

Note that when using the Edit Data step type, the variable available are slightly different. Refer to [Edit Data Syntax](#) for details.

The following global variables exist for BPA scripts:

Variable Name	Comments
%PARM-<name>	This is the value of a parameter of that name passed in to the application when launched via the standard system URL. Refer to Launching A Script When Starting the System for more information on these parameters.
%PARM-NOT-SET	This is to be used to compare against %PARM-< > parameters to check if the parameter has been set or not when the application was launched. A parameter that has not been set would be considered equal to this global variable. It is recommended to compare parameters against this global variable before using them for the first time.
%BLANK	A constant that contains a blank value (no value).
%SPACE	A constant that contains a single space value.
%CURRENT-DATE	The current date as known by the browser, not the server.
%SYSTEM-DATE	The server date. Note that this date is affected by the system date override logic)
%SAVE-REQUIRED	A flag that contains an indication of whether the data on a page has been changed (and thus requires saving). You may want to interrogate this flag to force a user to save their work before executing subsequent steps. This flag will have a value of TRUE or FALSE .
%NEWLINE	A constant that contains a new line character (carriage return). Upon substitution, a line break is inserted in the resultant text. NOTE: This constant does not have the desired effect when the resultant text is HTML. For example, a step's text and prompt strings. This is because HTML ignores special characters such as new lines. Refer to How To Use HTML Tags And Spans In Text to learn how to cause a line break in an HTML text.

To refer to a [global context](#) variable, use %FIELD_NAME. For example, if the field SP_ID is in the global context, you may reference %SP_ID to reference the ID of the service point currently in context. In addition, the following special values are supported:

Variable Name	Comments
%CONTEXT-PERSONID	A constant that contains the ID of the current person.
%CONTEXT-ACCOUNTID	A constant that contains the ID of the current account.
%CONTEXT-PREMISEID	A constant that contains the ID of the current premise.

In addition, if the script is invoking something else via one of the various “Invoke” step types and an error is returned, the following global variables contain information about the error:

Variable Name	Comments
%ERRMSG-CATEGORY %ERRMSG-NUMBER	The unique identifier of the error message number.
%ERRMSG-TEXT	The brief description of the error.
%ERRMSG-LONG	The complete description of the error.

How To Name Temporary Storage Fields

Input Data and **Move Data** steps can create fields in temporary storage. You specify the name of the temporary storage field in the step's **Field Name**. The name of the field must not begin with % and must not be named the same as the [global variables](#). Besides this restriction, you can use any **Field Name** that's acceptable to JavaScript (i.e., you can name a field in temporary storage almost anything). Keep in mind that field names are case-sensitive.

How To Work With Dates

Before we discuss how to work with dates in your scripts, we need to point out that there are two types of date fields: date-only and date-time. Date-only fields only contain a date. Date-time fields contain both a date and a time. The following topics describe how to work with dates on the various step types.

NOTE: If you're working with a field that resides on the database (as opposed to a temporary storage field), the database field name will tell you what type of date it is: date-only fields are suffixed with **DT**, and date-time fields are suffixed with **DTTM**.

Move Data

If you intend to use a **Move data** step to populate a *date-time* field, please be aware of the following:

- If the destination field resides in the *page data model*, the source field value must be in the format YYYY-MM-DD-HH.MM.SS or YYYY-MM-DD. If the field is in the format YYYY-MM-DD, the time of 12:00 am will be defaulted.
- If the destination field resides in the *user interface*, you must use two steps if you want to populate both date and time. To explain this, we'll assume the field you want to populate is called EXPIRE_DTTM:
 - First, you populate the date portion of the field. To do this, you'd move a date (this value can be in any valid date format that a user is allowed to enter) to a field called EXPIRE_DTTM_FWDDTM_P1. In other words, you suffix **_FWDDTM_P1** to the field name.
 - If you want to populate the time, you'd move the time (again, the field value can be in any format that a user could use to enter a time) to a field called EXPIRE_DTTM_FWDTTM_P2. In other words, you suffix **_FWDDTM_P2** to the field name.

If you intend to use a **Move data** step to populate a *date-only* field, please be aware of the following:

- If the destination field resides in the *page data model*, the source field value must be in the format YYYY-MM-DD.
- If the destination field resides in the *user interface*, the source field can be in any valid date format that a user is allowed to enter.

NOTE: %CURRENT-DATE. Keep in mind that the [global variable](#)%CURRENT-DATE contains the current date and you can move this to either a page data model, user interface, or temporary storage field. If you move %CURRENT-DATE to a temporary storage fields, it is held in the format YYYY-MM-DD.

Mathematical Operation

If you intend to use a **Mathematical operation** step to calculate a date, you can reference both date-only and date-time fields. This is because mathematical operations are only performed against the date portion of date-time fields.

Mathematical operations are limited to adding or subtracting days, months and years to / from a date.

NOTE: A useful technique to perform date arithmetic using the current date is to move the [global variable](#)%CURRENT-DATE to a temporary storage field and then perform the math on this field.

Input Data

If you intend to use an **Input data** step on a *date-time* field, please be aware of the following:

- If the field resides in the *page data model*, the user must enter a value in the format YYYY-MM-DD-HH.MM.SS (and therefore we do not recommend doing this).
- If the field resides in the *user interface*, you must use two steps if you want to populate both date and time. To explain this, we'll assume the field you want to populate is called EXPIRE_DTTM:
 - First, you populate the date portion of the field. To do this, you'd input the date (this value can be in any valid date format that a user is allowed to enter) in a field called EXPIRE_DTTM_FWDDTM_P1. In other words, you suffix **_FWDDTM_P1** to the field name.
 - If you want to populate the time, you'd input the time (again, the field value can be in any format that a user could use to enter a time) in a field called EXPIRE_DTTM_FWDTTM_P2. In other words, you suffix **_FWDDTM_P2** to the field name.

If you intend to use an **Input data** step to populate a *date-only* field, please be aware of the following:

- If the field resides in the *page data model*, the user must enter a value in the format YYYY-MM-DD (and therefore we do not recommend doing this).
- If the field resides in the *user interface*, the user can enter any valid date format.

How To Use To Do Fields

As described under [Executing A Script When A To Do Entry Is Selected](#), you can set up the system to automatically launch a script when a user selects a To Do entry. These types of scripts invariably need to access data that resides on the selected To Do entry. The following points describe the type of information that resides on To Do entries:

- **Sort keys.** These values define the various ways a To Do list's entries may be sorted. For example, when you look at the bill segment error To Do List, you have the option of sorting the entries in error number order, account name order, or in customer class order. There is a sort key value for each of these options.
- **Message parameters.** These values are used when the system finds *%n* notation within the message text. The *%n* notation causes field values to be substituted into a message before it's displayed. For example, the message text **The %1 non-cash deposit for %2 expires on %3** will have the values of three fields merged into it before it is displayed to the user (%1 is the type of non-cash deposit, %2 is the name of the customer, and %3 is the expiration date of the non-cash deposit). Each of these three values is stored as a separate message parameter on the To Do entry.
- **Drill keys.** These values are the keys passed to the page if a user drilled down on the entry (and the system wasn't set up to launch a script). For example, a To Do entry that has been set up to display an account on the account maintenance page has a drill key of the respective account ID.
- **To Do ID.** Every To Do entry has a unique identifier referred to as its To Do ID.

You can access this information in the following types of steps:

- **Move Data** steps can move any of the above to any data area. For example, you might want to move a To Do entry's drill key to the page data model so it can be used to navigate to a specific page.
- **Conditional Branch** steps can perform conditional logic based on any of the above. For example, you can perform conditional logic based on a To Do entry's message number (note, message numbers are frequently held in sort keys).
- **Mathematical Operation** steps can use the above in mathematical operations.

A To Do entry's sort key values are accessed by using a **Field Type** of **Current To Do Information** and a **Field Name** of **SORTKEY[index]**. Note, you can find an entry's potential sort keys by displaying the entry's To Do type and navigating to the [Sort Keys](#) tab. If you want to reference the first sort key, use an index value of **1**. If you want to use the second sort key, use an index value of **2** (and so on).

A To Do entry's drill key values are accessed by using a **Field Type** of **Current To Do Information** and a **Field Name** of **DRILLKEY[index]**. Note, you can find an entry's potential drill keys by displaying the entry's To Do type and navigating to the [Drill Keys](#) tab. If you want to use the first drill key, use an index value of **1**. If you want to use the second drill key, use an index value of **2** (and so on).

A To Do entry's message parameters are accessed by using a **Field Type** of **Current To Do Information** and a **Field Value** of **MSGPARAM[index]**. Note, because a To Do type can have an unlimited number of messages and each message can have different parameters, finding an entry's message parameters requires some digging. The easiest way to determine these values is to display the To Do entry on [To Do maintenance](#). On this page, you will find the entry's message category/number adjacent to the description. Once you know these values, display the message category/number on [Message Maintenance](#). You'll find the message typically contains one or more %n notations (one for each message parameter). For example, the message text **The %1 non-cash deposit for %2 expires on %3** has three message parameters. You then need to deduce what each of the message parameters are. You do this by comparing the message on the To Do entry with the base message (it should be fairly intuitive as to what each message parameter is). If we continue using our example, **%1** is the non-cash deposit type, **%2** is the account name, and **%3** is the expiration date. You can access these in your scripts by using appropriate index value in **MSGPARAM[index]**.

A To Do entry's unique ID is accessed by using a **Field Type** of **Current To Do Information** and a **Field Value** of **TD_ENTRY_ID**.

In addition, any of the above fields can be [substituted into a text string or prompt](#). Simply prefix the To Do field name with a % as you would fields in temporary storage. For example, assume you want your script to display the following text in the script area: "ABC Supply does not have a bill cycle" (where ABC Supply is the account's name). If the first sort key linked to the To Do entry contains the account's name, you'd enter a text string of **%SORTKEY[1] does not have a bill cycle**.

How To Reference Fields In Data Areas

Various step types involve referencing field elements residing in the [script's data areas](#). To reference an element in a data area you need to provide its absolute XPath notation starting from the data area name. For example, use "F1-BatchControl/batchControl" to reference a top-level "batchControl" element in a script data area called "F1-BatchControl".

You don't have to type in long XPath notations. Use the **View Script Schema** hyperlink provided on the [Script - Step](#) tab page to launch the script's data areas schema.

Figure 4: Schema Viewer

Doing this opens the [schema viewer](#) window where you can:

- Click on the field element you want to reference in your script step. The system automatically populates the text box on the top with the element's absolute XPath notation.
- Copy the element's XPath notation from the text box to your script.

You can also use the **View Data Area**, **View Service Script Data Area**, or **View Plug-In Script Data Area** links on [Script - Data Area](#) to the same effect. These open up the schema viewer for a specific data area respectively.

Script Engine Version 2 and Above Notes

Scripting using the engine version 2 or above requires some extra syntax to take advantage of XPath 2 functionality. In general, any variable declared will be assumed to be a string. This means, that if you intend to construct a mathematical statement then it is necessary to explicitly declare the data type of variables as integers, numbers, or dates.

NOTE: Unless otherwise noted, all XPath examples in this topic are for the Version 1 engine – which means XPath 1. Statements that function using XPath 1 will not necessarily work for XPath 2. This is especially true when executing math, see below for examples.

Date and Time Arithmetic

XPath date/time and interval data types support arithmetic operations ('+', '-', '*' etc.) and functions, which can be used for time calculations in the same way as '1 + xs:integer(value)' is used for numeric calculations.

Compare time duration:

```
if ("xs:dateTime(fn:current-dateTime()) - xs:dateTime($updateDateTimeX)
    ge xs:dayTimeDuration(concat('PT', BO/hoursBetweenStatisticsUpdate, 'H'))")
    goto 60;
end-if;
```

Compare one date to another:

```
if ("xs:date(parm/endDate) < xs:date(parm/startDate)")
    terminate with error (11108, 11507 element='endDate');
end-if;
```

Compare a date against today's date:

```
if ("xs:date(parm/startDate) <= xs:date($CURRENT-DATE)")
    terminate with error (11108, 11507 element='endDate');
end-if;
```

Calculate the end of month:

```
// covert to ISO
move "concat($year, '-', $mon2, '-01T00:00:00')" to $monthStart;

// calculate
move "xs:dateTime($monthStart) + xs:yearMonthDuration('P1M') - xs:dayTimeDuration('P0DT1S')"
    to $monthEnd;

// convert from ISO to OUAF
move "concat($year, '-', $mon2, '-', substring(string($monthEnd), 9, 2), '-23.59.59')" to $endDateTime;
```

NOTE: XPath date/time/interval formats use the ISO standard, which needs to be converted to/from formats supported in the framework.

Comparing Date/Times in String Format

Any ISO-like string format for date/time preserves the YYYY MM DD HH MM SS sequence, which is zero-padded. Regardless of separators, this format will remain appropriate for comparison operations. In particular, date/time values in the framework format “YYYY-MM-DD.HH.MM.SS” can be used with “=”, “!=”, as well as “>”, “>=”, “<”, “<=” operators.

```
// retrieve framework date/time value
```

```

invokeBS 'CM-MAXMSRMT' using "CM-MAXMSRMT";
move "string(cm-MAXMSRMT/results[1]/measurementDateTime)" to $lastMsmtDT;

// construct another date/time
move "concat($year,'-01-01-00.00.00')" to $startDateTime;

// compare using string operators
if ("{$lastMsmtDT >= $startDateTime}")
    move "substring($lastMsmtDT,1,4)" to $latestMsmtYear;

```

Converting Date/Times Between Framework and ISO

Conversion of date/time from framework format to ISO is only necessary for date/time arithmetic. Comparisons can be done with the framework format directly. The only difference between the framework format and ISO date/time formats is in the separators:

Framework: “YYYY-MM-DD.HH.MM.SS”

ISO: “YYYY-MM-DDTHH:MM:SS”

Example of converting from the framework format to ISO:

```

move "concat(substring($ouafDT, 1, 10), 'T', translate(substring($ouafDT, 12), '.', ':'))" to $isoDT;

```

Example of converting from ISO to the framework format:

```

move "concat(substring($isoDT, 1, 10), '.', translate(substring($isoDT, 12), ':', '.'))" to $ouafDT;

```

Round Money With a Dynamic Currency Scale

Because different currencies support a different number of decimals, the framework provides an API for rounding a monetary amount based on a given currency.

```

move "parm/amount" to $qty;
move "currency/decimals" to $decimals;
move "fn:round(xs:decimal($qty) * math:exp10(xs:double($decimals)))
    div math:exp10(xs:double($decimals))" to "parm/roundedAmount";

```

Looping through Sequences

In XPath 2 it is possible to organize a for-loop over a sequence of integers, not only a node list.

This example shows a loop over a range of months. This is a sequence-forming construct in XPath. The XPath node list, which we are familiar with, is just another type of sequence.

```

for ($month in "1 to 12")

```

This example shows a loop over a give range of years in descending order:

```

for ($year in "fn:reverse(parm/startYear to parm/endYear)")
    move "concat($year,'-01-01-00.00.00')" to $startDateTime;
    move "concat($year,'-12-31-23.59.59')" to $endDateTime;
    ...

```

This example shows a loop through a node list using ‘index’, so that other node lists can be accessed:

```

for ($idx in "1 to count(parm/touData/touList)")
    move "parm/touData/touList[$idx]" to $tou; // access any list with this index

```

The above syntax can be used as an elegant alternative to maintaining indices separately, for example instead of the following:

```

move "0" to $idx;
for ($item in "parm/touData/touList")
    move "1 + xs:integer($idx)" to $idx;

```

String Padding and Decimal Formatting

This is used with specific input formats or output formatting. It is applicable to zero, space and other types of padding.

This example shows prefixing for date/time components, for example producing “2010-01-02” instead of “2010-1-2”.

```
move "substring(concat('0',string($month)), string-length(string($month)), 2)" to $mon2;
```

This example shows suffixing for adding decimal zero-padded alignment, for example producing “12.30” and “4.00” instead of “12.3” and “4”. The example performs 3 tasks: rounding to 2 decimals, inserting a period if necessary, and zero padding.

```
// round and zero-pad to 2 decimals
move "$item/amount" to $qty;
move "fn:round(xs:double($qty) * 100) div 100" to $qty;
move "string($qty)" to $qty;
move "concat(substring-before(concat($qty, '.'), '.'), '.', substring(concat(substring-
after($qty, '.'), '00'), 1, 2))" to $qty;
```

Ternary Operation

This makes a choice between values based on a condition, so that it could be used in a single expression instead of an if/else block. It is known in C/C++ as ‘cond ? value1 : value2’ or in BASIC as ‘IFF(cond, value1, value2)’. In XPath the syntax is: “if (cond) then value1 else value2”. Note this is not the top-level scripting if-statement block.

In XPath this is an expression, which can be combined with other expressions. In scripting it can be used as:

```
move "if (string(D1-UnitOfMeasure/
measuresPeakQuantity) = 'D1MP') then 'D1MX' else 'D1SM' " to $func;
```

Pipeline Processing

In scripting, it is not easy to create a simple reusable piece of code as there are no local functions, and a separate script call is a coding overhead and requires packing/unpacking parameters. To avoid copying and pasting the same code block between similar script stages, consider ‘pipelining’, which is breaking the overall process into separate top-level steps, some of which could be shared between alternating paths. This is common for parameter preparation and output formatting. An intermediate result between stages can be stored in a “parm” substructure.

Instead of this code:

```
if ("type = A")
  prepare params ...
  call services for A ...
  format output ...
end-if;
if ("type = B")
  prepare params ...
  call services for B ...
  format output ...
end-if;
```

Consider this alternative:

```
prepare params ...
if ("type = A")
  call services for A ...
end-if;
if ("type = B")
  call services for B ...
end-if;
format output ...
```

XPath 2 Functions

Script engine versions 2 and above support XQuery 1.0 Functions and Operators, and the XQuery 1.0 standard itself with some minor limitations. Below are the URLs to both specifications. The first link has the functions/operators available to use from XQuery.

- <http://www.w3.org/TR/xpath-functions/>
- <http://www.w3.org/TR/xquery/>

The following can only access local file systems. (For other protocols like http they will return an empty sequence):

- fn:doc
- fn:collection

Script - Data Area

Use this page to define the data areas used to pass information to and from the server or any other data area describing your temporary storage. Open this page using **Admin > System > Script** and then navigate to the **Data Area** tab.

NOTE: Conditional tab page. This tab page does not appear for [Groovy Library scripts](#) or [plug-in scripts](#) using the **Groovy** engine version.

Description of Page

The grid contains the script's data areas declaration. For steps that invoke an object that is associated with a schema, you must declare the associated schema as a data area for your script. In addition, if you have defined one or more data areas to describe the script's temporary storage, you need to declare them too. The following bullets provide a brief description of each field on a script data area:

- **Schema Type** defines the type of schema describing the data area's element structure.
- The data area's schema is the one associated with the referenced **Object**. Only objects of the specified Schema Type may be selected.
- **Data Area Name** uniquely identifies the data area for referencing purposes. By default, the system assigns a data area with the associated object name.
- Click on the **View Data Area** link to view the data area's schema in the [schema viewer](#) window.

The **View Service Script Data Area** link appears for service scripts only. Use this link to view the script's parameters data area schema in the [schema viewer](#) window.

The **View Plug-In Script Data Area** link appears only for plug-in scripts using a script engine version. Use this link to view the script's parameters data area schema in the [schema viewer](#) window.

FASTPATH: Refer to [A Script May Declare Data Areas](#) for more information on data areas.

Script - Schema

Use this page to define the data elements passed to and from a service script. Open this page using **Admin > System > Script** and then navigate to the **Schema** tab.

NOTE: Conditional tab page. This tab page only appears for [service scripts](#).

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays the script name and description.

The [Schema Designer](#) zone allows you to edit the service script's parameters schema. The purpose of the schema is to describe the input and output parameters used when invoking the script.

NOTE: Refer to [Schema Nodes and Attributes](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Script - Eligibility

Use this page to define a script's eligibility rules. Open this page using **Admin > System > Script** and then navigate to the **Eligibility** tab.

NOTE: Conditional tab page. This tab page only appears for [BPA scripts](#).

Description of Page

Use the **Eligibility Option** to indicate whether the script is **Always Eligible**, **Never Eligible** or to **Apply Eligibility Criteria**. The remaining fields on the page are only visible if the option is **Apply Eligibility Criteria**.

CAUTION: The following information is not intuitive; we strongly recommend that you follow the guidelines under [The Big Picture Of Script Eligibility](#) before attempting to define this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sort Sequence** to control the relative order in which the group is executed when the system determines if the script should appear in the [script search](#).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of **True**.
 - Choose **Eligible** if this script should appear.
 - Choose **Ineligible** if this script should not appear.
 - Choose **Check Next Group** if the next criteria group should be checked.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of **False**.
 - Choose **Eligible** if this script should appear.
 - Choose **Ineligible** if this script should not appear.
 - Choose **Check Next Group** if the next criteria group should be checked.

The grid that follows contains the script's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being true or false. For example, you might have a row that indicates the script is eligible if the current account in context belongs to the residential customer class. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to [Defining Logical Criteria](#) for several examples of how this information can be used.

- Use **Sort Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
 - Choose **Algorithm** if you want to compare anything other than a characteristic. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
 - Some products may also include an option to choose **Characteristic**. Choosing this option displays adjacent fields to define the object on which the characteristic resides and the characteristic type. The objects whose characteristic values may be available to choose from depend on your product.
- Use **Criteria Comparison** to define the method of comparison:
 - Choose **Algorithm** if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data. Push the adjacent search button to select the algorithm that is responsible for performing the comparison.

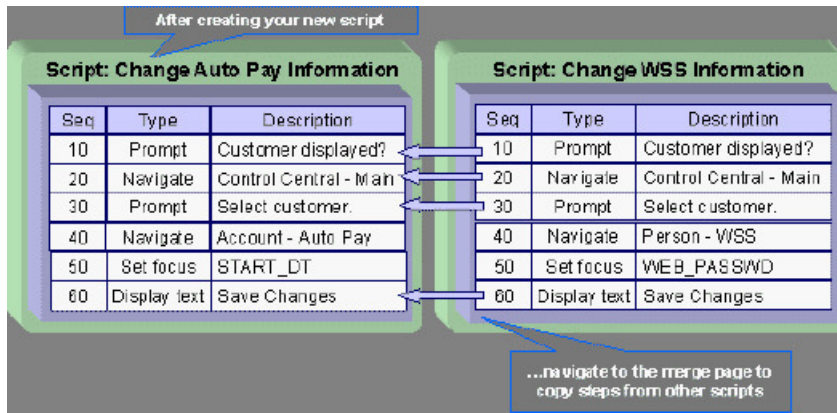

- Choose any other option if you want to compare the **Criteria Field** using a logical operator. The following options are available:
 - Use **>**, **<**, **=**, **>=**, **<=**, **<>** (not equal) to compare the **Criteria Field** using standard logical operators. Enter the comparison value in the adjacent field.
 - Use **IN** to compare the **Criteria Field** to a list of values. Each value is separated by a comma. For example, if a field value must equal **1, 3 or 9**, you would enter a comparison value of **1,3,9**.
 - Use **BETWEEN** to compare the **Criteria Field** to a range of values. For example, if a field value must be between **1 and 9**, you would enter a comparison value of **1,9**. Note, the comparison is inclusive of the low and high values.
- The next three fields control whether the related logical criteria cause the eligibility group to be considered true or false:
 - Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate **Group is true** or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate **Group is true** or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate **Group is true** or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.

Merging Scripts

Use the Script Merge page to modify an existing script by copying steps from other scripts. The following points summarize the many diverse functions available on the Script Merge transaction:

- You can use this transaction to renumber steps (assign them new sequence numbers).
- You can use this transaction to move a step to a different position within a script. When a step is moved, all references to the step are changed to reflect the new sequence number.
- You can use this transaction to delete a step.
- You can use this transaction to copy steps from other scripts. For example:
 - You may want to create a script that is similar to an existing script. Rather than copying all the information from the existing script and then removing the inapplicable steps, this page may be used to selectively copy steps from the existing script to the new script.
 - You may have scripts that are very similar, but still unique. You can use this transaction to build large scripts from smaller scripts. In this scenario, you may choose to create special 'mini' scripts, one for each of the various options that may make a script unique. Then, you could use the script merge page to select and merge the mini scripts that are applicable for a main script.

NOTE: The target script must exist prior to using this page. If you are creating a new script, you must first create the [Script](#) and then navigate to the merge page to copy step information.

NOTE: Duplicate versus Merge. The **Script** page itself has **duplication** capability. You would duplicate a script if you want to a) create a new script and b) populate it with *all* the steps from an existing script.

Script Merge

Open **Admin > System > Script Merge** to open this page.

Description of Page

For **Original Script**, select the target script for merging steps.

For **Merge From Script**, select the template script from which to copy the steps.

NOTE: You may only copy steps from one Merge From script at a time. If you want to copy steps from more than one script, select the first Merge From script, copy the desired steps, save the original script, and then select the next Merge From script.

The left portion of the page displays any existing steps for the **Original Script**. The right portion of the page displays the existing steps for the **Merge From Script**.

You can use the **Copy All** button to copy all the steps from the **Merge From** script to the **Original** script. If you use **Copy All**, the steps are added to the end of the original script.

Each time you save the changes, the system renumbers the steps in the original script using the **Start From Sequence Number** and **Increment By**.

Merge Type indicates **Original** for steps that have already been saved in the original script or **Merge** for steps that have been merged, but not yet saved. The **Sequence**, **Step Type** and **Description** for each step are displayed.

The topics that follow describe how to perform common maintenance tasks:

Resequencing Steps

If you need to resequence the steps:

- Use the up and down arrows in the Original Script grid to reorder the steps.
- Make any desired changes to the **Start From Sequence Number** or **Increment By**.
- Click Save.

The steps are given new sequence numbers according to their order in the grid.

Removing a Step from Script

If you want to remove a record linked to the Original script, click the delete button to the left of the record.

For example, to remove the **Reset existing bundle XML** step, click the  icon.

		Merge Type	Sequence	Step Type	Description
	 	Original	10	Edit data	Edit data - Check that the BO is an Export Bundle
	 	Original	20	Edit data	Edit data - Read the Bundle
	 	Original	30	Edit data	Edit data - Reset existing bundle XML
	 	Original	40	Edit data	Edit data - Create new bundle XML

After removal, the grid displays:

		Merge Type	Sequence	Step Type	Description
	 	Original	10	Edit data	Edit data - Check that the BO is an Export Bundle
	 	Original	20	Edit data	Edit data - Read the Bundle
	 	Original	40	Edit data	Edit data - Create new bundle XML

NOTE: You cannot delete a step that is referenced by other steps unless you also delete the referencing steps, such as **Go to step** or **Prompt** type steps. The system informs you of any missing referenced steps when you attempt to save the original script.

Adding a Step to a Script

You can move any of the steps from the Merge From script to the Original Script by clicking the left arrow adjacent to the desired step. Once a record is moved it disappears from the Merge From information and appears in the Original information with the word **Merge** in the Merge Type column.

For example, to copy the **Navigate to a page** step, click the left arrow.

	Merge Type	Sequence	Step Type	Description
		10	Height	Height - 0%
		20	Move data	Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID'
		30	Move data	Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID'
		40	Navigate to a page	Navigate to a page - userGroupAppService
		50	Conditional branch	Conditional branch - Compare ACTION with UPDATE
		60	Press a button	Press a button - IM_scrollSec_add
		70	Move data	Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID'
		80	Label	Label - End of Script

The step is moved to the left portion of the page.

	Merge Type	Sequence	Step Type	Description
↔	Merge	40	Navigate to a page	Navigate to a page - userGroupAppService

Sequence	Step Type	Description
10	Height	Height - 0%
20	Move data	Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID'
30	Move data	Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID'
50	Conditional branch	Conditional branch - Compare ACTION with UPDATE
60	Press a button	Press a button - IM_scrollSec_add
70	Move data	Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID'
80	Label	Label - End of Script

NOTE: If you add a step, such as **Go to step** or **Prompt** type steps, that references other steps, you must also add the referenced steps. The step references are updated to use the new sequence numbers when you save the original script. The system informs you of any referenced steps that haven't been added when you attempt to save the original script.

Removing an Uncommitted Step from a Script

	Merge Type	Sequence	Step Type	Description
↔	Merge	40	Navigate to a page	Navigate to a page - userGroupAppService

Remove Merged Step - Script Merge - row 1

Sequence	Step Type	Description
10	Height	Height - 0%
20	Move data	Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID'
30	Move data	Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID'
50	Conditional branch	Conditional branch - Compare ACTION with UPDATE
60	Press a button	Press a button - IM_scrollSec_add
70	Move data	Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID'
80	Label	Label - End of Script

Maintaining Functions

NOTE: Functions were implemented prior to the introduction of business services (BS), service scripts (SS) and business objects (BO). The functionality is still supported, but the recommendation for implementations going forward is to use one of the above configuration tool objects in a script rather than defining a function. The documentation has not been updated throughout this section to highlight where BS, SS or BO could be used to perform the equivalent logic.

Invoke function steps may be used to retrieve or update data independent of the page currently being displayed. For example, if you design a script that takes different paths based on the customer's customer class, you could invoke a function to retrieve the customer's customer class. Doing this is much more efficient than the alternative of transferring to the account page and retrieving the customer class from the Main page.

An **Invoke function** step retrieves or updates the relevant data by executing a service (on the server). These types of steps do not refer to the service directly. Rather, they reference a "function" and the function, in turn, references the service.

NOTE: Functions are abstractions of services. A function is nothing more than meta-data defining the name of a service and how to send data to it and retrieve data from it. Functions allow you to define a scriptwriter's interface to services. They also allow you to simplify a scriptwriter's set up burden as functions can handle the movement of data into and out of the service's XML document.

The topics in this section describe how to set up a function.

NOTE: You can retrieve data from all base-package objects. If you know the name of the base-package "page" service used to inquire upon an object, you can retrieve the value of any of its fields for use in your scripts. To do this, set up a function that sends the unique identifier of the object to the service and retrieves the desired fields from it.

Function - Main

Use this page to define basic information about a function. Open this page using **Admin > System > Function**.

Description of Page

Enter a unique **Function** code and **Description** for the function.

Use the **Long Description** to describe, in detail, what the function does.

Define the **Internal Service** that the function invokes.

NOTE: Only page services can be invoked.

The tree summarizes the following:

- The fields sent to the service. You can use the hyperlink to transfer to the **Send Fields** tab with the corresponding field displayed.
- The fields received from the service. You can use the hyperlink to transfer to the **Receive Fields** tab with the corresponding field displayed.
- Scripts that reference the function. You can use the hyperlink to transfer to the script page.

Function - Send Fields

Use this page to add or update the fields sent to the service. Open this page using **Admin > System > Function** and then navigate to the **Send Fields** tab.

NOTE: Displaying a specific field. Rather than scrolling through each field, you can navigate to a field by clicking on the respective node in the tree on the Main tab. Also note, you can use the Alt+right arrow and Alt+left arrow accelerator keys to quickly display the next and previous entry in the scroll.

NOTE: You're defining the service's input fields. On this tab, you define which fields are populated in the XML document that is sent to the service. Essentially, these are the service's input fields.

Description of Page

Use **Sequence** to define the order of the **Send Fields**.

Enter a unique **Function Field Name** and **Description** for each field sent to the application service. Feel free to enter **Comments** to describe how the field is used by the service.

Use **Field Value Source** to define the source of the field value in the XML document sent to the service:

- If the field's value is the same every time the function is invoked, select **Defined On The Function**. Fields of this type typically are used to support "hard-coded" input values (so that the scriptwriter doesn't have to populate the field every time they invoke the function). Enter the "hard-coded" **Field Value** in the adjacent field.
- If the field's value is supplied by the script, select **Supplied By The Invoker**. For example, if the function retrieves an account's customer class, the script would need to supply the value of the account ID (because a different account ID is passed each time the function is invoked). Turn on **Required** if the invoker must supply the field's value (it's possible to have optional input fields).

Regardless of the Field Value Source, use **XML Population Logic** to define the XPath expression used to populate the field's value in the XML document sent to the service.

Function - Receive Fields

Use this page to add or update the fields received from the service. Open this page using **Admin > System > Function** and then navigate to the **Receive Fields** tab.

NOTE: Displaying a specific field. Rather than scrolling through each field, you can navigate to a field by clicking on the respective node in the tree on the Main tab. Also note, you can use the Alt+right arrow and Alt+left arrow accelerator keys to quickly display the next and previous entry in the scroll.

NOTE: You're defining the application service's output fields. On this tab, you define which fields are populated in the XML document that is received from the service. Essentially, these are the service's output fields.

Description of Page

Use **Sequence** to define the order of the **Receive Fields**.

Enter a unique **Function Field Name** and **Description** for each field received from the service. Feel free to enter **Comments** to describe the potential values returned from the service.

Turn on **Required** if the invoker must use the field.

Regardless of the Field Value Source, use **XML Population Logic** to define the XPath expression used to retrieve the field's value from the XML document received from the service.

NOTE: Fields in multiple lists. If a field within the list is unique across the service, the generic list reference is sufficient for the XML population logic. However, if the field you are trying to reference is in multiple lists, the XPath must include the list name. For example, instead of `/pageBody/list/listBody/field[@name='FIELD_NAME']`, the XPath Population Logic must read `/pageBody/list[@name='LIST_NAME']/listBody/field[@name='FIELD_NAME']`.

Maintaining Managed Content

The Managed Content object is used to store various types of text content. Some content is used internally such as Allowlists. Other content may be used by implementations such as XSL files used for communicating messages with an external system, JavaScript include files, and CSS files. These files may then be maintained in the same manner as the HTML in UI Maps.

Open this page using **Admin > System > Managed Content**.

Use the **Managed Content Query** portal to search for an existing managed content entry. Once the managed content is selected, you are brought to the maintenance page to view and maintain the selected record.

Most fields on the page are self explanatory.

Use **Managed Content Type** to indicate the type of content.

- **Allowlist**

is used to capture a list of supported values for given functionality. For example, the product provides allowlists for SQL functions and valid HTML tags.

- **XSLTC** is used to reference XSL files. These may be used internally for user interface referencing. Additionally, the XSLs may be referenced for sending messages to external system using [outbound message](#) and for receiving messages in SOAP as [inbound messages](#).

NOTE: The value FIX (XSLT) is no longer supported and will be deprecated in a future release. Other managed content values are not currently supported by any current framework functionality and are reserved for future use.

Use the **Schema** tab to view and maintain the contents of the managed context text.

Defining Entity Tags

This portal is used to maintain an entity tag along with the list of entities associated with it. Entity tagging supports grouping of configuration, demo and test related entities so they can better describe a logical function. Each group is represented by a unique tag name and entities may be associated with multiple tags.

An entity tag may explicitly restrict the type of entities it can be associated with by referencing a specific maintenance object as part of the entity tag record.

You can access the portal from the **Admin Menu > Implementation Tools > Entity Tag**. You are brought to a query portal with options for searching for a specific tag name. Once an entity tag has been selected you are brought to the maintenance portal to view and maintain the selected record.

A **Tags** dashboard zone allows you to review, add and remove tags for the current entity you review. For configuration type of entities, you may use this portal to tag multiple entities at once.

The following zones may appear as part of the portal's **Main** tab page

- **Entity Tag.** This zone provides information about the selected entity tag.
- **Tagged Entities.** This zone lists entities associated with the selected entity tag. You may also use the zone to remove entities from the list.
- **Tag Entities.** Use this zone to add configuration entities to the selected tag.

Advanced Schema Topics

The topics in this section describe some advanced information related to schemas used for business objects, business services, service scripts and UI maps.

Schema Nodes and Attributes

For business object definition, the purpose of the schema is to create a link between the schema and a maintenance object. For business service definition you are specifying the link between the schema and a service (either a general service, search service, or a maintenance object service). For service script definition, you are defining the API for passing information to and from the script. The following documentation is a complete list of the XML nodes and attributes available to you when you construct a schema.

The Four Element Types

A schema element can be one of four different structure types. Note that there are two classes of element types: the structural nodes group and list, and the data containing nodes of field and raw.

Mnemonic	Valid Values	Description	Examples
type=	"field"	The field type is the default type for any element not explicitly labeled as something other than a field. Therefore, you virtually never have to explicitly label an element as a field. Note that a field element, unlike group or list, will contain information in its nodes - rather than other nodes.	
	"group"	<p>The group element is typically a structural element of the schema only, in which case it has no mapping.</p> <p>Note that when grouping several elements that are all used to map an XML structure of a CLOB / XML field of a business object driven record, the mapping may be at the group level.</p>	<p>Example where a group is used to create a structure</p> <pre><schema> <input type="group" <userId/> </input> <output type="group"> <firstName/> <lastName/> </output> </schema></pre> <p>Example where the group includes the mapping:</p> <pre><parameters type="group" mapXML="BO_DATA_AREA" mdField= "F1_TODOSUMEMAIL_PARM_LBL" / > <numberOfDays mdField="F1_NBR_DAYS" required="true" /> <frequency mdField="F1_FREQUENCY" / ></pre>
	"list"	The list node is structural node like the group node. The only difference is that the list structure	<p>Example of a schema with a list:</p> <pre><schema> <statesList type="list"></pre>

Mnemonic	Valid Values	Description	Examples
		has the ability to repeat multiple times in an XML document.	<pre><state isPrimeKey="true" /> > <description/> </statesList> </schema></pre> <p>Example of a schema with a list:</p> <pre><xml> <statesList> <state>AK</state> <description>Alaska</ description> </statesList> <statesList> <state>AL</state> <description>Alabama</ description> </statesList> ... </xml></pre>
	"raw"	The raw data type is used to capture a chunk of raw text that doesn't have any inherent structure associated with it.	<pre><sendDetail type="raw" /></pre> <p>Example of an XML instance for the above schema:</p> <pre><sendDetail> <messageInfo> <senderAddress>123 W. Main St, </senderAddress> <corpZone>3A</ corpZone> </messageInfo> </sendDetail></pre>

The Data Type of a Field Element

Of the four different element types, only a field can have a data type.

Mnemonic	Valid Values	Description	Examples
dataType=	"string"	By default, a field element is a string. Therefore, there is no requirement to specify the string data type.	<pre><schema> <custName dataType="string" /> > </schema></pre>
	"number"	<p>Defines an element that is a number.</p> <p>NOTE: UI hints include a setting to Suppress Automatic Number Formatting.</p> <p>NOTE: Use currencyRef attribute for auto-display of currency symbol that is associated with the referenced currency code. The currency decimal positions are ignored by this formatting allowing you</p>	<p>Examples</p> <pre><schema> <count dataType="number" /> > </schema></pre> <pre><schema> <taxRate dataType="number" currencyRef="currency" /> > </schema></pre>

Mnemonic	Valid Values	Description	Examples
		to display a currency symbol for a unit rate with many decimals.	
"money" Optional additional attributes currencyRef ="element name"		Defines an element that represents a monetary amount. The currency reference is optional and if left blank the installation currency will be used. Automatic formatting and validation to be applied based on the currency. For example, the currency symbol will be shown when auto-rendering. In addition, the number of decimal places must not exceed the valid number defined for the currency. NOTE: Refer to Referencing Other Elements for supported syntax for referring to other elements.	<pre><schema> <currency default="USD" suppress="true" /> <balance dataType="money" currencyRef="currency" / > </schema></pre>
"lookup" Required additional attribute lookup ="field name"		Defines an element that has valid values defined using a lookup. The lookup field is required.	<pre><schema> <status dataType="lookup" lookup="STATUS_FLG" /> </schema></pre>
"lookupBO" Required additional attribute lookupBO ="bo name"		Defines an element that has valid values defined using an extendable lookup. The extendable lookup's business object is required.	<pre><schema> <category dataType="lookupBO" lookupBO="CM- BusinessCategory" /> </schema></pre>
"boolean"		Defines an element that has values of "Y" and "N".	<pre><schema> <allowsEdit dataType="boolean" / > </schema></pre>
"date"		Defines an element that represents a date.	<pre><schema> <startDate dataType="date" / > </schema></pre>
"dateTime"		Defines an element that represents a date and time. NOTE: Refer to Standard Time Considerations for additional configuration available for date / time fields that represent standard time.	<pre><schema> <startDateTime dataType="dateTime" /> </schema></pre>
"time"		Defines an element that represents a time.	<pre><schema> <startTime dataType="time" / > </schema></pre>
"uri"		Defines an element captures a URI. Elements defined with	<pre><schema></pre>

Mnemonic	Valid Values	Description	Examples
		this type enable the support for URI Allowlist and Substitution as described in Referencing URIs .	<pre><exportDirectory dataType="uri" /> </schema></pre>

Referencing Other Elements

There are several attributes that allow for a reference to another element in the same schema. The supported syntax of the XPath reference is the same in every case. This section provides examples using the default reference attribute (**defaultRef**).

Reference a sibling element:

```
<schema>
  <id mapField="ACCT_ID" required="true" />
  <altId defaultRef="id" required="true" />
</schema>
```

Reference an element in a higher group:

```
<schema>
  <id mapField="ACCT_ID" required="true" />
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId defaultRef="../id" required="true" />
  </msgInfo>
</schema>
```

Reference an element in a lower group:

```
<schema>
  <id mapField="ACCT_ID" defaultRef="msgInfo/altId" required="true" />
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId required="true" />
  </msgInfo>
</schema>
```

Reference an element in another group:

```
<schema>
  <acctInfo type="group">
    <id mapField="ACCT_ID" required="true" />
  </acctInfo>
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId defaultRef="../acctInfo/altId" required="true" />
  </msgInfo>
</schema>
```

Standard Time Considerations

Most date / time fields represent "legal" time such that if a time zone changes their clocks for winter and summer time, the date / time field captures the current observed time. However, some date / time fields should always be captured in standard time to avoid confusion / ambiguity. A good example is a date and time related to detailed interval data. Refer to [Designing Time Zones](#) for more information.

When defining an element with **dataType="dateTime"**, you may optionally configure **stdTime="true"** indicating that data captured in the element always represents standard time in the 'base' time zone. The 'base' time zone is specified on the [Installation options](#).

NOTE: If an element is mapped to a table / field with a Standard Time Type of **Physical**, then **stdTime="true"** is implied. Refer to [Fields](#) for more information.

Example:

```
<schema>
  <startTime dataType="Time" stdTime="true" />
</schema>
```

If the time zone that represents the date / time field is not the installation time zone, use the optional setting **stdTimeRef**="XPath to time zone element" on a date / time element to indicate that the element represents standard time and indicates the time zone to use. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements. .

Example:

```
<schema>
  <alternateTimeZone fkRef="F1-TZONE" suppress="true"/>
  <startDateTime dataType="dateTime" stdTimeRef="alternateTimeZone" />
</schema>
```

NOTE: If an element is mapped to a table / field with a Standard Time Type of **Referenced**, then **stdTime**="XPath" is implied. Refer to [Fields](#) for more information.

NOTE: When schema elements are captured in standard time the UI map supports HTML notation to automatically display the data applying a daylight savings time / summer time correction. Refer to the HTML attribute **oraType**="dateTime; stdTime:true" for more information.

There may be cases where the date / time is captured as standard time in one time zone, but should be displayed using a different time zone. In this case, the attribute **displayRef**="XPath" may be used in addition to the appropriate attribute that identifies the time zone that the data is capture in. Refer to [Referencing Other Elements](#) for supported syntax.

```
<schema>
  <displayTimeZone fkRef="F1-TZONE" suppress="true" />
  <startDateTime dataType="dateTime" stdTime="true" displayRef="displayTimeZone" />
</schema>
```

The Mapping Attributes

When constructing your schema, you can choose from one of the following mapping attributes.

Mnemonic	Valid Values	Description	Examples
mapField=	"field name"	In the case of a business object, the mapField attribute is used to identify the database column the element is related to. For business service schemas, the mapField= attribute is used to link a schema element with a service element.	<pre><schema> <factId mapField="FACT_ID" /> </schema></pre>
mapChild=	"table name"	<p>The mapChild attribute is used only for business object mapping. It is used in two ways:</p> <ul style="list-style-type: none"> First, to create a list in the business object that corresponds to a child table of an MO. Second, you can use mapChild to identify the child table a flattened field lives in. For more information on flattening, refer to flattening section below. 	<p>Example of a list within a child table in a BO:</p> <pre><persons type="list" mapChild="CI_ACCT_PER" <personId mapField="PER_ID" / > </persons></pre>

Mnemonic	Valid Values	Description	Examples
mapList=	"list name"	<p>The mapList attribute is used only for business service mapping. It is used in two ways:</p> <ul style="list-style-type: none"> First, to create a list in the business service that corresponds to a list in the service. Second, you can use mapList to identify the list that a flattened field lives in. For more information on flattening, refer to flattening section below. 	<p>Example of a list within a business service:</p> <pre><selectList type="list" mapList="DE" <value mapField="COL_VALUE"> <row mapList="DE_VAL"> <SEQNO is="2"/> </row> </value> </selectList></pre>
mapXML=	"field name"	<p>The mapXML attribute is typically used to map XML structures into a large character / XML field of the service. Note that when you use mapXML to map either a list or group structure (type="list" or type="group") you don't have to map all the child elements within the structure. It is also possible to map list elements to a large character field associated with the list child.</p>	<pre><enrollmentRequest type="group" mapXML="CASE_CLOB"> <messageID/> <sender/> </enrollmentRequest> <enrollmentKey mapXML="CASE_CLOB" /> <enrollmentInfo type="list" mapChild="CI_CASE_CHILD"> <sequence mapField="CHILD_SEQ" /> <name mapXML="CASE_CHILD_CLOB" / > <value mapXML="CASE_CHILD_CLOB" / > </enrollmentInfo></pre>
isPrimeKey=	"true"	<p>You must specify a primary key for a list defined within a mapped XML element (type="list" mapXML="CLOB"). The primary key is used by the framework to determine whether a list element add, update or delete is required during a business object update.</p> <p>NOTE: You do not need to specify the prime key for a business object list mapped to maintenance object list. When a physical list is mapped, the prime key is derived from existing physical meta-data.</p>	<pre><questionnaire type="list" mapXML="CASE_CLOB"> <question isPrimeKey="true" /> <answer/> </questionnaire></pre>
orderBy=	"XPath asc desc, XPath asc desc"	<p>By default, a list defined within a mapped XML element (type="list" mapXML="CLOB") is sorted by the first element of the list. A different sort order may be specified using the orderBy attribute. The attribute value is a comma separated list of</p>	<pre><questionnaire type="list" orderBy="page/section, page/sequence" mapXML="CASE_CLOB"> <question isPrimeKey="true" / > <answer/> <page type="group"> <section/> <sequence/> </page> </questionnaire></pre>

Mnemonic	Valid Values	Description	Examples
		field XPath(s) (relative to the list element) with an optional sort order (ascending is the default).	
		NOTE: This is only available for lists mapped as XML within business objects.	

Descriptive Attributes

The following attributes can be used to describe a schema element and provide additional configuration related to the element. Typically, these attributes are useful for field elements only.

Mnemonic	Valid Values	Description	Examples
<code><!-- comment --></code>		Use this to add a comment to a schema by using special open and close characters: <code><!--</code> and <code>--></code> .	<pre><schema> <!-- This schema is used to capture business information only, please refer to the 'HUMAN' BO for person information --> </schema></pre>
<code>description=</code>	"text"	The description of an element may be used to provide an internal description of the element to help a reader of the schema to understand the business reason for the element.	<pre><schema> <active type="boolean" description="active account" label="Active" /> </schema></pre>
<code>label=</code>	"text"	The label of an element is meant to be a short bit of verbiage that would typically precede the element in a user interface.	<pre><schema> <active type="boolean" description="active account" label="Active" /> </schema></pre>
<code>required=</code>	"true"	Used to require the existence of an element during object interaction. NOTE: For included schemas, the <code>required="true"</code> attribute is not processed on business object and business service schemas when they are included within a service script schema. This is to support the ability of the service script to populate required elements before an embedded business object or business service is invoked from the service script.	<pre><schema> <logDate mapField="LOG_DT" default="%CurrentDate" required="true" private="true" </schema></pre>
<code>mdField=</code>	"field code"	The meta-data field attribute is used to associate an element with a field's metadata. The field defines data type, as well as its	<pre><schema> <active mdField="CM_ACTIVE_SW" /> </schema></pre>

Mnemonic	Valid Values	Description	Examples
		<p>label and help text. If you link an element with a meta-data field, you don't need to specify any of these attributes.</p> <p>NOTE: For a business object schema, the mapField attribute is used to derive the data type and label. An mdField attribute may be provided to override these attributes, if needed. If the element is mapped to an XML column, the mdField is needed to provide the appropriate data type and label.</p>	
fkRef=	"FK Reference Code"	<p>If the element is a foreign key, defining its FK Reference will enable framework validation of the element during schema interaction and automatically provide descriptions and navigation capability.</p>	<pre><schema> <person fkRef="PER" mapField="CHAR_VAL_FK1"> <row mapChild="CI_SA_CHAR"> <CHAR_TYPE_CD is="PER"/ > </row> </person> </schema></pre>
private=	"true"	<p>Marking an element as private will prevent it from being exposed in schema interaction.</p> <p>NOTE: A private element requires a default.</p>	<pre><schema> <type mdField="SA_TYPE_CD" default="E1" private="true"/ > </schema></pre>
suppress=	"true"	<p>This setting prevents an element from appearing in automatically generated user interfaces.</p> <p>NOTE: This attribute can be specified on a group, in which case all elements of the group will be suppressed.</p> <p>NOTE: Refer to Defaulting and System Variables for advice related to default values for suppressed elements.</p>	<pre><schema> <ls mdField="LIFE_SUPPORT_FLG" default="N" suppress="true"/ < </schema></pre>
	"blank"	<p>This setting means that automatic UI rendering in display mode will hide the element if its value is blank. The element will still</p>	<pre><schema> <email mdField="EMAIL" suppress="blank"/> </schema></pre>

Mnemonic	Valid Values	Description	Examples
		<p>be modifiable on the input map whether blank or not.</p>	
	<p>"input"</p>	<p>This setting means that automatic UI rendering will suppress the element for input, although it may still be displayed if it is not blank.</p> <p>NOTE: Elements marked as suppress="input" will behave as with suppress="blank". If the value is blank, no value will be displayed on either the display or input map. If the element's value is present, then the element will be displayed on both the display and input map.</p> <p>NOTE: Refer to Defaulting and System Variables for advice related to default values for suppressed elements.</p>	<pre><schema> <email mdField="EMAIL" suppress="input" /> </schema></pre>
<p>noAudit=</p>	<p>"true"</p>	<p>This setting prevents an element from appearing as a changed element in the business object's audit plug-in spot. If specified on a group or list node it applies to the whole node. You cannot specify it on the schema root node, only on schema elements.</p> <p>NOTE: This attribute is only applicable to business object schemas.</p>	<pre><schema> ... <version mapField="VERSION_NBR" noAudit="true" /> ... <workFields type="group" noAudit="true" <lastProcessedId/> <lastProcessedTime/> </workFields> </schema></pre>
<p>storeEmptyNodes=</p>	<p>"true"</p>	<p>By default, empty nodes are removed from a business object instance when saved. This setting allows a group or a list element to explicitly keep its empty nodes.</p> <p>This attribute may be useful in situations where business object data is exchanged with an external system and there is a need to distinguish between an empty value for an element that participates in the synchronization and an element that does not participate and therefore omitted from the message altogether.</p>	<pre><schema> <message type="group" storeEmptyNodes= ... </message> </schema></pre>

Mnemonic	Valid Values	Description	Examples
		<p>NOTE: This is only available for group and list elements.</p>	
emitEmptyGroups=	"true"	<p>By default, empty nodes are not included in the output of a business object or a business service call. This attribute is set at the top level schema node, allowing empty nodes of all groups and list elements to be included in the output.</p> <p>This attribute may be useful in the same situations that may require the use of the storeEmptyNodes= attribute.</p> <p>NOTE: This is only available for business object and business service schemas.</p>	<pre><schema emitEmptyGroups="true"> <message type="group"> ... </message> </schema></pre>
emitEmptyElements=	"true"	<p>This attribute is similar to the emitEmptyGroups= attribute but may also be specified at the field level. The attribute is applicable to all schema types.</p>	<pre><schema> <messageNumber type="field" emitEmptyE... ... </message> </schema></pre>
adheresToDA=	"comma separated list of data area names."	<p>This attribute is applicable to the schema, group and list nodes. It claims that this sub-schema node is intended to "look like" the schema of one of the listed data areas, for polymorphism reasons in general.</p> <p>NOTE: The recommended approach for enforcing the structure of a shared data area is by including it in the schema. This attribute should be limited to use cases where the ability to include the data area is not possible.</p>	<pre><schema> <messageNumber type="group" adheresToD... ... </message> </schema></pre>

Schema Constants

There are some product owned schemas where the design warrants a value to be defaulted in the schema, but where the value is implementation specific and therefore cannot be defined by the product. For these situations, the product may use a technique called a schema constant. The design of the schema will include a declared constant. At implementation time, a configuration task will include defining the appropriate value for the constant.

For example, imagine the product delivers an algorithm that will create an outbound message when a certain condition occurs. The outbound message type to use must be configured by the implementation. To use a schema constant to define the outbound message type, the base product will configure the following:

- An option type lookup value for the lookup **F1CN_OPT_TYP_FLG** is defined. For example, **M202 - Activity Completion Outbound Message Type** with a Java Value Name of **outmsgCompletion**
- The base schema that is used to create the "complete activity" outbound message references the schema constant using the Java Value Name of the option type's lookup value

```
...
<outboundMessageType mapField="OUTMSG_TYPE_CD" default="%Constant(outmsgCompletion)"/>
...
```

At implementation time, the administrative users must configure the appropriate outbound message type for "activity completion". Then, navigate to [Feature Configuration](#), choose the **Schema Constants** feature type, choose the option type **Activity Completion Outbound Message Type** and enter the newly created outbound message type in the option value.

Schema constants may also be used in the flattening syntax to define [the row elements required for flattening](#).

Defaulting and System Variables

The default attribute can be used to default values into field elements as well as [the row elements required for flattening](#). You can default a field to a constant or to one of several system variables.

When an element is required, the default value is applied at the server level when adding or changing the record where no value is provided for this element.

When an element is optional, a default value may be configured to provide a suggested value to the user when populating the record on the user interface in Add mode. Users should be able to remove the default value for this type of element and the system will not attempt to populate it at save time.

NOTE:

The standard for our 'list' maintenance is to show an empty row for a new list that a user may or may not choose to populate. As such, UI default values are not shown for list elements.

It is not recommended to configure a default attribute for an optional element that is not editable or visible on the user interface in Add mode (for example an element with **suppress="true"** or **suppress="input"** or a list element whose default value is not shown per the previous point). The default for this type of element is still applied but the user doesn't have the ability to reset the value. This may result in inconsistencies as defaulting does not occur for optional fields added by a use case other than the UI interaction.

Mnemonic	Valid Values	Description	Examples
default=	"value"	Use this attribute to default an element to a specified value. The values that are valid depend on the dataType setting.	<pre><schema> <perType mapField="PER_OR_BUS_FLG" default="P" required="true"/ > </schema> <schema> <frequency dataType="number" default="1" required="true"/ > </schema></pre>
	"%CurrentDate"	Used to default the element to the current date. This is only applicable to date elements.	<pre><schema> <logDate mapField="LOG_DT" default="%CurrentDate" required="true"/ > </schema></pre>
	"%CurrentDateTime"	Used to default the element to the current date / time. This is	<pre><schema> <logDateTime mapField="LOG_DTTM" default="%CurrentDateTime" required="true"/></pre>

Mnemonic	Valid Values	Description	Examples
		only applicable to date / time elements.	</schema>
"%StandardDateTime"		Used to default the standard date and time. The standard date and time is identical to the current date and time, unless daylight savings time / summer time is in effect for the base time zone. This may be used with the stdTime attribute. NOTE: Refer to Standard Time Considerations for more information.	<schema> <startDateTime mapField="START_DTTM" default="%StandardDateTime" required="true"/> </schema>
"%ProcessDate"		You can default the process date. The process date differs from the current date because the process date will remain constant throughout the duration of the process being executed. The current date will reflect the actual date of processing. This is similar to the batch business date that is a standard batch parameter .	<schema> <billDate mapField="BILL_DT" default="%ProcessDate" required="true"/> </schema>
"%ProcessDateTime"		This is similar to " %ProcessDate " but for date / time fields.	<schema> <calcDateTime mapField="CALC_DTTM" default="%ProcessDateTime" required="true"/> </schema>
"%CurrentUser"		Used to default the element to the current user.	<schema> <logUser mapField="LOG_USER" default="%CurrentUser" required="true"/> </schema>
"%CurrentUserTimeZone"		Used to default the element to the current user's time zone. If the current user's time zone is not found, the installation time zone is used.	<schema> <timeZone default="%CurrentUserTimeZone" required="true"/> </schema>
"%CurrentUserLanguage"		Used to default the element to the current user's language.	<schema> <custLanguage mapField="CUST_LANG" default="%CurrentUserLanguage" required="true"/> </schema>
"%InstallationCurrency"		Used to default the currency from the installation record.	<schema> <currency mapField="CURRENCY_CODE" default="%InstallationCurrency" required="true"/> </schema>
"%InstallationCountry"		You can default the country from installation record.	<schema> <country mapField="COUNTRY" default="%InstallationCountry" required="true"/> </schema>

Mnemonic	Valid Values	Description	Examples
			</schema>
	"%InstallationLanguage"	You can default the language from the installation record.	<pre><schema> <language mapField="LANGUAGE" default="%InstallationLanguage" required="true"/> </schema></pre>
	"%Constant()"	You can default an element value using a schema constant .	<p>The following is an example of a schema constant used as a default value, where the Java Value Name of the Lookup Value is 'customerLanguage'.</p> <pre><language mapField="CUSTOMER_LANG" default="%Constant(customerLanguage)" required="true"/></pre>
	"%Context()"	<p>You can default a value contained in a context variable.</p> <p>WARNING: Context variables must be initialized within a server script before the schema context default can be applied. Refer to Context Variables for more information.</p>	<p>An example of a context variable used as a default value:</p> <pre><source mapField="PER_ID" default="%Context(source)" required="true"/></pre> <p>NOTE: When defining a context variable in scripting, it should be prefixed with \$\$. When referring to the variable in the %Context() syntax, the prefix is not included.</p>
defaultRef=	"XPath"	Use this attribute to default the value of one element to the value of another one.	Refer to Referencing Other Elements for supported syntax for referring to other elements.

The Flattening Nodes and Attributes

The term "flattening" is used to describe the act of defining one or more single elements for a schema that are actually part of a list within the maintenance object. Flattening is possible if there are other attributes of the list that can be defined to uniquely describe the element or elements. A common use case for flattening is a characteristic. Rather than defining the characteristics of an object using a collection where the user must choose the characteristic type and then define the value, the characteristics are defined as actual elements with the appropriate label already displayed. This technique enables the designer of the schema and the user interface to display each separate characteristic in the logical place in the user interface rather than all lumped together.

NOTE: A flattened element represents a unique row in the database. This row is inserted when the flattened values are created. The row is updated when any of the flattened values are changed. The row is deleted when all the flattened values are removed. The behavior of effective dated elements is slightly different - please see [Flattening an Effective Dated List](#).

NOTE: The flattening feature can also be used to define a list, see [Flattened List](#).

Identifying the List or Child Table

When flattening a child table, the row node is required to identify the list / child table that the element comes from. Within the row node, at least one element must be defined with an **is=** definition that ensures that the element is a unique row in

the database. It may also define elements or fields in the row that are suppressed and are populated using default value configuration.

- For a business object, the row node defines the child table the flattened field belongs to.

The syntax is `<row mapChild="table name">`. This example is for the list of persons for an account in the customer care and billing product. One person may be marked as the "main" person. This illustrates how to define an explicit element for the main person ID to simplify references to that field. It is part of the CI_ACCT_PER child table. What makes it unique is that the MAIN_CUST_SW is **true** (and only one row may have that value)

```
<custId mapField="PER_ID" mdField="CM-MainCust">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
```

NOTE: The above example illustrates that the row node may also define elements within the list that are suppressed and assigned a default value. This syntax is never used to identify a particular row. Note that a default value can either be a literal string, or a [system variable](#).

- For a business service, the row node identifies the list name the flattened field belongs to.

The syntax is `<row mapList="list name">`. This example shows two entries from a list being flattened to a field value and description.

```
<selectList type="list" mapList="DE">
  <value mapField="COL_VALUE">
    <row mapList="DE_VAL">
      <SEQNO is="2" />
    </row>
  </value>
  <description mapField="COL_VALUE">
    <row mapList="DE_VAL">
      <SEQNO is="3" />
    </row>
  </description>
</selectList>
```

Uniquely Identifying the Flattened Field or List

The `is=` syntax within a row or rowFilter element is used to uniquely identify the row.

Mnemonic	Valid Values	Description	Examples
<code>is=</code>	"value"	Use this attribute to reference a value directly.	<pre><tdTypeCd mapField="CHAR_VAL_FK1"> <row mapChild="F1_EXT_LOOKUP_VAL_CHAR"> <CHAR_TYPE_CD is="CM-TD-TYPE" /> </row> </tdTypeCd></pre>
	<code>"%Constant()"</code>	You can configure a flattened element using a schema constant . During a service interaction the value of the schema constant will be used to identify the flattened element in its child row.	<p>An example of a schema constant used in flattening syntax where the Java Value Name of the Lookup field value is 'cmRate'.</p> <pre><unitRate mapField="CHAR_VAL" dataType="number"> <row mapChild= "F1_EXT_LOOKUP_VAL_CHAR"> <CHAR_TYPE is ="%Constant(cmRate)" /> </row></pre>

Mnemonic	Valid Values	Description	Examples
	%n	The %n substitution value is used to reference a relative list instance. A relative list instance is typically used to configure a flattened element for a child table keyed by sequence number. The value of n should be a positive integer value. During a business object read interaction the relative list instance (position) specified by the integer will be returned.	<pre></unitRate></pre> <p>An example with a relative list instance - where the first instance of the row is returned.</p> <pre><schema> <mainPhone mapField="PHONE"> <row mapChild="CI_PER_PHONE"> <PHONE_TYPE_CD is="%Constant(mainPhoneType)"/> > <SEQ_NUMis="%1"/> </row> </mainPhone> </schema></pre>

FASTPATH: Additional values for `is=` are used when [Flattening an Effective Dated List](#). Refer to that section for more information.

Flattening a Pre-defined Characteristic Type

If the flattened field is in a characteristic collection and the characteristic type is a predefined characteristic, automatic UI rendering will generate a dropdown for the list of valid values. For example, the schema below will generate a dropdown for the Usage element showing the valid values of the Status Reason Usage (**F1-SRUSG**) characteristic type.

```
<usage mdField="STATUS_RSN_USAGE" mapField="CHAR_VAL">
  <row mapChild="F1_BUS_OBJ_STATUS_RSN_CHAR">
    <CHAR_TYPE_CD is="F1-SRUSG"/>
    <SEQ_NUM is="1"/>
  </row>
</usage>
```

Defining Multiple Elements from the List

When attempting to include multiple columns from the same list, the system provide shorthand notation for copying the flattening rules defined on another element so that the flattening rules do not need to be repeated. To do this, the row node includes the **rowRef** attribute and it indicates the other element name that defines the mapping information. The following example illustrates flattening the fields Customer ID and Receives Copy of Bill from the same list of Persons for an Account (where the `MAIN_CUST_SW` is **true**).

```
<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
<copyBill mapField="RECEIVE_COPY_SW" rowRef="custId"/>
```

Note that the above notation also illustrates that the **rowRef** may be defined directly in the element's attribute definition.

NOTE: Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

Flattening Two Layers Deep

If your maintenance object or service has nested lists two layers deep, the system supports flattening an element within a flattened element. This technique also uses the **rowRef** attribute. The flattening of the second level refers to the flattened element of the first level. The following example illustrates flattening a characteristic into an element called `legalContact` for the "main" customer. Notice that the `legalContact` element has two row nodes: one to refer to the flattening information for its parent record and one to define its child table

```
<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
```

```

    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
<legalContact mapField="CHAR_VAL_FK1">
  <row rowRef="custId">
    <row mapChild="CI_ACCT_PER_CHAR" >
      <CHAR_TYPE_CD is="LEGAL" />
    </row>
  </row>
</legalContact>

```

Note that the above notation also illustrates that the **rowRef** may be defined as an attribute of a row node rather than directly in the element's attribute definition.

Defining a Flattened List

There are times that a list or child table supports multiple values of the same "type" and these should be presented as a list. To continue with the example above, the list of persons for an account may identify one person as the "main" person. This person has been flattened to a single element (with the account relationship type defaulted and suppressed). To maintain the other persons related to an account, you can define a list where each row captures the Person Id and the Account Relationship Type.

Rather than a row node, the flattened list is configured with a **rowFilter** element. The following schema illustrates the described example. The list node defines the child table. The **rowFilter** includes the criteria that identify the rows within the table to include. The elements of the list are defined within the list node outside the **rowFilter** element.

```

<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
<miscPersons type="list" mapChild="CI_ACCT_PER">
  <rowFilter>
    <MAIN_CUST_SW is="false" />
  </rowFilter>
  <relType mapField="ACCT_REL_TYPE_CD" />
  <personId mapField="PER_ID" />
</custId>

```

Note that the system will validate that if a schema contains flattened single elements and flattened lists from the same child table, the criteria that defines what makes them unique must be analogous.

Flattening an Effective Dated List

There are some lists in the application that are effective dated (and still others that have effective date and time). For example, there are some effective dated characteristic collections. In these collections, the design is to capture a single value for a characteristic type that may change over time. It is not meant to support multiple characteristic values in effect at the same time.

There are some maintenance objects that have effective dated characteristics and no sequence based characteristics. For those entities, implementations may want to use the characteristic to define an additional field that doesn't require effective dates.

When considering designing an element for your schema that represents a value in an effective dated collection, consider if the value is one that is used in processes, like calculating a bill, such that it is important to capture changes to the value over time.

- If it is not important to track the changes to the value, the recommendation is to set the effective date to a fixed value in the schema. (Examples below).
- If it is important to track the changes to the value, then you need to consider how you want to design the schema.
 - One option is to define a flattened list as described above. Both the value and the effective date are elements in this list. In this use case, you manage the list just like any list. You can add or remove values.

- Another option is to define a flattened single value in the schema. With this option, when retrieving the record, the latest effective value is returned. In this design, the important question is how is the reference date defined.

NOTE: Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

Flattened Elements Where Changes Are Not Tracked

The following is an example of flattening an element in an effective dated collection where the value does not need to be effective dated. The recommendation in this case is to simply hard-code the date in the `is=` attribute.

```
<schema>
  <externalReference mapField="ADHOC_CHAR_VAL" mdField="CM_EXT_REF" dataType="string">
    <row mapChild="CI_SA_CHAR">
      <CHAR_TYPE is="CM_EXT_REF"/>
      <EFFDT is="2000-01-01"/>
    </row>
  </externalReference>
</schema>
```

Flattened Elements Where Changes Are Effective Dated

If you want the BO schema to flatten an effective dated value that should keep track of changes over time, the flattened value will represent the latest effective entry. In this case, the recommendation is to explicitly define the date or date/time field as an element. Then there is syntax for the `is=` attribute to indicate that the explicit date field is the date to use for the value.

Mnemonic	Valid Values	Description	Examples
<code>is=</code>	<code>"%effectiveDate()"</code>	Use this configuration to indicate that the date to use is the value of another element. NOTE: Refer to Referencing Other Elements for supported syntax for referring to other elements.	<pre><schema> <price mapField="CHAR_VAL" dataType="number" required="true"> <row mapChild="CI_SA_CHAR"> <CHAR_TYPE is="PRICE"/ > <EFFDT is="%effectiveDate(priceEdate)" / > </row> </price> <priceEdate mapField="EFFDT" rowRef="price"/> </schema></pre>
	<code>"%effectiveDateTime()"</code>	Use this configuration to indicate that the date / time to use is the value of another element. NOTE: Refer to Referencing Other Elements for supported syntax for referring to other elements.	<pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="RATE_CHAR"> <CHAR_TYPE is="PRICE"/ > <EFFDTTM is="%effectiveDateTime(priceEdatetime)" / > </row> </price> <priceEdatetime mapField="EFFDTTM" rowRef="price"/> </schema></pre>

You should consider if the explicit date or date/time element should be displayed on the user interface when the flattened field is shown or if that should be suppressed. Designers should also consider the user dialogue for updating the value. It may be more intuitive for the flattened field to be display only and to have a separate dialogue for updating the effective dated value.

For this option, the suggestion is that the maintenance page for the object includes a separate zone that shows the history of the effective dated values over time. The latest value may be included in that zone as well.

Note that for backward compatibility, the system also supports the following options. However, they are not recommended. They implicitly defined the reference date as the current date at all times. The options supported adding new effective dated

rows when the value changed. But the technique also caused new effective dated rows to appear when other elements of the same schema were updated. The new rows would have the current date or date/time with the same row value because the reference date or date/time is the current date, which is a change. The product does not recommend managing an effective dated characteristic without defining the date or date/time as an explicit element.

Mnemonic	Valid Values	Description	Examples
is=	"%effectiveDate"	This configuration is not recommended	<pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="CI_SA_CHAR"> <CHAR_TYPE is="PRICE"/ > <EFFDT is="%effectiveDate"/> </row> </price> </schema></pre>
	"%effectiveDateTime"	This configuration is not recommended	<pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="RATE_CHAR"> <CHAR_TYPE is="PRICE"/ > <EFFDT is="%effectiveDateTime" / > </row> </price> </schema></pre>

Search Zone

A UI Map schema element can be configured to enable an automatic search dialog when the schema is included within a maintenance UI map.

NOTE: Please note that an fkRef can be configured with a search zone. If a schema element has an fkRef but no explicit search attributes (as described here) then the fkRef search information will be used in the UI map. In other words, if the schema element already has an fkRef, then these explicit search attributes in the schema are only used to override the fkRef search information.

NOTE: Refer to the [UI Map Attributes and Functions](#) for more information on search zone configuration.

search="search zone"

The search attribute can be used within a UI map schema and is used to automatically generate the oraSearch UI map attribute. The search zone is an explorer zone configured as a search.

```
<person fkRef="PER" search="C1_PSRCH"/>
```

searchField="search field:element|'literal';"

The searchField attribute can only be used in conjunction with the search attribute. The searchField attribute is used to build the oraSearchField UI map attribute. The searchField value is used to populate a search zone filter with an initial value when the search zone is launched. The initial value can be a literal also. The searchField value is used to match to the filter mnemonic also named searchField.

Search field: element|'literal'. The search field represents the search zone filter to populate on launch. The element is the map's schema element used to populate the filter. The element is optional, if left blank, it will default to the element that this attribute is specified on. The searchField also takes 'literal' as input value

NOTE: Multiple filters can be populated within the search zone at launch, but multiple search field pairs must be constructed within the attribute value. The value specified here will be used to directly build the HTML attribute `oraSearchField` within the UI map where this schema is specified.

NOTE: Note that the element reference is *relative*. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

```
<person fkRef="PER" search="C1_PSRCH" searchField="PERSON; PER_TYPE:personType; "/>
```

searchOut="search field:element;"

The `searchOut` attribute can only be used in conjunction with the `search` attribute. The `searchOut` attribute is used to build the `oraSearchOut` UI map attribute. The `searchOut` value is used to capture a selected value from the search zone and move it to a UI map element. The `searchOut` value specified should match the `ELEMENT_NAME` mnemonic within the search result zone parameter.

Search field: element. The search field represents the search zone result brought back to the UI map. The element is the map's schema element to be populated. The element is optional, if left blank, it will default to the element that this attribute is specified on.

NOTE: Multiple elements can be populated as a result of search zone selection, but multiple search field pairs must be constructed within the attribute value. The value specified here will be used to directly build the HTML attribute `oraSearchOut` within the UI map where this schema is specified.

NOTE: Note that the element reference is *relative*. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

```
<person fkRef="PER" search="C1_PSRCH" searchField="PER_ID"
searchOut="PER_ID;PRIMARY_PHONE:personPhone; "/>
```

Extend Security for Service Script

Application service security will be enforced when either a business object or a service script is invoked from a BPA script or a UI map, but not from a service script. If you want security to be enforced when the business object or a service script is invoked from a service script, you must add the following attribute to the service script's schema.

appSecurity="true"

The `appSecurity` attribute is only available for service script schemas. If specified, any business object or service script directly invoked by the service script will have their application service evaluated for access.

```
<schema appSecurity="true">
  ...
</schema>
```

Overriding Action for a Business Service

If you want to invoke a business service with an action other than 'read', you need to specify the action attribute on the primary node business service schema.

pageAction="add, change, delete"

The action attribute is used to override the default action of read on a business service schema. Valid values are:

- add
- update (only allowed for maintenance object service)
- change (not allowed for maintenance object service)

- delete
- read (this is the default action if no pageAction specified)

Example:

```
<schema pageAction="change">
  <parm type="group">
    <ele1/>
    <ele2/>
  </parm>
</schema>
```

Specifying searchBy for a Search Service

If you want to invoke a search service then you must explicitly specify the searchBy attribute appropriate for the elements mapped in the schema.

searchBy="MAIN"

The value values of the searchBy attribute can be found by viewing the XML schema linked to the business service, use the View XML URL. Typical values are:

- MAIN
- ALT
- ALT2
- ALT3
- etc.

```
<schema searchBy="MAIN">
  <AccountID mapField="ACCT_ID" />
  <Results type="list">
    <AccountID mapField="ACCT_ID" />
  </Results>
</schema>
```

Including Other Schemas

There are no limitations on your ability to include a schema into another schema - all types can be included in all other types. Nested includes are also allowed - and at present there is no limitation on the depth of the nesting.

Including a schema requires two parts:

1. The include node
2. The name attribute

The following table highlights the supported include statements.

Mnemonic	Description	Examples
<includeBO name=""/>	<p>Including a business object schema into another schema is allowed.</p> <p>Note that the mapping rules of a business object or business service schema may or may not make sense in the context of the parent schema. Include other schemas at your own risk. However, a very useful aspect of XML processing is that the framework ignores non-pertinent attributes. In other</p>	<pre><schema> <cust type="group"> <includeBO name="C1-Person"/> </cust> <spouse type="group"> <includeBO name="C1-Person"/> </spouse> </schema></pre>

Mnemonic	Description	Examples
	words, it will not hurt to have mapping attributes included into a script schema.	
<code><includeBS name=" "/></code>	Used to include a business service schema.	<pre><schema> <includeBS name="F1-ReadMOLog" /> </schema></pre>
<code><includeDA name=" "/></code>	Used to include a data area schema.	<pre><schema> <includeDA name="F1CommonSchemaFieldData" / > </schema></pre>
<code><includeMP name=" "/></code>	Used to include a UI map schema.	<pre><schema> <includeMP name="F1-DisplayRecordActions" / > </schema></pre>
<code><includeSS name=" "/></code>	Used to include a service script schema.	<pre><schema> <includeSS name="F1-ActShowZn" /> </schema></pre>

Compatibility Attributes

These attributes were added as part of upgrades from previous versions of the Framework.

fwRel="2"

This attribute has been added to schemas created in Framework 2 as part of a Framework 4 upgrade. New schemas will not need this attribute. It is not advisable to modify this attribute without understanding the following behavior differences as improper changes could result in errors:

NOTE: Schemas created in Framework 2 with the `fwRel="2"` attribute will store any XML mapped fields under groups as top-level XML elements in the `mapXML` field. This means that if two or more fields, in different group structures, were to have the same field name, their storage would conflict with one another resulting in errors. The new behavior, without the `fwRel="2"` attribute, will preserve the group structure and avoid the conflicts.

```
<schema fwRel="2"
  ...
</schema>
```

UI Hint Syntax

- [Auto Capitalize the Input Data](#)

Working Examples

For working examples of uiHint functionality, refer to the following business objects:

BOs with User Assigned Keys

The following examples illustrate the patterns used to enable uiHints on an object with a user specified key.

- **F1-OutcomeStyleLookup.** This extendable lookup BO does not require state transition, but does allow duplicate and delete actions.
- **F1-TodoSumEmailTyp.** This request type illustrates the hints required to support state transition on a display map.
- **F1-WebSvc.** This web service BO is a good example for management of complex JavaScript requirements. Both display and input maps have functionality that requires specialized javascript.

BO with System Generated Key

The following example illustrates the pattern used to enable uiHints on an object with a system generated key.

- **F1-GenericAttachment.** This attachment BO has a system assigned key, which entails the following special handling:
 - **F1-AttachmentMain.** This is the main section data area contains the elements common to all attachments, including the key, bo, and version. Because this data area is used to define the main section of the generated maps, the main section of the map can be extended by an implementation via data area extension functionality.
 - **F1-AttachmentActions.** This record actions map contains the standard actions, Edit and Delete, plus custom actions used only by attachments, View and Upload.
 - **F1-AttachmentIDFrag.** This record information map contains the primary key of the attachment.

Display Map Service Script

Display map service scripts can be fully supported via dynamic HTML generation. However, to help eliminate the need for a display service script, self-contained uiHint functionality has been developed to write the business object status and determine valid state transitions. So the two most common reasons to craft a display service script have been eliminated.

A typical reason to use a display pre-script is if you have an embedded map fragment that contains a business service schema. The display service script can be used to invoke the business service. Both the map fragment and the display service script must declare the business service schema to support this scenario.

WARNING: The zone used to display the object's map must have a derivation script, like **F1-GncDsMpDZ** or **F1-GenDss**, that will invoke a display service script for the business object if it has been defined as a BO option - but not require an explicit display map BO option. In addition, the display service script's schema must be enabled for uiHint functionality - as the script's schema will be dynamically rendered by the zone - and not the BO schema.

- **F1-ExcelSpreadsheet.** This attachment BO has a display service script used to manipulate the attachment business object before displaying it:
- **F1-AttchDtU.** This display map service script's schema has been defined with the uiHint namespace, and will have a display map generated for it.

Maintenance Pre-Processing Service Script

Maintenance pre-processing service scripts can be used with uiHints.

- **F1-ExcelSpreadsheet.** This attachment BO has a maintenance pre-processing service script used to manipulate the attachment business object before rendering the maintenance map:
- **F1-AttchPre.** This pre-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked before the maintenance map is rendered.

Maintenance Post-Processing Service Script

Maintenance post-processing service scripts can be used with uiHints.

- **F1-ExcelSpreadsheet.** This attachment BO has a maintenance post-processing service script used to manipulate the attachment business object after rendering the maintenance map:
- **F1-AttchPost.** This post-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked after the maintenance map is rendered.

Technical Notes

The following prerequisites are required to support dynamic HTML generation:

Schema Requirements

To support automated UI generation, the business object schema must contain the following:

- `<schema xmlns:uiHint="http://oracle.com/ouafUIHints">`. The schema node must name the uiHint namespace.
- `isPrimeKey="true"`. Every element of the business object schema that is part of the primary key must be identified.

Maintenance Script Requirements

The maintenance script for the MO must be enabled for dynamic generation.

CAUTION: The business object maintenance BPA script must be declared as an MO Option for uiHint maintenance functionality to work!

If the script performs **F1-BOProc** then it is likely no special functionality is needed. However, if the maintenance script contains its own call to **F1-GetValOpt** then the following statement is required prior to that call:

```
move 'false' to "F1-GetBOOpts/input/maintenanceMapRequired";
performScript 'F1-GetValOpt';
```

After the call to **F1-GetValOpt** the following logic must be included to dynamically declare the map schema if the business object does not have a maintenance map of its own:

```
// Perform Main Processing
if ("F1-GetBOOpts/output/maintenanceMap = $BLANK")
  declareBOWithBOGroup "$bo" as 'map_schema';
else
  declareMap "F1-GetBOOpts/output/maintenanceMap" as 'map_schema';
```

end-if;

Format an Input Map Title

NOTE: Throughout this topic the term "field" to refer to both the generic concept of displaying and capturing data in a 'field' as well as referring to the meta-data object supplied in the product to define [Fields](#). When referring to the latter, the term "MD Field" (meta-data Field) is used.

A uiHint element can be used to build a title for a maintenance map. The title will only print on the maintenance map, not on the display map. It will be printed as the first line in the map, centered, with a heading style.

Syntax	Description	Examples
<code><uiHint:title mdField=" "/></code>	Displays the label of a referenced MD field as the title.	<pre><schema xmlns:uiHint="http:// oracle.com/ouafUIHints"> <uiHint:title mdField="STATUS_RSN_LBL" /> ... </schema></pre>
<code><uiHint:title text=" "/></code>	Displays the indicated text as the title. (Do not use this mechanism when multiple languages are supported.)	<pre><schema xmlns:uiHint="http:// oracle.com/ouafUIHints"> <uiHint:title text="Status Reason" /> ... </schema></pre>

Create a Section

The uiHint namespace supports the definition of a UI map section. Note that sections are currently created in generated UI Maps when the schema has a group or list node with a label or mdField. The functionality described here enables the creation of a section without requiring a labeled group or list node within the schema. Every section must be bounded by **startSection** and **endSection** element pair.

Syntax	Supporting Attributes	Description
<code><uiHint:startSection .../></code>	<code>sectionColumn="left right fullWidth float"</code>	The default is that the section will be the full width in display maps. To override that setting, specify if you want a half-width section to appear in either the left (left) or right (right) column or to float (float). Sections that are marked as 'float' will display half-width and be aligned according to whether prior sections are displayed or conditionally hidden. For example, if a left-aligned section is followed by a floating section, the floating section will appear in the right column if the left section is populated but will display in the left column if the left section is hidden / collapsed.
	<code>editColumn="left right fullWidth float"</code>	By default a section appears as full width in maintenance maps. To override that setting, specify if you want a half-width section to appear in either the left (left) or right (right) column or to float (float). The behavior is the analogous to the sectionColumn behavior.

Syntax	Supporting Attributes	Description
	sectionOpen="false"	By default a section is open on initial display. Specify this attribute to initially display the section as closed (collapsed).
	mdField=" "	Specify the name of a MD field whose label should be used as the section heading.
	label=" "	Specify the explicit text to use as the section heading.
	visibleOn="displayMap inputMap"	By default a section appears on both the display and the input maps. Use this attribute to limit the display of the section to either the display map (displayMap) or input map (inputMap).

The syntax for the end section attribute is `<uiHint:endSection/>`

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <uiHint:startSection label="Main" sectionColumn="left" />
  ...
  <uiHint:endSection/>
</schema>
```

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <uiHint:startSection mdField="F1-ADD-
INFO" sectionColumn="fullWidth" editColumn="float" sectionOpen="false" visibleOn="displayMap" />
  ...
  <uiHint:endSection/>
</schema>
```

NOTE: The sectionColumn, editColumn and sectionOpen attributes are available for group and list nodes as well.

Include a Map Fragment

You can specify a UI map fragment to inject HTML into a generated map using the **includeMap** element name. This allows for you to support more sophisticated behavior on your user interface. For any element that is included for rendering in the map fragment, be sure to suppress the element in its schema definition, otherwise HTML will automatically be generated for the element.

Syntax	Supporting Attributes	Description
<code><uiHint:includeMap .../></code>	map=" "	Specify the name of the map.
	visibleOn="displayMap inputMap"	By default the details from the map fragment appear on both the display and the input maps. Use this attribute to limit the display of the section.

Example:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap" />
  ...
</schema>
```

NOTE: Important note on the map fragment schema: If a map fragment contains a schema, then the fragment schema structure will be injected into the dynamically generated schema when the business object is rendered for input.

Technically, the fragment schema will be inserted after the boGroup structure within the map's schema. This method may be used to support the implementation of maintenance pre and post script processing for a business object and oraInvokeBS function calls within embedded JavaScript.

If JavaScript is required within an XHTML UI Map fragment, it is necessary to bound it within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/*  */
//
//javascript
//
/* ]&gt; */
&lt;/script&gt;</pre>
</div>
<div data-bbox="88 273 896 334" data-label="Text">
<p><b>Flush the cache:</b> For performance reasons, the Framework automatically caches business object schemas, data areas, and UI maps. When you update a business object, the cache is automatically flushed. However, if the business object includes either a data area or embedded UI map fragment, the cache must be manually flushed in order for your changes to be recognized. Refer to <a href="#">Server Cache</a> for more information.</p>
</div>
<div data-bbox="88 352 257 370" data-label="Section-Header">
<h2>Build A Dropdown</h2>
</div>
<div data-bbox="88 375 896 404" data-label="Text">
<p>Syntax is provided to build a dropdown list in an edit map. The dropdown may be built using data returned from a service script, a business service or a table.</p>
</div>
<div data-bbox="88 410 906 500" data-label="Table">

<div data-bbox="467 943 913 959" data-label="Page-Footer">
<p>Oracle Utilities Customer to Meter Administrative User Guide • 359</p>
</div>
```

Conditionally Hide Elements

The **displayNone** attribute is used to suppress elements on the map based on conditions.

Syntax	Values	Description
uiHint:displayNone=	"XPath','value','!=' '='"	Used to conditionally hide this element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This may be overridden using '!='.
	"function name, true false "	Used to indicate a JavaScript function, which must return a Boolean.

WARNING:

Embedded spaces are not supported within the comma separated string values of this attribute.

This setting may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be hidden conditionally.

The following example illustrates that two elements (currency reference and lookup) that will be hidden or displayed based on the value of the data type element. Note that this example also illustrates [Trigger Dependent Behavior](#) because the data type element's value may change and if it does, the condition for hiding the subsequent elements should be re-evaluated.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <dataType mdField="F1_SE_DATA_TYPE" dataType="lookup" lookup="F1_SE_DATA_TYPE"
    uiHint:dependents="currencyRef;lookup; "/>
    <currencyRef mdField="F1_SE_CURR_REF_LBL" uiHint:displayNone='dataType','F1MO','!=' />
    <lookup mdField="F1_SE_LOOKUP_LBL" fkRef="F1-LKUPF" uiHint:displayNone='dataType','F1LP','!'
      =' ' />
  ...
</schema>
```

The following example illustrates referring to a function where the function receives parameters:

```
<uiHint:startSection mdField="F1_SE_DEFAULT_SECT"
  uiHint:displayNone="isApplicableForSchemaType(item,'F1MP'),true" />
```

Conditionally Protect Elements

The **protect** attribute is used to protect elements on the map based on other factors.

Syntax	Values	Description
uiHint:protect=	"XPath','value','!=' '='"	Used to conditionally protect this element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This may be overridden using '!='.
	"function name, true false "	Used to indicate a JavaScript function, which must return a Boolean.
	" action ','A' 'C','!=' '='"	Use the ' action ' setting to protect the element based on the current action. For example, certain elements may only be specified when adding a record. Any subsequent changes to

Syntax	Values	Description
		the record should protect the element from being changed. When using this option, the valid values for the 'value' are A (add) and C (change).

WARNING:

Embedded spaces are not supported within the comma separated string values of this attribute.

The protect UI Hint may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be protected conditionally.

The following UI Hint will protect the statistics category when the action is 'C'.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
...
<statisticsCategory dataType="lookup" mapField="STAT_CATEGORY_FLG"
  lookup="STAT_CATEGORY_FLG" uiHint:protect="'action','C','='"/>
...
</schema>
```

Trigger Dependent Behavior

The dependents attribute is used to trigger behavior on a child element when a parent element is changed.

Syntax	Values
uiHint:dependents=" "	A list of one or more dependent elements separated by semicolons.

The following example illustrates that the dropdown list of one element is driven by the value of another element. In this example, when the Country changes, the list of States to choose from should change to only show the states for the indicated country.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
<country label="Country" uiHint:select="table:CI_COUNTRY" uiHint:dependents="state" />
<state label="State" uiHint:select="ss:CM-RetrieveCountryStates"
  uiHint:selectIn="input/country:country;" uiHint:selectOut="valuePath:output/state/stateCode;
  descPath:output/state/stateDesc" />
...
</schema>
```

NOTE:

Dependent targets may only name elements, not group or list nodes.

Do not modify the "id" attribute value of dependent and parent element. Data population in dependent is done based on the "id" attribute value.

Control Rendering Target

By default all elements that are not suppressed are visible on both the display map and the input map. Use the **visibleOn** attribute to limit the inclusion of an element to either the display or input map.

Syntax	Values
uiHint:visibleOn=	"displayMap"
	"inputMap"

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
...
```

```
<uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap"
...
</schema>
```

Generate a Text Area

By default, a standard text box is rendered in an input map for any string element. If the field is larger and you wish to have a bigger text area (with a scroll bar), use the **textArea** attribute.

Syntax

uiHint:textArea="true"

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
...
<message label="Message" uiHint:textArea="true"/>
...
</schema>
```

Modify FK Reference Defaults

By default, when an element with **fkRef** is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

Syntax

uiHint:fkRef="info:false;context:false;navigation:false;search:false;"

Only the feature that you wish to turn off needs to be specified. The following example illustrates turning off the navigation capability, meaning the text will not be rendered as hypertext.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
...
<attachmentID fkRef="F1-
ATTCH" primeKey="true" suppress="input" uiHint:fkRef="navigation:false;"/>
...
</schema>
```

FASTPATH: Refer to [FK Reference Formatting](#) in the UI Map Attributes section for more information on each FK reference setting.

Suppress Automatic Number Formatting

By default numeric fields (**dataType="number"**) are formatted as numbers. An attribute is provided to instead apply alphanumeric formatting.

Note: If **dataType** is not specified explicitly, it is derived from **mdField** or **mapField**.

Syntax

uiHint:alphaFormat="true|false"

By default, its value is **false** (and therefore can be left out altogether).

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
...
<numberCount mdField="" dataType="number" uiHint:alphaFormat="true"/>
...
</schema>
```

Auto Capitalize the Input Data

The `uiHint` provides syntax to automatically capitalize input data.

Syntax

`uiHint:capitalize="true|false"`

By default, its value is **false** (and therefore can be left out altogether).

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <toDoTypeCd mdField="TD_TYPE_CD" uiHint:capitalize='true' isPrimeKey="true"/>
</schema>
```

NOTE: This attribute is ignored if `uiHint:textArea="true"` is configured.

The attribute is only available in the schema designer when the `isPrimeKey` is set to **true**. The attribute may be added to any string element when using the source viewer.

Schema Designer

The Schema Designer is a user-friendly interface for performing the following common schema editing tasks:

- Displaying existing schemas.
- Creating schema elements.
- Moving elements within a schema.
- Adding attribute values.

The designer provides two view modes:

- **Text** mode shows the schema elements and their attributes written in the proper syntax and allows for direct text entry.
- **Tree** mode is a view showing the elements in a tree format with many of the key attributes of each element in tabular form. While in this mode, the **Node Display** controls allow the user to choose between displaying the elements by their internal identifiers or their associated screen labels while viewing or editing the schema.

NOTE: Schemas that are not owned by the current installation owner are protected in both view modes.

The following sections provide more information about functionality available in the Tree mode.

- If the schema definition refers to another schema using an 'include' statement, a triangle is visible to the left of the tree area. One can expand that schema by clicking the triangle.
- Detailed information about an element's definition can be displayed and if applicable, updated from the **Tree** view by clicking the edit icon for that element, which appears on the right.  Note that the element attributes are only editable if the element is defined in this schema. When viewing the attributes of an element that is part of an 'include' of another schema, the attributes are display only.
- Context-sensitive embedded help is provided for fields and controls in the edit pane by clicking the Help icon 
- There is a menu dropdown icon visible to the left of the tree for any element that is defined in the current schema being viewed. It is not visible for elements included from another schema. New elements may be added in the **Tree** mode.

Clicking that dropdown displays options to Add, Delete or Move an element. Note that not all options are visible, based on what is allowed for the element adjacent to the menu. For example, on the main "schema" node, only the Add option is visible as deleting or moving the "schema" node is not applicable.

When adding a new element, you are prompted first for the element position, which is either a sibling node to the current element or a child node of that element. For either option, the new element is added below the one adjacent to where the menu is clicked. You are then prompted for the element type.

The following lists the possible element types. Most are self explanatory and represent standard schema options.

- **Characteristic List.** This is a special type of Flattened List element that is used to map list elements that include a sequence and a characteristic value for a given characteristic type. This element is only applicable for maintenance objects that have one or more characteristic child tables where the primary key is the maintenance object's key, characteristic type and sequence. Effective dated characteristic collections are not supported. The user defines the list name, the characteristic value element name and the characteristic type. The system will configure the remaining flattening information accordingly.
- **Characteristic.** This is a special type of Flattened Field element that is used to map a single element to the characteristic for a given characteristic type. This element is only applicable for maintenance objects that have one or more characteristic child tables where the primary key is the maintenance object's key, characteristic type and sequence. Effective dated characteristic collections are not supported. The user defines the element name and the characteristic type. The system will configure the remaining flattening information accordingly.
- **Comment.** This adds a comment to the schema.
- **Embedded HTML.** This is specific to a schema enabled for UI Hints. It is used to include a UI map fragment.
- **Field**
- **Flattened Field**
- **Flattened List**
- **Group**
- **Include BO Schema**
- **Include BS Schema**
- **Include DA Schema**
- **Include Map Schema**
- **Include SS Schema**
- **Input Map Title.** This is specific to a schema enabled for UI Hints. It is used to define a title element for the map.
- **List**
- **Nested Flattened Field.** This is a flattened field from a child table.
- **Raw Element.** This element is used to capture text as is. It is typically used to capture an XML structure without any details of the definition of the individual nodes.
- **Section.** This is specific to a schema enabled for UI Hints. It is used to define a section within the map.
- **Simple Field.** This is a special type of Field element that is used to define an element that is mapped to a column that supports data defined in an XML structure. (This is either a column with the character large object data type (CLOB) or the XML data type).

The **Schema Designer** is available by choosing the **Schema** tab on the [Business Object](#), [Data Area](#), [UI Map](#), [Business Service](#), and [Script](#) pages.

Schema Viewer

The schema viewer shows a tree-view presentation of a schema in its expanded form.

The schema illustrates the structure to be used when communicating with the schema's associated object. The following takes place when a schema is expanded:

- If the schema definition includes references to other schemas, these references are replaced with the corresponding schema definitions.
- Also, if the schema definition contains **private** elements, they are omitted from this view.

Clicking on any node on the tree populates the text box on the top with the node's absolute XPath expression. You will find this feature very useful when writing scripts interacting with schema-based objects. [Scripting](#) often involves referencing elements in a schema-based XML document using their absolute XPath expression. You can use this feature on the schema viewer to obtain the XPath expression for an element and copy it over to your script.

Business Event Log

Business Event Log may be viewed as a tool designed to capture any type of business event worth noting. You configure business objects to represent the various types of events your application calls for. The following type of details may be captured for each event:

- The business object representing the type of event.
- The date and time the event took place and who initiated it.
- The business entity for which this event is logged.
- Standard application message to describe the event.
- Additional context information that is available at the time of the event and varies for each type of event. The Business Event Log maintenance object supports a standard characteristics collection as well as an XML storage (CLOB) field. The event's business object determines where each piece of information resides. Refer to [Business Objects](#) for more information.

One common type of event may be the audit of changes made to sensitive data, for example, tracking an address change. Whenever an entity associated with a business object is added, changed, or deleted the system summarizes the list of changes that took place in that transaction and hands them over to **Audit** business object algorithms to process. You may design such an algorithm to audit the changes as business event logs. Refer to [a business object may define business rules](#) for more information.

You can also allow users to initiate business event logs to capture important notes about a business entity by exposing a [BPA Script](#) to invoke the event's corresponding business object.

Bottom line is that any process can create a business event log by invoking the business object representing the appropriate type of event.

Miscellaneous Topics

The following sections describe miscellaneous system wide topics.

Javadocs Viewer

The system provides a Javadocs viewer and a Groovy Javadocs viewer, which are interactive tools that allows you to browse Java documentation files (Javadocs) for Java classes that execute on the application server. For information about how to use Javadocs and navigate within the viewer, refer to Javadocs help.

Javadocs

To launch the Javadocs viewer, open open **Admin > Implementation Tools > Javadocs**.

NOTE: Proprietary Java Classes. A small number of Java classes have been suppressed due to their proprietary nature.

Additionally, when viewing a record that references a Java program in the [algorithm type](#) page, the [batch control](#) page or the [FK reference](#) page, an icon adjacent to Java program allows you to view the Javadocs for that program.

Groovy Javadocs

The Groovy Javadocs viewer includes the Java classes that are accessible to Groovy code within scripts. Launch this viewer using the 'View Groovy Javadocs' link in the Script Tips zone on the [script](#) page.

Module Configuration

The system provides the ability to simplify the user interface based on functionality areas practiced by your organization.

Menu items and other user interface elements are associated with function modules. By default, all function modules are accessible. If a function module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information on how to turn off a module.

If a function module is made non-accessible, i.e. turned off, its related elements are suppressed from the user interface. In addition the system may validate that related functionality is not accessed. This also means that turning off the wrong module may cause any of the following to occur:

- Menu items may not appear. Refer to [Menu Item Suppression](#) to better understand how menu item suppression works.
- Entire menus may not appear. Refer to [Menu Suppression](#) to better understand how menu suppression works.
- Tabs on pages may not appear.
- Fields may not appear.
- The system may return an error message when you attempt to use a function (indicating the function is turned off).

To correct the above situation, simply remove the module from the turned off list thus making it accessible again.

Your module configuration setup is displayed on the [installations](#) record.

Menu Item Suppression

The following points describe how your module configuration can suppress [menu items](#).

- Menu items that are owned by the base product (as opposed to those your implementation adds) are associated with one or more function modules. If your module configuration has turned off all of the menu item's modules, the menu item is suppressed. If at least one of the modules is accessible, i.e. turned on, the menu item is not suppressed.
- If a menu line doesn't contain any accessible items, the menu line is suppressed.

- If all lines on the [Admin menu](#) are suppressed, the menu itself is suppressed in the application toolbar. This is not expected to ever occur for the Main menu as the user preferences is on that menu and the expectation is that all users have access to their preferences.
- Menu items that are suppressed are not visible in the [Menu Item Search](#) results.

Menu Suppression

In addition to the above Menu Item Suppression logic, the following points describe how your module configuration can suppress an entire menu.

- Menus that are owned by the base product (as opposed to those your implementation adds) are associated with one or more function modules.
- If your module configuration has turned off all of the menu's modules, the entire menu is suppressed. If at least one of the modules is accessible, i.e. turned on, the menu is not suppressed.

Turn Off A Function Module

The base package is provided with a **Module Configuration** [Feature Configuration](#) that allows your organization to turn off base package function modules.

To turn off any of the base package function modules add a **Turned Off** option to this feature configuration referencing that module. Refer to the **MODULE_FLG** lookup field for the complete list of the application's function modules.

Any module not referenced on this feature configuration is considered turned on, i.e. accessible. To turn on a module, simply remove its corresponding **Turned Off** option from this feature configuration.

You may view your module configuration setup on the [installation options](#) page.

NOTE: Only one. The system expects only one **Module Configuration** feature configuration to be defined.

Global Context Overview

The framework web application provides each product the ability to nominate certain fields to act as a "global context" within the web application. For example, in Oracle Utilities Customer Care and Billing, the global context fields include Account ID, Person ID and Premise ID. The values of these fields may be populated as a result of searching or displaying objects that use these fields in their keys. If you navigate to the Bill page and display a bill, the global context is refreshed with the Account ID associated with that bill. The global context for Person ID and Premise ID are refreshed with data associated with that account.

The fields designated as global context for the product are defined using the lookup **F1_UI_CTXT_FLDS_FLG**.

Changing the values of the global context typically cause data displayed in zones on the dashboard to be refreshed to show information relevant to the current values of these global context fields.

When the value of one of the global context fields changes, an algorithm plugged into the [installation record](#) is responsible for populating the remaining global context values accordingly. Refer to your specific product for more information about the base algorithm that is provided for that product.

System Data Naming Convention

There are several maintenance objects in the system that include owner flag in one or more of its tables. We refer to the data in these tables as "system data". Some examples of system data tables include Algorithm Type, Batch Control, Business Object and Script. Implementations may introduce records to the same tables. The owner flag for records created by an implementation is set to **CM** (for customer modification), however the owner flag is not part of the primary key for any

of the system data tables. As a result, the base product provides the following guidelines for defining the primary key in system data tables to avoid any naming conflict.

Base Product System Data

For any table that includes the owner flag, the base product will follow a naming convention for any new data that is owned by the base product. The primary key for records introduced by the product is prefixed with **xn-** where **xn** is the value of the owner flag. For example, if a new background process is introduced to the framework product, the batch code name is prefixed with **F1-**.

NOTE: There are some cases where the hyphen is not included. For example, portal codes omit the hyphen.

For most system data, the remainder of the primary key is all in capital case. An exception is schema oriented records. For business objects, business services, scripts, data areas and UI maps, the product follows the general rule of using CapitalCase after the product owner prefix. For example, **F1-AddToDoEntry** is the name of a base product business service.

NOTE: Data Explorer Business Services. For business services used to invoke a data explorer zone, it is recommended to name the Business Service the same name as the related zone rather than defining a different CapitalCase name for the business service.

Please note that this standard is followed for all new records introduced by the base product. However, there are base product entries in many of these system data tables that were introduced before the naming convention was adopted. That data does not follow the naming convention described above.

NOTE: Schema naming conventions. A context sensitive "Schema Tips" zone is associated with any page where a schema may be defined. The zone provides recommended naming conventions for elements within a schema along with a complete list of the XML nodes and attributes available to you when you construct a schema.

Implementation System Data

When new system data is introduced for your implementation you must consider the naming convention for the primary key. The product recommends prefixing records with **CM**, which is the value of the owner flag in your environment. This is consistent with the base product naming convention. This convention allows your implementation to use the CM packaging tool in the Software Development Kit as delivered. The extract file provided with the tool selects system data records with an owner flag of **CM** and with a **CM** prefix.

NOTE: If you choose not to follow the CM naming convention for your records and you want to use the CM packaging tool, your implementation must customize the extract file to define the appropriate selection criteria for the records to be included in the package. Refer to the Software Development Kit documentation for more information.

Also note that owner flag may be introduced to an existing table in a new release. When this happens, the CM packaging tool is also updated to include these new system data tables. Your implementation will have existing records in those tables that probably do not follow any naming convention. After an upgrade to such a release, if you want to include this data in the CM packaging tool, you must customize the extract file for the tables in question.

Accessibility Considerations

This section provides information about topics related to accessibility that should be considered when extending the system via configuration tools.

Color Contrast

The HTML color **red** (RGB code #FF0000) when used for text on a white background does not comply with the accessibility color contrast guidelines. When it is desired to use red for text for emphasis in a zone, map or in a text string, the product recommends the shade of red with the RGB code #E0292F.

Note that in addition, the product provides a special CSS class **textColorRedOnWhite** which may be used when HTML references are used for applying the red color. For example, UI map, zone help text and scripting.

Referencing URIs

There are some configuration objects that require a reference to a URI, including file path URIs. The following sections highlight some functionality supported by the product with respect to defining / accessing URIs.

NOTE: In order for the functionality described below to occur, specific APIs must be used by the underlying code related to the fields that capture or process the file path or URL information. If you find that there is a URI-related field that does not provide the functionality described here, please contact customer support.

NOTE: For schema elements in a business object that reference a [Field](#) with the **URI** data type or define the element with the **URI** data type configured in the [schema](#) will automatically use the appropriate API that validates the value that may reference a substitution variable or must be checked against the allowlist if applicable.

Validation Against an Allowlist

Based on a property setting, your implementation may be configured to define a allowlist of URIs. If this setting is enabled, the system will issue an error if the URI is not defined in the allowlist. Consult your system administrator to verify if this setting is enabled or not for your implementation.

FASTPATH: Refer to [URI Substitution](#) for information about how defining substitution tokens for URIs using the properties file technique automatically adds the defined URI to the allowlist.

URI Substitution

The system supports the ability to define substitution variables (sometimes referred to as tokens) for both URL values and file path values that reference native file storage locations. For URLs, the system supports defining variables in a Substitution Variable properties file. For native file storage paths, there are two options: the Substitution Variable properties file or via a File Storage configuration extendable lookup. More details on both these options are found below.

- Substitution variables properties file. A substitution variable for all or part of the URI definition may be configured in a properties file. This allows the system administrators to define the proper URI locations in a properties file whereas the configuration users only need to know the variable name. For example, when defining a location for an extract file in an extract batch job, instead of typing a file path of **h:\oracle\serverName\1.0.0\batch\extract**, the batch user can enter **@FILE_EXTRACT@**, assuming there is an entry in the substitution variables file with a name of **FILE_EXTRACT**, and a value of **h:\oracle\serverName\1.0.0\batch\extract**. Another example is that the batch user could enter **@BATCH_FILES@\extract**, assuming that the URI variable for **BATCH_FILES** is defined as **h:\oracle\serverName\1.0.0\batch**.

NOTE: The product automatically populates the value of **SPLOUTPUT** in the properties file so that this may be used in URI configuration. In addition, the product may supply some pre-defined variable names for other common references. As part of this, the 'advanced' menu in the system installation steps may prompt for installers to define the

values of these pre-defined variables, if desired. Installations may opt to define additional substitution variables for various URI references. Refer to the *System Administration Guide* for more information.

- File Storage extendable lookup. Specifically for file paths that reference the native file system, the system also supports the ability to define a path using the **File Storage Configuration** extendable lookup. The following points highlight the steps to take for this option.
 - Navigate to [Extendable Lookup](#) and search for the **File Storage Configuration** lookup.
 - Click **Add** to create a new entry. Define a lookup value name. This will be used when configuring a file path that uses this value. Choose the File Adapter value of **Native File Storage**. Enter the desired file path value. The values defined here may in turn refer to values defined in the Substitution Variables properties file. For example, the file path can reference @SPLOUTPUT@.
 - To reference this value in system configuration, use the syntax **file-storage://XXXX**, where XXXX is the extendable lookup value. Using the same example from above, if you define an extendable lookup value of CM-FileExtract with a file path of **h:\oracle\serverName\1.0.0.0\batch\extract**, then when configuring the extract file path for an extract batch job, enter **file-storage://CM-FileExtract**. Another example is that if the extendable lookup value's file path is configured as **h:\oracle\serverName\1.0.0.0\batch**, then the user configuring the file path on the batch extract can enter **file-storage://CM-FileExtract/extract**

When should you define substitution variables in the properties file and when you define them in the extendable lookup? The following points highlight differences between the options that may help this decision.

- Substitution variables for URLs are only supported via the properties file.
- The properties file can typically only be modified by a system administrator. If there are values that are set at installation time and don't change, then defining the values in the properties file may be beneficial.
- When defining additional environments, such as test environments or production, the values in the extendable lookup may be copied using CMA. Ideally the values are defined such that they are the same between various regions.

External File Storage

The system supports using Oracle Cloud Object Storage for managing files in cloud implementations and can be configured to read files from or write files to this external location. Refer to Oracle Cloud Object Storage documentation for more information about obtaining an account and defining appropriate file locations or "buckets".

Once your cloud storage information is defined, the following points highlight the configuration steps required in the application.

- Define a [signature key ring](#). When the system tries to communicate with cloud object storage, it must provide a signature key so that cloud storage can confirm that the request is from a trusted source.
 - Navigate to [Key Ring](#) in add mode and select the **RSA Signature Key Pair** business object.
 - Define a key ring code, which will be used in the File Storage configuration (below) along with a description.
 - Once the key ring is added, click **Generate Key** to generate a private / public key pair.
 - Click View Public Key to launch a pop-up that displays the public key, allowing the user to copy the key.
- At this point, the user should navigate to cloud object storage and register the public key. Once this is done, the key ring is now ready to be configured in file storage configuration.
- Use a File Storage extendable lookup to define the location and connection information so that you may reference this location in system configuration. The following points highlight the steps to take for this option.
 - Navigate to [Extendable Lookup](#) and search for the **File Storage Configuration** lookup.
 - Click **Add** to create a new entry. Define a lookup value name. Note that the lookup value should not have a slash or backslash in its name. This will be used when configuring a file path that uses this value. Choose the File Adapter

value of **Oracle Cloud Object Storage**. Provide the following information that identifies the cloud storage options: User, Tenancy, Compartment, Namespace and Region. For the Key Ring, choose the value defined above.

- To reference this value in system configuration, use the syntax **file-storage://XXXX/...**, where XXXX is the extendable lookup value and any additional path information that is appropriate. For example, if you define an extendable lookup value of **CM-CloudStorage** and you have a bucket defined in Cloud Storage for processUpload, when configuring the file path for the upload batch job, enter **file-storage://CM-CloudStorage/processUpload**.
- The product supports referencing virtual folders for a bucket. Simply add the virtual folder name(s) after the bucket name. For example, if there is a bucket called 'financials' and a virtual folder for 'paymentUpload', the file path may have this value: **file-storage://CM-CloudStorage/financials/paymentUpload**. For extract processes, if the file path references a virtual folder that does not exist for the referenced bucket, the virtual folder is created as part of the extract process.
- You may optionally use a Bucket Name Prefix on the file storage configuration to support defining different Bucket Names for different environments. For example, imagine you want to have a separate "processUpload" bucket for a development region, a test region and a production region. In the Cloud Storage configuration you can define separate buckets for "DEV_processUpload", "TEST_processUpload" and "PROD_processUpload". If you needed to define the full bucket on each file path reference on various batch jobs, migrating the batch job configuration from one environment to another would require a manual step to change all the bucket references. Instead, the system supports defining a Bucket Name Prefix, which if populated will be prepended to bucket reference before connecting to Cloud Storage. This means that the prefix is defined once and all the references throughout the system can keep the common part of the Bucket name (such as "processUpload"). Then only the File Storage configuration needs to differ between the different regions.
- If your implementation integrates with an external reporting tool that can write the report output to specific delivery channels (buckets) check the Reporting Configuration switch. Define one or more Bucket Names for the buckets that the reporting tool may use for delivery channel options.

NOTE: Refer to the [Key Ring](#) documentation for information about practicing key rotation.

Caching Overview

A great deal of information in the system changes infrequently. In order to avoid accessing the database every time this type of information is required by an end-user or a batch process, the system maintains a cache of static information on the web server and in the batch thread pool worker. These are referred to as the "application caches". Some examples of application caches include

- System messages
- Field label and other field information
- Security Information

The framework product provides many specific caches for commonly used (and infrequently changed) data. In addition, specific edge applications may introduce additional caches as appropriate.

Information may also be cached on each user's browser.

The following topics highlight information about refreshing the various caches.

Server Cache

The server cache refers to data that is cached on the web server. An important use of this cache is for users' online access to the application. The caches aid in better performance while navigating throughout the system, allowing for data to be accessed from the cache rather than by always accessing the database. Besides user access to the web server cache, other functionality deployed to the web server uses caches in a similar way. For example, web services are deployed to the web server and access their own version of the cache.

The contents of the cache are cleared whenever the web server is restarted. This means that fresh values are retrieved from the database once users and web services start using the application again.

The product also supplies a flush command that one can issue in the browser's URL to immediately clear the contents of the cache. The command **flushAll.jsp** flushes every cache.

For example, assume the following:

- the web server and port on which you work is called **OU-Production:7500**
- you add a new record to a control table and you want it to be available on the appropriate transactions immediately

You would issue the following command in your browser's address bar: **http://OU-Production:7500/flushAll.jsp**. Notice that the command replaces the typical `cis.jsp` that appears after the port number.

If your system has been configured correctly, the **flushAll** command will submit a request to do a "global" flush of caches (including the web services cache and the thread pool worker cache). This functionality uses a JMS Topic to publish the flush request. Refer to the *Server Administration Guide* for details on how to configure the JMS topic.

Also note that the system provides a business service **F1-FlushAllService**, which is equivalent to the `flushAll` command (except that it does not restart your browser session). This may be useful for any processes that are built to orchestrate updates to configuration data where you want to ensure that the cache is immediately flushed. This business service is also exposed as a REST web service.

Batch Cache

When submitting a batch job, the batch component uses a Hibernate data cache to cache administrative data that doesn't change very often. The tables whose records are included in this cache are configured using the Caching Regime value of **Cached for Batch**. This is often referred to as the "L2 cache". Refer to [Tables](#) for more information. When starting a thread pool worker, data in tables marked as cached is loaded and cached for as long as that thread pool is running.

In addition batch jobs may also access application caches when applicable. When starting a thread pool worker, application data that is cached is loaded and cached for as long as that thread pool is running.

If there are any batch jobs that update any tables that are marked as **Cached for Batch**, you must run that batch job using a special thread pool that is configured with the caching disabled. Contact your system administrator to confirm the thread pool that is configured this way.

If there is a change in cached data that should be available for the next batch job, the following points highlight how the cache can be refreshed:

- By default the system is configured to automatically refresh the Hibernate cache every 60 seconds. However, an implementation may override the configuration to either change the number of seconds between intervals or to disable the automatic caching altogether. Application caches used by the batch jobs are not impacted by this refresh.
- Restart the thread pool workers.
- Run the **F1-FLUSH** (Flush all Caches) background process. This background process will flush the application data cached for all thread pool workers for all thread pools.
- If your the region has configured the thread pool workers to "listen" to requests for global flush as described in the [Server Cache](#) section, the thread pool worker caches are also refreshed when a **flushAll** command is issued.

Client Cache

In addition to the web server's cache, information is also cached on each user's browser. After clearing the cache that's maintained on the web server, you must also clear the cache that's maintained on your client's browser. To do this, follow the following steps (note that depending on the browser you use, the steps may vary slightly):

- Select **Tools** on your browser's menu bar
- Select **Internet Options...** on the menu that appears.
- Click the **Delete Files** button on the pop-up that appears.

- Turn on **Delete all offline content** on the subsequent pop-up that appears and then click **OK**.
- And then enter the standard URL to re-invoke the system.

NOTE: Automatic refresh of the browser's cache. Each user's cache is automatically refreshed based on the **maxAge** parameter defined in the web.xml document on your web server. We recommend that you set this parameter to **1** second on development / test environments and **28800** seconds (8 hours) on production environments. Please speak to system support if you need to change this value.

Expression Parser

The product provides support for defining expressions that may be of a mathematical or logical/boolean nature. The expression may include variables and functions.

The data explorer [column parameter](#) is an example of where this may be used. That parameter supports the definition of a formula. Edge applications may include support for a formula or expression using this parser as well. For example, several applications include a type of 'rule' object (calculation rule, form rule or usage rule) that is used for validation or calculation that may support applying a formula.

The following tables highlight what is supported in the expressions that use this parser.

Category	Supported in Expression	Description
Data types	Number	
	String	
	Boolean	
	List	
Literals	Numbers	
	Strings surrounded with either single quote or double quote.	
	NOTE: 'Escaping' special characters is not currently supported.	
	Boolean values: true and false .	
Operations	+	Plus
	—	Minus
	/	Division
	*	Multiplication
	^ or **	Power
	%	Modulus
Logical operations	=	Equal
	>	Greater than
	>=	Greater than or equal to
	<	Less than
	<=	Less than or equal to
	!= or <>	Not equal to

This table identifies the functions that are supported. Note that several of the functions are applicable to a list of values. Note that although the functions are listed in lower case, the column parameter syntax in data explorer indicates referencing the functions as all capital letters. The system converts the data explorer column formula to lowercase before being evaluated.

Function	Parameter	Results	Comments
size()	List element	Number of elements in the list.	
isEmpty()	List element	Returns true if the list is empty.	

Function	Parameter	Results	Comments
sum()	List element of type 'number'	Returns the sum of the numbers in the list.	
avg()	List element of type 'number'	Returns the average of the numbers in the list.	
	One or more numbers separated by commas	Returns the average of the number arguments.	
max()	List element	Returns the largest value in the list.	
	One or more comparable elements.	Returns the largest value of the number arguments.	
min()	List element	Returns the smallest value in the list.	
	One or more comparable elements.	Returns the smallest value of the number arguments.	
abs()	Number	Returns the absolute value.	
ceiling()	Number	Rounds the number to the ceiling.	
exp10()	Number	Raises 10 to the number power.	
acos()	Number	Returns the arc cosine of the number in radians.	The result will lose precision, as it uses double float based functions.
asin()	Number	Returns the arc sine of the number radians.	The result will lose precision, as it uses double float based functions.
atan()	Number	Returns the arc tangent of the number radians.	The result will lose precision, as it uses double float based functions.
cos()	Radian	Returns the cosine of the radian angle input.	The result will lose precision, as it uses double float based functions.
exp()	Number	Raises e to the number power.	The result will lose precision, as it uses double float based functions.
log10()	Number	Takes the log, base 10, of the number.	The result will lose precision, as it uses double float based functions.
log()	Number	Takes the natural log (base e) of the number.	The result will lose precision, as it uses double float based functions.
sin()	Radian	Returns the sine of the radian angle input.	The result will lose precision, as it uses double float based functions.
sqrt()	Number	Returns the square root of the number.	The result will lose precision, as it uses double float based functions.
tan()	Radian	Returns the tangent of the radian angle input.	The result will lose precision, as it uses double float based functions.
floor()	Number	Rounds the number to the floor.	
round()	Number	Assumes a scale of 0. The default rounding mode of "round half up" is applied.	
	Number, Scale	The default rounding mode of "round half up" is applied.	
	Number, Scale, Mode	The mode must be set to one of the following: <ul style="list-style-type: none"> • "ROUND_CEILING" • "ROUND_DOWN" • "ROUND_FLOOR" • "ROUND_HALF_DOWN" • "ROUND_HALF_UP" • "ROUND_HALF_EVEN" • "ROUND_UP" • "ROUND_UNNECESSARY" 	
negate()	Number	Returns the negative value of the number.	Only available in data explorer.

The following are special functions supported in the application for a list of values. In each case, the syntax is *function* [*indexVariable* in *listName* | *expression using indexVariable*], where the *indexVariable* is chosen by the formula writer to represent each entry in the list and the expression used to evaluate each entry must reference that variable.

NOTE: The syntax supported for a given use of the formula in a functional area is driven by that particular functional area. For example, in Oracle Public Sector Revenue Management, a formula is supported in the “conditional element validation” form rule. In that form rule all variables including lists are declared in the form rule using letters and the formulas in turn use these letters. In that scenario, the functions below would reference the declared variable letter as the “listName”. Other specific functional area that use this expression parser may support different syntax for referencing elements or lists.

Function	Description	Examples
any []	This function returns the value true if any of the entries in list satisfies the expression.	The following returns true if any entry in the Balance list is greater than 0. any [i in list/Balance i > 0]
all []	This function returns the value true if all of the entries in the list satisfy the expression.	The following returns true if all phone numbers are populated. all [i in list/phoneNumber i != ' ']
collect []	This function returns a new list of elements from the referenced list where the value of each entry of the new list is the result of the expression applied to each original value.	The following returns a new list with the tax rate applied to each amount. collect [i in list/amount i * taxRate]
select []	This function returns a list of all the values of the original list that satisfy the Boolean expression.	The following returns a new list with only the amounts that are negative numbers. select [i in list/amount i < 0]
reject []	This function returns a list of all the values of the original list that do not satisfy the Boolean expression.	The following returns a new list with only the amounts that are not negative numbers. reject [i in list/amount i < 0]

Debug Mode

Your implementation team can execute the system using a special mode when they are configuring the application. To enable this mode, enter **?debug=true** at the end of the URL that you use to access the application. For example, if the standard URL was **http://CD-Production:7500/cis.jsp**, you'd enter **http://CD-Production:7500/cis.jsp?debug=true** to enable configuration mode.

In addition, if you have security access to the application service **F1OUIDBUG**, you can enable this mode without changing the URL via the [Help Menu](#) - Enable Debug option. If debug mode is enabled, the help menu entry shows a Disable Debug option, allowing you to turn it off without changing the URL.

When in this mode certain debugging oriented tools become available via an icon visible.  Clicking the icon displays a slide-out panel with options defined below.

The following are only applicable in a non-Cloud environment:

- **Start Debug** starts a logging session. During this session the processing of various configuration tools objects are logged. For example, the log will show the data areas that are passed in at each step and the data areas returned after the step is processed.
- **Stop Debug** stops the logging session.
- **Show Trace** opens a window that contains the logging session. All of the steps are initially collapsed.
- **Clear Trace** clears your log file.

NOTE: The buttons are secured. An application service **F1CONFIGLOG** has been provided for this functionality to allow implementations to restrict user access to these buttons. An additional application service **F1DEBUG** is checked when the environment is not a 'development' environment. This allows implementations to provide an additional layer of security for their production users.

The following are available to view log entries captured while using the system.

- **Show User Log** allows you to view your own log entries. The number of "tail" entries to view may be specified in the adjacent **Log Entries** field before clicking the button. Limiting the number of entries to view allows the user to quickly and easily see only the latest log entries without having to manually scroll to the end of the log.
- **Show Log** allows for advanced settings. It provides for a date / time range to allow a user to target the output for a specific period. In addition, administrative users may request to view logs of other users. The following are examples of when this capability is needed:
 - Batch and integration logs are captured by special user codes created for this type of processing. These users typically do not represent a human and therefore wouldn't access logs using "show user log". Instead someone else would be accessing these logs.
 - Customer admins would like to retrieve logs for an end user possibly for support reasons. An end user might not have technical skills to gather or assess the logs nor would they be given the privilege to access the logs for security reasons
- Checking the **Global Debug** indication starts various tracing options that are added to the user log.

NOTE: Show User Log button is secured. An application service **F1USERLOG** has been provided for this functionality to allow implementations to restrict user access to this button. Only users with access to the **Administrative** access mode of the application service are allowed to view logs of other users. Such restrictions may be called for in production environments.

For Cloud implementations only, the following buttons are available in this mode:

- **Restart TPWs** - This button forces batch containers to terminate, interrupting all running batches. New containers will spin up and the interrupted batches resume. Refer to the Batch Best Practices technical reference paper for more information about this button and when to use it.
- **Restart CM Jar Servers** - This button is provided to aid with support in the cloud for custom Java code in certain use cases. Refer to the Cloud Services Implementation Guide for more information.

Other parts of the system may show additional configuration oriented icons when in this mode. For example, explorer zones may provide additional tools to assist in debugging zone configuration. These icons are described in the context of where they appear.

Also, in debug mode drop down lists in data explorer and UI map zones will contain the code for each item in addition to the item's display string.

Prepare Issue Details

When a user encounters an error with the product and submits a service request, information about the environment, the release and the configuration of the user is often very helpful in understanding the cause of the problem. The system provides a script to capture the environment details and issue description for reporting purposes.

To access the script use **Menu > Tools > Prepare Issue Details**. The option is also available in the help menu in the toolbar.

A pop-up window is provided to display the details that are being captured, including a generated Issue ID to uniquely identify the report. The pop-up allows the user to add additional information describing the specific issue. When the user presses Save, the details are added to the system log with the issue ID, which can be searched when investigating the problem. A message will be displayed to either confirm the details were successfully logged or indicate that an error occurred.

NOTE: The script and menu item are secured. An application service **F1-PREPISSUEDTLS** has been provided to allow implementations to restrict user access to this functionality.

System Override Date

The system provides a way to override the system date used for online operations. This feature is available if the server administrator has enabled it in the environment properties. For instructions on configuring environment properties see the *Server Administration Guide*. The system date override feature is not recommended for production environments.

Under the **General System Configuration** [Feature Configuration](#), the **System Override Date Option Type** holds the date the application will use as the global system date instead of retrieving the same from the database. This feature can be especially useful in running tests that require the system date to be progressed over a period of time.

The system override date feature is also available at the user level. This is useful when a user wants override the system date to run tests without affecting the system date for other users in the environment. In order to override the system date for the user, open the [User — Characteristics](#) page, add the **System Override Date** characteristic type with a characteristic value set to the desired date in the YYYY-MM-DD format.

If system override dates are defined at both the feature configuration level and the user level, the date set at the user level will take precedence.

Additional Search Options

The product supports fuzzy searching in explorer zone types using the Oracle Text CONTAINS operator.

Refer to the DBA guide for details on setting up the database to support fuzzy searching. Note that there are some implementations where fuzzy searching will not be possible. For example, it's only available for implementations using the Oracle database. Additionally, not all languages are supported. Refer to the Oracle Database documentation for more information about fuzzy searching.

For information about the particular syntax to use in the explorer zones, refer to [SQL Statement](#) in the zone parameter details section.

Extensions Dashboard

This portal provides a high level summary of configuration entities that have been customized and extended to meet your business requirements. Included are customer owned entities and extended product owned entities. The portal is intended to be used by your implementation team to get an appreciation of areas that have been customized and may need to be reviewed or retested for various reasons.

Use **Admin > Implementation Tools > Extensions Dashboard** to navigate to the portal.

The following zones may appear as part of the portal's **Main** tab page

- **Extensions Summary.** This zone provides a summary of customized entities by maintenance object. You may select a specific maintenance objects to review entities of this type.
- **Extension Entities.** This zone lists customized entities of the selected maintenance object. It is only visible when a maintenance object is selected on the Extensions Summary zone.
- **Extension Details.** This zone provides additional information as to which specific tables contain the custom owned content for the selected entity. It is only visible when a specific customized entity is selected.

To Do Lists

Certain events that occur within the system will trigger messages describing work that requires attention. For example, if a bill segment has an error, the system generates a To Do message to alert the person responsible for correcting such errors.

Each type of message represents a To Do list. For example, there are To Do lists for bill segment errors, payment errors, customer contact reminder, etc.

We refer to each message as a **To Do Entry**. Each To Do entry is assigned a specific **To Do Role**. The role defines the users who may work on the entry. A To Do entry has a **To Do log** that maintains record of the progress on the To Do entry. For example, the To Do log indicates when the To Do entry was created, when it was assigned to a user and to whom it was assigned, and when and by whom it was completed.

FASTPATH: Refer to [To Do Processing](#) for a description of end-user queries and tools assisting in reviewing, assigning and processing To Do entries.

The Big Picture of To Do Lists

The topics below provide more information about To Do configuration.

To Do Entries Reference A To Do Type

Every [To Do entry](#) references a To Do type. The To Do type controls the following functions:

- The page into which a user is taken when they drill down to the related object on an entry.
- The message associated with the To Do that appears on various pages. Note this message can be overridden for specific To Do messages by specifying a different message number in the process that creates the specific To Do entry. For example, the process that creates To Do entries associated with bill segments that are in error displays the error message rather than a generic "bill segment is in error" message.
- The To Do entry [sort keys](#). Note that the processes that create To Do entries are responsible for populating the sort key values.
- Whether (and how) the To Do entry is downloaded to an external system (e.g., an email system).
- The roles to which an entry may be reassigned.
- The default priority of the To Do entry. Note that this value may be overridden by a **Calculate Priority** algorithm.
- An indication of whether a To Do of that type may be created manually by a user.
- The algorithms used to perform specific business rules for To Do entries of this type.
- The characteristics applicable to the To Do.

To Do Entries Reference A Role

Every [To Do entry](#) references a role. The role defines the users who may be assigned to **Open** entries.

The permissible roles that may be assigned to a To Do entry are defined on the entry's To Do type. After an entry is created, its role may be changed to any role defined as valid for the entry's To Do type.

The base package determines the initial To Do Role as follows:

- The system checks if an entry's message category / number is rerouted to a specific role. If so, it defaults this role. Refer to [Adjusting the To Do Role](#) for more information.
- There may be some other condition related to the object linked to your To Do entry that warrants an override role. A [To Do pre-creation plug-in](#) would be used to check the conditional logic and override the role, if applicable.
- If a Role wasn't determined in one of the previous steps and a Role is provided by the initiating process (algorithm or background process), the entry is created with that Role.
- If the entry does not have a role after the above takes place, the entry's To Do type's default role is assigned to the entry.

NOTE:

At installation time, the system provides a default role assigned to the system To Do types when first installed called **F1_DFLT**. This is done to allow testing of the system prior to implementing of appropriate To Do roles for your organization. The recommendation is to configure all the To Do Types with appropriate business oriented To Do roles once they are defined.

Supervisors for a Role

Most organizations have the notion of a supervisor who is responsible for all entries assigned to a given role. A user that is considered a supervisor should be a valid user in a role. In addition, application security is used to provide supervisors access to additional capabilities, namely the ability to review To Do entries assigned to other users and the ability to assign To Do entries to other users.

The pages listed in [To Do Supervisor Functions](#) are meant for supervisors only. So security for these pages should be restricted to those users that are considered supervisors. The [To Do Management](#) portal and the [To Do Search](#) page are available to all users. There is a special access mode for Supervisors to allow those users the ability to assign To Do entries to other users.

The Lifecycle Of A To Do Entry

The following state transition diagram will be useful in understanding the lifecycle of a To Do entry.

A To Do entry is typically created in the **Open** state. Entries of this type can be viewed by all users belonging to the entry's role. Refer to [How Are To Do Entries Created?](#) for information about how entries are created.

An **Open** entry becomes **Being Worked On** when it is assigned to a specific user or when a user proactively assumes responsibility for the entry. While an entry is **Being Worked On**, it is visible on the To Do Summary page only by the user who is assigned to it.

NOTE: To Do entries may be created in the Being Worked On state. Some To Do background processes may create To Do entries in the **Being Worked On** state. When a user adds a To Do entry online and assigns the To Do to a user (as opposed to a role), the To Do entry is also created in the **Being Worked On** state.

A **Being Worked On** entry may be forwarded to a different user or role. If the entry is forwarded to a role, it becomes **Open** again. This may also be referred to as "reopening" or "unassigning" a To Do entry.

When an entry becomes **Complete**, it is no longer visible in various To Do queries (but it remains on the database for audit purposes). There are two ways an entry can become **Complete**:

- A user can manually indicate it is **Complete** (there are several ways to do this).
- For To Do entries that are logically associated with the state of some object, the system automatically marks the entry **Complete** when the object is no longer in the respective state. For example, an entry that's created when an account doesn't have a bill cycle is completed when the account has a bill cycle.

CAUTION: Important! The automatic completion of To Do entries occurs when the background process responsible for creating entries of a given type is executed. Therefore, if you only run these processes once per day, these entries remain **Being Worked On** even if the object is no longer in the respective state.

- The To Do monitor process may be used to evaluate whether or not the To Do entry can be closed automatically. Refer to [Monitoring a To Do Entry](#) for more information.

How Are To Do Entries Created?

A To Do Entry may be created in the following ways:

- A [background process](#) can create To Do Entries.
- An [algorithm](#) can create entries of a given type. Because the use of algorithms is entirely dependent on how you configure the control tables, the number of types of such entries is indeterminate.
- A user can create entries of To Do types that have a **Manual** usage. Refer to [To Do Entries Created Manually](#) for information about setting up manual To Do types.

For any base product process that includes logic to create a To Do entry, the system supplies a sample To Do type that may be used. Although the To Do types provided by the product are system data, the following information related to each To Do type may be customized for an implementation and is not overwritten during an upgrade:

- The creation process. If the To Do is created by a background process where the background process is referenced on a To Do type. Refer to [To Do Entries Created By Background Processes](#) for more information.
- The routing process. Refer to [To Do Entries May Be Routed Out of the System](#) for more information.
- The priority. Refer to [To Do Type - Main](#) for more information.
- The [roles](#) that may be associated with the To Do type. Refer to [To Do Entries Reference a Role](#) for more information.
- The [message override](#) information. Refer to [Suppress the Creation of the To Do Entry, Adjusting the To Do Role and Working on a To Do Entry](#) for more information.

Suppress the Creation of the To Do Entry

The system provides the ability to indicate that a To Do Entry should not be created based on conditions. When the system detects that no To Do should be created, there is no error. The system simply returns to the caller with an indication that no To Do was created. This functionality only applies to automatic To Do Entries created by an algorithm or background process. It does not apply to manually created To Do Entries.

Suppress Based on To Do's Message

There are some types of To Do Entries that are generated with a message that is specific to a condition that was found for a record. For example, business errors found when trying to update a record through a system process will generate a To Do entry using the error message as the To Do Entry's message. There may be some use cases where the error reported is not something that a user needs to address and it may be beneficial to your organization to suppress the To Do Entry. Note that this is only appropriate if the message generated is for informational or warning purposes and doesn't require action or if you know that the error will be resolved by a subsequent step.

The configuration to suppress a To Do entry based on its message is on the [To Do type's message overrides](#) page.

NOTE: Message Category / Message Number. Every error in the system has a unique message category / number combination. Refer to [The Big Picture of System Messages](#) for more information about message categories and numbers.

We do not supply documentation of every possible message that can be handled by a given To Do type. The best way to build each To Do type's reroute list is during the pre-production period when testing the system. During this period, compile a list of the messages that warrant special behavior described here.

Note that if the To Do type is configured to reference a specific message category / number, it means all To Do entries have the same message. If your organization does not want To Do entries created for this To Do type, then rather than using this suppression technique, you should identify the background process or algorithm that generates the To Do entries of this type and change the configuration there such that it does not try to create the To Do in the first place.

Suppress Based on a Condition

There may be use cases where a To Do entry should be suppressed based on some conditional logic. For example, consider the billing process in Oracle Utilities Customer Care and Billing. There is typically a bill cycle schedule that allows for attempting to bill all the accounts for the bill cycle over a multi-day window. There are some errors that occur on day 1 of the window that may be resolved by day 2 or 3. An implementation may choose to suppress To Do entries for this condition if this is day 1 or day 2 of the bill cycle. If the error still occurs on day 3, then the To Do entry should be generated. This type of condition needs to be determined using an algorithm. The To Do pre-creation plug-ins support returning an indication to suppress the To Do entry. Refer to [To Do Pre-creation Plug-ins](#) for more information.

To Do Entries Created By Background Processes

There are different types of To Do entries created by background processes:

- To Do entries created by dedicated To Do background processes
- To Do entries created for object-specific errors detected in certain background processes
- To Do entries created based on a specific condition

Dedicated To Do Background Processes

There are To Do entries that are created by system background processes whose main purpose is to create To Do entries based on a given condition. For these background processes, the To Do Type indicates the creation background process.

Note that the [Plug-in Driven batch program](#) cannot be used for this purpose. This program assumes that any To Do Type that references it as a creation process is using the link for the [Object-Specific Error Condition](#) use case. If you want to use the plug-in driven batch process to create To Do entries based on a given condition, then you need to follow the pattern described in [To Dos Created by Background Processes for Specific Conditions](#).

NOTE: If you don't schedule the background process, the entries will not be created! The To Do entries of this type will only be created if you have scheduled the associated background process. Therefore, if you want the system to produce a given entry, schedule the background process.

To Dos Created for Object-Specific Error Conditions

A system background process may create a To Do entry when an error is detected during object-specific processing. This is applicable for processes that do not have built in error handling, for example where there is an explicit "error" state or where the record has an explicit "exception" record.

For these background processes, the To Do Type must reference the creation background process.

To have the system create To Do entries for some or all of the errors generated by one of these processes, you must do the following:

- If you want the system to generate To Do entries for errors detected by one of the background processes below, go to the appropriate To Do type and populate the creation background process.

- If you want the system to generate To Do entries for some errors for the process, but not for all errors, populate the creation background process and then proceed to the [message overrides](#) tab to [suppress](#) certain messages. Do this by indicating the message category and message number you want to suppress. Any error that is suppressed is written to the [batch run tree](#).

The functionality will only create a new To Do entry if there is not already an existing (non-complete) To Do for the same To Do type, drill key and message category / message number. It will also check for an existing To Do for a successfully processed record and complete that To Do.

If you do not populate the creation background process, the errors are written to the [batch run tree](#).

NOTE: Errors received while creating a To Do entry. If the background process cannot successfully create a To Do entry to report an object-specific error, the error is written to the batch run tree along with the error encountered while attempting to create the To Do entry.

NOTE: System errors are not included. To Do entries are not created for a system error, for example an error related to validation of input parameter. These errors are written to the [batch run tree](#). Refer to [Processing Errors](#) for more information.

To Dos Created by Background Processes for Specific Conditions

There are some system background processes that create a To Do entry when the process detects a specific condition that a user should investigate. For each background process, the To Do type is an input parameter to the process. The system provides To Do types for each base package background process that may create a To Do entry.

NOTE: No Creation Process. These To Do types do not need (and should not have) a **Creation Process** specified.

To Do Entries Created By Algorithms

There are To Do entries that are created by algorithm types supplied with the base package. The system supplies a To Do Type for each of these To Do entries that you may use.

If you want to take advantage of these types of entries for system algorithm types, you must do the following:

- Create an [algorithm](#):
 - This algorithm must reference the appropriate Algorithm Type.
 - These algorithms have a parameter of the To Do Type to be created. You should specify the To Do Type indicated in the table.
- Plug the algorithm into the respective control table.

To Do Entries Created Manually

You must set up manual To Do entry types if you want your users to be able to create To Do entries online. Users may create a manual To Do entry as a reminder to themselves to complete a task. Online To Do entries may also be used like electronic help tickets in the system. For example, if a user is having a problem starting service, the user can create a To Do that describes the problem. The To Do can be assigned to a help resolution group that could either resolve the problem or send the To Do back to the initiating user with information describing how to resolve the problem.

If you want to take advantage of manual To Do entries, create a To Do type and specify the following information.

On the Main tab:

- Set the **To Do Type Usage** flag to **Manual**.
- Set the **Navigation Option** to **toDoEntryMaint** (To Do entry maintenance).

- Set the **Message Category** and **Message Number** to the message you want to be used for To Do entries of this type. The system will populate the message parameter with the Subject. To show only the subject in the To Do's message, use a message with "%1" as its text.

On the Roles tab:

- Specify the [To Do roles](#) that may be assigned to To Do entries of this type.
- Indicate the To Do role that should be defaulted when you create To Do entries of this type.

On the Sort Keys tab:

When a user adds a manual To Do entry, the system creates an entry with three sort key values. (Sort keys may be used on the To Do list page to sort the entries in a different order.) The To Do type should be set up to reference the sort keys as follows:

Sequence	Description
1	Created by user ID
2	Created by user name
3	Subject

We recommend that the keys have an **Ascending** sort order and that the Subject is made the default sort key.

NOTE: It is possible to define additional sort keys and use a To Do Post Processing algorithm to populate the values. In this case, the base sort keys defined above should still be defined.

On the Drill Keys tab:

When a user adds a manual To Do entry, it is created with a drill key value equal to the To Do entry's ID. When the user clicks the Go To button next to the message in the To Do list, the system uses the drill down application service (defined on the main tab) and the drill key to display the associated To Do entry.

The To Do type must be set up with a drill key that reference the To Do entry table and the To Do entry ID:

Sequence	Table	Field
1	CI_TD_ENTRY	TD_ENTRY_ID

Refining a To Do Entry's Details at Creation Time

When a To Do Entry is created, the key information provided to the system are the To Do Type and the drill key, which is the identifier of the object related to the To Do entry. With this information, system logic along with algorithms called at creation time can add details to the To Do entry or update important attributes so that the To Do can be worked on by the right team in the right priority.

The topics in this section will highlight the features provided to further refine a To Do Entry at creation time.

Linking Additional Information to a To Do Entry

Additional information may be linked to a To Do entry using characteristics. This may include master data so that the To Do entry is associated with one or more specific main objects in the system. It may also include other information that is helpful to any user that may be working on the To Do entry.

For **manual** To Do entries, the valid characteristic types that may be linked to the To Do entry must be defined on the [To Do Type](#) for that To Do entry. When create a manual To Do entry, the user populates the related characteristics as part of creating the To Do.

For **automatic** To Do entries, the program that generates the To Do may link related data to the To Do using characteristics.

In addition, the system [To Do Pre-creation plug-ins](#) can be used to link additional characteristics. These algorithms would use the drill key, which is the related object for the To Do entry. Based on the drill key, it can look up other information

and create appropriate characteristics. Your specific product may be providing one or more algorithms to determine key master data records associated with the related object. For example, Oracle Utilities Customer Care and Billing provides an algorithm that attempts to link a related person, account, premise, service agreement and service point for that drill key. Other edge applications provide a similar algorithm for their relevant entities.

Any information that your user may need to have to help work a To Do entry should be linked to the To Do via a characteristic. For example, if the Rate Class of an account is important or the amount of the previous bill will help determine the priority of the To Do entry, this information may need to be linked as a characteristic.

NOTE: With the volume of To Do entries in the system, it is recommended to carefully consider what information you are linking to the To Do as a characteristic. Users can drill down on details when investigating a To Do entry. Only very important and critical information that would help users in reviewing To Do entries in the [To Do Management](#) portal and make decisions about prioritization and assignments should be linked as characteristics.

Note, before you can set up these algorithms, you must define the characteristic types that you'll use to hold each of these entities. Also note that it is not necessary to define these characteristics as valid characteristic types on the To Do type.

If your To Do entries reference characteristics that are related to your global context data, you may want to configure an alert algorithm to display an alert if a related entry is **Open** or **Being Worked On**. Refer to [Installation Options](#) for more information.

NOTE: Count of related To Do entries. There are some user interfaces that display a count of related To Do entries. This logic looks at foreign key characteristics linked to the To Do entry where the underlying object is a master or transaction object. It counts the distinct list of other non-closed To Do entries that reference the same characteristic(s).

Adjusting the To Do Role

When creating a To Do entry, for a To Do type, there may be attributes of the To Do entry that require that a special set of users work on it. This is sometimes referred to as 'rerouting the To Do entry' to a different role. This section highlights ways to override the role based on conditions specific to a To Do entry.

The information in this section only applies to automatic To Do Entries created by an algorithm or background process. It does not apply to manually created To Do Entries.

Refer to [To Do Entries Reference A Role](#) for the hierarchy used to determine the role .

Reroute Based on To Do's Message

As described in [Suppress the Creation of the To Do Entry](#), To Do entries created for a given To Do type may have different messages based on the specific condition for a record. You may decide that based on the message, the To Do should be routed to a specific Role that is more knowledgeable about a specific error condition. The same [message override](#) configuration that may be used for suppression of a To Do entry, may alternatively be used to assign a specific Role. For example, if certain bill segment errors are always resolved by the rate specialist team, you can indicate the role for that team on the To Do type, message override.

Reroute Based on a Condition

The [To Do Pre-creation plug-ins](#) may be used to assign a specific role based on some condition related to the To Do entry's specific data.

The product provides configuration on [access group](#) to define To Do assignment overrides. The override list defines a To Do type and To Do role. This is useful if your product associates access groups with specific master data for row level security purposes and you would also like to direct To Do entries related to this data to a specific role.

Oracle Utilities Customer Care and Billing also defines similar To Do assignment override configuration on CIS division and Account Management Group.

A pre-creation algorithm is responsible for checking if data linked to the To Do entry is related to a configuration object that supports an assignment override and then looks for an override for the To Do type. You can decide if this algorithm should be plugged in at the To Do Type level or the Installation level. The decision is based on how many To Do types you define overrides for. If it's a small number, then it makes more sense to plug the algorithm in for each To Do type that you define

an override for. This ensure that the configuration is only checked for To Do entries that will have an override. However, if the number of To Do types that are eligible for overrides is larger or if the list changing or growing often, it may be better to plug the algorithm in at the Installation level to ensure that every To Do is checked for a possible override.

NOTE: Note that your product may already provide a base delivered pre-creation algorithm that is checking for this override. If so, that can be used by your implementation. If not, your implementation can provide an appropriate algorithm.

To Do Pre-creation Plug-ins

The system provides two To Do Pre-creation plug-in spots that allow for functionality to add or update information on the To Do Entry that is about to be created. The two plug-in spots are [To Do type](#) and [installation options](#). In general, the installation option To Do pre-creation algorithms would be used for logic that applies to many To Do types and the To Do type pre-creation algorithms would be used for logic that is specific to that To Do type.

If at least one To Do pre-creation algorithm is plugged in on the To Do type, only those algorithms are executed when creating the To Do entry and the installation option algorithms are ignored. The system provides a base delivered To Do type pre-creation algorithm that executes the Installation option To Do pre-creation algorithms. This allows you to control whether the installation algorithms should also be executed for a To Do type that has specific algorithms and if so, when.

The following points highlight functionality supported by both To Do pre-creation plug-in spots.

- Indicate that the To Do entry should be suppressed (not created). The expectation is that this type of algorithm is configured on the To Do type rather than at the installation options level, as this allows for more granular conditions to be checked for a given To Do entry. Refer to [Suppress the Creation of the To Do Entry](#) for more information.
- Linking context specific data to the To Do entry using characteristics. Refer to [Linking Related Information to a To Do Entry](#) for more information.
- Overriding the Role of a To Do entry based on specific configuration related to the To Do's characteristic data. Refer to [Adjusting the To Do Role](#) for more information.

Assigning a Priority

As described in [The Priority of a To Do Entry](#), a To Do type may reference a Calculate Priority algorithm. If so, this algorithm is called as part of the steps to create a To Do entry. The algorithm may use the drill key or any of the related information linked to the To Do as described above to determine priority information.

The Priority Of A To Do Entry

Some To Do entries may be more urgent to resolve than others. A To Do entry is associated with a priority level representing its relative processing order compared to other entries.

Priority level is assigned as follows:

- If one or more **Calculate Priority** plug-ins are defined on the To Do entry's type, the system calls them to determine the entry's priority. They are called initially when a To Do entry is created and each time it gets updated. You may want to use this method if an entry's priority is based on context or time-based factors. For example, when priority takes into consideration account specific attributes. The system also provides a batch process (**F1-TDCLP**) that calls the calculate priority algorithms "at will" for non-closed To Do entries. This is useful when the priority should be reassessed periodically based on factors external to the To Do entry's information. Refer to [To Do Type](#) for more information on priority calculation algorithms. When the priority is determined by one of the algorithms, a log entry is created indicating that the priority was calculated.
- If a priority value has not been determined by a plug-in, the system defaults a To Do entry's initial priority to the value specified on its type.

A user may manually override a To Do entry's priority at any time. When a user overrides the priority, a log entry is created indicating that the priority was overridden. Notice that once a To Do entry's priority is overridden, **Calculate Priority** plugins are no longer called so as to not override the value explicitly set by the user.

NOTE: The system does not use priority values to control order of assignment nor processing of To Do entries. Priority is available to assist your organization with supporting a business practice that ensures higher priority issues are worked on first.

Working On A To Do Entry

A user can drill down on a To Do entry. When a user drills down on an entry, the user is transferred to the maintenance page associated with the entry (the To Do entry's drill key). The page to which the user is taken is configured on the To Do type.

It is also possible to configure the To Do type to launch a script when a user drills down on an entry rather than taking the user to a specific page. The script can check conditions related to the To Do entry to determine a more appropriate page or could be configured to walk the user through the steps required to resolve the To Do entry.

A script is linked to a To Do type based on its message number using the [To Do type's message overrides](#). Refer to [Executing A Script When A To Do Is Selected](#) for more information.

After finishing work on an entry, the user can mark it as **Complete**. Completed entries do not appear on the To Do list queries (but they are retained on the database for audit purposes). If the user cannot resolve the problem, the user can forward the To Do to another user.

Monitoring A To Do Entry

A To Do type may reference a To Do monitor [algorithm](#). The algorithms are executed by the To Do monitor background process (F1-TDMON). The process executes the monitor algorithms for any non-complete To Do entry whose To Do type references at least one monitor algorithm.

Monitor algorithms may be useful if there are business requirements where a To Do could be automatically completed based on criteria that the algorithm can review. For example, an algorithm may be used to detect if the situation that caused the To Do Entry to be generated has been remedied in the meantime, allowing for the To Do Entry to be completed.

To Do Entries Have Logs

Each [To Do entry](#) has a To Do log that maintains a record of the To Do's progress in the system. For example, the To Do log indicates when the To Do entry was created, when it was assigned to a user and to whom it was assigned, and when and by whom it was completed. Users can view the log to see who assigned them a particular To Do and whether any work has already been done on the To Do.

A log entry is created for all actions that can be taken on a To Do entry. Log entries are created for the following events:

- A To Do entry is created (either by the system or by a user)
- A To Do entry is completed (either by the system or by a user)
- A user takes an open To Do entry
- A supervisor assigns a To Do entry
- A user forwards an entry to another user or role
- A user sends back a To Do to the user who forwarded it
- A user manually adds a log entry to record details about the To Do's progress
- A user manually overrides the To Do entry's priority
- The To Do entry's priority was updated as a result of a calculate priority algorithm.

FASTPATH: For information about the contents of log entries for each of the events, refer to [Log Entry Events](#).

Implementing Additional To Do Entry Business Rules

If your business practice calls for additional validation rules or processing steps to take place after a To Do Entry is created or updated, you may want to take advantage of the **To Do Post Processing** plug-ins defined on [To Do type](#).

For example, you may want to validate that To Do entries are only assigned to users with the proper skill levels needed to resolve them. Refer to **F1-VAL-SKILL** for a sample algorithm handling such validation.

To Do Entries May Be Routed Out Of The System

A To Do type can be configured so that its entries are interfaced to another system.

For example, a given To Do type can be configured to create an Email message whenever a new To Do entry is created. The following points describe how to do this:

- Define the name of the background process responsible for interfacing the new To Do entries to another system on the respective To Do type. The base package contains a batch process called **F1-TDEER** that can be used for most situations. This batch process invokes the [External Routing algorithms](#) defined on each entry's To Do type.
- Plug in an appropriate **External Routing** algorithm on the respective To Do type. The logic in this type of algorithm performs the interface efforts for a specific To Do entry. For example, if an Email message should be created for a To Do entry, the logic in the algorithm would compose and send the Email message(s) for a specific To Do entry.

To Do Information May Be Formatted By An Algorithm

A **To Do Information** algorithm may be plugged in on the [installation record](#) to format the standard To Do information that appears throughout the system. This algorithm may be further overridden by a corresponding plug-in on the [To Do Type](#).

Periodically Purging To Do Entries

Completed To Do entries should be periodically purged from the system by executing the **F1-TDPG** background process. This background process offers you the following choices:

- You can purge all To Do entries older than a given number of days.
- You can purge To Do entries for a specific list of To Do types that are older than a given number of days.
- You can purge all To Do entries except for a specific list of To Do types that are older than a given number of days.

We want to stress that there is no system constraint as to the number of **Completed** To Do entries that may exist. You can retain these entries for as long as you desire. However, you will eventually end up with a very large number of **Completed** entries and these entries will cause the various To Do background processes to degrade over time. Therefore, you should periodically purge **Completed** To Do entries as they exist only to satisfy auditing and reporting needs.

NOTE: Different retention periods for different types of To Do entries. Keep in mind that the purge program allows you to retain different types of entries for different periods of time.

Setting Up To Do Options

The topics in this section describe how to set up To Do management options.

Installation Options

There are a number of installation options that may be configured to govern various aspects of To Do processing.

- A **To Do Information** algorithm may be plugged in on the Installation record. Refer to [To Do Entries My be Formatted By An Algorithm](#) for more information.
- A **To Do Pre-creation** algorithm may be plugged in on the Installation record to set additional information for a To Do entry before it is created. Refer to [To Do Pre-creation Plug-ins](#) for more information.
- A **Next To Do Assignment** algorithm must be plugged into the Installation record if your organization opts to use the next assignment feature supported by the Current To Do dashboard zone. The algorithm is responsible for determining the next To Do entry the user should work on. Make sure you provide users with security access rights to the zone's next assignment action. Refer to the [Current To Do](#) zone for more information.
- If your To Do entries reference characteristics related to your global context data and your product supports dashboard alerts generated by algorithms, you may want configure an algorithm to display an alert if an entry is **Open** or **Being Worked On** for the data currently in context. Refer to your product's documentation to determine if these types of alerts are supported.

Messages

You need only set up new messages if you use algorithms to create To Do entries or prefer different messages than those associated with the base package's To Do types.

Feature Configuration

The base package is provided with a generic **Activity Queue Management Feature Configuration** type. You may want to set up a feature configuration of this type to define any To Do management related options supporting business rules specific to your organization.

For example, the base package provides the following plug-ins to demonstrate a business practice where To Do entries are only assigned to users with the proper skill levels to work on them.

- The base **To Do Post Processing** To Do Type algorithm **F1-VAL-SKILL** validates that a user has the necessary skill levels required to work on a given To Do entry.
- The base **Next To Do Assignment** installation options algorithm **F1-NEXT-TDSK** has the ability to assign To Do entries to users that have the proper skills to work on them. This plug-in is applicable if your organization practices [work distribution](#) "on demand."

You must set up such an **Activity Queue Management** feature configuration if you want to use any of the above base package plug-ins.

The following points describe the various **Option Types** provided with the base package:

- **Skill.** This option provides a reference to a skill category. For example, if you were using characteristics to represent skill categories then you should reference each characteristic type using this option.
- **Override Skill.** This option provides an override skill information reference for a specific message. For example, if you were using a To Do Type characteristic to specify an override skill category and level for a specific message category / number then you would reference this characteristic type using this option.

NOTE: Skill Setup. Refer to the description of the above base package algorithms for further details on how to setup skill level information.

NOTE: More Options. Your implementation may define additional options types. You do this by add new lookup values to the lookup field **F1QM_OPT_TYP_FLG**.

NOTE: Only one. The system expects only one **Activity Queue Management** feature configuration to be defined.

Defining To Do Roles

This section describes the control table used to maintain To Do roles.

To Do Role - Main

The **Main** page is used to define basic information about a To Do role.

To maintain this information, select **Admin > General > To Do Role**.

Description of Page

Enter a unique **To Do Role** and **Description** for the To Do role.

The grid contains the ID of each **User** that may view and work on entries assigned to this role. The First Name and Last Name associated with the user is displayed adjacent.

NOTE: System Default Role. The system supplies a default role **F1_DFLT** linked to each system To Do type. This is done so that To Do functionality may be tested prior to the creation of appropriate business oriented To Do roles.

In addition, various "type" objects or algorithms may reference a To Do role to use when creating a To Do for a given business scenario. This is dependent on your specific product.

To Do Role - To Do Types

The **To Do Types** page defines the To Do types that may be viewed and worked on by users belonging to a given To Do role.

To maintain this information, select **Admin > General > To Do Role** and navigate to the **To Do Types** page.

Description of Page

Enter the ID of each **To Do Type** whose entries may be viewed and worked on by the role.

Use As Default is a display-only field that indicates if the role is assigned to newly created entries of this type. You may define the default role for a given To Do type on the To Do Type maintenance page.

CAUTION: If you remove a To Do type where this role is the default, you must define a new role as the default for the To Do type. You do this on the To Do Type maintenance page.

Defining To Do Types

This section describes the control table used to maintain To Do types.

To Do Type - Main

The **Main** page is used to define basic information about a To Do type.

FASTPATH: Refer to [The Big Picture Of To Do Lists](#) for more information about To Do types and To Do lists in general.

To maintain this information, select **Admin > General > To Do Type**.

CAUTION: Important! If you introduce a To Do type, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter a unique **To Do Type** and **Description** for the To Do type.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

Use the **Detailed Description** to provide further details related to the To Do Type.

Enter the default **Priority** of To Do entries of this type in respect of other To Do types. Refer to [The Priority Of A To Do Entry](#) for more information.

For **To Do Type Usage**, select **Automatic** if To Dos of this type are created by the system (i.e., a background process or algorithm). Select **Manual** if a user can create a To Do of this type online.

Define the **Navigation Option** for the page into which the user is transferred when drilling down on a To Do entry of this type.

Use **Creation Process** to define the background process, if any, that is used to manage (i.e., create and perhaps complete) entries of this type. A **Creation Process** need only be specified for those To Do types whose entries are created by a background process. Refer to [To Do Entries Created By Background Processes](#) for more information.

Use **Routing Process** to define the background process that is used to download entries of a given type to an external system, if any. A **Routing Process** need only be specified for those To Do types whose entries are routed to an external system (e.g., an Email system or an auto-dialer). Refer to [To Do Entries May Be Routed Out Of The System](#) for more information.

Use **Message Category** and **Message Number** to define the message associated with this To Do type's entries. Note: this message will only be used if the process that creates the To Do entry does not supply a specific message number. For example, the process that creates To Do entries that highlight bill segments that are in error would not use this message; rather, the entries are marked with the message associated with the bill segment's error.

Use the characteristics collection to define a **Characteristic Type** and **Characteristic Value** common to all To Do entries of this type. You may enter more than one characteristic row for the same characteristic type, each associated with a unique **Sequence** number. If not specified, the system defaults it to the next sequence number for the characteristic type.

To Do Type - Roles

The **Roles** page defines the roles who may view and work on entries of a given To Do type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Roles** page.

Description of Page

Enter each **To Do Role** that may view and work on entries of a given type. Turn on **Use as Default** if the role should be assigned to newly created entries of this type. Only one role may be defined as the default per To Do type.

FASTPATH: Refer to [To Do Entries Reference A Role](#) for more information about roles and To Do entries.

To Do Type - Sort Keys

The **Sort Keys** page defines attributes that may be used to sort To Do entries.

The To Do Information zone on the To Do Management portal provides the ability to search for To Do entries using sort keys and includes up to five sort key values as columns in the results, which may be used for sorting as required.

The To Do list page includes an **Extra Information** option to allow To Do entries to be sorted by a selected sort key. Note the default sort key for this type of sorting is also defined on To Do type.

Note that this information is captured as a string and is meant for sorting purposes. The system does not capture data type information to be able to format the information for display. For example, dates are not going to display as per the user's display profile configuration.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Sort Keys** page.

CAUTION: Do not change this information unless you are positive that the process / algorithm that creates entries of a given type stores this information on the entries.

Description of Page

The following fields display for each sort key.

Sequence is the unique ID of the sort key.

Description is the description of the sort key that appears on various pages.

Use as Default indicates the default sort key that is initially used when a user opens the To Do List page. Only one sort key may be defined as the default per To Do type.

Sort Order indicates whether the To Do entries should be sorted in **Ascending** or **Descending** order when this sort key is used on the To Do List page.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

To Do Type - Drill Keys

The **Drill Keys** page defines the keys passed to the application service (defined on the Main page) when you drill down on an entry of a given type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Drill Keys** page.

CAUTION: Do not change this information unless you are positive that the process / algorithm that creates entries of a given type stores this information on the entries.

Description of Page

Navigation Option shows the page into which the user is transferred when drilling down on a To Do entry of this type.

The following fields display for each drill key.

Sequence is the unique ID of the drill key.

Table and **Field** are passed to the application service when you drill down on an entry of a given type.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

To Do Type - Message Overrides

The **Message Overrides** page is used if you want To Do entries that reference a given message category / number to be routed to a specific To Do role or suppressed altogether or if you want to associate a script to a given message category / number.

FASTPATH: Refer to [To Do Entries Reference A Role](#) and [Suppress the Creation of the To Do Entry](#) and [Adjusting the To Do Role](#) for more information.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Message Overrides** page.

Description of Page

The following fields display for each override.

Message Category and **Number** allow the message to be overridden.

Exclude To Do Entry indicates if a To Do entry of this type that references the adjacent **Message Category** and **Number** should not be created.

Override Role indicates the to do role to which a To Do entry of this type that references the adjacent **Message Category** and **Number** should be addressed. This field is protected if **Exclude To Do Entry** is on.

Script indicates the script that should execute when a user drills down on a To Do entry of this type that references the adjacent **Message Category** and **Number**. This field is protected if **Exclude To Do Entry** is on. Refer to [Working On A To Do Entry](#) for more information.

To Do Type - To Do Characteristics

The **To Do Characteristics** page defines characteristics that can be defined for To Do entries of this type. The characteristic types for characteristics that are linked to the To Do entry as a result of a pre-creation algorithm do not need to be defined here.

To maintain this information, select **Admin > General > To Do Type > Search** and navigate to the **To Do Characteristics** page.

Turn on the **Required** switch if the **Characteristic Type** must be defined on To Do entries of this type.

Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

To Do Type - Algorithms

The **To Do Algorithms** page defines the algorithms that should be executed for a given To Do type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important To Do functions. If you haven't already done so, you must [set up the appropriate algorithms](#) in your system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Calculate Priority	Optional	Algorithms of this type may be used to calculate a To Do entry's priority. Refer to The Priority of a To Do Entry for more information on when this plug-in is called. Note that it is not the responsibility of the algorithms to actually update the To Do entry with the calculated priority value but rather only return the calculated value. The system carries out the update as necessary.

System Event	Optional / Required	Description
		If more than one algorithm is plugged-in the system calls them one by one until the first to return a calculated priority.
External Routing	Optional	<p>Algorithms of this type may be used to route a To Do entry to an external system.</p> <p>The base package F1-TDEER background process invokes the algorithms for every To Do entry that its type references the process as the Routing Process and that the entry was not already routed. The background process marks an entry as routed by updating it with the batch control's current run number.</p> <p>If more than one algorithm is plugged-in the batch process calls them one by one until the first to indicate the To Do entry was routed.</p>
To Do Information	Optional	<p>We use the term "To Do information" to describe the basic information that appears throughout the system to describe a To Do entry. The data that appears in "To Do information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "To Do information" algorithm on installation options or the system default "To Do information" if no such algorithm is defined on installation options.</p>
To Do Monitor	Optional	Algorithms of this type are executed by the To Do Monitor background process and may be used to periodically review a To Do entry and perform actions, if needed. Refer to Monitoring a To Do Entry for more information.
To Do Post-Processing	Optional	Algorithms of this type may be used to validate and/or further process a To Do entry that has been added or updated.
To Do Pre-Creation	Optional	Algorithms of this type are called when a To Do entry is being added. Refer to Refining a To Do Entry's Details at Creation Time for more information. To Do Type pre-creation algorithms override the Installation level pre-creation algorithms.

Implementing The To Do Entries

To enable the To Do entries visible in the To Do Type page, you must configure the system as follows:

- Define the To Do roles associated with each To Do type and link the appropriate users to them. Once you have defined the roles appropriate for your organization's To Do types, remove the reference to this system default role **F1_DFLT**. Refer to [To Do Entries Reference A Role](#) for more information.
- For any To Do Type that is provided for a specific background process, the To Do simply needs to reference the appropriate Creation Background Process. When the background process is scheduled, To Dos are created based on the logic of the related background process. This applies to [To Dos Created for Object-Specific Error Conditions](#) and [Dedicated To Do Background Processes](#).
- For any To Do Type that is provided for creation by an algorithm or other process, there may be configuration required to populate that To Do type as an algorithm parameter or as an attribute on a control table.

NOTE: Refer to the description of the To Do type for more information.

Background Processes

This chapter covers various topics related to background processes. Besides providing an overview of background process functionality, the various tools available within the application to define, submit and monitor background processes are covered.

NOTE: Your specific source application may have additional background process topics. Please refer to the documentation section that applies to your source application for more information.

Understanding Background Processes

This section describes various topics related to the background processes that perform many important functions throughout your product such as:

- Processing To Do Entries
- Monitor processes that select records in a given state to progress them to their next state in their lifecycle
- Processes that purge data
- Processes that extract data
- And many more...

Background Processing Overview

While the system relies on a scheduler to secure and execute its background processes, there are additional issues that you should be familiar with:

- Batch control records are used for the following purposes:
 - Define the code that executes the logic associated with the background process.
 - For processes that extract information, the batch control record defines the next batch number to be assigned to new records that are eligible for extraction. For example, the batch control record associated with the process that routes To Do entries to an external system defines the next batch number to be assigned to new To Do entries that are configured with this batch control. When this To Do external routing process next runs, it selects all To Do entries marked with the current batch number (and increments the next batch number).
 - The batch control record for each background process organizes audit information about the historical execution of the background process. The system uses this information to control the restart of failed processes. You can use this information to view error messages associated with failed runs.
 - Many processes have been designed to run in parallel in order to speed execution. For example, the process that applies updates for a migration data set import for CMA can be executed so that multiple "threads" are processing a different subset of records (and multiple threads can execute at the same time). Batch control records associated with this type of process organize audit information about each thread in every execution. The system uses this information to control the restart of failed threads. Refer to [Parallel Background Processes](#) for more information.
 - Some processes define extra parameters. These parameters are defined with the batch control. Default values may also be captured for each parameter. They will be used when the [background process is submitted on-line](#).

The following diagram illustrates the relationships that exist for batch control records.

Results of each batch run can be viewed using the [Batch Run Tree](#) page.

Refer to [Batch Scheduler Integration](#) for information about the integration with the Oracle Scheduler.

Parallel Background Processes

Many processes have been designed to run in parallel in order to speed execution. This is referred to as running the process with multiple “threads”.

The system provides two strategies for distributing the data to the multiple threads.

- **Thread Level SQL Select.** This strategy is sometimes referred to as the “thread iterator” strategy. In this strategy, the batch job uses the primary key to figure out how to evenly distribute key ranges to each thread. Each thread is then responsible for selecting the records. In this strategy, the threads should also re-select the data periodically to release the cursor, which aids in performance. Note that this strategy is preferred but may only be used under the following conditions:
 - The data from only one maintenance object is being processed.
 - The primary key for the maintenance object is a single, numeric system generated key.

NOTE: Parameters may be used to override the low and high id. Refer to [Parameters Supplied to Background Processes](#) for more information.

- **Job Level SQL Select.** This strategy is sometimes referred to as the “standard commit” strategy. In this strategy, the keys for the records to be processed by the batch job are all selected first and stored in a temporary table. The batch job then supplies each thread with a range of keys that it should process. This strategy is used if multiple maintenance objects are being processed by the batch job; if the primary key of the maintenance object has multiple parts or if the primary key is non-numeric.

The multi-threading logic relies on the fact that primary keys for master and transaction data are typically system generated random keys. In addition, if the data is partitioned, it is expected to be partitioned based on the primary key.

NOTE: The detailed description in the metadata for each batch control provided with the system should indicate if it may be run in parallel. Note that the strategy used is not typically indicated in the detailed description.

NOTE: Overriding the thread ranges. Your implementation has the ability to override the thread ranges if certain data in your system takes longer to process. For example, imagine you have a single account in Oracle Utilities Customer Care and Billing that has thousands of service agreements (maybe the account for a large corporation or a major city). You may want to set up the thread ranges to put this large account into its own thread and distribute the other accounts to the other threads. To do this, you should create the appropriate batch thread records ahead of time in a status of **Thread Ready (50)** with the key ranges pre-populated. Note that the base product does not provide the ability to add batch thread records online. If you are interested in more information about this technique, contact Customer Support.

Optimal Thread Count

Running a background process in multiple threads is almost always faster than running it in a single thread. The trick is determining the number of threads that is optimal for each process.

NOTE: A good rule of thumb is to have one thread for every 100 MHz of application server CPU available. For example if you have four 450 MHz processors available on your application server, you can start with 18 threads to begin your testing: $(450 * 4) / 100 = 18$.

This is a rule of thumb because each process is different and is dependent on the data in your database. Also, your hardware configuration (i.e., number of processors, speed of your disk drives, speed of the network between the database server and the application server) has an impact on the optimal number of threads. Please follow these guidelines to determine the optimal number of threads for each background process:

- Execute the background process using the number of threads dictated by the rule of thumb (described above). During this execution, monitor the utilization percentage of your application server, database server and network traffic.
- If you find that your database server has hit 100% utilization, but your application server hasn't one of the following is probably occurring:
 - There may be a problematic SQL statement executing during the process. You must capture a database trace to identify the problem SQL.
 - It is also possible that your commit frequency may be too large. Commit frequency is a parameter supplied to every background process. If it is too large, the database's hold queues can start swapping. Refer to [Parameters Supplied to Background Processes](#) for more information about this parameter.
- It is normal if you find that your application server has hit 100% utilization but your database server has not. This is normal because, in general, all processes are CPU bound and not IO bound. At this point, you should decrease the number of threads until just under 100% of the application server utilization is achieved. And this will be the optimal number of threads required for this background process.
- If you find that your application server has not hit 100% utilization, you should increase the number of threads until you achieve just under 100% utilization on the application server. And remember, the application server should achieve 100% utilization before the database server reaches 100% utilization. If this proves not to be true, something is probably wrong with an SQL statement and you must capture an SQL trace to determine the culprit.

Another way to achieve similar results is to start out with a small number of threads and increase the number of threads until you have maximized throughput. The definition of "throughput" may differ for each process but can be generalized as a simple count of the records processed in the batch run tree. For example, in the Billing background process in Oracle Utilities Customer Care and Billing, throughput is the number of bills processed per minute. If you opt to use this method, we recommend you graph a curve of throughput vs. number of threads. The graph should display a curve that is steep at first but then flattens as more threads are added. Eventually adding more threads will cause the throughput to decline. Through this type of analysis you can determine the optimum number of threads to execute for any given process.

Parameters Supplied To Background Processes

This section describes the various types of parameters that are supplied to background processes.

General Parameters

The following information is passed to every background process.

- **Batch code.** Batch code is the unique identifier of the background process.
- **Batch thread number.** Thread number is only used for background processes that can be run in multiple parallel threads. It contains the relative thread number of the process. For example, if the billing process has been set up to run in 20 parallel threads, each of the 20 instances receives its relative thread number (1 through 20). Refer to [Optimal Thread Count for Parallel Background Processes](#) for more information.
- **Batch thread count.** Thread count is only used for background processes that can be run in multiple parallel threads. It contains the total number of parallel threads that have been scheduled. For example, if the billing process has been set up to run in 20 parallel threads, each of the 20 instances receives a thread count of 20. Refer to [Optimal Thread Count for Parallel Background Processes](#) for more information.
- **Batch rerun number.** Rerun number is only used for background processes that download information that belongs to given run number. It should only be supplied if you need to download an historical run (rather than the latest run).
- **Batch business date.** Business date is only used for background processes that use the current date in their processing. For example, a billing process may use the business date to determine which bill cycles should be downloaded. If this parameter is left blank, the system date is used. If supplied, this date must be in the format YYYY-MM-DD. Note: this parameter is only used during QA to test how processes behave over time.
- **Override maximum records between commits.** This parameter is optional and overrides each background process's Standard Commit. You would reduce this value, for example, if you were submitting a job during the day and you wanted more frequent commits to release held resources. You might want to increase this value when a background process is executed at night (or weekends) and you have a lot of memory on your servers.
- **Override maximum minutes between cursor re-initiation.** This parameter is optional and overrides each background process's Standard Cursor Re-Initiation Minutes. You would reduce these values, for example, if you were submitting a job during the day and you wanted more frequent commits to release held resources (or more frequent cursor initiations). You might want to increase these values when a background process is executed at night (or weekends) and you have a lot of memory on your servers.
- **User ID.** Please be aware of the following in respect of user ID:
 - Both the user submitting the job and the user ID recorded on the batch submission should have access to the application service for the batch control that secures execution.
 - Any batch process that stamps a user ID on a record it creates or updates uses this user ID in applicable processing.
 - This user ID's [display profile](#) controls how dates and currency values are formatted in messages.
- **Password.** Password is not currently used.
- **Language Code.** Language code is used to access language-specific control table values. For example, error messages are presented in this language code.
- **Trace Program Start, Trace Program Exit, Trace SQL and Trace Output.** These switches are only used during QA and benchmarking. If trace program start is checked, a message is displayed whenever a program is started. If trace program exit is checked, a message is displayed whenever a program is exited. If trace SQL is checked, a message is displayed whenever an SQL statement is executed. If trace output is checked, special messages formatted by the background process are written.

NOTE: The information displayed when the trace output switch is turned on depends on each background process. It is possible that a background process displays no special information for this switch.

Common Additional Parameters

Each batch control supports the definition of additional parameters. There are some additional parameters that are common to all batch processes or common to a specific type of batch process. The batch control should be delivered with the

appropriate additional parameters. However, when new additional parameters are introduced, existing batch controls may not be updated with the new additional parameter.

The following table highlights the common parameters that may be linked to a batch control. Note that for batch parameters, although there is a sequence number that controls the displayed order of the parameter, the batch process does not use the sequence to identify a particular parameter but rather uses the parameter name. In some cases multiple parameter names are supported (a 'camel case' version and an 'all caps' version).

Parameter Name	Description	Additional Comments
MAX-ERRORS / maxErrors	Each of the batch processes has, as part of its run parameters, a preset constant that determines how many errors that batch process may encounter before it is required to abort the run. A user can override that constant using this parameter.	The input value must be an integer that is greater than or equal to zero. The maximum valid value for this parameter is 999,999,999,999,999.
DIST-THD-POOL	Each batch process executes in a thread pool. This parameter is only necessary if the batch process should execute in a different thread pool than the default thread pool.	The default thread pool name is DEFAULT .
emailMode	When the batch job is submitted with an associated email address, the default logic is to send an email when the job completes regardless of success or failure. Use this parameter to limit the email based on the status of the job when it ends.	Valid Values <ul style="list-style-type: none"> • ERROR — send an email only when the job ends in Error status. • SUCCESS — send an email only when the job ends in successfully. • ALL — always send an email only when the job ends. (This is the default.)

The following parameters are only applicable to jobs that use the **Thread Level SQL Select** method of distributing work to threads as described in [Parallel Background Processes](#).

overrideLowIdValue	Specifies a new low id to use in calculating the range for a thread. The framework by default assumes that the Id is between 0's (e.g. 000000000) and 9's (e.g. 9999999999), but this parameter will override the low value.	The parameter value can be an actual number or it can be set to auto . If auto is configured, it is set to the lowest current value on the database table associated with the background process.
overrideHighIdValue	Specifies a new high id to use in calculating the range for a thread. The framework by default assumes that the Id is between 0's (e.g. 000000000) and 9's (e.g. 9999999999), but this parameter will override the high value.	The parameter value can be an actual number or it can be set to auto . If auto is configured, it is set to the highest current value on the database table associated with the background process.
idRangeOverrideClass	Use this parameter to specify a custom class to do thread range calculation. During batch execution, this override class is instantiated and the setter methods called to initialize the Ids as required. The low and high getter methods are called to retrieve the high and low ids to be used for the run.	The class name specified must implement interface <code>com.splwg.base.api.batch.BatchIdRangeOverride</code> .

The following parameters are only applicable to jobs that perform a single commit, for example for extract batch jobs.

numRecordsToFlush	This parameter defines how frequently to flush the Hibernate cache to prevent high heap consumption and Out Of Memory Errors.	
--------------------------	---	--

Specific Batch Parameters

Some background processes define additional parameters that are specific to their functionality. When a process receives additional parameters, they are defined and documented in the batch control entry in the application.

Indicating a File Path or File Name

Some of the system background processes use extra parameters to indicate a File Path and/or File Name for an input file or an output file. For example, most extract processes use File Path and File Name parameter to indicate where to place the output file.

For the file path parameter, refer to [Referencing URIs](#) for several points related to populating the file path and the supported syntax.

For the file name parameter, there are extract processes that support defining a file name that ends in ".zip" or ".gz", which will automatically result in writing the file with zip or gzip compression (based on the suffix). Similarly, there are upload processes that support decompression of files using the appropriate method based on the file name ending in ".zip" or ".gz". If the extract or upload process supports compression / decompression, it should be indicated accordingly in the description of the File Name parameter. If a batch control doesn't explicitly indicate that it supports compression or decompression in its description, the assumption should be that it is not supported.

In addition, there are extract and import processes that support automatic signing, encryption and decryption of the file content using PGP standards. File names ending in .pgp will be parsed to determine whether encryption, signing, compression or a combination of the three applies. If the file has a .pgp extension and requires decryption or signature verification, a runtime error will be issued if no encryption or signing key ring parameters are supplied.

Encrypting and Signing Files

Some files created by data export related batch processes, may need to be encrypted and/or digitally signed for security purposes. Similarly, batch upload processes may need to verify the signature and/or decrypt the content of the file being imported.

New batch parameters control whether encryption or digital signing applies to files extracted or uploaded by the process.

Extract Process Encryption Parameters

Parameter Name	Description	Additional Comments
encryptExternalKey	Use this key ring parameter to configure the external key provided by the recipient of the file.	If populated, the batch output file will be encrypted using a runtime generated key. The generated key will be encrypted using the active public key stored on the key ring. The recipient will use their private key to decrypt the generated key so the file may be decrypted. Only external public key rings may be used.
encryptSignatureKey	Use this key ring parameter to configure the internal key used to sign the file.	If populated, the batch output file will be signed using the active private key stored on the key ring. The assumption is that the corresponding public key has been shared with the recipient. Only internal file encrypting / signing key rings may be used.

Upload Process Encryption Parameters

Parameter Name	Description	Additional Comments
<code>decryptInternalKey</code>	Use this key ring parameter to configure the internal key to be used to decrypt the file to be uploaded.	If populated, the generated key received with the input file will be decrypted using the active private key stored on the key ring. The data is then decrypted using the generated key. Only internal file encrypting / signing key rings may be used.
<code>decryptSignatureKey</code>	Use this key ring parameter to configure the public signature key provided by the sender of the file.	If populated, the input file signature will be verified using the active public key stored on the key ring. Only external key rings may be used.

You may use the Batch Control Query portal to find all batch controls supporting these options.

Refer to [File Encryption and Signing Keys](#) for more information on maintaining internal and external encryption keys.

Manifest File

Batch processes that create files, for example data export related batch processes, may create one or more files in each processing thread. External applications that consume these files need to process them only when the entire batch process is successfully completed. To automate the consumption of such files, the external application may leverage a function to be triggered upon the creation of a manifest file to process all the files referenced by the manifest. The manifest file includes details such as content hash value, file size information etc that assist in confirming that file content is completed and has not been tampered with prior to processing the files.

The following sections provide additional information about manifest files.

The Manifest Option Batch Parameter

Manifest file creation is supported on certain base product extract related batch controls only. These batch controls include the **Manifest Option** batch parameter that controls whether a manifest file should be created or not upon successful completion of the batch process. You may use the Batch Control Query portal to find all batch controls supporting this option.

Manifest File Information

Manifest file content is provided in JSON format and includes the following information:

- The version of the manifest details structure.
- The batch control code, run number and rerun number identifying the batch run producing the files
- Total number of files created by the batch run.
- Total number of records processed by the batch run.
- The manifest creation timestamp in ISO format.
- The previously completed batch run number, if any.
- The manifest file produced by the previously completed batch run, if any. This may be used to ensure files are processed in a proper order and assist in detecting potential situations of missing files.
- A list of files created by the batch run that includes the following details for each file: the file's name, its size in bytes and the SHA-256 hash value of the file's content.

The manifest file name is constructed as follows:

```
[batch control]_[batch run number]_[batch rerun number]_manifest.json
```

The following is an example of the manifest file structure.

```
{
  "version": 1,
  "batchCode": "HD-PDE",
  "batchRunNumber": 106,
  "batchRerunNumber": 0,
  "totalFiles": 3,
  "recordsProcessed": 10,
  "timeStamp": "2020-05-02T16:55:43.000353Z",
  "previousBatchRunNumber": "105",
  "previousManifestFileName": "HD-PDE_105_0_manifest.json",
  "fileDetails": [
    {
      "fileName": "SOME_FILE_NAME_001.json.gz",
      "fileSize": 1543,
      "hashAlgorithm": "SHA-256",
      "hashValue": "ff7d4e466f93cad4a18ab009080916baff631e03b728e2f2684c4a4f92ccbe1"
    },
    {
      "fileName": "SOME_FILE_NAME_002.json.gz",
      "fileSize": 1182,
      "hashAlgorithm": "SHA-256",
      "hashValue": "78869e7ce971f28a70f5b35693a05726ba66109fecf492edb60291a62aeb1ba9f"
    },
    {
      "fileName": "SOME_FILE_NAME_003.json.gz",
      "fileSize": 1182,
      "hashAlgorithm": "SHA-256",
      "hashValue": "78869e7ce971f28a70f5b35693a05726ba66109fecf492edb60291a62aeb1ba9f"
    }
  ]
}
```

Verifying The Manifest File

The **Verify Manifest File** web service may be used by an external system to validate that the manifest file it has received for a specific batch run is not corrupted or tampered with. The service returns the manifest file name and the hash value of its content for the requested batch run allowing the caller to compare their file details with the returned values.

Sharing Customer Exported Data

Some data export related batch processes support an option that streamlines the process by which customer extracted data may be routed to and shared with Oracle so it can be uploaded to Oracle's data lake for analytic purposes. These batch controls include the **Copy to Oracle** batch parameter that controls whether a copy of the exported file should be sent to Oracle's data lake. You may use the Batch Control Query portal to find all batch controls supporting this option.

NOTE: The batch parameter is set to not share any content by default. Customers may opt in to share their data with Oracle by submitting such a batch process with the parameter explicitly set to do so.

NOTE: This option is only available in a cloud installation.

Processing Errors

When a background process detects an error, the error may or may not be related to a specific object that is being processed. For example, if the program finds an error during batch parameter validation, this error is not object-specific. However, if the program finds an error while processing a specific bill, this error is object-specific. The system reports errors in one of the following ways:

- Errors that are not object-specific are written to the error message log in the [Batch Run Tree](#).
- Some batch processes create entries in an "exception table" for certain object-specific errors. For example, an error detected in the creation of a bill in Oracle Utilities Customer Care and Billing may be written to the bill exception table. If an error is written to an exception table, it does not appear in the batch run tree. For each exception table, there is an associated to do entry process that creates a To Do Entry for each error to allow a user to correct the problem on-line.
- For some background processes, errors that do not result in the creation of an exception record may instead generate a To Do entry directly. For these processes, if you wish the system to directly create a To Do entry, you must configure the To Do type appropriately. Refer to [To Do entry for object-specific errors](#) for information about configuring the To Do type. If the background process detects an object specific error and you have configured the system to create a To Do entry, the error is not written to the batch run tree. If you have configured your To Do type to not create To Do entries for certain errors, these errors are written to the [batch run tree](#).

NOTE: Some processes create exceptions and To Do entries. It is possible for a background process to create entries in an exception table and create To Do entries directly, depending on the error. Consider batch billing in Oracle Utilities Customer Care and Billing; any conditions that cause a bill or bill segment to be created in **error** status result in a record added to the bill exception table or the bill segment exception table. However, any object-specific error that is not related to a specific bill or bill segment or any error that prevents a bill or bill segment from being created may result in a To Do entry for the object-specific error.

Error Post-Processing Logic

The product supports executing one or more algorithms when a batch process encounters an error that causes execution to stop. This allows for some special processing to occur to handle the failure of the batch job. Algorithms for this plug-in spot receive the batch control, batch run number, batch processing business date, number of threads and the list of the ad hoc parameters of the batch job.

NOTE: This plug-in spot is available for all Java based batch programs. For programs of type **Java (converted)**, the individual batch programs need to explicitly support this plug-in spot. Unless otherwise noted, assume that a **Java (converted)** program does not support it.

The following are some examples of functionality that may be executed when a batch job fails:

- Another object or record that is monitoring the batch job may have its status updated to reflect the batch status.
- An outbound message service may be invoked to perform a task related to the failure.

Note that the units of work for all threads are committed prior to executing the error post-processing logic.

Post-Processing Logic

The product supports executing one or more algorithms after all the threads of a given batch job have completed. This allows for some special processing to occur at the end of a batch job. Algorithms for this plug-in spot receive the batch control, batch run number, batch processing business date, number of threads and the list of the ad hoc parameters of the batch job.

NOTE: This plug-in spot is available for all Java based batch programs. For programs of type **Java (converted)**, the individual batch programs need to explicitly support this plug-in spot. Unless otherwise noted, assume that a **Java (converted)** program does not support it.

The following are some examples of functionality that may be executed at the end of a batch job:

- Another dependent batch job can be kicked off. Note that this use case is only needed when the multiple dependent jobs are not part of a scheduler (which can also detect the successful end of one batch job so as to submit the next job).

- Statistics for the batch run may be analyzed and based on results, a To Do Entry may be sent to an administrator.
- If the current batch job is processing a large number of child records in multiple threads, a parent record could be updated to a different status or with some other audit information.

Note that the units of work for all threads are committed prior to executing the post-processing logic. The algorithm should perform standard error handling. If an error occurs in one of the post-processing algorithms, the overall batch job's status is set to Error so that it can be re-submitted to retry the logic in the finalize step.

Timed Batch Processes

Most batch jobs are submitted via a batch scheduler. In the absence of a scheduler, a batch control may be configured as "timed" triggering the framework to monitor and schedule these batch jobs as defined by the timer interval. The timer interval defines the desired interval between starts (in seconds). The system schedules new batch runs at each interval if the last instance of the job has completed.

When configuring a batch control as "timed", other default information must be provided, including the User ID and Language to use for submitting the job and the email address for notification, if desired.

Timed batch controls also include an Active setting, allowing for an implementation to temporarily stop further executions of the batch job (but retain the other timer settings).

Timed jobs are controlled by the default threadpool and not by a scheduler. When the **DEFAULT** threadpoolworker starts it will start executing any job for a Batch Control configured as **Timed** with the Timer Active set to **Yes**. This is whether the batch daemon or batch server is enabled or not.

Monitor Background Processes

In many areas of the system, functionality is driven from business object configuration as a BO driven record progresses through its lifecycle. Refer to [Business Object Lifecycle](#) for details. As part of that functionality, it is possible that a background process, called a [monitor batch process](#), is used to execute functionality for the record. A single program is provided for the BO monitor functionality. The product also provides a batch control template (**F1-MNTPL**) that should be used as a starting point. Parameters are used to limit the records processed by maintenance object and other optional parameters that may further limit the records. The product typically provides at least one monitor batch control for each maintenance object that supports a configurable lifecycle on its business object.

This topic highlights the parameters supported by the monitor batch job. Not all parameters are applicable to all maintenance objects and therefore may not be configured on a given base monitor batch control.

Parameter Name	Description	Comments
maintenanceObject	Maintenance Object	For most base delivered batch controls, this parameter is delivered already populated with the value of the maintenance object value. Note that it is supported to leave this value blank, at which point, the program will determine the maintenance object (objects) to process by looking for an MO that refers to this batch control record as an option.
isRestrictedByBatchCode	Restrict by Batch Code	Set this to true to indicate whether the process should only select records that explicitly refer to this batch control on its current BO state. This is also referred to as "deferred" mode. If set to false , the program includes all records that refer to the current batch control in its BO state <u>and</u> records that don't refer to any batch control in its current state (but monitor algorithms exist in the current state). This is commonly referred to as "periodic" mode. Note that if the value is not set at all, the program will determine whether to run it as "deferred" or "periodic" based

Parameter Name	Description	Comments
		on whether the batch code is configured on the MO option as a State Monitor Process ("deferred") or a Periodic Monitor Process .
restrictToType	Restrict by Related Type	This parameter is only applicable to maintenance objects that have a related 'type' object and the maintenance object has configured an option indicating the field for the related type column. This parameter may be used to limit the processing to records that are in the indicated type.
restrictToBusinessObject	Restrict by Business Object	This parameter may be used to limit the processing to records that are in the indicated business object.
restrictToBOStatus	Restrict by Status	This parameter may be used to limit the processing to records that are in the indicated status.
restrictToDate	Restrict By Date	Enter a valid date on the record's primary table to limit processing to records that are have a value in this field that is on or before the batch business date. Optionally, enter "+" or "-" followed by a number to shift the comparison date to the batch business date plus or minus the given number. For example, entering REVIEW_DT -3 will retrieve all records whose review date is on or before the batch business date minus 3 days.
sampleRecordNumber	Sample Record Number	This is not a commonly used parameter. It is only applicable when the monitor is used for a business use case that supports processing a subset of the records during a testing phase. For example, if the process is validating a large number of records, it may be an option to only validate every 100 records to determine if there are repeated validation errors that may indicate a common problem that may be solved to fix many errors.

Also note that when submitting a monitor process with multiple [parallel threads](#), the program will use a **Thread Level SQL Select** strategy unless any of the following are true (in which case it will use the **Job Level SQL Select** strategy:

- The input maintenance object is left blank and the program finds more than one maintenance object that refers to this batch control in its options.
- A single MO is applicable but it has a multi-part primary key.
- A single MO is applicable and it has a single primary key, but it is a user defined key instead of a system generated key.
- The sample record number parameter is populated.

Plug-in Driven Background Processes

Although the product is delivered with a rich library of background processes, implementations may have business requirements that require new processes to be introduced. It is possible for an implementation to write a background process from scratch using a base process as a template. However, the product also provides base background processes that call algorithms to do the work that is needed. These are called plug-in driven background processes. There are three major types of plug-in driven batch processes:

- Processes that act on records that are stored in the database in the system. These types of processes require SQL to select the records along with the logic to process the records.
- Processes that extract information to a file. These types of processes require SQL to select the records along with the logic to select the information and return it such that the process can write the information based on various settings.

- Processes that import data from a file and store new records in the system as a result. These types of processes require an algorithm that is able to map the data from the file to appropriate new records in the system

The subsequent sections provide more detail about the three types of plug-in driven background processes.

Ad-hoc Processes

A process that retrieves records in the system and does some action on them requires an algorithm to select the records to be processed and another algorithm to process the records. We refer to this type of process as an Ad-hoc Process. The base batch control Plug-in Driven Generic Template (**F1-PDBG**) may be used as a template.

The base processes implement standard background process functionality including parallel background process logic and the ability to create To Do entries for errors. This allows for an implementation to take advantage of the pre-built support and provide plug-ins that include the logic that is unique to the specific use case.

The following sections provide more information about the functionality for ad-hoc processes. Note that extract processes share some of the same functionality. Refer to [Extract Record Processing](#) for additional information specific to extract processes.

Select Records Algorithm

The first important algorithm to design when implementing a plug-in driven batch process is the Select Records algorithm, plugged in on the [batch control](#) page. This algorithm type must define the first parameter as the SQL. The batch job will directly access the SQL parameter value in the metadata (rather than invoking the algorithm). All other parameters are available for the algorithm to use for its own logic.

In addition, when invoking the algorithm, it must return the strategy to use (**Thread Level SQL Select** or **Job Level SQL Select**). Refer to [parallel background processes](#) for more information about the two strategies and when to use each. When choosing the **Thread Level SQL Select** strategy, the algorithm should return the name of the primary key in the Key Field parameter. In addition, the SQL should include a **BETWEEN** clause that includes the bind variables for the low and high ID for the ranges. See below for the bind variable syntax.

If the SQL statement includes variables that are determined at execution time, it must use bind parameters. Bind parameters are referenced in the SQL statement using a colon and a parameter name (for example **:parameter**). There are some variables provided by the system that are populated by the batch job at execution time. These have **f1_** as its prefix.

The system supports the following pre-defined bind parameters:

- **:f1_lowID** and **:f1_highID** - these should be used in the **BETWEEN** clause for the **Thread Level SQL Select** strategy. The batch job will substitute the appropriate ID range as required.
- **:f1_batchCode** and **:f1_batchNumber** - these are common attributes of the batch control that are referenced on a record for selection purposes. Note that the batch run number is set according to whether the batch job is a re-run of a previous run or not.
- **:f1_businessDate** - the batch job will populate the input batch business date, if populated otherwise the current date.

NOTE: The system supports both "f1." and "f1_" as a prefix for the bind variables. However, the "f1." prefix will result in an error if the SQL security property setting is turned on. As such, the underscore syntax is recommended. The period syntax remains for backwards compatibility.

For any other custom parameters, the Select Records algorithm may return one or more sets of field name / variable name / value where the variable name matches a bind variable in the SQL. The field name provides information about the length that assists the SQL binding logic to properly substitute the values. Note that the variable name cannot start with **f1.** as its prefix. The batch job will use the value returned by the algorithm to set the bind parameter in the SQL statement. Also note that the logic binds all variables as a string, so for date variables the SQL must include the "TO_DATE" function.

The plug in spot receives a list of the ad hoc parameters for the batch job as name / value pairs. If the list includes parameters whose values are to be used in selecting records, your algorithm may be used to identify the relevant batch parameter passed as input and populate the field name and output bind variable appropriately.

The product provides a base algorithm type for this plug-in spot that simply defines a parameter for the SQL. It also includes parameters for the strategy and the key field name. This algorithm type may be used by any custom batch process where the SQL does not rely on any special bind variables that must be determined. Simply create an algorithm for the algorithm type and provide the appropriate SQL. Refer to the algorithm type **Select Records by Predefined Query (F1-PDB-SR)** for more information.

Process Records Algorithm

The other important algorithm to design when implementing a plug-in driven batch process is the Process Record algorithm, plugged in on the [batch control](#) page. This algorithm is called for each record selected for the process. It receives all the information that was selected from the Select Records plug-in.

For the ad-hoc processing batch process, algorithms plugged into this spot are responsible for doing the work for each record based on the desired logic.

For the extract batch process, algorithms plugged into this spot are responsible for returning the data that should be written to the file. Many of the parameters for this plug-in spot are only applicable to extract processes. Refer to [Extract Record Processing](#) for more information on the functionality specific to extract processes.

Also note that algorithms for this plug-in spot will be passed two Booleans, `isFirst` and `isLast`, to indicate if the current work unit is the first and/or last for that thread. This allows for the plug-in to do additional work if needed. Note that the `isFirst` indication is available for both types of batch processes, ad-hoc and extract. However, the `isLast` indication is only applicable for the file extract batch. For the ad-hoc batch process this value will always be set to **false**. Extracts will always execute in a single database transaction. In a single transaction run, any error causes the run to be aborted so that it restarts from the beginning when resubmitted. This is done to avoid partial files being written along with inaccurate setting of the `isLast` element.

Configuring a New Process

The following points summarize the steps needed to implement a new background process that acts on records in the system using plug-ins for the specific functionality:

- Verify the SQL that the background process should execute. Keep in mind that all the data selected in the SQL is available to pass to the plug-in that processes the records. If the performance of the background process is important, be sure to consult with a DBA when designing the SQL.
 - If the SQL does not require any custom variables to substitute at runtime, create an algorithm for the base algorithm type **F1-PDB-SR** and configure the SQL. In addition, configure the strategy and the primary key name (for the **Thread Level SQL Select** strategy).
 - If the SQL requires custom variables, a new [plug-in script](#) must be designed and coded to populate the variable names and values using the algorithm entity **Batch Control - Select Records**. Besides defining the variables, the algorithm must also indicate the strategy and the primary key name (for the **Thread Level SQL Select** strategy). Define the algorithm type for the newly created script. The first parameter of the algorithm type must be the SQL as illustrated in the base algorithm type. Note that the other parameters are available for use by this algorithm type if needed. Define the algorithm, populating the SQL as appropriate (using the custom variables).
- Design the logic required to process each record. If your edge product does not deliver a suitable plug-in, create a [plug-in script](#) where the algorithm entity is **Batch Control - Process Record**. Note that the plug-in receives all the information selected in the SQL defined in the Select Records plug-in. For an ad-hoc process, the algorithm should perform whatever process is required based on the business use case. Note that the background process is responsible for committing the records.

In either case, if a new processing script is required, define the algorithm type and algorithm for the newly created script.

- Create a batch control by duplicating the base template **F1-PDBG**. Plug in the algorithms created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the Select Records and Process Records plug in algorithms.

Extract Record Processing

A process that selects records and produces output for each record to write to a file to integrate with external systems is called an Extract Process. The base batch control Plug-in Driven Extract Template (**F1-PDBEX**) may be used as a template.

FASTPATH: Please read the topic [Ad-hoc Processes](#). Its information about the Select Records plug-in and some of the information about the Process Record plug-in apply to extract processes. This topic focuses on aspects that are unique to extract processes.

The system provided process includes parameters to configure the file path and file name for the created file. The file path supports all the functionality described in the topic [Referencing URIs](#). The file name supports system substitution variables, such as run number, thread number, user and date / time. The process also supports compression if an appropriate extension is used. Refer to the File Name parameter description in the batch control for more information.

NOTE: Refer to [Flexible File Name / Writing Multiple Files](#) for information about support for substituting a business value into the file name.

For extract processes, the Process Record algorithm is responsible for returning the data that should be written to the file in one or more XML instances along with the schema name(s) that describes the XML instance(s). The program will write the data to the file as per the format indicated in the File Format batch parameter. By default the service uses the OUA format for date and time. To override this and use XSD format, configure the Date Time Format batch parameter to 'XSD'.

If an existing schema satisfies the output requirements, it may be used. Otherwise, you should define a data area to indicate the output format of the records as appropriate.

There are two options for designing and configuring the Process Record algorithm:

- Create a specific **Process Record** algorithm type that encapsulates the extract logic. The product provides a base algorithm type that illustrates the basic technique to follow. Refer to the algorithm type General Process - Sample Process Record Extract (**F1-GENPROCEX**) for more information.
- Create a file integration type that defines the records to be included in the extract and configure a plug-in driven batch control that references that integration type. Refer to [Extract Using File Integration](#) for more information about implementing this type of functionality.

Your specific edge product may provide other Process Record algorithm types out of the box. Use the algorithm type query and search for records for this algorithm entity.

Grouping by Record XML Node

When configuring an extract process that should produce the output in XML format, your Process Record plug-in may return multiple schemas with information that is all part of the same overall record. For example, the output could include account information and related service agreement details:

```
<account type="group"
  <accountId>1234567890</accountId>
  ...
</account>
<sa type="group"
  <saId>123457665</saId>
  ...
</sa>
<sa type="group"
  <saId>1234588913</saId>
  ...
</sa>
```

In this case, it may be desired to wrap all that information in a grouping XML tag so that all the information for one record is grouped together. Because the Process Record plug-in could be returning header or footer records that are not part of a given selected record's extract information, the batch process doesn't know what schemas returned by the Process Record

plug-in belong together logically. The output parameter 'record XML node' in the schema collection should be used to indicate the outer XML node to use to group related information together. For example:

```
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-AccountRecord</schemaName>
<schemaType>F1DA</schemaType>
<data><account><accountId>1234567890</accountId>...</data>
</SchemaInstance>
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-SAInfo</schemaName>
<schemaType>F1DA</schemaType>
<data><sa><saId>123457665</saId>... </data>
</SchemaInstance>
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-SAInfo</schemaName>
<schemaType>F1DA</schemaType>
<data><sa><saId>1234588913</saId>... </data>
</SchemaInstance>
```

All schemas returned from a single call to the Process Record plug-in that have the same record XML node will be grouped in the written output within that XML tag, as per the example below:

```
<root>
<record>
<account>
  <accountId>1234567890</accountId>
  ...
</account>
<sa>
  <saId>123457665</saId>
  ...
</sa>
<sa>
  <saId>1234588913</saId>
  ...
</sa>
</record>
<record>
<account>
  <accountId>987654320</accountId>
  ...
</account>
<sa>
  ...
</sa>
</record>
</root>
```

Multi-threaded Extract

When extracting data, it's possible that the volume of data warrants running the job multi-threaded. In this case, a separate file is produced with the thread number included in the file name. You may proactively include the thread number as a substitution variable when indicating the file name. If not, the system appends the thread number.

As a convenience, the system supports concatenating the extract files produced by the various threads at the end. The system does this by finding files whose file names match except for the thread number. As such, the file name may not contain date or time if the concatenation parameter is true. Please note the following with respect to the concatenation feature:

- The content of each file is concatenated together "as is". If the individual files have header, footer or summary information, there is no logic to consolidate that information in the concatenated file. If you want a single header, footer or summary, you must run the extract single threaded.
- Concatenation is not supported if the file name indicates the zip compression should be used.
- The individual thread files are retained.

- Note that if the file format is XML, the files written for the individual threads will be written with an extension of ".tmp".

Skipping Records

By default, the extract process expects one or more schemas to be returned by each call to the Process Record plug-in. (Ideally when designing any process, the Select Records algorithm only selects records that should be processed and the Process Record algorithm does not need to confirm whether the record should be part of the processing or not.) If however there is a need to check a condition in the Process Record plug-in and it is found that no data needs to be extracted for this record, the process record algorithm should return the 'is skipped' output parameter to **true** so that the program doesn't write an empty row.

Note that the base process records algorithm for file integration types (**F1-FILEX-PR**) will set the 'is skipped' parameter to **true** if the file integration record extract record algorithm returns no data.

Configuring a New Process

The points documented in the topic related to [configuring a new adhoc process](#) with respect to the Select Records algorithm apply to extract processes.

For the Process Records algorithm, it is responsible for returning one or more schema instances populated with information that should be written to the file. If your edge product does not deliver a suitable plug-in, create a [plug-in script](#) where the algorithm entity is **Batch Control - Process Record**. Note that the plug-in receives all the information selected in the SQL defined in the Select Records plug-in.

Refer to [Configuring an Extract Process Using File Integration Type](#) for information on designing extracts using this configuration.

If a new processing script is required, define the algorithm type and algorithm for the newly created script. Create a batch control by duplicating the base template **F1-PDBEX**. Plug in the algorithms created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the Select Records and Process Records plug in algorithms.

Extract Using File Integration

The product provides separate configuration that may be used to define how to extract the data and how to format it. This configuration provides more metadata related to defining how to get the data to extract and how to format the data. You may have many use cases where using this configuration rather than having all the logic directly in the Process Records algorithm is beneficial.

The configuration can support simple extracts, containing a single record type and possibly a header or footer record. It also supports more complex integrations, involving multiple record types and parent/child relationships between the records.

File Integration Type Configuration

The framework supplies two objects that work together to define the processing needed to create a specific type of extract:

- The file integration type which describes and classifies the extract configuration.
- The file integration record where the sequence, format and logic to extract the data required for a given record type are captured.

File Integration Type

The file integration type defines the integration classification. Currently, only **Extract** is supported. In addition, the file integration type can be assigned to a category. The category may be used to identify extracts with a common purpose or target such as collection agency referrals. Your edge product may deliver a number of categories or you may define your own.

The system provides a business object for extract file integration types (**F1-ExtractFileIntegrationType**) that is expected to be used for most use cases

File Integration Record

The file integration record is the object that is responsible for defining a record's format and capturing the record details. A separate integration record must be defined for each record type included in the extract.

The record sequence defines the order that records are processed by the system. The parent sequence defines the record type of which this record is a child. Child records may also be referenced as a parent of lower level child records. The base Process Records algorithm provided by the framework processes all child records of a record type before processing the next record type in sequence.

For extracts that are XML format, the system supports creating a grouping node surrounding all the output that belongs to the same entity. File integration records define a record XML node that will be used as the grouping node. Each record type in the list that belongs within the same group would indicate the same value in the record XML node. Refer to the [Grouping by Record XML Node](#) section for more details.

NOTE: The system does not support nested record XML nodes. All child records of a record type must define the same record XML node as the parent.

Each file integration record references a data area that defines the extract record's format, allowing the data to be extended. The **Extract Records** algorithms are responsible for populating the data area. The file integration record supports multiple extract processing algorithms so that the custom information can also be populated.

The system provides a business object for extract file integration records (**F1-ExtractFileIntegrationRec**) that is expected to be used for most extract record use cases.

Configuring an Extract Process Using File Integration Type

The following points summarize the additional steps needed to implement a new extract background process that uses a file integration type to define the specific functionality:

- Choose or create data area objects to define the extract record formats.
- Define the logic required to populate each extract record type. Your edge product may deliver suitable plug-ins or you may need to create a [plug-in script](#) where the algorithm entity is **File Integration Record - Extract Record**. Note that the Extract Record plug-in receives most of the information defined in the Batch Control - Process Records plug-in.
- Define the algorithm type and algorithm for each newly created script.
- Choose or create a category for the file integration type using lookup **FILE_INT_OBJ_FLG**.
- Create the file integration type and configure the file integration records using the defined data areas and algorithms.
- Create a batch control by duplicating the appropriate base template for an extract background process. Include the File Integration Type parameter on the batch control and reference the appropriate file integration type.
- Plug in a Process Records algorithm that reads the file integration type configuration and processes the record types. The system provides a base file integration record extraction algorithm (**F1-FILEX-PR**) that is expected to be used for most file integration plug-in extract processes.

Extending a File Integration Extract Process

Your edge product may deliver file integration types and batch controls designed for standard extract processes. However, extending the delivered extracts to add custom data is common practice for most implementations. You can customize the output from a delivered extract by:

- Identifying the record types that need additional details
- Creating a data area that defines the additional details and using that to extend the data area configured on the record type
- Creating a File Integration Record — Extract Record [plug-in script](#), algorithm type and algorithm that populates the extra details
- Adding the algorithm to the integration record's extract algorithms collection

In some cases, you may wish to extend the extract by adding additional record types. To do this, add your custom file integration records to the file integration type, following the steps described in [Configuring an Extract Process Using File Integration Type](#).

Flexible File Name / Writing Multiple Files

By default, the data is written to the File Name defined in the batch parameter. The file name supports several dynamic substitution variables as defined in the detailed description for the batch parameter in the Plug-in Driven Extract Template batch control (**F1-PDBEX**). Also refer to [Extract Record Processing](#) for information about the file name and multi-threaded processes.

The system also supports more advanced file creation for a single batch run. Consider the following use cases

- An extract is for data associated with multiple service providers where each service provider should receive its own file. In this use case, the unit of work is the service provider so a file is produced for each work unit.
- An implementation operates with multiple jurisdictions represented by CIS Division. A certain extract should result in a file per division so that each division only gets its relevant data.
- An extract of Person information should separate individual person data from business person data. In addition, for each person, the contact information should result in a separate file. In this use case, one unit of work includes data to be written to more than one file.

To support the above use cases, the Process Record algorithm supports returning the File Name in the output:

- The file name is included in the output Schema Instance group. You would populate this if you want the data for a specific Schema entry to go to this file name. In the person extract example above, the schema that includes the contact information would indicate the specific contact file.
- The file name is an output field outside the schema list. You would populate this if you don't have different files for different schemas but you still want to override the file name defined in the batch parameter. The service provider and division examples above would populate this parameter with the desired file name. The person extract example could populate this field for all the non-contact information.

The batch process checks the output after each call to the Process Records algorithm. For each schema, if there is a specific File Name associated with the schema, the data for that schema is written to that file. Otherwise, if the output file name is provided, the data is written to that file. Otherwise, the File Name in the batch parameter is used.

NOTE: Substitution Variables. After the call to Process Records, if there are any system variables in the file name, they are resolved at this time.

Managing File Names

This type of requirements means that the Process Record algorithm needs to provide a file name that has some business value to distinguish the individual files. For example, the service provider or the division or the person type value must be part of the file name. However, the recommendation is not to have the file name entirely determined by the algorithm. Rather the suggestion is that you still allow the user submitting the batch job to provide a desired file name as a batch parameter. That way, it can include any of the supported substitution variables for system information (such as batch run number, or date /time stamp) that ensure your files are unique for a given batch run. The algorithm can designate a substitution variable that it looks for to replace with the business value.

For example, using the files per division use case, imagine the user indicates the file name `EXTRACT_FILE_<DIV>_{BN}_{RN}_{TN}.csv`. The process record algorithm receives this parameter. It knows to look for "`<DIV>`" and replace it with the actual division. Imagine the division code is A100, it would return the file name `EXTRACT_FILE_A100_{BN}_{RN}_{TN}.csv` in its output, along with the data to write to that file for this unit of work.

For the person information use case above, where two files are written, the suggestion is to use the File Name parameter for one of the files, for example the person information file. An additional parameter should be used to define the second file, the contact information file. So the users submitting the batch job would define the following parameters:

Parameter Name	Description	Value	Comments
fileName	File Name	persons_<personType>_{BN}.txt	This is the file name parameter provided with the extract.
contactFileName	Contact File Name	contacts_{BN}.txt	This is a special parameter defined by the CM extract batch control.

The Process Record algorithm would look for the File Name parameter provided as input, find the text "<personType>" and replace it with the person type value and return that file name in the output. When building the list of schemas to return in the output, the one that includes the person contact information would include the file name found in the Contact File Name parameter provided as input.

Multiple Threads

This functionality works as expected with multiple threads. Based on the use case and the implementation of the Select Records algorithm, each thread could be producing files for the same business value. Let's use the division use case. Imagine an implementation has three divisions: A100, B200, C300. Now imagine that the extract is for financial information for an account. The select records algorithm should be threading by account id so that the data is evenly distributed across the multiple threads. But within each thread, accounts could be in any of the 3 implementation's divisions. So each thread could produce 3 files for each of the 3 divisions.

As described in [Multi-threaded Extract](#), the system supports an option to concatenate, allowing you to consolidate the files such that you have 3 complete files for the 3 divisions. The same features and limitations described in that topic apply for this use case.

Closing Files

An important consideration when using this functionality is that attention should be paid to how many files are open during the batch process. Each open file takes some memory to manage it. As such, the product has imposed a limit of only 10 open files (per thread) during the run of the batch job. When designing a batch to write to multiple files, the product strongly encourages you to design the process so that whenever possible, all the data for one file can be written and that file can be closed before going on to the next file.

Let's look at our examples.

- For the service provider example, the unit of work for the batch process is service provider. In this case, after each call to process records, the data can be written to the file and then the file can be closed.
- For the division example, the data selected should be threaded by the proper unit of work related to the purpose of the extract, such as Account or Asset. But the data should be ordered by division so that all the data for each division is processed before the next division's data. Each division's file can be closed once the next division's data starts getting processed.
- For the person extract example, the contact file is used for all the data so that file needs to remain open throughout the duration of the job. However, the person information gets segregated by person type. The Select Records could order the data by person type so that all the data for one type could be written and then all the data for the other type could be written. However, given that for any run no more than 3 files will ever be open, this use case is one where there is no need to actively manage closing files during the process.

How will the batch program know when to close a file? Since the batch program is agnostic and does not know what type of data is being processed nor when files should be closed, the Process Record algorithm should provide this information.

NOTE: The batch process will issue an error if Process Records indicates that the file to write to is one that was already closed. Reopening closed files is not allowed. The design of the process needs to be reviewed if this error is received.

To manage this, the batch process provides the Process Record algorithm with the list of open files (with the system substitution variables unresolved) and a Boolean to mark whether the file should be closed. To explain further, we'll use our examples.

File Per Division Example

This use case is that there are 4 divisions in the implementation: NORTH, EAST, SOUTH, WEST and that the data (account data) should be grouped in separate files by division.

The recommendation is that the Select Records algorithm selects the data ordered by Division.

The batch process passes to the Process Record algorithm the list of open files (there should be only be zero or one). In this case, the only indication that the data for one division is finished is if the Process Record algorithm sees that its data is for one division and the open file listed is for a different division. Each call should prepare its file name. Then it should see if its file name is in the list of open files. If not, it should indicate that the other open file should be closed. (Note that it doesn't need to add itself to the 'open list'. The batch program is only looking for entries marked as closed. It will ignore entries that are not marked as closed).

Assume the file name in the batch parameter is myFile_<DIV>_{BN}.txt

The data is sorted so that the accounts in the EAST division are processed first. Let's imagine this is a work unit that is also in the EAST division. It receives the file name and the list of open files.

```
...
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>myFile_<DIV>_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <closeFile></closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

The algorithm substitutes its division into the <DIV> portion of the file and populates that in the output. It then compares its file name with the current list of open files. It finds its file so it doesn't need to do anything else.

```
<hard>
...
<fileName>myFile_EAST_{BN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile></closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

If we then imagine a call to the process records algorithm where the division is NORTH and it's the first entry for that division, here is what it receives:

```
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>myFile_<DIV>_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
```

```

<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>

```

The algorithm substitutes its division into the <DIV> portion of the file and populates that in the output. It then compares its file name with the current list of open files and doesn't find its file name. So it indicates that the existing open file should be closed.

```

<hard>
...
<fileName>myFile_NORTH_{BN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>

```

File Per Service Provider Example

In this use case, the unit of work is service provider and each service provider should have its own file. In this case, as the Process Record algorithm is preparing the data and the file name unique to its service provider, it can also indicate that the file can be closed. There is no need to wait for the next call to Process Record to indicate that the previous file can be closed. Let's assume the file name is MYFILE_<serviceProvider>_{BN}_{TN}.txt. Each call to Process Records will pass the batch parm file name and no open files.

```

<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>MYFILE_<serviceProvider>_{BC}_{TN}.txt</value>
