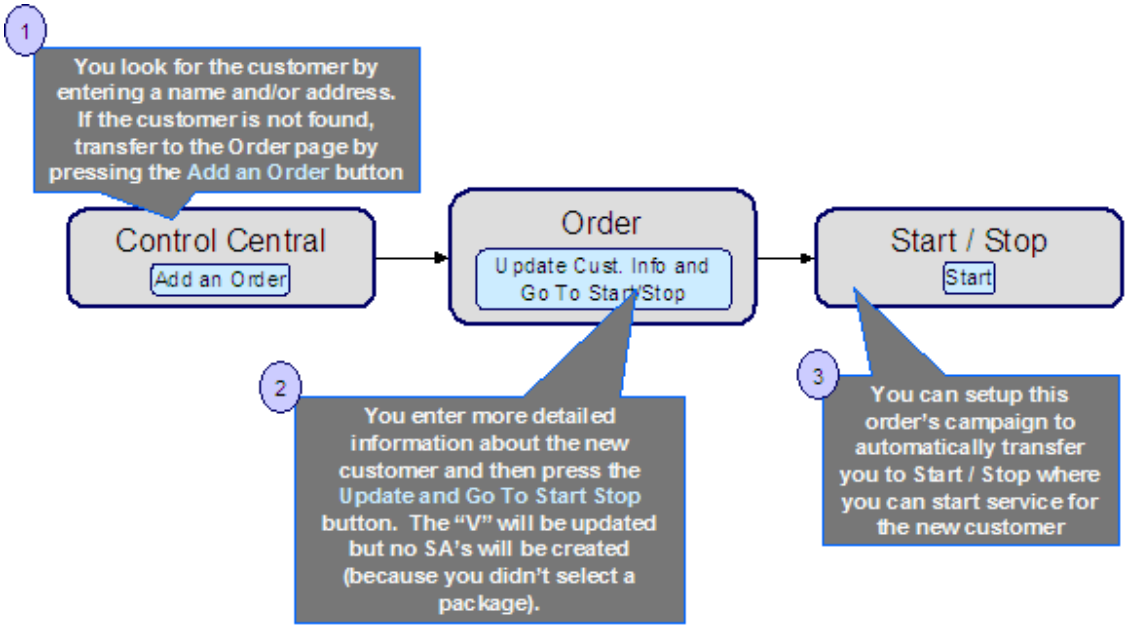
> We do not recommend using this business process if your organization's service territory is predefined (i.e., if you've set up the premises and service points for your entire service territory). Why? Because it can result in the creation of new premises and / or service points and you probably don't want this to happen if you've already set everything up. While it is possible to disable the creation of new service points and premises by developing new plug-ins, we'd recommend using the business process described under How To Add A New Customer From Control Central if a new customer calls in and you have predefined premises and service points.

Copyright © 2026, Oracle and/or its affiliates.

The following points describe the steps in this business process:

- You look for the customer using Control Central - Search. Because the customer is new, you push the Add Order button on Control Central to transfer to the Order transaction.
- You then process the order as described above.

In order to take advantage of the above business process, it's important that you understand the following points:



- When the order page is opened for a new customer, the order's campaign is defaulted from the installation record. The default campaign on the installation record is "generic" because we don't know anything about the customer (they are new) and therefore we cannot default a campaign targeted to their customer class or geography.
- This default campaign on the installation record must be constructed using one of the following approaches:
  - The default campaign has a package for every potential type of customer who can call up. While this is possible, it's probably not realistic as the data setup burden required to define every type of package could be onerous. However, if you have a limited number of service agreements, this approach is feasible.
  - The default campaign could just be a "dummy" campaign that has no packages. The "real" campaigns will only be shown after basic information about the customer has been recorded on the order and the "show eligibility" button is pressed. These campaigns appear in the order's eligibility tree. The selection of a campaign in this tree will cause the order's campaign to be switched. Note, because the "dummy" campaign has no packages, no packages will appear in the order's eligibility tree when the dummy campaign is referenced on an order.
- The order is then processed as described above.

Setting up a New Customer Prior To Using Start/Stop

The following business process flow illustrates how the sales and marketing functionality would be used to create a new customer prior to using Start/Stop to start service at an existing premise.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The following business process is similar to that described under How To Add A New Customer From Control Central. The only difference is that the Order transaction is used to create a new person and account rather than the Person transaction. The order transaction may be a better choice because it lets you define many attributes on person, account and premise that are not accessible on the person page. For example, the order transaction lets you define the customer's automatic payment option, bill after date, override due date, etc. In addition, on an order's campaign, you can define default values of many field values (both real fields and characteristics). These default values are presented on the order transaction and may be overridden by the user at will.

The following points describe the steps in this business process:

- You look for the customer using Control Central - Search. Because the customer is new, you push the "Add Order" button on Control Central to transfer to the Order transaction.
- You record additional demographic and geographic information about the new customer and confirm all values defaulted from the order's campaign. After all required information is entered, you press the Update Cust. Info and Go To Start/Stop button to create the new person and account and transfer to Start/Stop to identify the new services desired by the customer.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The button's existence and label are dynamic.** In the above example, we indicated that there is a button on the order page called **Update Cust. Info and Go To Start/ Stop**. This button's presence on the page and its label are controlled by fields on the campaign. When pressed, the "V" is updated with information on the order and the user is transferred to the "post completion" page (which is also defined on the campaign). You would only enable this button on campaigns whose orders can be completed without selecting a package. In the above example, the campaign doesn't have any packages (because service is intended to be started using Start/Stop). In Examples of Campaigns and Packages we show other examples of how these fields would be setup for different types of campaigns.

In order to take advantage of the above business process, it's important that you understand the following points:

- When the order page is opened as a result of pressing the Add Order button on Control Central - Search, the order's campaign is defaulted from the installation record. The default campaign on the installation record is "generic" because nothing is known about the new customer and therefore it is impossible to default a campaign targeted to their customer class or geography.
- The campaign on the installation record should be setup to contain default information for the "average" customer. For example, if you typically deal with residential customers, the information on the default campaign should be residential-oriented.
- When a user takes an order for a new customer, they'll change the default information when appropriate. For example, if an industrial customer were being added, they'd change the customer class to "industrial" and then ask to see the campaigns such a customer is eligible to choose (these alternate campaigns are displayed in the order's eligibility tree). For example, if you've setup campaigns with eligibility rules that are targeted at industrial customers and the customer class on the order has been changed to "industrial", the user will see these campaigns in the eligibility tree. The user can then change the campaign's order by simply clicking on the desired campaign.

> **Note**
>
> The above example illustrates how an order can be completed without causing the creation of service agreements. Refer to Marketing Surveys and Prelude to Start Stop for examples of such campaigns.

Examples of Campaigns and Packages

The topics that follow provide examples of campaigns and packages that support several different scenarios. Your organization's campaigns and packages may differ markedly from these examples. Factors that will influence your sales and marketing objects include:

- Whether the type of goods and services marketed to your customers / prospects differs depending on some trait of the customer or the region in which they are located. For example,

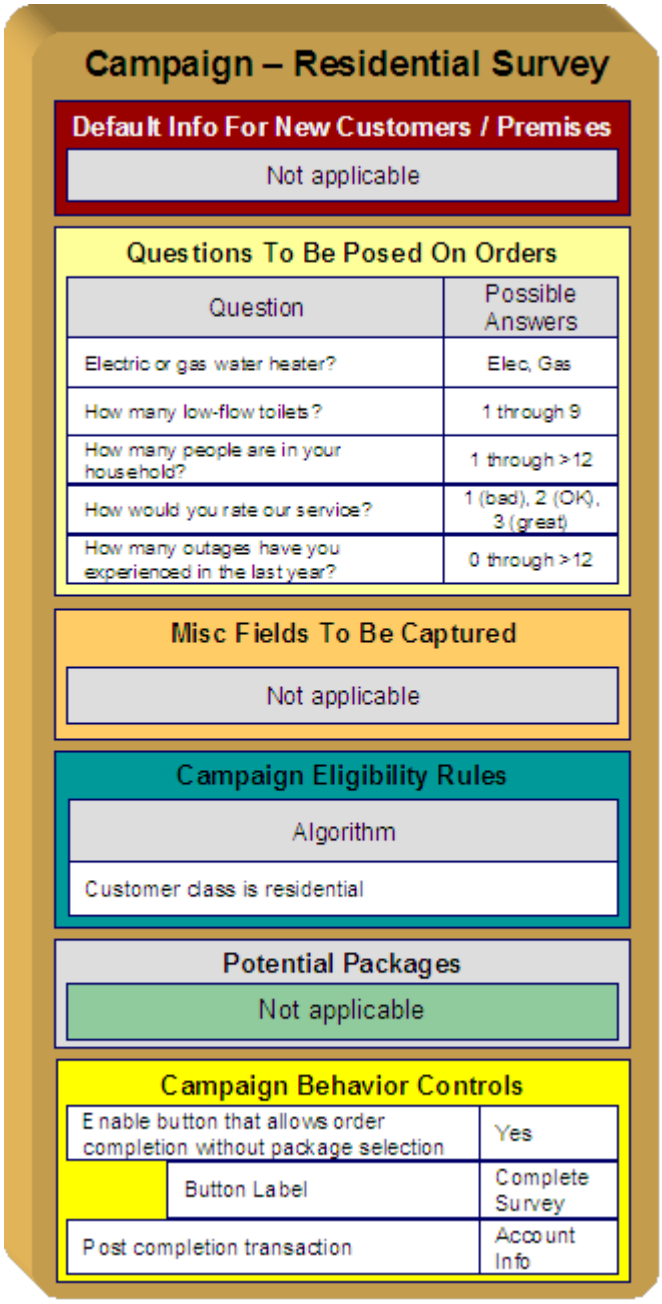
Copyright © 2026, Oracle and/or its affiliates.

  - Your company may have very straightforward packages that only differ based on whether the customer is industrial, residential or commercial. If this describes your company, the setup process will be simple.
  - Alternatively, your company might offer different packages to residential customers based on whether they pay automatically, whether the customer is a senior citizen, whether they purchase multiple services from you, etc. If this describes your company, then you'll have to define the various eligibility criteria and the respective packages applicable to customers who satisfy each criterion.
- Whether premises exist prior to order taking. For example, a company that distributes a commodity has a well-defined geographic area and therefore new premises typically don't arise when orders are taken.
- Whether your company offers many different types of goods and services.
- Whether your rates have charges / discounts that are only applied to some customers. For example, you might have discounts that are applied if the customer is a senior citizen or an employee.
- Which of the Supported Business Processes you implement.

Use the information that follows to form an intuitive understanding of campaigns and packages. After attaining this understanding, you'll be ready to design your own campaigns and packages.

- Campaigns Without Packages
- Campaigns With Simple Packages
- Campaigns With Complex Packages

Campaigns Without Packages



An order that references a campaign without packages will never create service agreements. The following topics describe scenarios when such a campaign would be used.

- Marketing Surveys
- Prelude to Start/Stop

Marketing Surveys

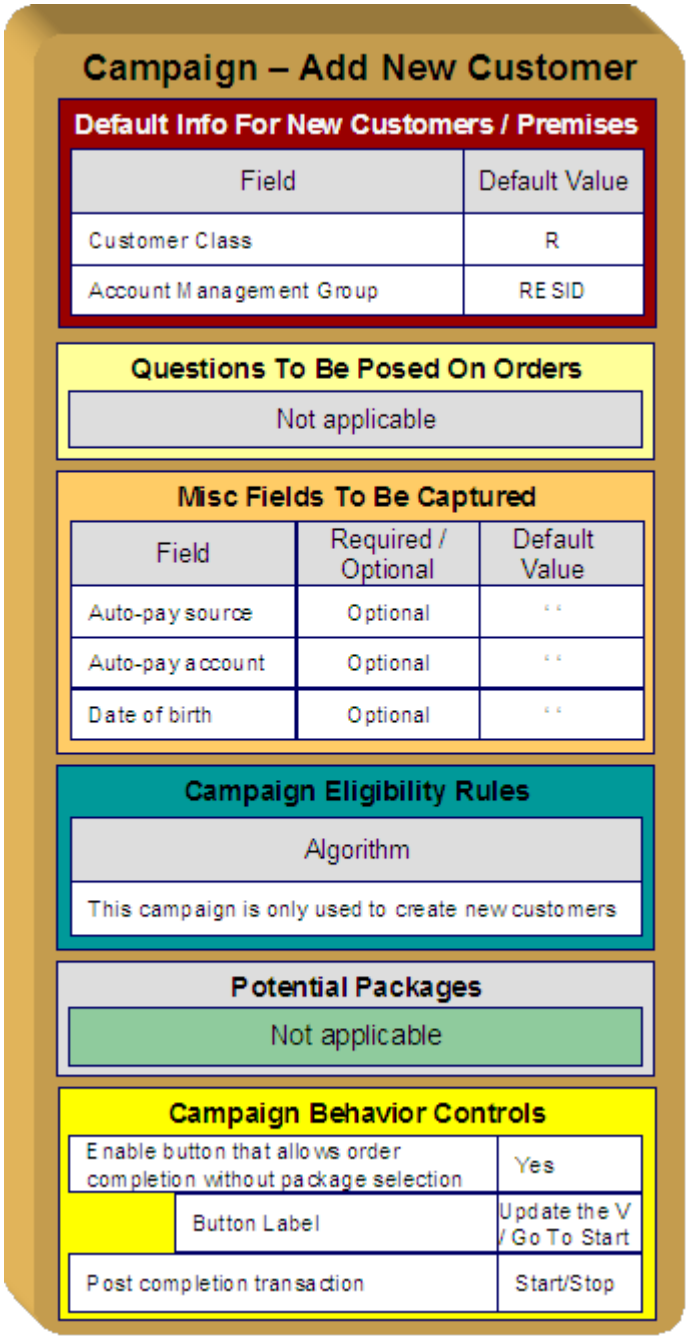
Some organizations conduct "marketing surveys" to determine general trends amongst their customer base. The following diagram illustrates how such a campaign might look:

Copyright © 2026, Oracle and/or its affiliates.

Note the following about this campaign:

- If the campaign is used to establish new customers, you can define information to default onto orders created for new customers. Because marketing surveys are targeted at existing customers, you don't need new customer default information on the campaign.
- You can define questions to be posed to customers when an order is taken when you setup a campaign. For a "marketing survey" campaign, you'd define each of the survey questions and the permissible answers. When a customer is surveyed, an order is created and their answers are saved on the order.
- On a campaign, you can define additional fields to be updated on persons, accounts and premises when orders associated with the campaign are completed. For example, you could indicate that the account's override due date and automatic payment options should be confirmed when an order is taken. Because marketing surveys are typically only asking

Copyright © 2026, Oracle and/or its affiliates.



questions, you wouldn't need to define additional customer information fields to be confirmed. However, you can if you want.

- All campaigns need at least one eligibility rule. These rules control whether the campaign appears in the "eligible campaigns" content zone when a customer is selected on Control Central. These rules also control whether the campaign appears on an order's eligibility tree (campaigns that appear in this tree are alternate campaigns that may be used on the order). Our example has assumed that this is a residential customer survey and therefore it only needs a single eligibility rule. Refer to The Big Picture Of Campaign Eligibility Rules for more information.
- Because this campaign is used purely to manage a marketing survey, it doesn't need any packages. Packages are only necessary if service agreements are created when an order is completed.
- Because this campaign doesn't have packages, we have indicated that the button that allows orders to be completed without selecting a package is enabled. If you don't enable this button, a user won't be able to complete a marketing survey (and it is only during order completion when the "V" is updated with the information on the order). Notice that we have assigned the button a label of Complete Survey.
- This campaign should be setup to transfer the user to Control Central - Account Info after the survey is completed.

Prelude to Start/Stop

Consider the example illustrated above under Setting up a New Customer Prior To Start/Stop. In this example, the order transaction is used to create a new person and account; no service agreements are created when the order is completed. Rather, after the order is completed, the user is automatically transferred to Start/Stop where they can create service agreements. The following diagram illustrates how such a campaign might look:

Copyright © 2026, Oracle and/or its affiliates.

Note the following about this campaign:

- Because this campaign is used to establish new customers, you should define new customer default information. The order taker can override these default values.
- If we assume you don't ask marketing / eligibility-oriented questions when you take-on a new customer then this campaign would not require any questions.
- On a campaign, you can define additional fields to be updated on the related person, account and premise when orders associated with the campaign are completed. For example, you could indicate that the account's override due date and automatic payment options should be confirmed when an order is taken. In our example, we are assuming that we want to define the customer's automatic payment options and their date of birth.

Copyright © 2026, Oracle and/or its affiliates.

- As described under Marketing Surveys, a campaign's eligibility rule(s) control whether the campaign appears in the "eligible campaigns" content zone and on an order's eligibility tree. This campaign is odd in that we don't want it to ever appear as an "eligible campaign" because it's only used for NEW customers. In order to make this work you must:
  - Define an eligibility algorithm on this campaign that prevents it from appearing as an "eligible campaigns". Refer to A Campaign That Is Never Eligible for more information.
  - Update the installation record to indicate that this campaign is the one that should be used on orders created when a user presses the "Add an Order" button on Control Central - Search. Refer to Setting up a New Customer Prior To Starting Service for more information about the flow of this business process.
- Because this campaign is used purely to add accounts and persons, it doesn't need any packages. Packages are only necessary if service agreements are created when an order is completed.
- Because this campaign doesn't have packages, we have indicated that the button that allows an order to be completed without selecting a package is enabled. If you don't enable this button, a user won't be able to complete the order (and it is only during order completion when the "V" is updated with the information on the order). Notice that we have assigned the button a label of Update The V and Go To Start.
- This campaign should be setup to transfer the user to Start/Stop after the order is completed.

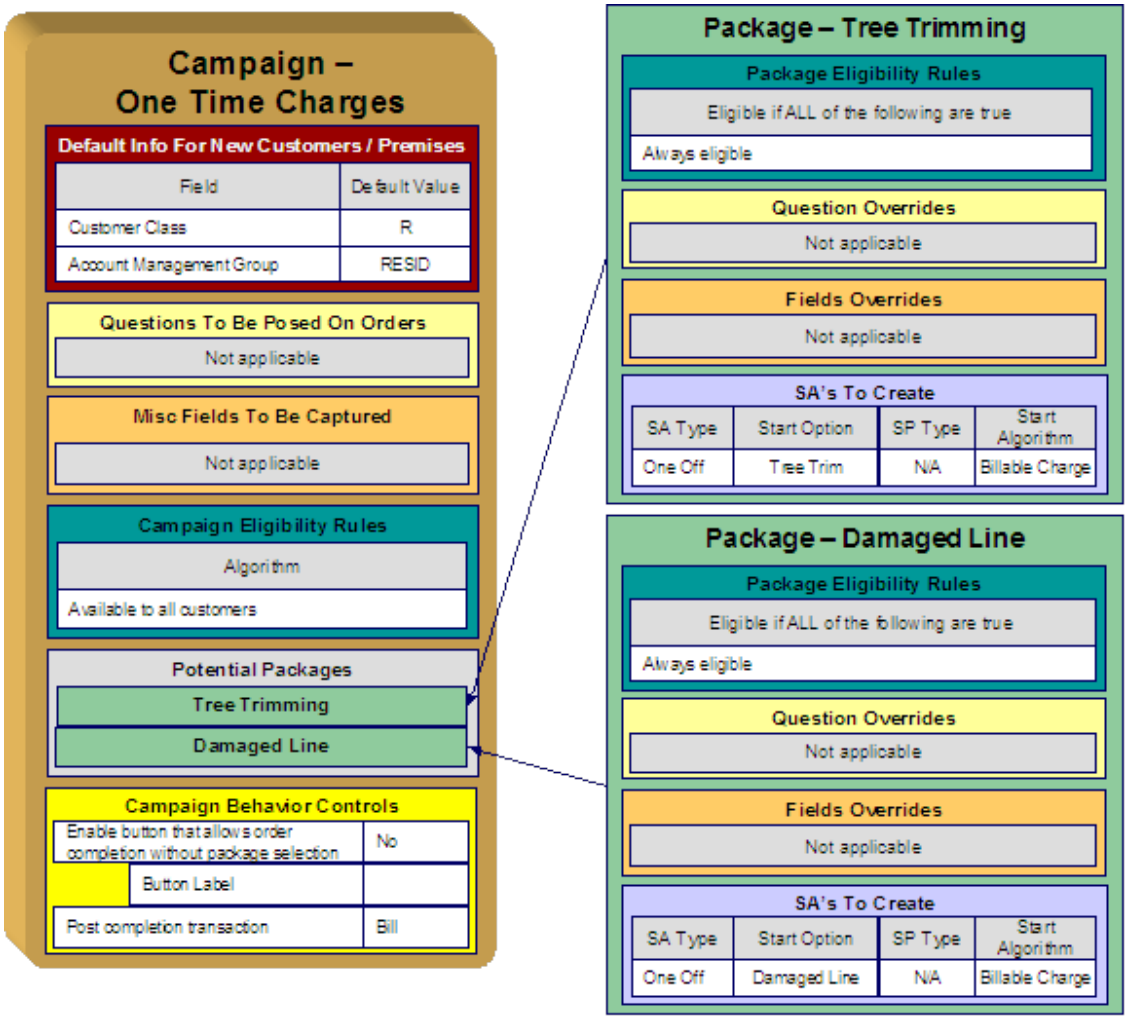
Campaigns With Simple Packages

As explained under Campaigns Without Packages, there are several situations that might necessitate a campaign without packages. In this section, we describe simple scenarios of campaigns with packages.

- An Easier Way To Create One Time Charges

An Easier Way To Create One Time Charges

We use the term "one-time charge" to describe ad hoc charges, e.g., tree trimming charges, damage assessments, etc. The following points describe how one-time charges are levied if you don't use the order transaction:



- Determine if the customer to be invoiced already has an appropriate "one-time charge" service agreement. If one doesn't exist, you must create one using Start/Stop Service.
- Next, a billable charge is added to the "one-time charge" service agreement (using Billable Charge Maintenance). The billable charge contains the invoice lines and amounts. The system will produce the bill for this charge when the account's bill cycle next executes.

Rather than going through the above multi-step process, you can also use the order transaction to create both a "one-time charge" service agreement AND create the billable charge. In addition, if the customer receiving the charge is new, the order transaction will also create a new person and account at the same time.

To take advantage of this facility, you must set up a campaign that has a separate package for each type of one-time charge as illustrated below. When an order is taken for such a campaign, the user simply selects the package that corresponds with the desired one-time charge. The system will then create the necessary customer and financial information when the package is confirmed.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Billing of one-time charges.** The order transaction will not cause a bill to be generated for the customer. Rather, the next time the account is billed, the system will see that there's an unbilled billable charge and create a bill segment for it. This bill segment will appear on the customer's regular bill along with their other charges. If you'd prefer to create the bill for the one-time charges immediately, you could setup the campaign to automatically transfer the user to the bill transaction where they can create an ad hoc bill. If you do this, you'll need to create a new plug-in algorithm on the billable charge SA type to automatically activate the service agreement when it is created (otherwise the user would have to manually activate the billable charge service agreement before the bill can be generated).

Note the following about this campaign:

- One-time charges can be levied against both new and existing customers. This means that orders associated with this campaign may cause new customers to be created. Therefore, we have specified information to default onto orders for new customers on the campaign. Note that we defined "residential-oriented" default values as the majority of one-time charges are levied against residential customers.

Copyright © 2026, Oracle and/or its affiliates.

- If we assume you don't ask marketing / eligibility-oriented questions when you levy a one-time charge then this campaign would not require any questions.
- We have assumed that you are not capturing miscellaneous fields when you levy a one-time charge.
- As described under Marketing Surveys, all campaigns need at least one eligibility rule. We have assumed that this campaign's packages can be selected by all types of customers and have therefore specified an eligibility algorithm that will be true for all customers.
- Because this campaign has packages, we have indicated that the button that allows an order to be completed without selecting a package is disabled. This means a user must choose one of the packages to complete the order.
- You might want to setup this campaign to automatically transfer the user to the bill transaction after the order is completed. See the note above the illustration for more information.
- We have assumed that this campaign can be used to levy two kinds of one-time charges - a tree trimming charge and a damaged line charge - and therefore this campaign requires two packages. Note the following about each package:
  - A package's eligibility rules control whether the package can be selected when an order is taken. With more sophisticated campaigns, you may have packages that are only applicable to certain types of customers. In our example, we've assumed that these types of one-time charges can be levied against all customers and have therefore used "universal" eligibility criteria (i.e., there are no eligibility restrictions). Refer to A Package That Is Always Eligible for more information.
  - On a package, it's possible to define additional questions to be posed if a package is selected. In our example, there are no additional questions to be posed for the one-time charge packages.
  - On a package, it's possible to define additional fields to be captured if a package is selected. In our example, there are no additional fields to be captured.
  - On a package, you define the types of service agreements to be created if a package is selected. In our example, we only need a single service agreement created / updated if the package is selected and therefore there's just one entry in **SAs To Create**. Please note the following about the information used to create this service agreement:
- The **SA Type** is one that's used for a billable charge service agreement.
- The SA Type's **Start Option** is one that will automatically create a billable charge when a service agreement is created (if a start option references a billable charge template, a billable charge will be created when this start option is used). In our example, we have assumed a different start option has been setup for each type of one-time charge.
- Billable charge service agreements do not require service points and therefore **SP Type** is not applicable.
- We've indicated a **Start Algorithm** of Billable Charge . Refer to STRM-AS for an example of such an algorithm (type).

Campaigns With Complex Packages

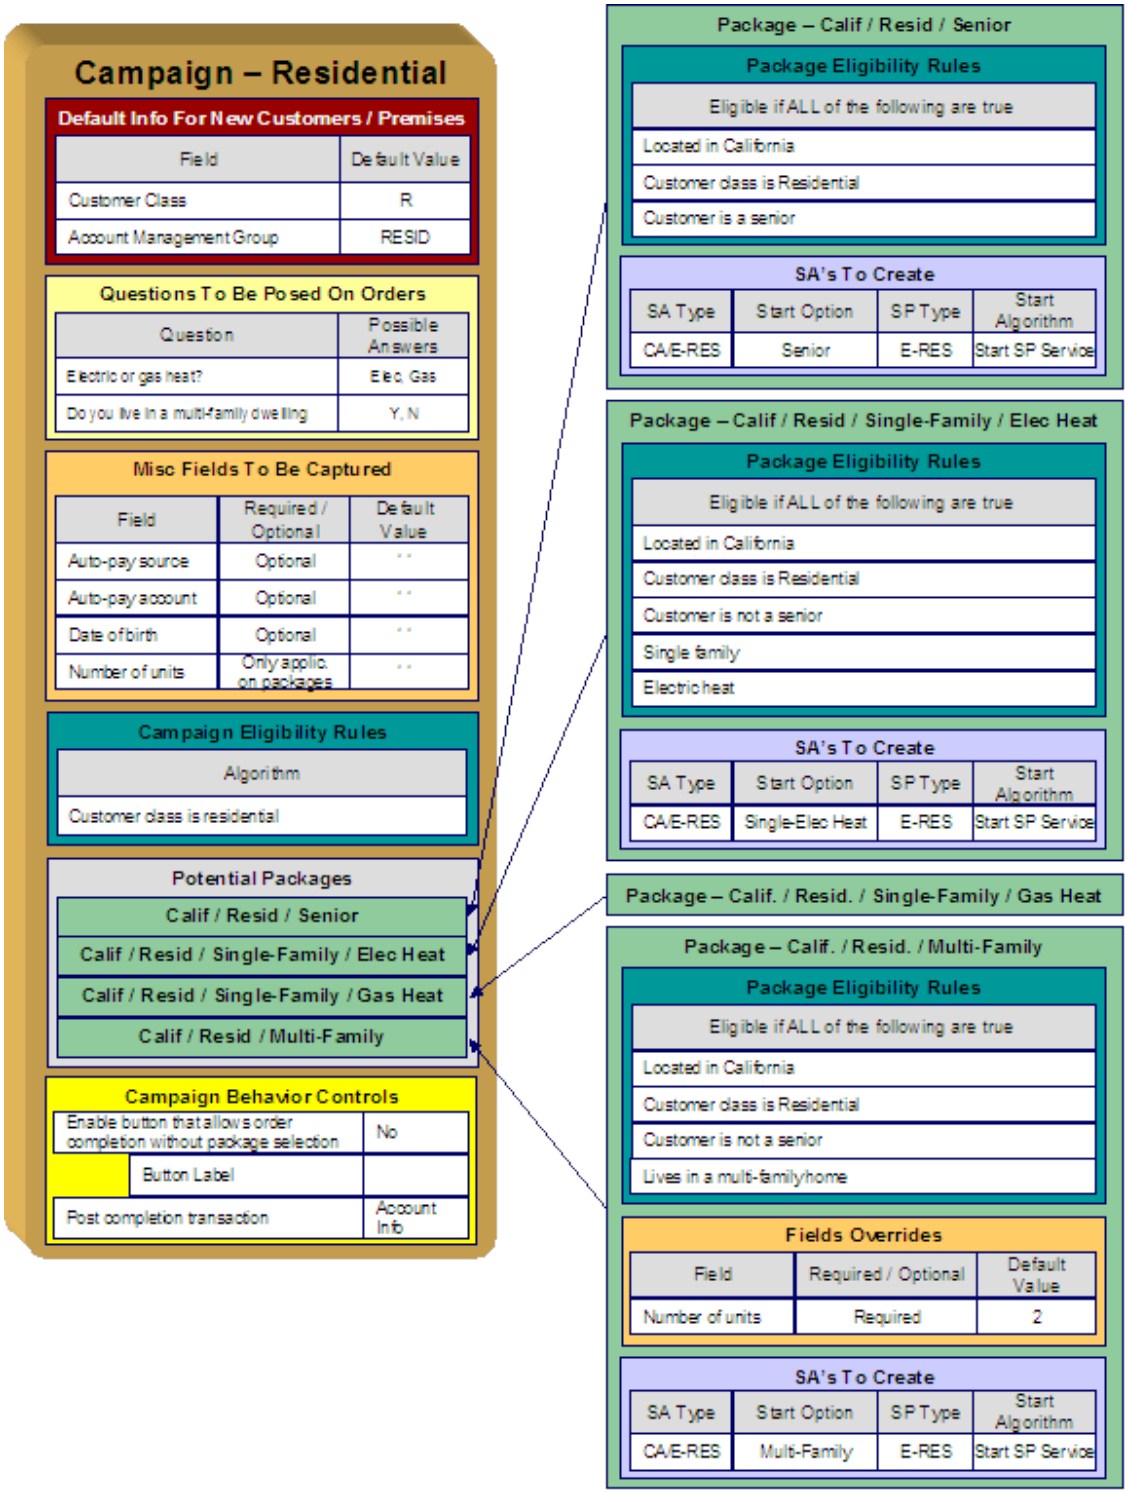
The Campaigns With Simple Packages illustrated campaigns with very simple packages. In this section, we describe a campaign with more complex packages.

- Packages Limited By Answers And Field Values

Copyright © 2026, Oracle and/or its affiliates.

- Packages Limited By Current State Of Service

Packages Limited By Answers And Field Values



Assume your organization has a campaign with several packages. Each package has the following restrictions in respect of its use:

- "Package 1" can be offered to residential customers in California who are senior citizens.
- "Package 2" can be offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with electricity.
- "Package 3" can be offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with gas.
- "Package 4" can be offered to residential customers in California who live in multi-family homes who are not senior citizens.

Also assume that all customers are encouraged to pay automatically.

The following diagram illustrates how such a campaign might look:

Copyright © 2026, Oracle and/or its affiliates.

The topics that follow describe the campaign and packages used to support this scenario. We'll start by explaining each package. Then we'll describe how the campaign will be setup. This seems backwards, but it mirrors how you should design this type of campaign:

- Senior Citizen Package
- Single-Family Electric Package
- Single-Family Gas Package
- Multi-Family Package

Copyright © 2026, Oracle and/or its affiliates.

- The Campaign

Senior Citizen Package

The package that is offered to residential customers in California who are senior citizens has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer class = Residential
  - Division = California
  - Birth date equates to that of a senior citizen
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
  - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
  - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for a senior citizen.
  - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

Top of the Page

Single-Family Electric Package

The package that is offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with electricity has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer class = Residential
  - Division = California
  - Birth date does not equate to that of a senior citizen
  - The premise is a single-family home
  - The premise is heated with electricity
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
  - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
  - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
  - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).

Copyright © 2026, Oracle and/or its affiliates.

  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

Top of the Page

Single-Family Gas Package

The package that is offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with gas has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer class = Residential
  - Division = California
  - Birth date does not equate to that of a senior citizen
  - The premise is a single-family home
  - The premise is heated with gas
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
  - The **SA Type** is one that's used for a gas residential service agreement (hence the G-RES SA type).
  - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
  - The service agreement needs to be linked to a gas residential service point (hence the G-RES SP type).
  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

Top of the Page

Multi-Family Package

The package that is offered to residential customers in California who live in multi-family homes who are not senior citizens has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer class = Residential
  - Division = California
  - Birth date does not equates to that of a senior citizen
  - The premise is a multi-family home
- This package requires additional information that was not requested at the campaign-level. We're going to assume that the multi-family rate needs to know the number of units in the building. This means that this package needs an additional field (number of units).
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:

Copyright © 2026, Oracle and/or its affiliates.

  - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
  - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
  - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions in this package. This is because this package doesn't have additional questions.

Top of the Page

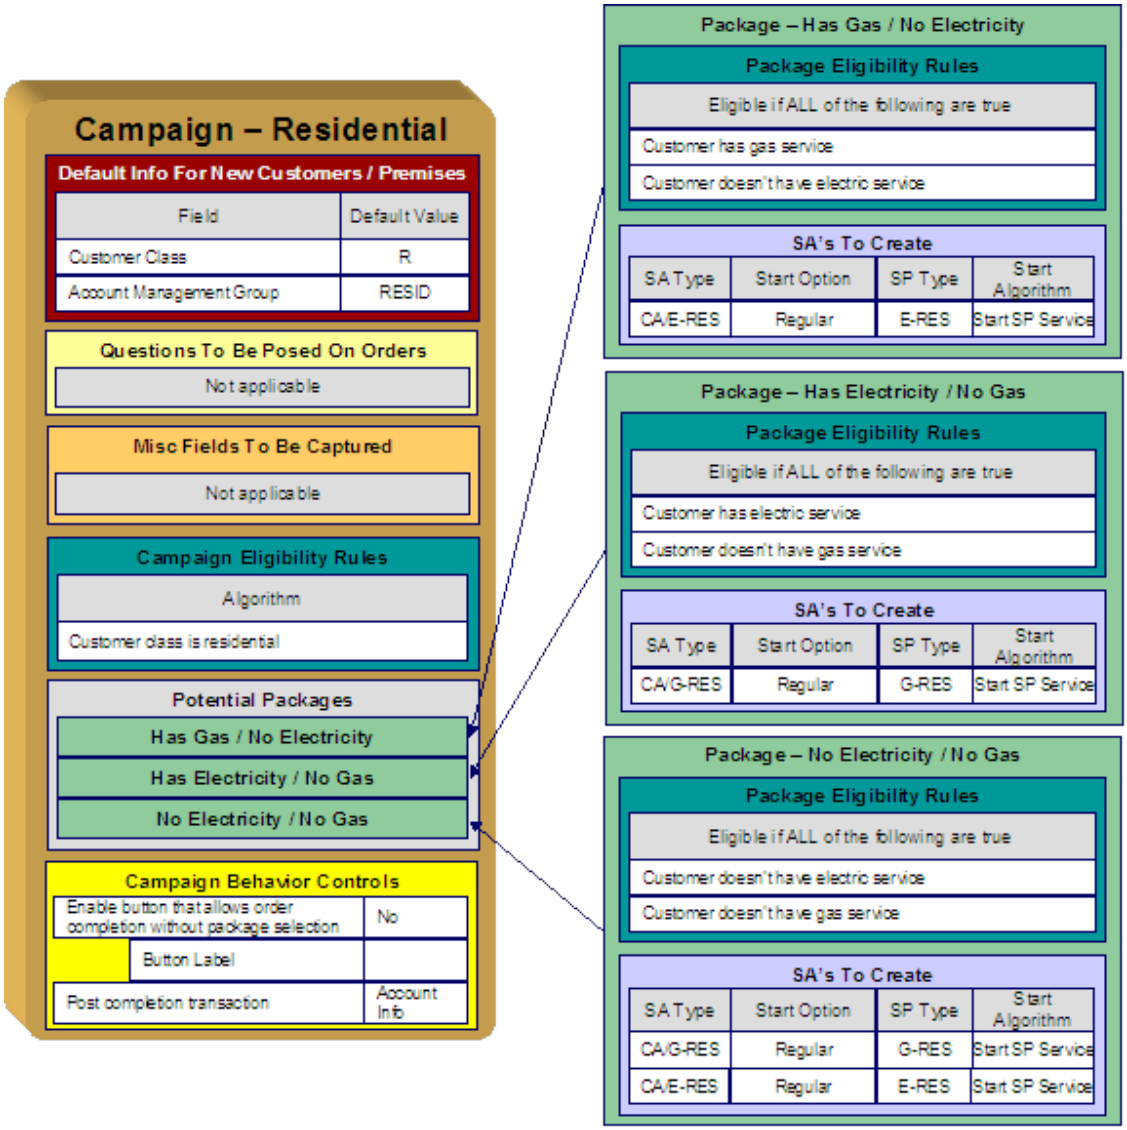
The Campaign

Note the following about this campaign:

- Orders can be created for both new and existing customers. Because new customers are possible, we have specified information to default onto orders for new customers. Note that we defined "residential-oriented" default values (but remember, these values can be overridden on the order).
- The questions on the campaign are those whose answers play a part in each package's eligibility. You could also ask additional marketing survey-oriented questions that have nothing to do with package eligibility.
- The miscellaneous fields highlight an interesting situation. Notice that the date-of-birth and "automatic payment" fields are optional. However the field that holds the number of dwelling units is "only applicable on packages". When a field has this designation, the user will only be prompted to supply this field's value if a package is chosen where this field is applicable. In our example, only the Multi Family Package uses this field. This package will be setup to indicate that this field is required whereas the other packages will be setup to indicate that this field is not used.

> **Note**
>
> **Bottom line.** The "miscellaneous fields" on a campaign must also include package-specific fields.

- All campaigns need at least one "highlight rule". These rules control whether the campaign appears in the "eligible campaigns" content zone when a customer is selected on Control Central. Also note that "highlight rules" also control whether the campaign appears on an order's eligibility tree (campaigns that appear in this tree are alternate campaigns that may be used on the order).
- We're going to assume that this is a residential campaign and therefore you would specify a highlight rule that returns true if the customer's customer class is residential.
- Because this campaign has packages, we have indicated that the button that allows an order to be completed without selecting a package is disabled. This means a user must choose one of the packages to complete the order.
- This campaign is setup so that the user will be transferred to Control Central - Account Info after the order is completed. This is a subjective decision as you could transfer the user to a variety of transactions. It's just that the Account Info page provides a nice confirmation of how the customer looks after the order has updated / created new information.



Copyright © 2026, Oracle and/or its affiliates.

Packages Limited By Current State Of Service

Assume your organization has a campaign with several packages. Each package has the following restrictions in respect of its use:

- "Package 1" can be offered to residential customers in California who have gas service, but don't have electric service.
- "Package 2" can be offered to residential customers in California who have electric service, but don't have gas service.
- "Package 3" can be offered to residential customers in California who have neither electric nor gas service.

The following diagram illustrates how such a campaign might look:

The topics that follow describe the campaign and packages used to support this scenario. We'll start by explaining each package. Then we'll describe how the campaign will be setup. This seems backwards, but it mirrors how you should design this type of campaign:

Copyright © 2026, Oracle and/or its affiliates.

- Has Gas / No Electricity Package
- Has Electricity / No Gas Package
- No Electricity / No Gas Package

Has Gas / No Electricity Package

The package that is offered to customers that currently have gas service, but don't have electricity service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer has gas service
  - Customer doesn't have electricity service
- Refer to A Package With Service Type Comparisons for more information.
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
  - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
  - The SA Type's **Start Option** is one that will setup the service agreement with the appropriate rate and contract options.
  - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

Top

Has Electricity / No Gas Package

The package that is offered to customers that currently have electric service, but don't have gas service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer has electric service
  - Customer doesn't have gas service
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
  - The **SA Type** is one that's used for a gas residential service agreement (hence the G-RES SA type).
  - The SA Type's **Start Option** is one that will setup the service agreement with the appropriate rate and contract options.
  - The service agreement needs to be linked to a gas residential service point (hence the G-RES SP type).
  - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

Copyright © 2026, Oracle and/or its affiliates.

Top

No Electricity / No Gas Package

The package that is offered to customers that don't currently have electricity or gas service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
  - Customer doesn't have electric service
  - Customer doesn't have gas service
- We need two service agreements created (one for electricity, one for gas).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

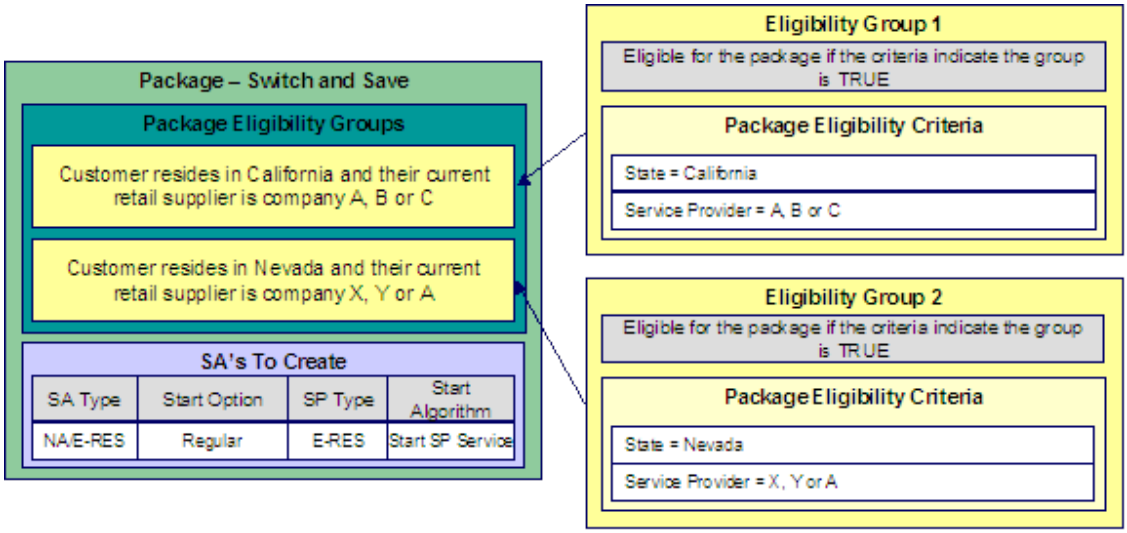
The Big Picture Of Package Eligibility Rules

The packages described under Examples of Campaigns and Packages have a variety of eligibility rules. Designing these rules can be easy or time-consuming; it all depends on the complexity of your business rules. We'll walk you through several examples to help you form an intuitive understanding of how to setup eligibility rules. Once you've acquired this intuition you'll be ready to design the eligibility rules for your own packages.

> **Note**
>
> Don't confuse package eligibility rules with those associated with a campaign. Package eligibility rules control whether a customer is allowed to choose a package on the order transaction. Campaign eligibility rules control whether a campaign is highlighted on the "eligible campaigns" content zone and on an order's eligibility tree.

- Criteria Groups versus Eligibility Criteria
- Defining Logical Criteria
- Examples Of Package Eligibility Rules

Criteria Groups versus Eligibility Criteria



Before we provide concrete examples of eligibility criteria, we need to explain two concepts: Criteria Groups and Eligibility Criteria. A package's criteria groups control whether a customer is eligible to choose a package. At a high level, it works like this:

- A criteria group has one or more eligibility criteria. A group's criteria control whether the group is considered TRUE or FALSE for a given customer.
- When you create a group, you define what should happen if the group is TRUE or FALSE. You have the following choices:
  - The customer is eligible to choose the package
  - The customer is not eligible to choose the package
  - The next group should be checked.

Copyright © 2026, Oracle and/or its affiliates.

We'll use the following example to help illustrate these points. Assume a package exists that can only be selected if:

- The customer resides in California and their current retail supplier is company A, B or C
- OR, the customer resides in Nevada and their current retail supplier is company X, Y or A

This package requires two eligibility groups because it has two distinct conditions:

- IF (STATE = CALIFORNIA AND (SERVICE PROVIDER IN (A, B, C))
- IF (STATE = NEVADA AND (SERVICE PROVIDER IN (X, Y, A))

If either condition is true, then the customer is eligible for the package.

You'd need to setup the following criteria groups in order to support this requirement:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Customer resides in California and their current retail supplier is company A, B or C	Eligible	Check next group
2	Customer resides in Nevada and their current retail supplier is company X, Y or A	Eligible	Ineligible

The following criteria will be required for each of the above groups:

Group 1: Customer resides in California and their current retail supplier is company A, B or C				
Seq	Logical Criteria	If Eligibility Criteria is TRUE	If Eligibility Criteria is FALSE	If Insufficient Data
10	State = California	Check next condition	Group is false	Group is false
20	Electric retail supplier in (A, B, C)	Group is true	Group is false	Group is false

Copyright © 2026, Oracle and/or its affiliates.

Group 2: Customer resides in Nevada and their current retail supplier is company X, Y or A				
Seq	Logical Criteria	If Eligibility Criteria is TRUE	If Eligibility Criteria is FALSE	If Insufficient Data
10	State = Nevada	Check next condition	Group is false	Group is false
20	Electric retail supplier in (X, Y, A)	Group is true	Group is false	Group is false

The next section describes how you'd setup the specific logical criteria in each of the groups.

Defining Logical Criteria

When you setup an eligibility criterion, you must define two things:

- The field to be compared
- The comparison method

You have the following choices in respect of identifying the **field to be compared**:

- You can choose one of the miscellaneous fields on the order (keep in mind that miscellaneous fields also hold the answers to any questions posed on the order).
- You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

You have the following choices in respect of identifying the **comparison method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value.
- You can execute an algorithm whose job it will be to perform the comparison (and return TRUE, FALSE or INSUFFICIENT DATA). This is also a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

The Examples Of Package Eligibility Rules provide numerous examples to help you understand this design.

Examples Of Package Eligibility Rules

The topics in this section provide examples about how to setup package eligibility rules.

- A Package That Is Always Eligible
- A Package With A Time Span Comparison
- A Package With Service Type Comparison
- A Package With More Complex Operators

A Package That Is Always Eligible

Copyright © 2026, Oracle and/or its affiliates.

If a package is always eligible, it still needs an eligibility group. Good examples of such packages are shown under An Easier Way To Create One Time Charges. A package that is always eligible would require the following eligibility information:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Always eligible	Eligible	Eligible

The following criteria will be required for this group:

Group 1: Always eligible					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's account	Algorithm: Always true	Group is true	Group is true	Group is true

This group's criterion is odd in that it's not comparing anything. In order to setup this criterion, you have to use the following "trick":

- Field to Compare. You can pick any miscellaneous field on the campaign. If the campaign has no miscellaneous fields, you'll need to setup an algorithm to retrieve a field from the order (refer to PKEL-ENRFLD for an example of this type of algorithm). In the above example, we used an algorithm to retrieve the order's account.
- Comparison Method. We chose a comparison algorithm that always returns a value of TRUE (refer to PKCC-DEFAULT for an example of this type of algorithm).
- You'll notice that if a value of TRUE is returned, the Group is true (and we've setup the group to indicate a true group means the customer is eligible for the package).

We understand this is a little complicated, but this design provides the power necessary to support very complex criteria. The following sections provide more examples to help you form a better understanding of these concepts.

A Package With A Time Span Comparison

The Senior Citizen Package has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the package. It would look as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Residential, Calif, Senior	Eligible	Ineligible

The following criteria will be required for this group:

Copyright © 2026, Oracle and/or its affiliates.

Group 1: Residential, Calif, Senior					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's customer class	= R	Check next condition	Group is false	Group is false
20	Algorithm: retrieve order's division	= CA	Check next condition	Group is false	Group is false
30	Misc Field On Order: Date of Birth	Algorithm: True if senior	Group is true	Group is false	Group is false

The first two criteria are easy; they simply retrieve a field on the order and compare it to a given value. If the comparison doesn't result in a TRUE value, the Group is false (and, the group indicates that if the group is false, the customer isn't eligible for the package). If the comparison results in a TRUE value, the next condition is checked.

The last criterion contains a time span comparison. Time span comparisons are used to compare a date to something. In our example, we have to determine the age of the customer based on their birth date. If the resultant age is > 65, they are considered to be a senior citizen. To pull this off, you can take advantage of a comparison algorithm supplied with the base package as described below.

- Field to Compare. The miscellaneous field in which the customer's birth date is held is selected.
- Comparison Method. We chose a comparison algorithm that returns a value of TRUE if the related field value (the customer's date of birth) is greater than 65 years (refer to PKCC-TIMESPN for an example of this type of algorithm).

You'll notice that if a value of TRUE is returned by the True if senior algorithm, the group is true (and we've setup the group to indicate a true group means the customer is eligible).

> **Note**
>
> **The time span algorithm can be used to compare days, weeks, months, etc.** Refer to PKCC-TIMESPN for more information about this algorithm.

A Package With Service Type Comparison

The Has Gas / No Electricity Package has the following eligibility rules:

- Customer has gas service
- Customer doesn't have electricity service

These rules require only one eligibility group on the package. It would looks as follows:

Copyright © 2026, Oracle and/or its affiliates.

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Has Gas, Doesn't Have Electricity	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Has Gas, Doesn't Have Electricity					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: check if customer has gas service	= TRUE	Check next condition	Group is false	Group is false
20	Algorithm: check if customer has electric service	= TRUE	Group is false	Group is true	Group is false

Both criteria are similar - they check if the customer has a given type of service and act accordingly. We used a "field to compare" algorithm to pull this off, but this algorithm is a bit counter intuitive (but understanding it will provide you with another way to implement complex eligibility criteria):

- Field to Compare. We chose a "field to compare" algorithm that checks if an account has service agreements that belong to a given set of service types. It returns a value of TRUE if the customer has an active service agreement that matches one of the service types in the algorithm. In our example, the "check if customer has gas service" algorithm returns a value of TRUE if the customer has at least one active service agreement whose SA type references the gas service type. The "check if customer has electric service" algorithm is almost identical, only the service type differs. Refer to PKEL-SVCTYP for an example of this type of algorithm.
- Comparison Method. We simply compare the value returned by the algorithm to TRUE and indicate the appropriate response.

> **Note**
>
> **Bottom line.** The "field to compare" algorithm isn't actually returning a specific field's value. Rather, it's returning a value of TRUE or FALS (this is not a misspelling). This value is, in turn, compared by the "comparison method" and the group is set to true, false or check next accordingly.

A Package With More Complex Operators

One of the eligibility groups described under Criteria Groups versus Eligibility Criteria has the following eligibility rules:

- Customer must live in California
- Service provider is A, B or C

Copyright © 2026, Oracle and/or its affiliates.

The eligibility group in which these rules would be defined looks as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Lives in California, current service provider is either retailer A, B or C	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Lives in California, current service provider is either retailer A, B or C					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's state	= CA	Check next condition	Group is false	Group is false
20	Misc Field On Order: Current electric supplier	IN A, B, C	Group is true	Group is false	Group is false

This example is very simple. The only thing worth pointing out is that a number of operators can be used when you define a "comparison method". Refer to Package - Eligibility for the complete list of operators.

The Big Picture Of Campaign Eligibility Rules

In the previous section, we explained how to Design Eligibility Rules For A Package. In this section, we explain how to design eligibility rules for a campaign.

A campaign's eligibility rules control two things:

- Whether the campaign appears in the Eligible Campaigns content zone. This content zone suggests possible campaigns for the current customer displayed on control central. You might want to use this zone if you have different campaigns that are offered to different types of customers. Refer to Real-time Marketing of Additional Services to a Customer for an example of how this content zone can be used to "up sell" additional services.
- Whether the campaign appears on an order's eligibility tree. Campaigns that appear in this tree are alternate campaigns that may be used on the order. Refer to Real-time Marketing of Services to a Prospect for an example of how an order's eligibility tree can contain alternate campaigns for an order.

Designing these criteria can be easy or time-consuming; it all depends on the complexity of your business rules. We'll walk you through several examples to help you form an intuitive understanding of how to setup campaign eligibility rules. Once you've acquired this intuition you'll be ready to design the eligibility rules for your own packages.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Don't confuse eligibility rules for a package with those associated with a campaign. Package eligibility rules control whether a customer is allowed to choose a package. Campaign eligibility rules control whether a campaign is highlighted on the Eligible Campaigns content zone and on an order's eligibility tree.

- Campaign Eligibility Rules Are Not Strictly Enforced
- Campaign Eligibility Rules Are Defined Using Algorithms
- Examples Of Campaign Eligibility Rules

Campaign Eligibility Rules Are Not Strictly Enforced

While the system prevents ineligible packages from being selected for an order (based on the package's eligibility rules), the system does not strictly enforce a campaign's eligibility rules. In other words, a user can change the campaign on an order to any active campaign. This "laxness" is intentional; otherwise it could become impossible to change an order's campaign.

It might be more helpful to think of campaign eligibility rules as "highlight conditions". These "highlight conditions" simply control whether the campaign appears in the Eligible Campaigns content zone and on an order's eligibility tree.

Campaign Eligibility Rules Are Defined Using Algorithms

You define a campaign's eligibility rules using one or more algorithms on the campaign. These algorithms are relatively straightforward as they simply return one of the following values:

- Eligible. Meaning the customer is eligible for the campaign.
- Ineligible. Meaning the customer is not eligible for the campaign
- Check Next Algorithm. Meaning that the next algorithm should be checked. You'd only design an algorithm to return such a value if multiple algorithms are used to determine a customer's eligibility for a campaign.

> **Note**
>
> **Bottom line.** A customer is eligible for a campaign if at least one of its eligibility algorithms returns a value of "eligible".

The Examples Of Campaign Eligibility Rules provide numerous examples to help you understand this design.

Examples Of Campaign Eligibility Rules

The topics in this section provide examples about how to setup campaign eligibility rules.

Copyright © 2026, Oracle and/or its affiliates.

- A Campaign That Is Always Eligible
- A Campaign That Is Never Eligible
- A Campaign For Residential Customers
- A Campaign For California, Residential Customers

A Campaign That Is Always Eligible

If a campaign is always eligible, it would require a simple eligibility algorithm that returns an indication that it is always eligible. A good example of such a campaign is shown under An Easier Way To Create One Time Charges. Refer to CAEL-DEFAULT for an example of this type of eligibility algorithm.

A Campaign That Is Never Eligible

If a campaign is never eligible, it would require a simple eligibility algorithm that returns an indication that it is ineligible. A good example of such a campaign is shown under Prelude To Start/Stop. Refer to CAEL-DEFAULT for an example of this type of eligibility algorithm.

A Campaign For Residential Customers

If a campaign should only be targeted at residential customers, it would require a simple eligibility algorithm that returns an indication of eligible if the customer's customer class is residential. A good example of such a campaign is shown under Marketing Surveys. Refer to CAEL-CC for an example of this type of eligibility algorithm.

A Campaign For California, Residential Customers

If a campaign should only be targeted at residential customers in California, it would require two eligibility algorithms:

Algorithm No	Algorithm	Example Algorithm
1	Indicate Check Next Algorithm if customer class is "residential"	Refer to CAEL-CC for an example of this type of eligibility algorithm.
2	Indicate Eligible if division is "California"	Refer to CAEL-DIV for an example of this type of eligibility algorithm.

Designing Campaigns and Packages

Designing campaigns and packages can be simple or challenging. Factors that will influence the complexity of the design process include:

Copyright © 2026, Oracle and/or its affiliates.

- Whether the type of goods and services marketed to your customers / prospects differs depending on some trait of the customer or the region in which they are located. For example,
  - Your company may have very straightforward packages that only differ based on whether the customer is industrial, residential or commercial. If this describes your company, the setup process will be simple.
  - Alternatively, your company might offer different packages to residential customers based on whether they pay automatically, whether they are a senior citizen, whether they purchases multiple services from you, etc. If this describes your company, then you'll have to define the various eligibility criteria and the respective packages applicable to customers who satisfy each criterion.
- Whether premises exist prior to order taking. For example, a company that distributes a commodity has a well-defined geographic area and therefore new premises typically don't arise when orders are taken.
- Whether your company offers many different types of goods and services.
- Whether your rates have charges / discounts that are only applied to some customers. For example, you might have discounts that are applied if the customer is a senior citizen or an employee.
- Which of the Supported Business Processes you implement.

The topics in this section provide a structured approach to design your campaigns and packages.

- Determine The Place Of Start/Stop
- Determine Which Types Of Service Agreements Are Created
- Determine The Different Start Options That Exist For Each Type Of Service Agreement
- Determine The SP Type (if any) For Each Service Agreement
- Determine The Method Used To Create Each Service Agreement
- Extract Algorithms From The Start Method
- Determine Which Combinations Can Be Grouped Under A Package
- Determine Package Eligibility Rules
- Extract Algorithms From The Eligibility Rules
- Extract Miscellaneous Fields From The Eligibility Rules
- Determine Additional Information That Is Required If A Package Is Selected
- Determine If There Are Additional Questions / Fields For Your Packages
- Determine If Additional Instructions Should Be Shown
- Determine If There Are Campaign-Level Fields / Questions
- Determine The Properties Of Every Miscellaneous Field
- Extract Characteristic From The Miscellaneous Fields
- Extract Column References From The Miscellaneous Fields
- Extract Algorithms From The Column References
- Determine Account / Premise Dependency For Each Column Reference
- Determine If Any Properties Are Overridden On Any Package
- Determine The Eligibility Rules For The Campaign

Copyright © 2026, Oracle and/or its affiliates.

- Determine How The Campaign Behaves
- Setup Sequence

Determine The Place Of Start/Stop

Before you can design your campaigns and packages, you must determine if your organization will use start / stop to initiate new service agreements or whether new service can be initiated using the order transaction. Refer to Order versus Start / Stop for information to help you make this decision.

If you decide to use start / stop to initiate service, we'd recommend creating the following types of campaigns:

- Create a campaign similar to that described under Prelude to Start / Stop.
- If you levy one-time charges, you may also want to create a campaign similar to that described under An Easier Way To Create One Time Charges.
- If your organization performs marketing surveys, you may also want to create a campaign similar to that described under Marketing Surveys.

If you decide to use the order transaction to initiate new service, follow the steps outlined in the following sections. Note that we use the example described under Packages Limited By Answers And Field Values when describing the design process.

Determine Which Types Of Service Agreements Are Created

> **Warning**
>
> We have assumed that you have already designed your organization's SP types, SA types, start options and rates. If you have not yet done this, we recommend familiarizing yourself with the concepts described in Designing SP Types, Rates and Defining Service Agreement Types before designing your campaigns and packages.

Start off by determining the different types of service agreements that can be created if a package is selected. In our example campaign, only one SA type is used - E-RES (electric residential service).

Determine The Different Start Options That Exist For Each Type Of Service Agreement

After you know which SA types are going to be created, determine the potential start options that can be used for each SA type. In our example campaign, several start options are possible for the E-RES (electric residential service):

SA Type	Start Option

Copyright © 2026, Oracle and/or its affiliates.

E-RES	Senior
E-RES	Single-Elec Heat
E-RES	Single-Gas Heat
E-RES	Multi-Family

Determine The SP Type (if any) For Each Service Agreement

The SA types and start options control how the service agreement will look (i.e., they control the rate, contract riders, characteristics, interval profiles, time-of-use maps, etc. defaulted onto new service agreements created when a package is selected). During this step, you define the SP type of the service point that will be linked to the service agreement. If several different types of SP types can be used for a service agreement, you'll have to choose one as this is the type of service point that will be created when the service agreement is created. If you plan to allow the package to be used to start service at an existing premise (and you don't want the system to create new service points), you will have to develop new plug-ins. Please speak to your implementation group if you need more information.

In our example campaign, only one SP type is created (or reused if the premise already has a service point of this type) - E-RES (electric residential service point):

SA Type	Start Option	SP Type
E-RES	Senior	E-RES
E-RES	Single-Elec Heat	E-RES
E-RES	Single-Gas Heat	E-RES
E-RES	Multi-Family	E-RES

> **Note**
>
> **Many service agreements don't need SP types.** For service agreements that don't use service points (e.g., deposit service agreements, charitable contributions, one-time charges, etc.), you don't have to reference a SP type.

Determine The Method Used To Create Each Service Agreement

For each SA Type / Start Option / SP Type combination, determine the algorithm that will be used to create the service agreement and the service point. The base package is supplied with a limited number of such algorithm types (refer to STRM-AS and STRM-VT for examples).

SA Type	Start Option	SP Type	Start Method
E-RES	Senior	E-RES	Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists

Copyright © 2026, Oracle and/or its affiliates.

E-RES	Single-Elec Heat	E-RES	Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists
E-RES	Single-Gas Heat	E-RES	Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists
E-RES	Multi-Family	E-RES	Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists

Extract Algorithms From The Start Method

The start methods illustrated above all require the same algorithm:

Algorithm Type	Algorithm	Parameter Values
Create SP and create SA (see STRM-VT)	Always create new SA and stop existing SA	2 (stop existing service)

Determine Which Combinations Can Be Grouped Under A Package

Now you determine which combinations of service agreements can be offered to a customer as a package. In our example campaign, a customer can only choose one type of service agreement (i.e., each entry in our table is mutually exclusive). This means that each entry is a separate package:

Package	SA Type	Start Option	SP Type	Algorithm
1	E-RES	Senior	E-RES	STRM-VT (Switch Option)
2	E-RES	Single-Elec Heat	E-RES	STRM-VT (Switch Option)
3	E-RES	Single-Gas Heat	E-RES	STRM-VT (Switch Option)
4	E-RES	Multi-Family	E-RES	STRM-VT (Switch Option)

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Packages Limited By Current State Of Service for an example of a package that has multiple service agreements.

Determine Package Eligibility Rules

The topics in this section describe the eligibility rules for each package in our example campaign.

Note

Assumption. This section assumes you are comfortable with the information in The Big Picture Of Package Eligibility.

- Eligibility Rules For Package 1
- Eligibility Rules For Package 2
- Eligibility Rules For Package 3
- Eligibility Rules For Package 4

Eligibility Rules For Package 1

Package 1 (the senior package) in our example campaign has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the package. It would looks as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Residential, Calif, Senior	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Residential, Calif, Senior					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's customer class	= R	Check next condition	Group is false	Group is false

Copyright © 2026, Oracle and/or its affiliates.

20	Algorithm: retrieve order's division	= CA	Check next condition	Group is false	Group is false
30	Misc Field On Order: Date of Birth	Algorithm: True if senior	Group is true	Group is false	Group is false

Eligibility Rules For Package 2

Package 2 (the single-family / electric heat package) in our example campaign has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date does not equate to that of a senior citizen
- Lives in a single-family home
- House is heated with electricity

These rules require only one eligibility group on the package. It would looks as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Residential, Calif, Non Senior, Single Family, Electric Heat	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Residential, Calif, Non Senior, Single Family, Electric Heat					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's customer class	= R	Check next condition	Group is false	Group is false
20	Algorithm: retrieve order's division	= CA	Check next condition	Group is false	Group is false
30	Misc Field On Order: Date of Birth	Algorithm: True if senior	Group is false	Check next condition	Group is false
40	Misc Field On Order: Type of Residence	= S (single family home)	Check next condition	Group is false	Group is false
50	Misc Field On Order: Type of Heat	= E (electric)	Group is true	Group is false	Group is false

Copyright © 2026, Oracle and/or its affiliates.

Eligibility Rules For Package 3

Package 3 (the single-family / gas heat package) in our example campaign has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date does not equate to that of a senior citizen
- Lives in a single-family home
- House is heated with gas

These rules require only one eligibility group on the package. It would looks as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Residential, Calif, Non Senior, Single Family, Gas Heat	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Residential, Calif, Non Senior, Single Family, Gas Heat					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's customer class	= R	Check next condition	Group is false	Group is false
20	Algorithm: retrieve order's division	= CA	Check next condition	Group is false	Group is false
30	Misc Field On Order: Date of Birth	Algorithm: True if senior	Group is false	Check next condition	Group is false
40	Misc Field On Order: Type of Residence	= S (single family home)	Check next condition	Group is false	Group is false
50	Misc Field On Order: Type of Heat	= G (gas)	Group is true	Group is false	Group is false

Eligibility Rules For Package 4

Package 4 (the multi-family package) in our example campaign has the following eligibility rules:

- Customer class = Residential

Copyright © 2026, Oracle and/or its affiliates.

- Division = California
- Birth date does not equate to that of a senior citizen
- Lives in a multi-family home

These rules require only one eligibility group on the package. It would looks as follows:

Group No.	Group Description	If Group is TRUE	If Group is FALSE
1	Residential, Calif, Non Senior, Multi Family	Eligible	Ineligible

The following criteria will be required for this group:

Group 1: Residential, Calif, Non Senior, Single Family, Gas Heat					
Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: retrieve order's customer class	= R	Check next condition	Group is false	Group is false
20	Algorithm: retrieve order's division	= CA	Check next condition	Group is false	Group is false
30	Misc Field On Order: Date of Birth	Algorithm: True if senior	Group is false	Check next condition	Group is false
40	Misc Field On Order: Type of Residence	= M (multi family home)	Group is true	Group is false	Group is false

Extract Algorithms From The Eligibility Rules

The eligibility rules illustrated above require the following algorithms:

Algorithm Type	Algorithm	Parameter Values
Retrieve a field from the order for eligibility comparison (see PKEL-ENRFLD)	Retrieve Order's Customer Class	Field name: CUST_CL_CD
Retrieve a field from the order for eligibility comparison (see PKEL-ENRFLD)	Retrieve Order's Division	Field name: CIS_DIVISION
Time span comparison (see PKCC-TIMESPN)	Determine if birth date equates to that of a senior	Time span type: YEAR Operator: >= Comparison Value: 65

Extract Miscellaneous Fields From The Eligibility Rules

Copyright © 2026, Oracle and/or its affiliates.

During this step, you extract miscellaneous fields that must be captured on the order in order drive your eligibility rules.

Misc. Field	Where Stored	Why Is It Needed
Date of birth	Person characteristic	Numerous eligibility rules use this field to determine if a customer is a senior citizen
Type of Residence	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Type of Heat	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package

> **Note**
>
> **Fields explicitly referenced on every order.** You'll notice that we didn't list those fields referenced in the eligibility rules that are explicitly referenced on every order (e.g., customer class, state, division, etc.). This is because these types of fields come "for free".

Determine Additional Information That Is Required If A Package Is Selected

During this step, you determine if there's any information that needs to be created when a package is selected that can't be defaulted from its start option. In our example campaign, package 4 (the Multi-Family Home package), also needs to know the number of housing units at the premise (this information is probably needed to calculate a specific charge in the rate). None of the other packages require additional information. The extra field has been appended to our miscellaneous field table.

Misc. Field	Where Stored	Why Is It Needed
Date of birth	Person characteristic	Numerous eligibility rules use this field to determine if a customer is a senior citizen
Type of Residence	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Type of Heat	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Number of Units in House	Premise characteristic	The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments

Determine If There Are Additional Questions / Fields For Your Packages

Copyright © 2026, Oracle and/or its affiliates.

Our example campaign indicates that all customers are encouraged to pay automatically. In order to pay automatically several fields are required (Start Date, End Date, Autopay Source (i.e., bank / credit card), Account Number, Account Name, Expiration Date). These fields are not "explicitly referenced" on the order and therefore must be captured as miscellaneous fields. We have appended these fields to our list of miscellaneous fields:

Misc. Field	Where Stored	Why Is It Needed
Date of birth	Person characteristic	Numerous eligibility rules use this field to determine if a customer is a senior citizen
Type of Residence	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Type of Heat	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Number of Units in House	Premise characteristic	The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments
Auto Pay Start Date	Account / Autopay Start Date Column	Used if a customer pays automatically
Auto Pay End Date	Account / Autopay End Date Column	Used if a customer pays automatically
Auto Pay Source	Account / Autopay Source	Used if a customer pays automatically
Auto Pay Account Number	Account / Autopay Account ID	Used if a customer pays automatically
Auto Pay Account Name	Account / Autopay Account Name	Used if a customer pays automatically
Auto Pay Account Expiration Date	Account / Autopay Account Expiration Date	Used if a customer pays automatically

We're going to assume that we don't capture any additional marketing-oriented questions. If we did, we'd need additional fields to hold the response to each question.

Determine If Additional Instructions Should Be Shown

If a package is selected, you can present additional instructions to the user informing them of special tasks they should perform (or special instructions they should give to the customer). For example, you could instruct the user to inform customers who aren't senior citizens that they should call back if they become seniors as they may qualify for a better rate. These instructions can be defined on each package.

For the sake of brevity, we will assume no additional instructions are necessary when a package is selected.

Determine If There Are Campaign-Level Fields / Questions

Copyright © 2026, Oracle and/or its affiliates.

Next, you determine if there are additional fields that need to be captured regardless of the package that's selected. For example, you may want to capture additional demographic or geographic information for marketing purposes.

While our example campaign has no such requirement, for illustration purposes we'll assume you ask the customer to rate the quality of service they have experienced (assuming they are a current customer). This additional question requires another entry in our list of miscellaneous fields.

Misc. Field	Where Stored	Why Is It Needed
Date of birth	Person characteristic	Numerous eligibility rules use this field to determine if a customer is a senior citizen
Type of Residence	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Type of Heat	Premise characteristic	Numerous eligibility rules use this field to qualify a customer for a package
Number of Units in House	Premise characteristic	The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments
Auto Pay Start Date	Account / Autopay Start Date Column	Used if a customer pays automatically
Auto Pay End Date	Account / Autopay End Date Column	Used if a customer pays automatically
Auto Pay Source	Account / Autopay Source	Used if a customer pays automatically
Auto Pay Account Number	Account / Autopay Account ID	Used if a customer pays automatically
Auto Pay Account Name	Account / Autopay Account Name	Used if a customer pays automatically
Auto Pay Account Expiration Date	Account / Autopay Account Expiration Date	Used if a customer pays automatically
Service Rating	Person characteristic	Campaign level marketing question

Determine The Properties Of Every Miscellaneous Field

At this point, you have amalgamated all miscellaneous fields required for the campaign and its packages. Now you have to define the following for each field:

- Prompt On Order. This is the prompt that will prefix the field when the order is taken. The following table provides examples.
- Campaign Applicability. This controls whether the field is optional , required, or only applicable on package(s).
  - A value of required means the order taker must enter a valid value before packages are displayed for selection.

Copyright © 2026, Oracle and/or its affiliates.

  - A value of optional means the order taker can leave the field blank prior to package selection. You can make an optional field required on individual packages. For example, you would probably make **Date of birth** required on the Senior package.
  - A value of only applicable on packages is used for fields that are only captured for specific packages. Fields of this type are suppressed prior to package selection. When you setup a package, you indicate if the field is applicable (if so, the user is only prompted for the field if the package is selected).
- Type Of Response. This controls where the field is stored when the order is completed and how it is validated. You have two options: characteristic or column.
  - If a field is a Characteristic, you must define which entity the characteristic value is to be stored on when the order is completed (Person, Account, Premise or Order). You must also define the **Characteristic Type** as this controls the characteristic value entered by the user.
  - If a field's value resides is a column (as opposed to a characteristic value), you must define the column reference. A field's column reference controls three things:
- How the field's value is retrieved. A field's value is retrieved when an existing person / account / premise is referenced on an order.
- How the field's value is validated. A field's value is validated before package eligibility is determined and before the order is completed.
- How the field's value is posted (i.e., updated on the database). A field's value is posted when an order is completed.

NOT_SUPPORTED

Refer to Extract Column References From Miscellaneous Fields for more information about column references.

- Default Value On Order. This controls whether the order taker is supplied with a default value when an order is created. Note well: for optional and only applicable on package fields, you can specify a different default value on each package.

Misc. Field	Prompt On Order	Campaign Applicability	Type Of Response	Default Value On Order
Date of birth	What is your date of birth (used to qualify for senior discount)?	Optional	Characteristic **Entity:** Person **Char Type:** Date of birth	
Type of Residence	What type of residence do you live in?	Required	Characteristic **Entity:** Premise **Char Type:** Type of residence	S (single family)
Type of Heat	How do you heat your home?	Required	Characteristic **Entity:** Premise **Char Type:** Type of heat	E (electric)

Copyright © 2026, Oracle and/or its affiliates.

Number of Units in House	How many units are in the entire house?	Only applicable on package(s)	Characteristic **Entity:** Premise **Char Type:** Number of units in house	
Auto Pay Start Date	What day would you like to start automatic payment processing (YYYY-MM-DD)?	Optional	Column **Column Reference:** Auto Pay Start Date	
Auto Pay End Date	What day would you like to stop automatic payment processing (leave blank if not applicable)?	Optional	Column **Column Reference:** Auto Pay End Date	
Auto Pay Source	From what type of credit card / bank will the funds be debited?	Optional	Column **Column Reference:** Auto Pay Source	
Auto Pay Account Number	What is your credit card / bank account number?	Optional	Column **Column Reference:** Auto Pay Account Number	
Auto Pay Account Name	What is the name on your account?	Optional	Column **Column Reference:** Auto Pay Account Name	
Auto Pay Account Expiration Date	If paying with a credit card, what is the expiration date (MM-YYYY)?	Optional	Column **Column Reference:** Auto Pay Credit Card Expiration Date	
Service Rating	Please rate our service	Optional	Characteristic **Entity:** Person **Char Type:** Service rating	1 (excellent)

Extract Characteristic From The Miscellaneous Fields

Characteristic Type	Type	Valid Values	Entities On Which Characteristic Can Be Defined

Copyright © 2026, Oracle and/or its affiliates.

Date of birth	Ad hoc value: use validation algorithm to confirm date is > 1-Jan-1900 and < 28-Feb-2002	Not applicable	Person, Order
Type of Residence	Predefined value	S: Single-Family M: Multi-Family	Premise, Order
Type of Heat	Predefined value	E: Electric G: Gas	Premise, Order
Number of Units in House	Ad hoc value: use validation algorithm to confirm value is > 0	Not applicable	Premise, Order
Service Rating	Predefined value	0: Not applicable 1: Excellent 2: Very Good 3: Good 4: Poor	Person, Order

Extract Column References From The Miscellaneous Fields

The miscellaneous fields illustrated above require the following column references (we describe the referenced algorithms at the bottom of the table):

Column Reference	Retrieval Algorithm	Validation Algorithm	Post Algorithm	Foreign Key Reference
Auto Pay Start Date	Retrieve account's current automatic payment information	Validate automatic payment information	Post automatic payment information	
Auto Pay End Date	N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date	N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date	N/A - this field is handled by the Post Algorithm on Auto Pay Start Date	
Auto Pay Source	N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date	N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date	N/A - this field is handled by the Post Algorithm on Auto Pay Start Date	Auto pay source
Auto Pay Account Number	N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date	N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date	N/A - this field is handled by the Post Algorithm on Auto Pay Start Date	

Copyright © 2026, Oracle and/or its affiliates.

Auto Pay Account Name	N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date	N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date	N/A - this field is handled by the Post Algorithm on Auto Pay Start Date
Auto Pay Expiration Date	N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date	N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date	N/A - this field is handled by the Post Algorithm on Auto Pay Start Date

There are three types of algorithms referenced in the above table:

- Retrieval algorithm. A column's retrieval algorithm retrieves the column's current value from the database. You'll notice that only one of our columns uses a retrieval algorithm. This is because we've used a sophisticated example of a group of columns that are retrieved at the same time. When you have such a group of columns, nominate one of the columns to do the retrieval work and specify the retrieval algorithm on it.
- Validation algorithm. A column's validation algorithm validates the column's value prior to the database being updated. You'll notice that only one of our columns uses a validation algorithm. This is because we've used a sophisticated example of a group of columns that are validated as a group. When you have such a group of columns, nominate one of the columns to do the validation work and specify the validation algorithm on it.
- Post algorithm. A column's post algorithm updates the column's value on the database when the order is completed. You'll notice that only one of our columns uses a post algorithm. This is because we've used a sophisticated example of a group of columns that are posted together. When you have such a group of columns, nominate one of the columns to do the posting work and specify the posting algorithm on it.

Notice that we have indicated that one of the columns has a "foreign key reference". You declare a "foreign key reference" if the valid values for a column are defined on another table in the system (this also affects the order user interface as a dropdown appears for columns that have foreign key references). In our example, Auto Pay Source is the only column whose valid values are defined on the automatic payment source control table.

Extract Algorithms From The Column References

The column references illustrated above require the following algorithms:

Algorithm Type	Algorithm	Parameter Values

Copyright © 2026, Oracle and/or its affiliates.

Retrieve automatic payment information from an account (see CRRT-AP)	Retrieve automatic payment information from an account	Param 1 = Auto Pay Start Date Column Reference Param 2 = Auto Pay End Date Column Reference Param 3 = Auto Pay Source Column Reference Param 4 = Auto Pay External Account Id Column Reference Param 5 = Auto Pay Expiration Date Column Reference Param 6 = Auto Pay Name Column Reference
Validate automatic payment information (see CRVL-AP)	Validate automatic payment information	Param 1 = Auto Pay Start Date Column Reference Param 2 = Auto Pay End Date Column Reference Param 3 = Auto Pay Source Column Reference Param 4 = Auto Pay External Account Id Column Reference Param 5 = Auto Pay Expiration Date Column Reference Param 6 = Auto Pay Name Column Reference
Post automatic payment information (see CRPS-AP)	Post automatic payment information	Param 1 = Auto Pay Start Date Column Reference Param 2 = Auto Pay End Date Column Reference Param 3 = Auto Pay Source Column Reference Param 4 = Auto Pay External Account Id Column Reference Param 5 = Auto Pay Expiration Date Column Reference Param 6 = Auto Pay Name Column Reference

Determine Account / Premise Dependency For Each Column Reference

Later in the design process (see Determine How The Campaign Behaves), you define on the campaign whether an account (and premise) is required, optional or not allowed on its orders. Your selection impacts how you setup column references. This is a little complicated so let's use an example:

- Assume you've setup a campaign to indicate a premise can optionally be defined on its orders.
- If the order-taker doesn't define a premise on an order, any premise-oriented questions and miscellaneous fields (Q&MF) should be suppressed on the order.
- It's easy for the system to know which Q&MFs to suppress when a Q&MF's response is held in a characteristic (because you must define on the campaign if the response will reside in an account, premise, person or order characteristic). For column reference

Copyright © 2026, Oracle and/or its affiliates.

Q&MFs, the system doesn't know if the response is account-oriented, premise-oriented or neither because algorithms handle the validation / updating of the response.

- Therefore, when you use column references on a campaigns Q&MFs, you must define if the responses are account-oriented or premise-oriented (so that the system can suppress the Q&MF when the user doesn't enter an account or premise on the order).

The following table contains the column references defined above as well as their dependency

Column Reference	Question Dependency
Auto Pay Start Date	Must have account
Auto Pay End Date	Must have account
Auto Pay Source	Must have account
Auto Pay Account Number	Must have account
Auto Pay Account Name	Must have account
Auto Pay Expiration Date	Must have account

You'll notice that each column reference is account-oriented (this is because automatic payment fields are stored on the respective account).

Determine If Any Properties Are Overridden On Any Package

At this point, you have defined the properties of all miscellaneous fields at the campaign level. You now need to determine if any of your packages need to override any of these properties. In general, you can only override miscellaneous fields whose campaign applicability is optional or only applicable on package(s).

Our example campaign has only two overrides:

Package 1 requires the following miscellaneous field overrides:

Misc. Field	Override Prompt (seen if a package is selected)	Override Package Applicability	Override Default Value
Date of birth	Not overridden	Required	Not overridden

Package 4 requires the following miscellaneous field overrides:

Misc. Field	Override Prompt (seen if a package is selected)	Override Package Applicability	Override Default Value
Number of Units in House	Not overridden	Required	2

> **Warning**
>
> If you override field properties on a campaign's packages, you will not be able to change the properties of the field at the campaign level.

Copyright © 2026, Oracle and/or its affiliates.

Determine The Eligibility Rules For The Campaign

> **Note**
>
> **Assumption.** This section assumes you are comfortable with the information in The Big Picture Of Campaign Eligibility.

The easiest way to determine a campaign's eligibility is to examine each package's eligibility criteria and abstract common eligibility restrictions onto the campaign. It's important to remember that campaign-level eligibility is only used to highlight if the campaign MAY contain applicable packages; campaign-level eligibility is not strictly enforced.

The packages on our example campaign are all targeted at residential customers in California. Therefore we'll take advantage of two base package algorithms to construct the campaign's eligibility criteria.

Algorithm Type	Algorithm	Parameter Values
Check if account's customer class is in a predefined list (see CAEL-CC)	If customer class is "residential", check next algorithm	If customer's customer class is in list: 30 (check next) If customer's customer class is not in list: 20 (ineligible) List of customer classes: R
Check if account's division is in a predefined list (see CAEL-DIV)	If division is "California", customer is eligible	If customer's CIS division is in list: 10 (eligible) If customer's CIS division is not in list: 20 (ineligible) List of customer classes: CA

Determine How The Campaign Behaves

The final step before you're ready to setup the campaign involves defining a variety of behavioral functions as described below:

- You need to define how the campaign uses accounts and premises. Specifically, on a campaign you define if an account / premise is required / optional / not allowed on its orders. In addition, if an account / premise is required or optional, you can control whether new accounts / premises can be created when an order is completed (the alternative is to force each order to use an existing account / premise). These controls prevent the unwanted proliferation of new accounts and premises for campaigns that are targeted at existing accounts and premises.
- Many fields on an order (e.g., phone type, customer class, division, account management group) can be defaulted on orders created for new customers. You will see these fields on Order - Main. Think about each such field and whether a default value is appropriate. Keep in mind that the order taker can override any of these default values.
- An order taker can indicate that they want to hold an order if they need to do further research before continuing with an order. A background process (TD-ECBK) will create a

Copyright © 2026, Oracle and/or its affiliates.

To Do entry for held orders as a reminder to get back in touch with the customer on a future date. You can define the default To Do role assigned to such To Do entries when you create a campaign. Keep in mind that this value can be overridden when the order taker holds an order.

- You can indicate on a campaign the transaction to which the user should be transferred when orders are completed. Refer to Supported Business Processes for examples of how you might want to use this field.

Setup Sequence

And now you're ready to set up your campaign. The following points describe the order in which this should be done:

> **Warning**
>
> We have assumed that you have already designed your organization's SP types, SA types, start options and rates. If you have not yet done this, we recommend familiarizing yourself with the concepts described in Designing SP Types, Rates and Defining Service Agreement Types before designing your campaigns and packages.

- Setup any new column references required by the campaign's miscellaneous fields. You will have to leave the retrieve, validate and post algorithms blank until after the next step.
- Setup any new algorithms required by:
  - The packages' eligibility rules.
  - The packages' start methods.
  - The campaign's eligibility rules.
  - The campaign's column references.
- Update the relevant column references with the appropriate retrieve, validate and post algorithms.
- Setup any new characteristic types required by the campaign's miscellaneous fields.
- Create the campaign using the information you designed above. Specifically:
  - You defined the question and miscellaneous fields under Determine The Properties Of Every Miscellaneous Field.
  - You defined the eligibility rules under Determine The Eligibility Rules For The Campaign.
  - You defined everything else under Determine How The Campaign Behaves.
  - We recommend leaving the campaign's status as Inactive until all packages are entered.
- Create the campaign's packages using the information you designed above. Specifically:
  - You defined the question and miscellaneous field overrides under Determine If Any Properties Are Overridden On A Package.
  - You defined the eligibility rules under Determine Package Eligibility Rules .
  - You defined the instructions under Determine If Additional Instructions Are Required.

Copyright © 2026, Oracle and/or its affiliates.

- Change the campaign's status to Active.

> **Note**
>
> **The default campaign on the installation record.** If the campaign you've setup is the "default" campaign used when a user presses the Add Order button on Control Central, make sure to specify it as the default campaign on the installation record. Refer to Setting up a New Customer Prior To Starting Service for more information.

Other Useful Information

The topics in this section contain miscellaneous information about the sales & marketing functions.

- Order versus Start/Stop
- Orders Cannot Be Changed After They Are Completed
- Premise and SP Characteristics May Be Populated From Postal Defaults
- To Do List Processing
- Hold and Cancel Reason Codes
- Automatically Cancelling Old Orders
- Additional Things Can Happen When An Order Is Completed
- New Premises and Accounts Are Only Created if an Order is Completed
- Premise Geographic Types Are Populated In An Unusual Way
- Account And Premise Usage Are Controlled By The Campaign

Order versus Start/Stop

There are three different ways to start service for a customer:

- There is the process flow based start service process that supports starting premise-based service, adding new or using existing customers, and has many user configurable settings. For details please refer to The Start Service Process and Request. The following explains the feature of the other two methods.
- As described under definitions, you can use the order transaction to start service.
- Alternatively, you can use start / stop.

The following table provides insight into the pros and cons of each method (after this table you will find our recommendations):

Issue	Order	Start/Stop

Copyright © 2026, Oracle and/or its affiliates.

New customer setup	Information about the new customer can be entered on the order page. A person / account will be setup when the order is completed.	A new person and account must be setup prior to using Start/Stop. See How To Add A New Customer From Control Central for more information.
New premise setup	Information about the new premise can be entered on the order page. A premise (and service points) will be setup when the order is completed.	A new premise and service point(s) must be setup prior to using Start/Stop.
Updates to existing customer information	Changes to a customer's existing account and/or person info may be entered on the order page. The related person and/or account will be updated when the order is completed.	Start/Stop cannot be used to update person or account information. Rather, you must transfer to the person or account page and make the necessary changes.
Incomplete orders	The order transaction allows you to record customer information and hold it without starting service. The customer can call back in the future and you can continue where you left off.	You cannot leave a start half-finished - you either have to complete the start or cancel it.
Stop current service, start new service	The order transaction does not currently provide a mechanism for stopping service (it can only be used to start service).	Start/Stop can be used to stop a customer's current service and start new service.
Automatic versus manual start option selection (start options are used to default a great deal of information onto a service agreement)	If a customer selects a package, the system creates service agreements using the start options defined in the package (i.e., you do not have to select a start option for each service agreement that's created).	When you start service, you must define the specific start option for each service agreement created (actually, you only have to do this for those types of service agreements that use start options).
Starting premise and non-premise oriented services	If a customer selects a package, the system can create both premise and non-premise oriented service agreements. For example, when a package is selected, the system can create electric, gas, deposit, and charitable contribution SAs (based on the information defined on the package).	Multiple premise-oriented service agreements can be created in one interaction. However, a separate interaction is required for each non-premise oriented service agreement.
Changes after completion	An order cannot be modified after it is completed. Any changes (cancellations prior to starting service, changes of the start date, etc.) must be performed using the start/stop transaction.	The start/stop transaction allows you to cancel and make changes to pending start service agreements.

Copyright © 2026, Oracle and/or its affiliates.

Field activity visibility	After an order is completed, the user is transferred to control central where field activities associated with the premise can be seen in trees and context zones.	All field activities associated with all premises associated with all pending starts / stops are shown on the start / stop transaction.
Address changes	Address changes entered on the order transaction are applied when an order is completed (i.e., when a package is selected). They are not held awaiting service agreement activation.	When you enter an address change on the start / stop transaction, this address changed is saved until the first pending start or stop is activated. This means that the address change is effectively held until the start/stop is activated.

Based on the above, we'd recommend the following:

- If your organization has well-defined service locations (i.e., premises) AND a premise's service point type controls the types of services offered to the customer, you should probably only use the order transaction to setup new customer information. The new service agreements should be setup using start / stop. See Prelude To Start/Stop for more information.
- In all other situations, we'd recommend using the order transaction to start service. If customers typically stop and start service in tandem, we'd recommend the following steps:
  - Stop the customer's existing service using start / stop.
  - Return to Control Central - Account Info and select the appropriate campaign from the appropriate portal zone. Keep in mind that the portal zones displayed on this page are based on the user's preferences and security profile. Therefore this zone may not be available to all users.
  - When you select the appropriate campaign, you'll be transferred to the order transaction where you can start the desired package for the customer.

Orders Cannot Be Changed After They Are Completed

The Lifecycle of an Order indicates that once an order is complete, it cannot become pending again. In addition to this rule, we'd like to stress that once an order is complete, you cannot make any changes to the order except to add new log entries.

Premise and SP Characteristics May Be Populated From Postal Defaults

If you specify a new premise on the order transaction and you complete the order, a new premise will be created. This premise's characteristics can be populated from two different sources:

- You could have designed the campaign to have its orders capture premise characteristics. You do this by adding miscellaneous fields to the campaign that are premise characteristics.
- You could have set up postal defaults for the premise's country and postal code.

Copyright © 2026, Oracle and/or its affiliates.

If a given characteristic is referenced on both of the above, the characteristic value on the campaign is used as the premise's characteristic value.

As described above, service points may be created when a package is selected (it depends on the SA to Create algorithm that you've used on the selected package). The base package algorithms that create a new service point when a package is selected will populate the service point's characteristics using the information on the postal defaults (if specified). Refer to STRM-VT for an example of this type of SA to create algorithm.

To Do List Processing

In the base package, there are two To Do lists that may be affected by orders:

- Highlight pending orders. This To Do list contains orders that are in the pending state. Refer to Pending To Do Entries (TD-EPND) for more information about this To Do list.
- Highlight held orders. This To Do list contains orders that are in the held state. Refer to Held To Do Entries (TD-ECBK) for more information about this To Do list. Refer to Order - Hold Dialog for more information about holding orders.

Hold and Cancel Reason Codes

In Lifecycle of an Order, we illustrated how a user can hold a pending order. Before a user can hold an order, they must supply an Order Hold Reason .

The same is true if a user wants to cancel a pending or held order (i.e., they must supply a Order Cancellation Reason).

These reason codes are purely for audit purposes.

Automatically Cancelling Old Orders

The system is delivered with a batch process, Cancel Pending/Held Orders (C1-CNPHO), that can be used to cancel held and/or pending orders that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the Plug-in Driven Background Processes framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the order. Adjust the batch parameters to align with any custom logic you introduce.

Additional Things Can Happen When An Order Is Completed

An optional plug-in spot exists on customer class where you can introduce additional logic to be executed when an order is completed for an account that belongs to this customer class.

Another optional plug-in spot exists on campaign where you can introduce additional logic to be executed when an order is completed for the campaign.

Copyright © 2026, Oracle and/or its affiliates.

New Premises and Accounts Are Only Created if an Order is Completed

It's important to understand that a premise and account are only created when an order is completed. This means you can explore alternatives with a prospect who resides at a new premise without introducing the premise / account. However, the system creates a person if you save an order so that an audit of the customer interaction exists in the system.

Premise Geographic Types Are Populated In An Unusual Way

A premise's geographic ID's are used by Control Central when you look for a customer / premise using geographic identifiers.

> **Note**
>
> **Geographic coordinates are optional.** An installation option controls whether at least one geographic coordinate is required on every premise.

The following points describe how the geographic ID's are populated on premises that are created when an order is completed:

- If a postal default exists for the new premise's country / postal code, any geographic identifiers on the postal default are copied onto the new premise.
- If a postal default hasn't been setup for the new premise's country / postal code, the premise will have a single geographic identifier. It is constructed as follows:
  - The geographic type is defaulted from the campaign.
  - The geographic value is set to ***.

> **Note**
>
> **Potential error.** If neither the campaign nor the postal defaults results in a geographic type AND the installation record indicates at least one geographic type is required on a premise, an error is generated explaining that either postal defaults or the campaign should be populated with default geographic information.

Account And Premise Usage Are Controlled By The Campaign

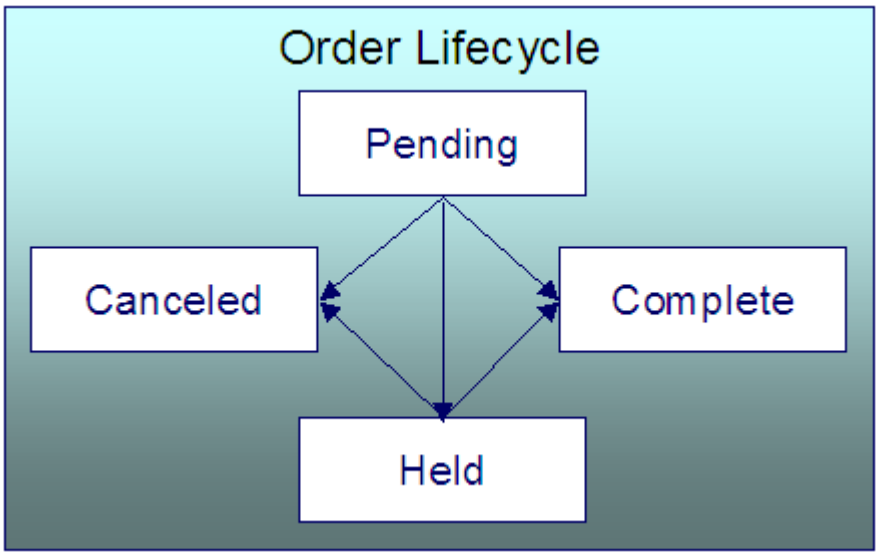
When you set up a campaign, you define how the campaign's orders use accounts and premises. Refer to the description of Account Usage and Premise Usage under Campaign - Main for more information.

Copyright © 2026, Oracle and/or its affiliates.

Maintaining Orders

The order transaction can be used to satisfy many diverse requirements. For example, you can use an order to:

- Enroll new customers using a single transaction (i.e., you don't have to use the person, premise, service point, and start / stop transactions to enroll a new customer who resides at a new premise).
- Sell new products to existing customers.
- Update existing person, account and premise information using a single transaction.
- Market your services to prospects uploaded from a marketing list (and measure the success of your efforts). If the customer responds to your sales efforts, the system will automatically setup the customer, premise and related service agreements.
- Setup marketing surveys and record your customers' responses.
- Quickly create one-time charges.
- Set up proposals for prospective services (and then send a quotation to the customer for these services).
- And more...



The topics in this section describe the order transaction. Refer to The Big Picture of Campaigns, Packages and Orders for general information about orders.

- Lifecycle of an Order

- Order - Questions & Misc Fields
- Order - Log
- Order - Package Confirmation
- Order - Hold Dialog
- Order - Cancel Dialog

Lifecycle of an Order

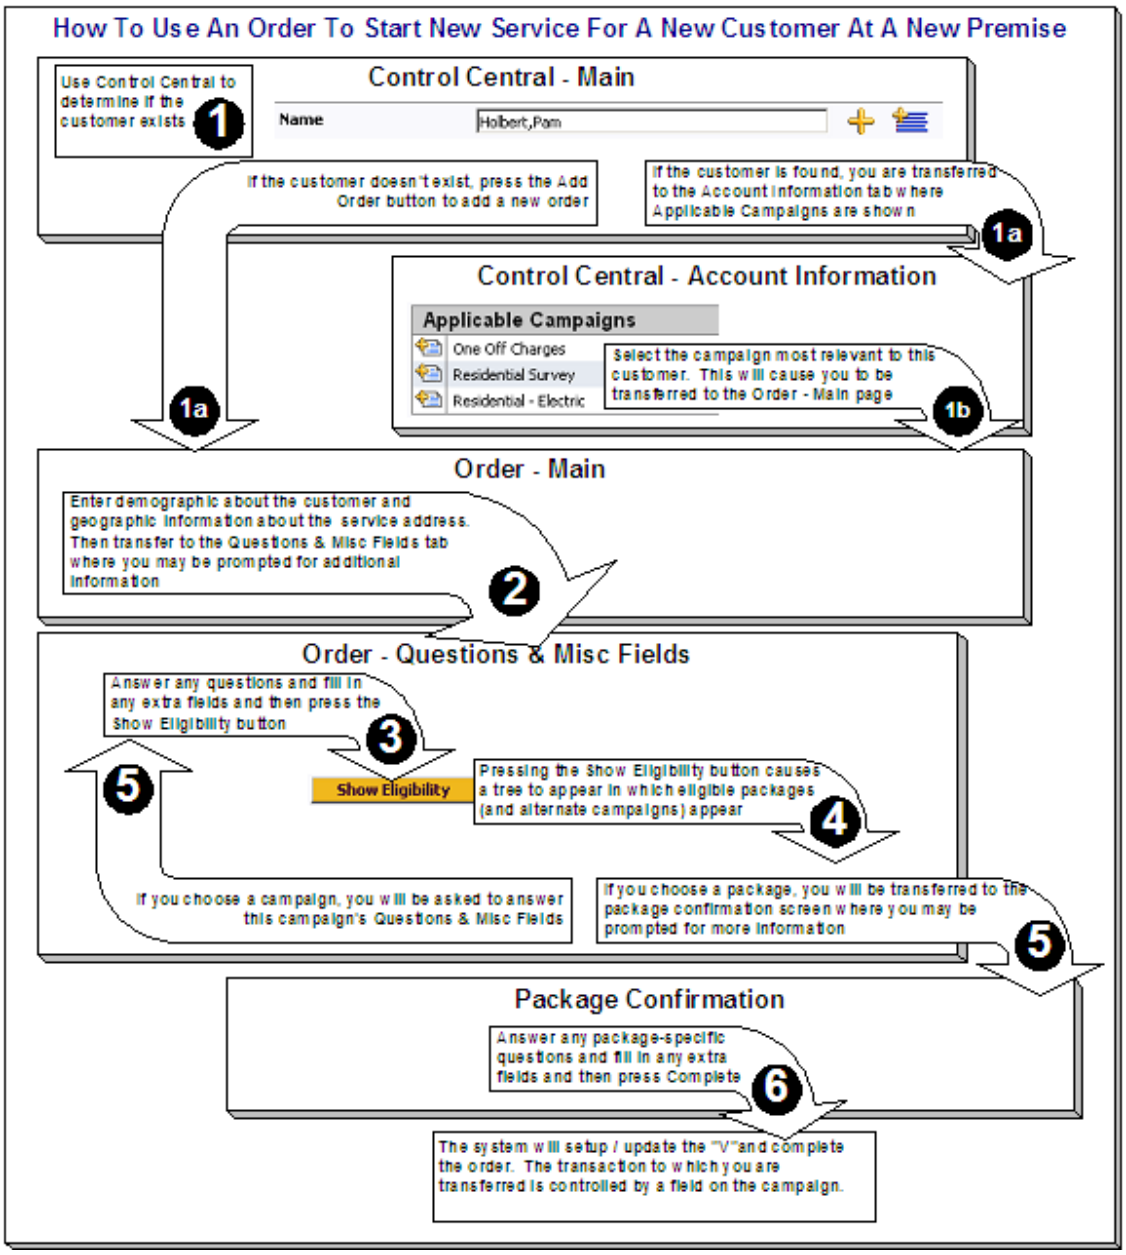
The following diagram illustrates the lifecycle of an order.

Copyright © 2026, Oracle and/or its affiliates.

Pending An order starts its life in the Pending state. An order remains in this state until you Cancel, Complete or Hold it.

Held You Hold an order when you want to save an order pending future information. For example, you would hold an order if you need to perform research on the perfect rate for the customer before completing the order. A Held order can be Completed or Canceled.

Complete When a customer selects a package of goods and services, the "V" is updated, service agreements are initiated, and the order becomes Complete. No changes may be made to a Complete order.



Canceled A Pending or Held order may be Canceled.

Order User Interface Flow

The diagram that appears below illustrates the anticipated navigation path used to process an order.

> **Warning**
>
> An order's campaign controls many aspects of the user interface flow. The illustration that appears below is a sample of what's possible; it may not mirror how your team has setup your company's campaigns.

Copyright © 2026, Oracle and/or its affiliates.

Order - Main

This page is used to define demographic and geographic information about the customer / prospect.

NOT_SUPPORTED

Refer to The Big Picture of Campaigns, Packages and Orders for more information about orders.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Order**, and then **Search.**

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Order User Interface Flow for information about how to use this page.

Description of Page

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to Lifecycle of an Order for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.
- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to Order - Hold Dialog for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to Order - Cancel Dialog for a description of the pop-up window used to cancel an order.

If the **Campaign** has been setup to allow the completion of orders without selecting a package, a button appears to the right of **Cancel**. The label that appears in the button is defined on the **Campaign**. When pressed, the order is completed. When the order is completed,

- The "V" is setup / updated.
- All questions and miscellaneous fields (defined on the next tab) are posted to the appropriate object.
- Optional plug-ins are executed.
- You will be transferred to the order completion transaction that's defined on the **Campaign** (if any).

If the order references an existing person, account, or premise and the related person / account / premise has changed after their information was snapshot on the order, the **Out of Sync** section appears. This section highlights which objects have changed since the order was last saved. In addition, the **Sync** button appears. When pressed, the order is updated with the current field values for these objects.

An order's **Campaign** controls many aspects of the order's behavior. For example, it controls:

- The type of information defaulted onto an order.
- The eligibility-oriented questions that are displayed on the next tab.
- The superset of packages that can be offered to a customer.
- In addition to the above, campaigns also control high-level eligibility rules and business process flows.

Copyright © 2026, Oracle and/or its affiliates.

An order's **Campaign** is defaulted as follows:

- When you select a customer on Control Central - Search, you are automatically transferred to the Account Information portal. One of the zones on this portal page contains the campaigns that can be offered to the customer. If you select a campaign from this zone, you are transferred to the Order transaction with the respective Campaign defaulted. Note, the Applicable Campaigns zone only appears if the CSR has modified their preferences to display this zone.
- In all other situations, the order's campaign defaults from the Installation Record.

You may change an order's **Campaign** at will. Note that changing the campaign will result in the **Questions & Misc Fields** (the next tab) being refreshed with values associated with the new campaign. However, other values typically defaulted from the campaign (such as default customer class) do not get refreshed so that data you may have entered does not get overwritten.

Start Date defines the date on which service will start. This date becomes the start date on service agreements created when this order is completed. If you need to change the start date on these service agreements, transfer to Start/Stop (where all of the pending start service agreements will appear).

> **Note**
>
> Manual date entry is disabled on the start date and the date picker must be used when the Disable Manual Date Entry **Option Type** on the Customer Information Options Feature Configuration has been enabled.

The topics that follow describe the remaining sections on this page

- Order - Main - Person Information
- Order - Main - Service Address
- Order - Main - Account Information

Order - Main - Person Information

The **Person Information** section contains demographic information about the customer / prospect.

> **Warning**
>
> This page contains a subset of person-oriented information. If you need to define other person-oriented information, transfer to Person - Main after the order is completed.

If this is a new customer, select Create New Person and enter demographic information in the fields that follow. Otherwise, select Use Existing Person and use the **Name** field or press the search button to find the customer. After you select an existing person, the following events takes place:

- The person's name appears beneath the person search (and the person context menu can now be used to drill down to person-oriented pages). Note, the person's name is formatted

Copyright © 2026, Oracle and/or its affiliates.

by a plug-in algorithm on the installation record. Refer to the base package's name format algorithm (PERS-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.

- If any of the Questions & Misc Fields (on the next tab) are used to capture person-oriented characteristics, the person's existing characteristic values are defaulted.
- If the selected person has at least one account, information about the account is displayed in the **Account Information** section (if the **Campaign** makes uses of accounts). In addition, if any of the Questions & Misc Fields (the next tab) are used to capture account-oriented characteristics, the account's existing characteristic values are populated in the respective rows on this tab.
- Information about the person is displayed in the fields that follow.

Use **Person/Business** to indicate if the customer is a Person or a Business. This value controls how the person's primary name is validated. Note, for new customers, this value defaults based on the **Campaign**.

Names are used by Control Central when you look for a customer based on their name. In addition, a person's primary name is the addressee on the person's bill unless overridden by the **Override Mailing Name** (defined on Person - Correspondence Information). To modify a name, simply move to a field and change its value. To add a new name, press + to insert a row, then fill in the information for each field. The following fields display:

- Use **Name Type** to indicate if the name is an Alias, Alternate Representation, Doing Business As, Legal, or Primary name. Note, for new persons, a value of Primary is defaulted.
- Use **Person Name** to define the person's name. Note well, the name is case sensitive.

> **Note**
>
> **Alternate representations of a person's name.** You would use an Alternate Representation for a person's name when you have an alternate ways to define the person's primary name. Alternate representations are typically used in countries that use multiple character sets (e.g., the Primary name is entered in Chinese, the Alternate Representation is entered in English). When a person has an alternate name, both the main and alternate names can be used to search for a person. The Alternate Representation **Name Type** only appears if you have enabled alternate addresses on the installation record. Refer to the description of the Alternate Representation field under Installation - Main for more information.
>
> **Validation and formatting are performed by plug-ins.** The validation that is applied to **Person Name** (e.g., a comma separating the last and first name - Smith,Patricia) is controlled by a plug-in algorithm on the installation record. More than one algorithm can be plugged into this plug-in spot. Algorithms plugged into this plug-in spot can also perform formatting such as removing special characters that your implementation's business rules do not allow in person names. Other algorithms can be configured to remove or replace text.

- The **Do Not Format** switch can be used to bypass any person name formatting done by the algorithms described above. Validation such as requiring name separator is still applied, but no further formatting is applied. Setting the switch only applies while the record is being saved and is then reset. The switch is reset because the formatting is only applied when the record is subsequently changed. This switch is only shown if the Enable Person

Copyright © 2026, Oracle and/or its affiliates.

Name Format Bypass **Option Type** on the Customer Information Options Feature Configuration has been enabled

Person Contacts are used by Control Central to look for accounts and persons. For new customers, the person contact type(s) default based on the Campaign. To modify a person contact, simply move to a field and change its value. To add a new person contact, press + to insert a row, then fill in the information for each field. The following fields display:

- **Person Contact Type** indicates the type of contact such as, home phone, cell phone, or work email.
- **Contact Information** contains the specific contact information such as, the phone number or email address. Enter the contact information in the format described.

> **Note**
>
> **Formatting is performed by a plug-in.** The format that is applied to **Contact Information** is controlled by the algorithm that is plugged in on the respective person contact type (refer to Setting Up Person Contact Types for more information). If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the contact information. (This field is only active when the contact's contact routing is phone or fax.)
- The **Primary** switch must be set for exactly one person contact for each contact routing.
- **Do Not Disturb (From)** and **Do Not Disturb (To)** indicate the times when a person contact should not be used. (**Note:** these fields are active when the Person Contact Type's Allow Do Not Disturb information is set to *Optional*.

Phone numbers are used by Control Central to look for accounts and persons. For new customers, the phone type(s) default based on the **Campaign**. To modify a telephone number, simply move to a field and change its value. To add a new telephone number, press + to insert a row, then fill in the information for each field. The following fields display:

- **Phone Type** indicates the type of phone number, e.g., Home, Mobile, Business, ...
- Use **Phone Number** to define the telephone number. Enter the telephone number in the format described by the **Phone Format**.

> **Note**
>
> **Formatting is performed by a plug-in.** The format that is applied to a **Phone Number** is controlled by the algorithm that is plugged in on the respective Phone Type. You can also have this plug-in convert input values into formatted values, e.g., this algorithm could transform all numbers into a formatted string. If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the telephone number.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The Person Phone grid appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

A person's **ID** has several uses:

- It is used by Control Central when you look for a customer / premise based on their ID.
- It is used to highlight potential duplicate persons.
- Control Central displays a person's primary identification in the search results area to help a user identify the customer when multiple customers match the search criteria.

The person ID usage flag on the installation record indicates whether or not at least one id for a person is required or optional. The ID Type defaults from the installation record based on the **Person Type** (Person versus Business). The following fields are used to define a customer's primary ID.

- Select the type of identification from the **ID Type** drop down.
- Enter the identification number in the **ID Number** field. Please note that if the ID number should be formatted (e.g., dashes in an American social security number), you do not have to include the delimiter (e.g. dashes). You can enter the ID number as a contiguous value and the system will format it for you. The format is shown adjacent to the **ID Number** field.

> **Note**
>
> **Formatting is performed by a plug-in.** The format that is applied to a person ID number(e.g., dashes in an American social security number) is controlled by the algorithm that is plugged in on the respective ID Type. If you prefer a different format, your system administrator should configure this algorithm appropriately.
>
> **A person can have many forms of identification.** The order transaction only caters for a single form of ID (as this is the most typical situation). If you want to specify additional person ID's, you must transfer to Person - Main after the person is created (persons are created when the order is saved).

Specify the customer's **Email ID** (if any).

> **Note**
>
> **EmailID** appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

Define the **Language** in which the person prefers their bills and correspondence printed.

> **Note**
>
> **Default note.** The person's language defaults from Installation Options - Person.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Customer Language for more information on options for supporting multiple languages for your customers.

Use **Life Support / Sensitive Load** to indicate if the person has life support or sensitive load equipment. Valid values are: LS/SL (i.e., the person has life support / sensitive load equipment), None. If the customer has LS/SL equipment, make a note of the type of equipment in the **Life Support / Sensitive Load Notes**.

Note

A premise can also have life support / sensitive load information. If the equipment is physically linked to the premise (e.g., a hospital has life support equipment), you should NOT specify the life support information on the person. Rather, after the premise is added, transfer to Premise - Misc and specify life support information on the premise.

Life support affects alerts and C&C. If life support / sensitive load information is specified, an alert will appear when the person is displayed on control central. In addition, if a person has life support or sensitive load equipment, it is possible for a different credit & collection severance process to be kicked off if the person's account associated has overdue debt. Refer to Designing Your Severance Procedures for more information.

Order - Main - Service Address

The **Service Address** section contains geographic information about the service address:

Warning

This page contains a subset of premise-oriented information. If you need to define other premise-oriented information, transfer to Premise - Main after the order is completed.

Whether or not a premise is required or even allowed on an order is controlled by an option on the **Campaign**. If the **Campaign** disallows the use of a premise, this section will be suppressed. If the **Campaign** allows the use of a premise, an indication of whether a premise is optional or required is displayed adjacent to **Service Address**.

If a premise is allowed on the order, use the dropdown at the top of this section to tell the system about this order's premise:

- Select No Premise Information if you do not want to associate a premise with this order (e.g., for a one-time charge).
- Select Create New Premise if this is a new premise. You should enter the new premise's address in the remaining fields in this section.

Copyright © 2026, Oracle and/or its affiliates.

- Select Use Existing Premise if an existing premise should be used on the order. Use the **Address** and **City** fields or press the search button to find the premise. Refer to Control Central - Search Facilities for suggestions in respect of how to use these fields. After you select an existing premise, the following events takes place:
  - The premise's description appears beneath the premise search fields (and the premise context menu can now be used to drill down to premise-oriented pages).
  - If any of the Questions & Misc Fields (the next tab) are used to capture premise-oriented characteristics, the premise's existing characteristic values are defaulted.
  - Information about the premise is displayed in the fields that follow.

Use **Premise Type** to describe the type of service location.

The address's constituent fields vary based on the **Country**. Please refer to the Country page for more information.

Populate **Trend Area** if the **Postal** is blank. The **Postal** and the **Trend Area** cannot both be blank as the **Trend Area** is a required field on the premise and its value is typically defaulted from postal defaults.

> **Note**
>
> **Default note.** The values of several fields on this and the next page default based on the **Country** and the **Postal**. Refer to Setting Up Premise & Service Point Postal Defaults for more information. Also note, there are several premise-oriented fields that do not appear on this transaction that will be populated on the premise based on the **Country** and **Postal** (e.g., characteristics, time zone, trend area, geo ID's).

Use **CIS Division** to define the jurisdiction in which the premise is located.

Order - Main - Account Information

The **Account Information** section contains account-oriented information.

> **Warning**
>
> This page contains a subset of account-oriented information. If you need to define other account-oriented information, transfer to Account - Main after the order is completed.

Whether or not an account is required or even allowed on an order is controlled by an option on the **Campaign**. If the **Campaign** disallows the use of an account, this section will be suppressed. If the **Campaign** allows the use of an account, an indication of whether an account is optional or required is displayed adjacent to **Account Information**.

If an account is allowed on the order, use the dropdown at the top of this section to tell the system about this order's account:

- Select No Account Information if you do not want to associate an account with this order (e.g., for a person-oriented marketing survey).

Copyright © 2026, Oracle and/or its affiliates.

- Select Create New Account if this is a new account. You should enter the new account's information in the remaining fields in this section.
- Select Use Existing Account if an existing account should be used on the order. If an existing person was selected above, one of the person's accounts (if any) will be automatically displayed in the **Account Information**. In addition, if the order references an existing person, the account search will be limited to accounts associated with this person. If an **Existing Account** is selected, the following takes place:
  - Basic information about the account appears beneath the search area (and the account context menu can now be used to drill down to account-oriented pages).
  - If any of the Questions & Misc Fields on the next tab are used to capture account-oriented characteristics, the account's existing characteristic values are defaulted.
  - Information about the account is displayed in the fields that follow.

If you have set the Installation Option CIS Division Control flag**,** you must define the new account's **CIS Division.** The values are restricted to the user's CIS Division(s). See Users and CIS Division for more information. The value is defaulted to user's primary CIS Division.

Customer Class plays a part in:

- If and when a customer is subject to late payment charges.
- The account's default collection class and when the account debt monitor reviews an account. Refer to The Big Picture of Credit & Collections for more information about how and when an account's debt is reviewed.
- And several other functions. Refer to and Setting Up Customer Classes for more information.

> **Note**
>
> **Default note.** For new accounts, the **Campaign** can default the **Customer Class**. If the campaign does not define a customer class, it can be defaulted from the CIS Division, if shown, or installation options.

The optional Account **Management Group** controls the roles assigned to To Do entries associated with an account. Refer to Setting Up Account Management Groups for more information.

> **Note**
>
> **Default note.** For new accounts, **Management Group** defaults based on the **Campaign**.

The remaining fields are used to describe how the bill should be routed to the customer.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> When an order is completed, several fields that do not appear on this page that reside on Account - Person are populated. For example, **Account Relationship Type, Bill Format**, **Number of Copies**, **Receives Notification** are all populated with default values. If you need to override the default values, transfer to Account - Person after the account is added.

Use **Bill Route Type** to define how the bill is sent to the customer. This field's value defaults from the Installation Record. This value is important as it controls many options on the remainder of this page. If the **Bill Route Type** indicates that bills are routed via Fax, the person's fax number is displayed adjacent (the system knows which of a person's phone numbers is a fax number by the **Phone Type**). If the **Bill Route Type** indicates that bills are routed via Email, the person's **Email** address is displayed adjacent. If the **Bill Route Type** indicates that bills are routed via the Postal service, you must choose an appropriate **Address Source** to define which address should be used. Refer to Setting Up Bill Route Types for more information about bill route types.

If the **Bill Route Type** indicates that bills are routed via the Postal service, you must choose the appropriate **Address Source** to define which address should be used.

- Choose Mailing Premise on Account if bills should be sent to the address associated with the Mailing Premise on the first page. This address is displayed adjacent.
- Choose Person if bills should be sent to the person's mailing address . This address is displayed adjacent.
- Choose Account Override if bills should be sent to an override address specified below. Typically, you would only choose this option if the person has multiple accounts and each account's bills should be sent to a different address.

If you select a **Address Source** of Account Override , you must enter the address to which bills will be sent in the following address constituents. The number and type of address constituents is based on the **Country** (refer to Defining Countries for more information on address constituents). These fields will be protected for other **Address Sources**. Note, the **Country** defaults from Installation Options - System and several other constituents default based on the **Country** and **Postal** if a Postal Default exists for the postal code.

> **Note**
>
> By default, the **Address Source** field is protected on Order – Main page if the **Bill Route Type** is set to a value other than Postal. To enable the **Address Source** field for all **Bill Route Types** in most circumstances, set the Always Enable Address Source option type on the General System Configuration feature configuration to Y.
>
> Regardless of the **Always Enable Address Source** option value, **Address Source** and **Address Information** are displayed but both are disabled when **Bill Routing Method** is ***Not Postal*** and **Quote Routing Method** (on Account – Persons page) is ***Postal***. A message "*The Main Person receives Quotes at this address. To edit it, go to the 'Persons' tab on the Account.*" is displayed next to the **Address Source.**

Copyright © 2026, Oracle and/or its affiliates.

Order - Questions & Misc Fields

This page has several purposes:

- The order's Campaign can define questions to be posed to customers when an order is taken. For example, you could ask the customer "marketing survey" questions (e.g., please rate our service, how do you heat your home?, etc.). This page allows you to capture the customer's response.
- The order's Campaign can also be setup to capture additional fields to be updated on the order's person / account / premise when the order is completed. For example, you could indicate that the account's override due date and automatic payment options should be captured when an order is taken. This page allows you to capture these field values.
- The order's Campaign can also be setup to pose eligibility-oriented questions that qualify the customer for packages of goods and services. For example, you might have a campaign with packages that can only be selected if the customer commits to a year's worth of service. This page allows you capture the customer's response to these types of questions.
- After entering the above information (and the information on the Main page), you can use this page to select a package of goods and services for the customer.
- You can use this page to switch the campaign on the order (which would result in new questions and miscellaneous fields appearing).

NOT_SUPPORTED

Refer to The Big Picture of Campaigns, Packages and Orders for more information.

Open this page using **Sales & Marketing, Order** and then navigate to the **Questions & Misc Fields** tab.

NOT_SUPPORTED

Refer to Order User Interface Flow for information about how to use this page.

Description of Page

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to Lifecycle of an Order for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.

Copyright © 2026, Oracle and/or its affiliates.

- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to Order - Hold Dialog for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to Order - Cancel Dialog for a description of the pop-up window used to cancel an order.

If the **Campaign** has been setup to allow the completion of orders without selecting a package, a button appears to the right of **Cancel**. The label that appears in the button is defined on the **Campaign**. When pressed, the order is completed. When the order is completed,

- The "V" is setup / updated.
- All questions and miscellaneous fields (defined on the next tab) are posted to the appropriate object.
- Optional plug-ins are executed.
- You will be transferred to the order completion transaction that's defined on the **Campaign** (if any).

If the order references an existing person, account, or premise and the related person / account / premise has changed after their information was snapshot on the order, the **Out of Sync** section appears. This section highlights which objects have changed since the order was last saved. In addition, the **Sync** button appears. When pressed, the order is updated with the current field values for these objects.

The number and type of **Questions & Misc Fields** is controlled by the Campaign.

> **Note**
>
> **Some questions can be suppressed.** The campaign contains an indication if each question is account-oriented, person-oriented, premise-oriented or order-oriented. If the question is account-oriented and no account is defined on the **Main** tab, the question will be suppressed. If the question is premise-oriented and no premise is defined on the **Main** tab, the question will be suppressed.

Each row in this grid has a **Prompt** and a **Response**. The value of each **Prompt** is defined on the **Campaign**. The **Response** holds the answer supplied by the customer. Please note the following about the **Response** field:

- On a **Campaign**, you can indicate which questions / miscellaneous fields are required. The Response for a required field is prefixed with an asterisk - * .
- The value of a Response can default from a variety of sources:
  - If an existing person was selected on the **Main** page AND the response is used to capture a person characteristic, the existing characteristic value will be defaulted.
  - If an existing premise was selected on the **Main** page AND the response is used to capture a premise characteristic, the existing characteristic value will be defaulted. If no value exists, the characteristic values will default based on the postal defaults associated with the service address's **Country** and **Postal**.

Copyright © 2026, Oracle and/or its affiliates.

  - If an existing account was selected on the **Main** page AND the response is used to capture an account characteristic, the existing characteristic value will be defaulted.
  - Otherwise, the characteristic value is defaulted from the **Campaign**.
- The type of field used to capture a Response is controlled by the Campaign. Depending on the type of Response you may see Go To buttons and Search buttons.

After entering the **Responses** to the **Questions & Misc Fields**, press the **Show Eligibility** button.

The following may occur when this button is pressed:

- If a new customer is specified on the Main page, a warning will advise you that a new person will be added. The system needs to add a new person so that an audit of the customer interaction exists.
- The tree expands to show the Order - Eligibility Tree containing package, ineligible package, error package, and other campaign nodes:
  - Each **Package** node contains a package that is linked to the campaign whose Eligibility Criteria allows its selection by the customer. You can expand this node to see the various service agreements that will be created if you select the package. Selecting one of these packages causes the Order - Package Confirmation page to appear in which you can confirm your selection.
  - The **Ineligible Package(s)** node contains packages whose Eligibility Criteria prevents their selection by the customer.
  - The **Error Packages** node contains packages whose Eligibility Criteria have returned errors (if any).
  - The **other campaign(s)** node contains alternative campaigns that may be substituted for the current campaign on the package. Selecting one of these campaigns will cause the campaign to be changed on this order. Changing a campaign on an order will result in new questions and miscellaneous fields appearing. Refer to The Big Picture Of Campaign Eligibility for more information.

> **Note**
>
> **Some nodes can be suppressed.** To increase page performance with large campaigns, you can define a feature configuration to suppress the display of the Ineligible Packages, Error Packages or Other Campaign nodes. If a node is suppressed, it does not appear on the eligibility tree and the system does process the information necessary to display the node.

Order - Log

This page contains an audit trail of significant events that transpired in the history of this order.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Order**, and then **Search** and navigate to the **Log** page.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to Lifecycle of an Order for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.
- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to Order - Hold Dialog for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to Order - Cancel Dialog for a description of the pop-up window used to cancel an order.

Campaign contains basic information about the order's campaign.

Package only appears if the order has been completed. It contains basic information about the package.

Start Date contains the date on which the service agreement's created by the order will be started.

The **Log** contains an audit trail of significant events that transpired in the history of this order. There are two types of entries in the log:

- The system automatically adds log entries when key events occur. These entries may not be removed or changed.
- Users may add log entries by pressing the + button and then specifying the Details.

Order - Package Confirmation

The Package Confirmation page allows you to check the package you selected before the V is created / updated for the customer. This page opens when you select a package from the eligibility tree on Order - Questions & Misc Fields.

> **Warning**
>
> If you press the **Complete** button, a variety of objects may be created (service agreements, service points, a premise, an account, field activities, etc.). If you need to change any of these objects after order completion, you must transfer to the respective page on which the object is maintained. You can also use Start/Stop to make changes to the service agreements created by this transaction.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

Order contains a concatenation of basic information about the order. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Campaign contains basic information about the order's campaign.

Package contains basic information about the package.

Premise is the address at which service will be delivered.

Person is the name of the customer.

Account is the name of the customer and their customer class.

Start Date contains the date on which the service agreement's created by the order will be started.

The **Questions & Misc Fields** grid contains the questions and miscellaneous fields that appeared on the order. Note well, it is possible to design a campaign and a package where some fields are optional on the campaign but required for a specific package. The **Response** of all required fields for the selected package are prefixed with an asterisk. Refer to Order - Questions & Misc Fields for information about the rows in this grid.

> **Note**
>
> **Changing your answers could cause the package to become ineligible.** As described earlier, the fields you enter on an order play are what the system uses to determine if a package can be selected for a customer. If you change the answers to the **Questions & Misc Fields**, the package may no longer be eligible and an error will be presented to you. You will have the choice of reverting to the original answers or returning to the order page where you can select an eligible package.
>
> **Additional questions / misc fields are possible.** It is possible to design a campaign where certain field values are only visible on specific packages. In this scenario, the **Questions & Misc Fields** grid may contain additional rows for a given package. Refer to Designing Campaigns and Packages for more information.

The **Instructions** grid contains package-specific suggestions. These instructions are defined on the package.

The **Messages** grid contains system-generated messages that summarize what will happen if you press the **Complete** button.

Press the **Complete Order** button if you are satisfied with the information on the order. Otherwise, press **Do Not Use this Package** to change or cancel the order.

Order - Hold Dialog

The **Order - Hold** dialog opens if you press the **Hold** button on the order transaction. You use it to define why the order is being held and when you want to be reminded to check up on the order.

Description of Page

Use **Hold Reason** to define why the order is being held.

Copyright © 2026, Oracle and/or its affiliates.

The following fields are used to control the To Do entry that will be created to remind you about this order.

- Use **Reminder Date / Time** to define the latest date on which the To Do entry should be created. The reason we indicated this should be the latest date is because the background process (TD-ECBK) that's responsible for creating these To Do entries has a parameter called "lead time". This parameter is used to define the number of days before the **Reminder Date** that the To Do entry should be created.
- If the To Do entry should be addressed to a group of users, choose a **Reminder Type** of Send to Role and enter the user group's **To Do Role**. Note, the To Do Role will default from the order's campaign.
- If the To Do entry should be addressed to a specific user, choose a **Reminder Type** of Send to User and enter the user's User ID in **To Do User**.
- **Log Notes** are used to describe why the order is being held. This information appears in the log entry that is created by the system when you hold an order.

If there are any To Do entries (with a status of Open or Assigned) that drill down to this order, a message is displayed indicating that existing To Do entries for this order will be completed. If the order is already in Hold status, existing To Do entries are completed when you click the OK button and a new To Do entry is created when the background process responsible for creating the To Do entries runs.

Order - Cancel Dialog

The Order - Cancel dialog opens if you press the **Cancel** button on the order transaction. You use it to define why the order is being canceled.

Description of Page

Use **Cancel Reason** to define why the order is being canceled.

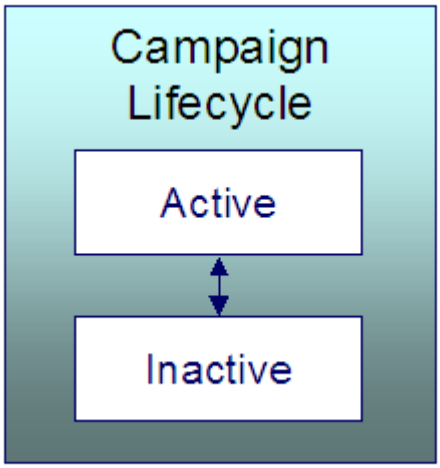
Use **Log Notes** to describe why the order is being canceled. This information appears in the log entry that is created by the system when you cancel an order.

Maintaining Campaigns

When you add an order, you must reference its campaign. An order's campaign controls:

- The type of information defaulted onto an order. For example, you can setup a campaign to default a given account management group on all orders linked to this campaign. This account management group will then default onto accounts created when the campaign's orders are completed.
- The eligibility-oriented questions that are posed to the customer when an order is taken. For example, the questions indicated above - Who is your current energy service provider? / Would you like to pay automatically? / What is your date of birth? - are all defined on the order's campaign.
- The superset of packages that can be offered to a customer whose order references this campaign. An order's campaign defines the types of packages that may be selected.
- In addition to the above, campaigns also control high-level eligibility rules and business process flows.

Copyright © 2026, Oracle and/or its affiliates.



The topics in this section describe the campaign transaction.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Campaigns, Packages and Orders for general information about campaigns. Refer to The Big Picture Of Campaign Eligibility Rules for a discussion of how to control which campaigns can be used for different types of customers. Refer to Designing Campaigns and Packages for guidelines describing how to design your campaigns.

Lifecycle of a Campaign

The following diagram illustrates the lifecycle of a campaign.

Active An Active campaign may have orders created in respect of it.

Inactive By Inactivating the campaign, you are preventing it from being used on future orders. In addition, Inactive campaigns do not appear in the Applicable Campaigns zone.

Campaign - Main

This page is used to define basic information about a campaign.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture of Campaigns, Packages and Orders and Designing Campaigns and Packages for more information.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Campaign**, and then **Search.**

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

Description briefly describes the campaign.

Campaign Status describes the state of the campaign. Refer to Lifecycle of a Campaign for more information.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new persons - they will not override field values defined on existing persons.

- The system requires all persons to be defined as either a Person or a Business. Use **Default Person / Business** to define the default value for persons created by this campaign's orders.
- Every person contact defined for a person must reference a person contact type. Use **Default Person Contact Type 1**, **Default Person Contact Type 2**, and **Default Person Contact Type 3** to define the first three person contact type defaults for persons created by this campaign's orders.

Note

Person Contact Types appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has **not** been enabled

- Every phone number defined for a person must reference a phone type. Use **Default Phone Type 1** and **Default Phone Type 2** to define the first two phone types defaults for persons created by this campaign's orders.

Note

Phone Types appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

Premise Usage controls if and how this campaign's orders use premises. You have the following options:

- Select Not Allowed if this campaign's orders do not reference a premise.
- Select Optional if this campaign's orders do not have to reference a premise. This option also means that a new OR existing premise may be specified on the order. Note, if an order references a new premise, the premise will be created when the order is completed.

Copyright © 2026, Oracle and/or its affiliates.

- Select Optional - Existing Premise Only if this campaign's orders do not have to reference a premise. This option also means that only an existing premise may be specified on an order.
- Select Required if this campaign's orders must reference a premise. This option also means that a new OR existing premise may be specified on the order. Note, if an order references a new premise, the premise will be created when the order is completed.
- Select Required - Existing Premise Only if this campaign's orders must reference a premise. This option also means that only an existing premise may be specified on an order.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new premises - they will not override field values defined on existing premises.

- The system requires all premises to reference a premise type. Use **Default Premise Type** to define the default value for premises created by this campaign's orders.
- Every geographic ID defined for a premise must reference a geographic type . Use **Default Premise Geo Type** to define the default value for premises created by this campaign's orders. Refer to Premise Geographic Types Are Populated In An Unusual Way.

Account Usage controls if and how this campaign's orders use accounts. You have the following options:

- Select Not Allowed if this campaign's orders do not reference an account.
- Select Optional if this campaign's orders do not have to reference an account. This option also means that a new OR existing account may be specified on the order. Note, if an order references a new account, the account will be created when the order is completed.
- Select Optional - Existing Account Only if this campaign's orders do not have to reference an account. This option also means that only an existing account may be specified on an order.
- Select Required if this campaign's orders must reference an account. This option also means that a new OR existing account may be specified on the order. Note, if an order references a new account, the account will be created when the order is completed.
- Select Required - Existing Account Only if this campaign's orders must reference an account. This option also means that only an existing account may be specified on an order.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new accounts - they will not override field values defined on existing accounts.

- The system requires all accounts to belong to a customer class. Use **Default Customer Class** to define the default value for accounts created by this campaign's orders.
- An account may reference an account management group. Use **Default Acct Management Group** to define the default value for accounts created by this campaign's orders.

If a user holds one of the campaign's orders, they can have a To Do entry generated on a future date to remind them about the order. Use **Default Hold To Do Role** to define the group of users to whom the To Do entry will be sent. Note well, the user who holds an order can indicate that the related To Do entry should be addressed to a specific user ID rather than a **Role**.

Use **Order Open Option** to define the page that is displayed when a user adds a new order for this campaign. This field is only relevant when the order transaction is invoked in "add mode"

Copyright © 2026, Oracle and/or its affiliates.

and a campaign is passed to this transaction (e.g., if a user adds an order from the Applicable Campaigns Zone).

A user can be automatically transferred to a different transaction when they complete an order. Refer to Supported Business Processes for examples of transactions that we anticipate being used. Use **Navigation Option** to define this transaction. Note,

- Leave **Navigation Option** blank if the user should remain on the order transaction after completion.
- You can setup **Navigation Options** to transfer to the user to a tab other than the main tab.

If a user is allowed to complete this campaign's order's without selecting a package,

- Turn on **Allow Order Compl w/o Package** and
- Use **Order Compl w/o Package Label** to define the message to appear in the button used to complete such orders.

> **NOT_SUPPORTED**
>
> Refer to Campaigns Without Packages for examples of campaigns where you would enable the above fields.

Use **Long Description** to provide an overview of this campaign.

The grid at the bottom of the page summarizes this campaign's questions and miscellaneous fields. To change this information, press the adjacent go to button (which will transfer you to the Questions and Misc Fields tab). To add additional information, transfer to the Questions and Misc Fields tab and press the + button.

Campaign - Questions and Misc Fields

This page is used to define the following type of information:

- An order's campaign can define questions to be posed to customers when an order is taken. For example, you could ask the customer "marketing survey" questions (e.g., please rate our service, how do you heat your home?, etc.).
- An order's campaign can also be setup to capture additional fields to be updated on the order's person / account / premise when the order is completed. For example, you could indicate that the account's override due date and automatic payment options should be captured when an order is taken.
- An order's campaign can also be setup to pose eligibility-oriented questions that qualify the customer for packages of goods and services. For example, you might have a campaign with packages that can only be selected if the customer commits to a year's worth of service.

> **NOT_SUPPORTED**
>
> Refer to Designing Campaigns and Packages for information describing how to design this type of information for your campaigns.

Copyright © 2026, Oracle and/or its affiliates.

Open this page using **Sales & Marketing, Campaign** and navigate to the **Question & Misc Fields** tab.

Description of Page

> **Warning**
>
> This information is not intuitive; we strongly recommend that you follow the guidelines under Designing Campaigns and Packages before attempting to enter this information.

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

The **Questions & Misc Fields** scroll contains one row for each question / miscellaneous field captured on this campaign's orders. The following fields are used:

- **Prompt on Order** contains the prompt that is shown to the user when the order is taken. Refer to Determine The Properties Of Every Miscellaneous Field for examples.
- **Brief Description** is simply a brief description of the question / miscellaneous field.
- **Sort Sequence** controls the order in which the question appears on the order.
- **Applicability** controls whether the field is Optional , Required, or Only Applicable on Package.
  - A value of Required means the order taker must enter a valid value before packages are displayed for selection.
  - A value of Optional means the order taken can leave the field blank prior to package selection. You can make an Optional field Required on individual packages.
  - A value of Only Applicable on Package is used for fields that are only captured for specific packages. Fields of this type are suppressed prior to package selection. When you setup a package, you indicate if the field is applicable (if so, the user is only prompted for the field if the package is selected).
- **Type of Response** controls where the field is stored when the order is completed and how it is validated. You have two options: Characteristic or Column.
  - If a field is a Characteristic, you must define which entity the characteristic value is to be stored on when the order is completed (Person, Account, Premise or Order). You must also define the **Characteristic Type** as this controls the characteristic value entered by the user.
  - If a field's value resides in a Column (as opposed to a characteristic value), you must define the column reference. A field's **Column Reference** controls three things:
- How the field's value is retrieved. A field's value is retrieved when an existing person / account / premise is referenced on an order.
- How the field's value is validated. A field's value is validated before package eligibility is determined and before the order is completed.
- How the field's value is posted (i.e., updated on the database). A field's value is posted when an order is completed.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Extract Column References From Miscellaneous Fields for more information about column references.

- If a field's value resides in a Column (as opposed to a characteristic value), you must also define whether the question / field is dependent on the order referencing an account or premise. You do this by populating **Question Dependency** with one of the following values:
- Select Must Have Account if this question / field should only appear if the order references an account (new OR existing).
- Select Must Have Premise if this question / field should only appear if the order references a premise (new OR existing).
- Select No Dependency if this question / field should always appear.

NOT_SUPPORTED

Refer to Determine Account / Premise Dependencies For Column References for more information.

- **Default Column Value** / **Default Char Value** controls whether the order taker is supplied with a default value when an order is created. Note well: for Optional and Only Applicable on Package fields, you can specify a different default value on each package.

Campaign - Algorithms

This page defines plug-in algorithms that are executed for orders associated with this campaign. Open this page using **Menu**, and then **Sales & Marketing**, and then **Campaign**, and then **Search** and navigate to the **Algorithms** page.

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

The grid contains **Algorithms** that control campaign-oriented functions. You must define the following for each plug-in algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each **System Event**. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description

Copyright © 2026, Oracle and/or its affiliates.

Campaign Eligibility	Required	A campaign's eligibility algorithms control two things: - Whether the campaign appears in the Applicable Campaigns Zone. This content zone suggests possible campaigns for the current customer displayed on control central. You might want to use this zone if you have different campaigns that are offered to different types of customers. Refer to Real-time Marketing of Additional Services to a Customer for an example of how this content zone can be used to "up sell" additional services. - Whether the campaign appears on an order's eligibility tree. Campaigns that appear in this tree are alternate campaigns that may be used on an order. Refer to Real-time Marketing of Services to a Prospect for an example of how an order's eligibility tree can contain alternate campaigns for an order. Refer to The Big Picture Of Campaign Eligibility for information about these algorithms.
Order Completion	Optional	When an order is completed for this campaign, algorithms plugged into this spot are called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when an order is completed for this campaign.

Campaign - Package

A package controls the various types of service agreements that will be created if the customer selects the package. This page summarizes all packages that may be selected on orders associated with this campaign. Open this page using **Menu**, and then **Sales & Marketing**, and then **Campaign**, and then **Search** and navigate to the **Package** page.

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains an entry for every package associated with this campaign. To view or change a package, press the adjacent go to button (which will transfer you to Package - Main). To add a new package, use the **Campaign** context menu to transfer to Package - Main in add mode.

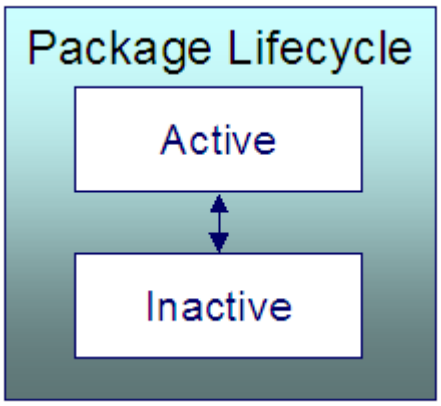
Maintaining Packages

After a user enters basic information about a customer on an order, they are shown the various packages that may be offered to the customer. A package controls the various types of service agreements that will be created if the customer selects the package.

If the customer elects to take a package, the system sets up / updates the "V" (along with all of the ancillary things that happen when service is initiated, e.g., field activities are created).

The topics in this section describe the package transaction.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Campaigns, Packages and Orders for general information about packages. Refer to The Big Picture Of Package Eligibility Rules for a discussion of how to control which packages can be used for different types of customers. Refer to Designing Campaigns and Packages for guidelines describing how to design your packages.



> **Note**
>
> **An order can be completed without selecting a package.** It is possible to use the order transaction to simply create / update persons and accounts. Refer to Campaigns Without Packages for more information.

- Lifecycle of a Package
- Package - Main
- Package - SAs To Create
- Package - Questions & Misc Fields
- Package - Eligibility
- Package - Instructions

Lifecycle of a Package

The following diagram illustrates the lifecycle of a package.

Copyright © 2026, Oracle and/or its affiliates.

Active An Active package may be selected on an order.

Inactive By Inactivating a package, you are preventing it from being selected on future orders.

Package - Main

This page is used to define basic information about a package.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Campaigns, Packages and Orders and Designing Campaigns and Packages for more information.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Package**, and then **Search.**

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Use **Campaign** to define the campaign to which this package belongs.

Use **Description** and **Long Description** to describe the package.

Status defines the state of the package. Refer to Lifecycle of a Package for information about the valid values and the state transition rules.

The tree at the bottom of the page summarizes the information that appears on the remaining tabs. You can click on a hyperlink to transfer you to the appropriate tab with the relevant information displayed.

Package - SAs To Create

This information on this page controls the type of service agreement(s) / service point(s) that are created if this package is selected on an order.

Copyright © 2026, Oracle and/or its affiliates.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Campaigns, Packages and Orders and Designing Campaigns and Packages for more information.

Open this page using **Sales & Marketing, Package** and navigate to the **SAs To Create** tab.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

> **Warning**
>
> This following information is not intuitive; we strongly recommend that you follow the guidelines under Designing Campaigns and Packages before attempting to enter this information.

The **SAs To Create** scroll contains one row for every service agreement that will be created if this package is selected on an order. The following fields are used:

- **CIS Division** and **SA Type** define the type of service agreement to be created.
- **Start Option** controls how the system will populate the new service agreement with default values. Refer to start options for more information.
- **SP Type** defines the type of service point that will be created / reused. Refer to Designing SP Types for more information.
- **Start Method Algorithm** controls how the system creates the new service agreement and service point. Refer to Determine The Method Used To Create Service Agreements for more information.
- **Create Proposal SA** controls if the new service agreement is a real or a proposal SA. This switch only appears if the quotation Contract Management module is not turned off. Refer to Proposal Service Agreements Must Exist for more information.

Package - Questions & Misc Fields

It is possible to design a campaign so that the user is prompted for additional information when a package is selected on an order. This page is used to define how the package overrides the questions and miscellaneous fields defined on the campaign.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Campaigns, Packages and Orders and Designing Campaigns and Packages for more information.

Copyright © 2026, Oracle and/or its affiliates.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Package**, and then **Search** and navigate to the **Questions & Misc Fields** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Campaign contains a concatenation of basic information about the campaign.

> **Warning**
>
> The following information is not intuitive; we strongly recommend that you follow the guidelines under Designing Campaigns and Packages before attempting to enter this information.

The grid contains one row for every Questions & Misc Field defined on the **Campaign**. You need only modify this information if this package behaves differently than the campaign (e.g., a field is required on the package, but optional on the campaign). To override a field on this package, turn on the **Override** switch and change the appropriate fields. There are several restrictions in respect of what can be overridden as described below:

- If a question / miscellaneous field is Required on the campaign, no fields may be overridden on the package.
- If a question / miscellaneous field is Optional on the campaign, you may override all field values. However, if the package has been used on a Completed order, you may not change its **Applicability** to be Required.
- If a question / miscellaneous field is designated as only applicable on package on the campaign, you should designate its applicability as Required, Optional or Not Used On This Package. If the field is either Required or Optional on this package, you may also override the other field values. Please note that if the package has been used on a Completed order, you may not change its **Applicability** to be Required.

> **NOT_SUPPORTED**
>
> Please refer to the Description of Page that appears under Campaign - Questions & Misc Fields for a description of the fields on the page.

Package - Eligibility

This page is used to define the conditions under which a package can be selected on an order.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture Of Package Eligibility and Determine Package Eligibility Rules for more information.

Copyright © 2026, Oracle and/or its affiliates.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Package**, and then **Search** and navigate to the **Eligibility** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

> **Warning**
>
> The following information is not intuitive; we strongly recommend that you follow the guidelines under The Big Picture Of Package Eligibility and Determine Package Eligibility Rules before attempting to enter this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sequence** to control the relative order in which the group is executed when the system determines if the package can be selected on an order (smaller numbers are executed before larger numbers).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of True.
  - Choose Eligible if this package can be selected on the order.
  - Choose Ineligible if this package cannot be selected on the order.
  - Choose Check Next Group if the next criteria group should be checked.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of False.
  - Choose Eligible if this package can be selected on the order.
  - Choose Ineligible if this package cannot be selected on the order.
  - Choose Check Next Group if the next criteria group should be checked.

The grid that follows contains the package's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being True or False. For example, you might have a row that indicates the customer is eligible for the package if their customer class is residential. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to Defining Logical Criteria for several examples of how this information can be used.

- Use **Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
  - Choose Field if you want to compare a response to a question / miscellaneous field to a given value. Push the adjacent search button to select the field.
  - Choose Algorithm if you want to compare anything other than a response to a question / miscellaneous field. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
- Use **Criteria Comparison** to define the method of comparison:

Copyright © 2026, Oracle and/or its affiliates.

- Choose Algorithm if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data.
- Choose any other option if you want to compare the **Criteria Field Type** using a logical operator. The following options are available:

- Use >, <, =, >=, <=, <> (not equal) to compare the **Criteria Field Type** using standard logical operators. Enter the comparison value in the adjacent field.
- Use In to compare the **Criteria Field Type** to a list of values. Each value is separated by a comma. For example, if a field value must equal 1, 3 or 9, you would enter a comparison value of 1,3,9.
- Use Between to compare the **Criteria Field Type** to a range of values. For example, if a field value must be between 1 and 9, you would enter a comparison value of 1,9. Note, the comparison is inclusive of the low and high values.
  - The next three fields control whether the related logical criteria cause the eligibility group to be considered True or False:
    * Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.
    * Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.
    * Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false , then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.

Package - Instructions

This page is used to define special instructions that should be presented to the user when they select this package. This information appears on the Order - Package Confirmation page.

NOT_SUPPORTED

Refer to Determine If Additional Instructions Are Needed for more information.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Package**, and then **Search** and navigate to the **Instructions** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains a row for each instruction to be presented to the user when they select a package. The following fields are used:

- Use **Sort Sequence** to control the relative order of the instruction.
- Use **Display Icon** to control the icon that prefixes the instruction. Refer to Display Icons for more information.
- Use **Description** to define the text of the instruction.

The Big Picture of Program Management

The program management functionality satisfies many diverse requirements. For example, you can use this functionality to:

- Market your products and/or services to customers and measure the success of your efforts.
- Encourage customers to enroll in various sales and marketing initiatives. For example, you can use program management to organize a campaign to encourage customers to participate in a conservation program, or to sign up for special contract options.
- Set up marketing surveys and record your customer's responses.
- Assign representatives to accounts.
- And more…

The topics in this section provide more information about the program management functionality.

- The Big Picture of Initiatives, Leads, and Representatives
- Maintaining Initiatives
- Maintaining Leads
- Maintaining Sales Representatives
- Maintaining Third Party Representatives

The Big Picture of Initiatives, Leads, and Representatives

Three objects are at the heart of the program management functionality: **Initiatives**, **Leads**, and **Representatives.**

- An **initiative** defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.
- A **lead** is an instance of an initiative for targeted customers.
- There are two types of Representatives:
  - A **Sales Representative** is a user or group of users who can be assigned to follow up or manage leads. This representative is also responsible to sell or encourage the customer to participate in a program.
  - A **Third Party Representative** is a third party (typically external) who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection, and installation work)

The topics in this section provide background information about these objects.

Copyright © 2026, Oracle and/or its affiliates.

- The Big Picture of Initiatives
- The Big Picture of Leads
- The Big Picture of Sales Representatives
- The Big Picture of Third Party Representatives

The Big Picture of Initiatives

An initiative defines a structured campaign designed to encourage customers to participate in a program. An initiative can:

- Target a market segment by specifying criteria that must be satisfied before leads are generated for customers.
- Ensure that customers are still eligible to participate in a program at sign up or enrollment time.
- Define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in the program.
- Define whether the lead is related to other objects (such as, the premise) in addition to the account.
- Contain sub-initiatives. Together, an initiative and its subsidiary initiatives form an initiative hierarchy. This supports reporting purposes and the analysis of the success of different market segments and marketing efforts.

Refer to Maintaining Initiatives for more information.

- About Initiative Hierarchies
- The Components of an Initiative
- The Lifecycle of an Initiative
- Initiative Information Can Be Overridden

About Initiative Hierarchies

Initiatives form an initiative hierarchy when one initiative is configured as a sub-initiative to a parent initiative. An initiative hierarchy can be used when a program is targeted at several market segments, or when different market segments each require a unique marketing effort to be executed. Initiative hierarchies can be up to five levels deep.

The following is a general example of a multi-level initiative hierarchy:

- Level 1 could be a “strategy” initiative.
- Level 2 could contain multiple campaigns. Each campaign can have a different way of marketing the strategy.
- Level 3 could define multiple marketing efforts. Each effort can have a different method for marketing the campaign.
- Level 4 could contain market segments that are the targets of a marketing effort.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The terms used above are just for the example. Your implementation would define the actual terms used for the levels in an initiative hierarchy.

A **parent initiative** may be set up for reporting purposes, in which case you could choose to configure the initiative so that no leads are generated for it. For example, a “strategy” may not have eligibility criteria or lead event type profile defined against it. It may simply have sub-initiatives to define segments, and those segments could be the initiatives for which leads are generated. Reporting is able to be performed at the multiple levels in order to summarize the effectiveness of the sub-initiatives.

The Components of an Initiative

The topics in this section provide information about the components of an initiative.

- About Initiative Eligibility Criteria
- About Related Object Criteria
- Examples of Initiative Criteria
- About the Lead Event Type Profile
- About the Initiative Log

About Initiative Eligibility Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program. It can also confirm that the customer is still eligible to participate in a program at sign up or enrollment time. An initiative may have zero, one, or many eligibility criteria. Each customer is subjected to these criteria to determine whether they will have a lead generated for them for the initiative and/or whether they are still eligible to sign up or enroll into a program.

Designing these criteria can be easy or time-consuming; it all depends on the complexity of your business rules. The base product provides a number of initiative eligibility criteria types. Most of them perform comparisons based on a specific field; for example, one of the criteria types checks whether an account has submitted a rebate claim for a specific conservation program. Some types of eligibility criteria could simply check whether or not a specific condition is true. For instance, a base-supplied eligibility criteria business object checks that there is no active credit and collection process for the account.

Other types of eligibility criteria perform comparisons with scalar values (such as, a number of days, number of kwh) or with derived values (such as, attributes of an account). The base product provides a Freeform Criteria business object that can be used for these purposes. This business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered with this business object. Your implementations can add to these algorithm types as needed.

Your implementation can decide to use specific criteria business objects (base-supplied and/or implementation-specific), extend the base-supplied Freeform Criteria business object, or a mixture of both. Refer to Designing Initiative Eligibility Criteria for more details.

To set up an eligibility criterion, you must define the following:

- When the eligibility criterion should be executed - also called criteria execution point

Copyright © 2026, Oracle and/or its affiliates.

- The field to be compared
- The comparison method

For the **criteria execution point**, the options include:

- Prior to a lead being generated for a customer
- Prior to the customer being signed up or enrolled into a program
- Both of the above

For the **field to be compared**, you can execute an algorithm to:

- Retrieve a field value or values from someplace else in the system (such as, the customer class or types of services associated with the customer)
- Derive a value based on some data from someplace else in the system (such as, the number of days since the last lead was created for the customer)

For the **comparison method**, you select the operator to perform the comparison on the field to be compared. The result from the algorithm will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the customer is eligible
- Indicate that the customer is not eligible
- Check the next condition
- Issue an error (this option is only available for Insufficient Data)

Refer to Defining Eligibility Criteria for an Initiative for more information about setting up eligibility criteria on an initiative.

About Related Object Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program (see About Initiative Eligibility Criteria for more information). An initiative may also be targeted at a specific entity (or related object) for that customer; for example, assume a customer has two properties in two different states - one in State A and one in State B. The customer may only be invited to participate, or be eligible, for a program for their specific property located in State A. In this situation, each eligible customer may then be subjected to Related Object Criteria following the execution of Initiative Eligibility Criteria to determine which of their properties are eligible to participate in a program (meaning, have one lead generated just for the account if one of their properties meets the criteria or a lead generated for each of the customer's eligible properties).

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes the object nomination algorithm after executing initiative eligibility criteria. The base-supplied Initiative parent business object (C1–Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account's active and pending start service agreement's service points. The algorithm applies the related object criteria (configured on the initiative) to each premise and if the premise is deemed eligible, it is returned as a related object for the lead.

Designing related object criteria can be easy or time-consuming. It all depends on the complexity of your business rules. The base product provides examples of related object criteria that looks for one or more premises to associate with a lead. One example checks for premises with a specific service point type. Another looks for a premise using its geographic value. For additional ways to find premises to link to a lead, implementations can either add specific related object criteria business objects (similar to the base samples) or extend the

Copyright © 2026, Oracle and/or its affiliates.

base-supplied Freeform Premise Criteria business object. The Freeform Premise Criteria business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered with this business object. Your implementation can add to these algorithm types as needed. Refer to Designing Related Object Criteria for more details.

When you set up a related object criterion, you must define two things:

- The field to be compared.
- The comparison method.

For the **field to be compared**, you can execute an algorithm to retrieve a field value or values from someplace else in the system; for example, retrieve a premise's service point types for which the customer has service.

For the **comparison method**, select the operator to perform the comparison on the field to be compared. The result from the comparison will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the related object is eligible
- Indicate that the related object is not eligible
- Check the next condition
- Issue an error

Refer to Defining Related Object Criteria for an Initiative for more information.

Examples of Initiative Criteria

The following is an example of how to set up initiative criteria.

Initiative: Smart Rate Program For Residential Customers

The program targets summertime pricing for residential customers. Customers are required to reduce energy use between 2 PM and 7 PM for no more than 15 summer days, which are referred to as smart days. A higher rate is charged during this time period. A discounted rate is applied for all other times during the season.

Initiative Eligibility Criteria

To be eligible for this initiative, the account must be a residential account with an average daily usage that is more than 10 kWh, not currently on a smart rate program, and is on either the ERES1 or ERES2 rate schedule. The account must also not have any active credit and collection process.

Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data	Criteria Execution Point
10	Residential customers	**Retrieve Customer Class** (Define an algorithm instance for base algorithm type C1-ICGETACEL, Retrieve account attribute)	=	R	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)

Copyright © 2026, Oracle and/or its affiliates.

Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data	Criteria Execution Point
20	Average daily usage > 10 kWh	**Retrieve average daily kWh usage** (Define an algorithm for base algorithm type C1-ICGETAVSQ, Retrieve average service quantity)	>	10	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)
30	Not on a smart rate program	**Retrieve all contract options** (Use base algorithm C1-ICGETCOPT)	=	295076574659 (Contract option for smart day events)	Not Eligible	Check next condition	Not Eligible	Both (lead generation and enrollment)
40	Account is current	**Check if Account Is Current** (Use base algorithm C1-ICCHKACCU)	=	true	Check next condition	Not Eligible	Not Eligible	Both (lead generation and enrollment)
50	Active service on eligible rate	**Retrieve all active rates** (Use base algorithm C1-GETACTVRT)	IN	ERES1, ERES2	Eligible	Not Eligible	Not Eligible	Both (lead generation and enrollment)

Related Object Criteria

If the account is eligible, the premise(s) associated with the account's active and pending start service agreement's service points of type E-RES will be linked to the lead as related object(s).

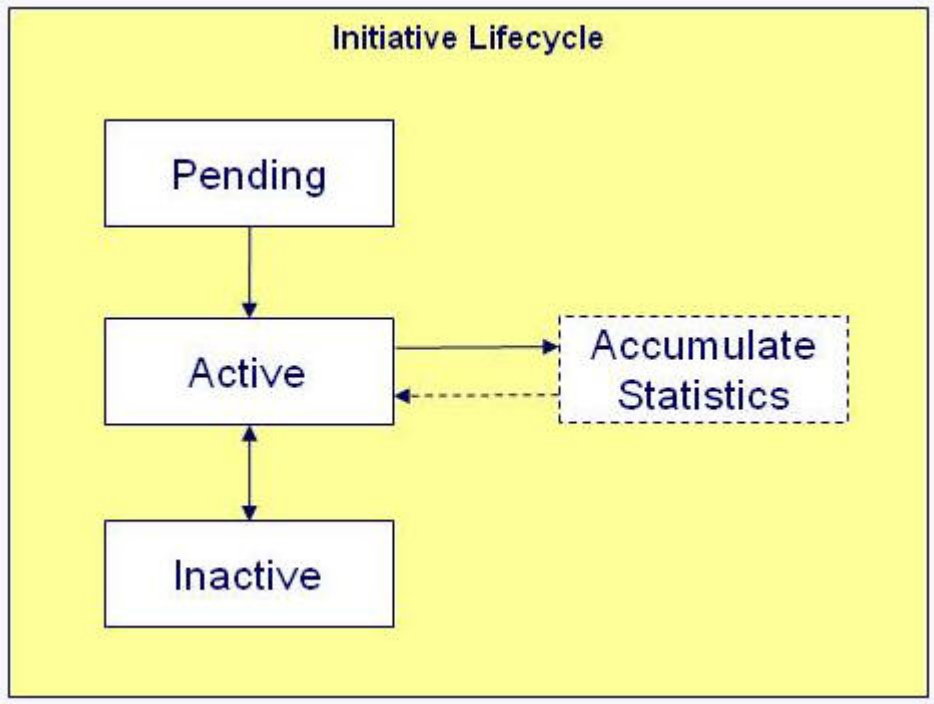
Sequence	Description	Criteria Field Algorithm	Operator	Comparison Value	If True	If False	If Insufficient Data
10	Premises with E-RES (electric residential) service points	**Retrieve Premise SP Types** (Base algorithm C1-ICPRMSPTY)	=	E-RES	Eligible	Not Eligible	Not Eligible

About the Lead Event Type Profile

Each initiative can define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in a program. Each event or action is defined by a Lead Event Type. For example, one event could be that a letter or an email is sent to a customer. The collection and sequencing of lead event types defined on an initiative is referred to as the Lead Event Type Profile.

Refer to Creating Initiatives and Maintaining Initiatives for more information on setting up and maintaining the Lead Event Type Profile on an initiative.

Copyright © 2026, Oracle and/or its affiliates.



About the Initiative Log

Every initiative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When an initiative is created.
- When an initiative's status changes (e.g. transitions to the active, accumulate statistics, inactive states).
- When lead related background processes are submitted for execution.
- When users want to manually add log entries as desired.

The Lifecycle of an Initiative

The following diagram shows the possible lifecycle of an Initiative:

Pending state: An initiative starts out in a pending state.

Active state: An initiative is transitioned manually by a user to the active state. Leads can only be generated for an initiative in an active state.

Accumulate Statistics state: A user or the system may transition an active initiative to a periodically transitioning accumulate statistics state. During this state, statistics for the initiative are accumulated prior to returning back to the active state.

Inactive state: An initiative may be transitioned manually by a user to the inactive state when they want to deactivate the initiative either temporarily or permanently. A user can manually place the initiative back to the active state from the inactive state.

Refer to Maintaining Initiatives for more information.

Copyright © 2026, Oracle and/or its affiliates.

Initiative Information Can Be Overridden

“Initiative info” is the concatenated string of information that summarizes an initiative throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the initiative
- Start date and end date (if available) of the initiative

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Initiative’s maintenance object.

The Big Picture of Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program.

Refer to Maintaining Leads for more information about working with Leads.

- How Leads Are Created
- The Components of a Lead
- The Lifecycle of a Lead
- Advanced Analysis of Leads
- Lead Information Can Be Overridden
- Leads Are Highlighted As Alerts
- How and When Are Leads Activated
- How are Leads Completed
- How Are Leads Discarded
- Sign Up Options Can Be Overridden
- The Big Picture of Lead Events

How Leads Are Created

Leads are created as follows:

- The system can generate a lead, or leads, for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative.
- Users can manually create a lead at their discretion.

Refer to section Creating Leads from an Initiative and Manually Creating a Lead for more information.

The Components of a Lead

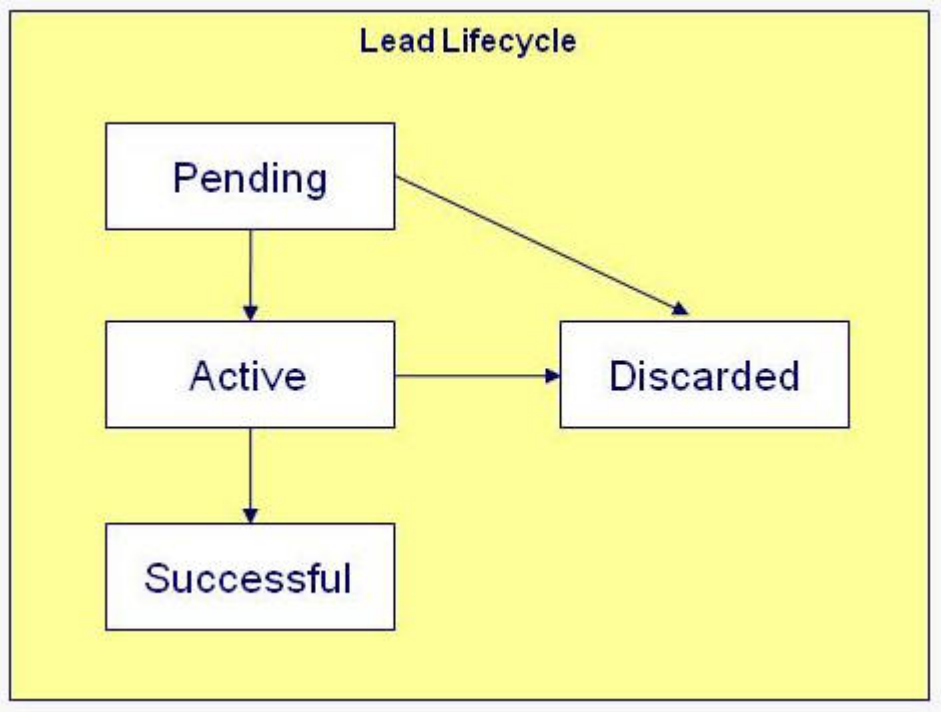
A lead has two components: A **Lead Event** and a **Lead Log.**

Lead Event

Copyright © 2026, Oracle and/or its affiliates.

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

Refer to The Big Picture of Lead Events for more information.



Lead Log

Every lead has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a lead is created
- When a lead's status changes (e.g. transitions to the active, successful or discarded state)
- When a lead event executes
- Users can manually add log entries as desired.

The Lifecycle of a Lead

The following diagram shows the possible lifecycle of a Lead:

Pending state: Leads can be created in either the **Pending** or **Active** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Active state: Leads can be created in either the **Pending** or **Active** state. When a lead is created or transitioned to the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

Copyright © 2026, Oracle and/or its affiliates.

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

Discarded state: An unsuccessful lead transitions to the **Discarded** state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, the lead remains in the active state until a user manually discards it.

Refer to Maintaining Leads for more information.

Advanced Analysis of Leads

Leads can be sent to an external system (such as Oracle DataRaker) for advanced analysis prior to activating the lead.

The base product provides Advanced Analysis System Lead (C1–AdvancedAnalysisLead) business object for this purpose. Its lifecycle includes steps to send the lead to the external system and activate/discard the lead based on the result of analysis..

Additional configuration is needed in Program Management master configuration to enable external analysis/validation. See master configuration embedded help for more details.

- The Lifecycle of a Lead with Advanced Analysis

The Lifecycle of a Lead with Advanced Analysis

The following describes the states of a Lead that is sent to an external system for advanced analysis prior to activation..

(Refer to the C1–AdvancedAnalysisLead business object to view the lifecycle diagram.)

Pending state: Leads can be created in either the **Pending** or **Ready for Extract** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Ready for Extract state: At this state, leads are ready to be sent to the external system for analysis. A monitor batch process is defined on this state, to ensure that leads in this state are transitioned only when the batch process runs.

Waiting for Analysis state: When a lead is transitioned to this state, an outbound message containing lead information is sent to the external system.

Error state: The lead is transitioned to this state if the system is unable to send the outbound message. Retry logic on this state will attempt to resend the lead to the external system. Leads in this state can also be **Discarded** if needed.

Active state: When a lead completes external analysis, the External Validation and External Activation Priority flags on the lead are updated. An inbound web service sends back the lead and transitions the lead into the **Active** state. An enter algorithm evaluates the External Activation Priority flag. If the lead is marked as being a priority for activation (based on settings in master configuration), the lead stays in the **Active** state. Otherwise, the lead is **Discarded**.

Copyright © 2026, Oracle and/or its affiliates.

When a lead is in the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

An enter algorithm on this state sends an outbound message, to notify the external system about lead success.

Discarded state: Leads that are evaluated as non-priority for activation are transitioned to this state. Unsuccessful leads also transition to this state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, unsuccessful leads remain in the **Active** state until a user manually discards it.

Refer to Maintaining Leads for more information.

Lead Information Can Be Overridden

"Lead info" is the concatenated string of information that summarizes a lead throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the lead
- Creation date/time of the lead.

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead's maintenance object.

Leads Are Highlighted As Alerts

If you plug-in the appropriate alert algorithm (C1-OPENLDALR) on the Installation record, alert(s) will be shown for open leads associated with the person, account and premise in context. A separate alert is shown for each unique Lead that is in a non-final state. Each alert message shows the Lead's info string.

How and When Are Leads Activated

Leads are activated as follows:

- The system can generate a lead for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative. The leads can be

Copyright © 2026, Oracle and/or its affiliates.

created in either a Pending or Active state. These leads can then be activated by a background process when required by the user.

- Users can manually activate a lead at their discretion.

Refer to section Creating Leads from an Initiative and Maintaining a Lead for more information.

How are Leads Completed

The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative, to perform one or more tasks, the lead is determined to be successful if the Notify Third Party lead event is completed.

Users can also manually transition a lead to the Successful state at their discretion. Refer to Maintaining a Lead for more information about working with Leads.

How Are Leads Discarded

When leads are sent to an external system for analysis prior to lead activation, a possible result of the analysis is that the lead is flagged as non-priority for activation. When this occurs, the lead is discarded.

Unsuccessful leads transition to the Discarded state after a certain amount of time has passed, as defined on the initiative. The initiative's lead event type profile can include an event that automatically discards a lead after a designated number of days. If the initiative does not specify this auto-discard event, the lead remains in the active state until a user manually discards it.

Some types of lead events can also trigger a lead to be discarded when specific conditions are met; for example, a lead that is assigned to a third party representative can be automatically discarded when the third party representative finds that the account is ineligible for the initiative. Refer to The Lifecycle of a Third Party Representative for more details.

In addition, automatic lead discards capture a lead discard reason. Lead event types that support auto-discard define their respective default lead discard reasons. Refer to Setting Up Lead Event Types and Maintaining a Lead for more information

Sign Up Options Can Be Overridden

The lead's Sign Up special action button performs the following:

- Displays a Sign Up UI map (if one exists) to capture additional inputs for sign up processing.
- Executes a Sign Up service script to process the sign up.
- Displays a confirmation map if the sign up is successful.

Copyright © 2026, Oracle and/or its affiliates.

The Sign Up UI map and Sign Up service script can be overridden via options on the initiative's business object. Refer to Overriding Initiative Sign Up Options for more details.

The Big Picture of Lead Events

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

You define the number and type of events to be initially inherited by a lead by configuring the Lead Event Type Profile on an initiative. Refer to About the Lead Event Type Profile for more information.

A lead event can include one or more steps. The lead event type defines a list of step types, if applicable.

The topics in this section provide additional information about lead events.

- How are Lead Events Created
- The Components of a Lead Event
- The Lifecycle of a Lead Event
- The Lifecycle of a Third Party Lead Event
- Lead Event Information Can Be Overridden
- Third Party Lead Event Step Information Can Be Overridden
- How and When Lead Events Are Activated
- Activating Events Should Add a Log Entry
- How Lead Events Are Cancelled

How are Lead Events Created

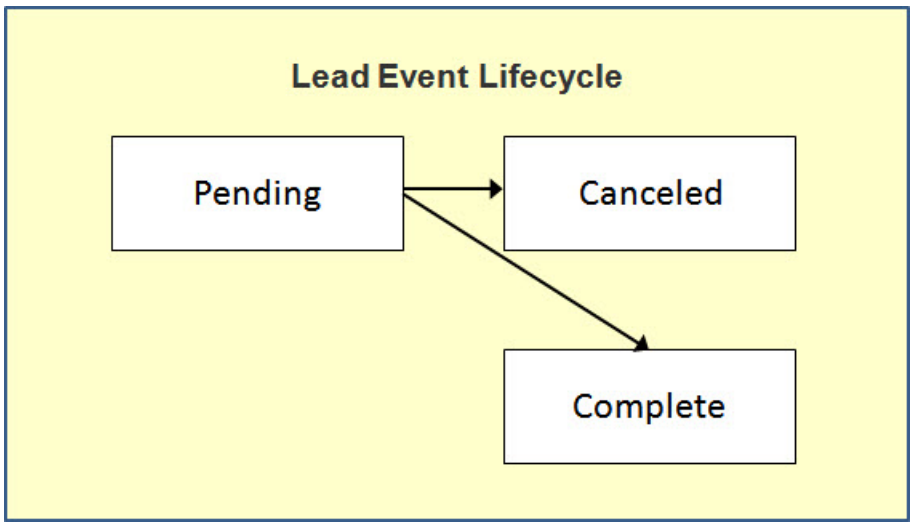
If a lead is created in a Pending state, there are no lead events associated with the lead. It is only when leads are created in or transitioned to the Active state, that lead events are created for the lead. The initial number of events and when the events shall occur are inherited from the lead's initiative.

Some types of events can also get created as a result of special actions on the lead. For instance, when a lead process requires a third party representative to perform one or more tasks after signup, the Sign Up action on the Lead portal automatically creates the Notify Third Party lead event.

The Components of a Lead Event

A lead event can have one or more steps. The lead event's business object defines whether or not steps are applicable to that type of event. The corresponding lead event type defines the valid step types. For an example, refer to the Third Party Lead Event (C1-ThirdPartyLeadEvt) and Send Notification to Third Party Lead Event Type (C1-LETypeNotifyThirdParty) business objects provided in base.

Lead Event Log



Every lead event has a log holding its history. Entries are added to the log when meaningful events occur, for example:

Copyright © 2026, Oracle and/or its affiliates.

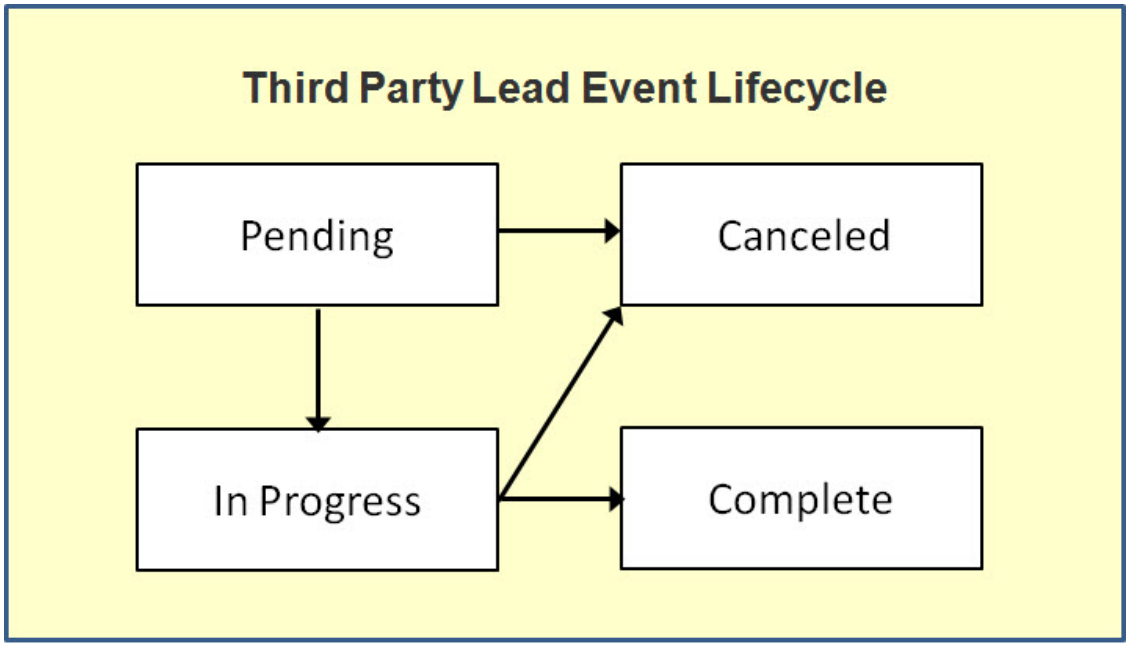
- When a lead event is created.
- When a lead event's status changes (e.g. transitions to the completed or cancelled state).
- Details of the content sent (if applicable).
- Users can manually add log entries as desired.

The Lifecycle of a Lead Event

The following diagram shows the possible lifecycle of a Lead Event business object:

Pending state: Lead events are initially created in the Pending state. A lead event can take a number of paths after it is created; it all depends on how you've configured the system.

Complete state: A lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. A user may complete a pending event at their discretion.



Cancelled state: A pending event will be cancelled automatically by the system when a lead is canceled. A user may cancel a pending event at their discretion.

Refer to Maintaining Lead Events for more information.

The Lifecycle of a Third Party Lead Event

The following diagram shows the possible lifecycle of a Third Party Lead Event business object:

Copyright © 2026, Oracle and/or its affiliates.

Pending state: Third party lead events are initially created in the Pending state. A third party lead event can take a number of paths after it is created; it all depends on how you've configured the system.

In Progress state: A third party lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. The lead event is set to In Progress and the lead event is sent to the third party representative.

Complete state: A third party lead event may be completed based on updates received from the third party. In most cases, the third partly lead event is completed when all the event steps are complete. In addition, a user may complete an In Progress event at their discretion.

Cancelled state: A Pending or In Progress third party lead event will be cancelled automatically by the system when the lead is canceled. A user may cancel a Pending or In Progress event at their discretion.

Refer to Maintaining Third Party Lead Events for more information.

Lead Event Information Can Be Overridden

"Lead Event info" is the concatenated string of information that summarizes a lead event throughout the system. The base-package logic constructs this string by concatenating the following information:

- Lead event type description
- Status of the lead event
- Trigger date of the lead event

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead Event's maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

Third Party Lead Event Step Information Can Be Overridden

The **Initiative Leads** zone on the **Third Party Representative** portal shows an event step information string for **Last Complete Step** and **Next Pending Step**. A base-package service script constructs this string by concatenating the following information:

- Step type description
- Intended Work Date/Time
- Completion Date/Time

You can override this by specifying an **Override Step Information Script** on the Program Management Master Configuration.

See Program Management Master Configuration for more details.

How and When Lead Events Are Activated

A lead event contains the date it should be activated; this is referred to as its trigger date. On this date, the Lead Event Periodic Monitor Process (a background process (C1-LDEVT)) invokes the algorithm associated with a lead event's event type. The algorithm, in turn, will decide on the state in which to leave the lead event.

If a user can't wait for the Lead Event Periodic Monitor Process real-time, they can click a button on Lead Event – Main to activate / trigger an event online in real-time. Refer to Maintaining Lead Events for more information.

You control how a lead event's trigger date is populated by configuring the Lead Event Type profile in an initiative. You indicate the number of days the lead event should be activated after the creation of the lead. Refer to Maintaining Initiatives for more information.

Activating Events Should Add a Log Entry

As described previously, a lead and lead event have a log holding a history of meaningful events in their lives. Most algorithms associated with a lead event's event type will add an entry to both the lead and lead event logs.

These log entries are more than just an audit trail as they also reference the objects that are created during execution. For example, if an algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

How Lead Events Are Cancelled

A pending lead event will be cancelled automatically by the system when the lead is canceled.

A user may cancel a pending lead event at their discretion. Refer to Maintaining Lead Events for more information.

A third party representative can also initiate the cancellation of a lead event. Refer to The Lifecycle of a Third Party Lead Event for more details.

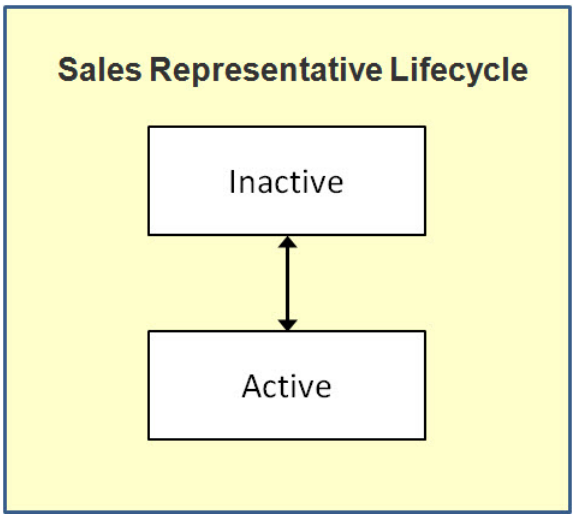
Copyright © 2026, Oracle and/or its affiliates.

The Big Picture of Sales Representatives

A sales representative is a group or individual who can be assigned to follow up and manage leads.

Individual sales representatives can be members of one or more groups, and they can be an internal user or an external party.

Groups can be used to control which sales representatives are allocated to the leads for an initiative. For example, you can set up a group whose sales representatives are responsible for industrial customers. Initiatives that target industrial customers can then be configured so that this group is specified as the only one whose sales representatives can be assigned the initiative's leads.



Because many reports will aggregate information for all sales representatives in a group, you may choose to set up a sales representative group just for reporting purposes.

The topics in this section provide additional information about Sales Representatives.

- The Lifecycle of a Sales Representative
- Sales Representative Log

The Lifecycle of a Sales Representative

The following diagram shows the possible lifecycle of a Sales Representative:

Active state: A Sales Representative starts out in an active state.

Inactive state: A Sales Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Sales Representative either temporarily or permanently. A user can manually place the Sales Representative back to the active state from the inactive state.

Refer to Maintaining Sales Representatives for more information.

Copyright © 2026, Oracle and/or its affiliates.

Sales Representative Log

Every Sales Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Sales Representative is created
- When a Sales Representative's status changes (e.g. transitions to the inactive state)
- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.

The Big Picture of Third Party Representatives

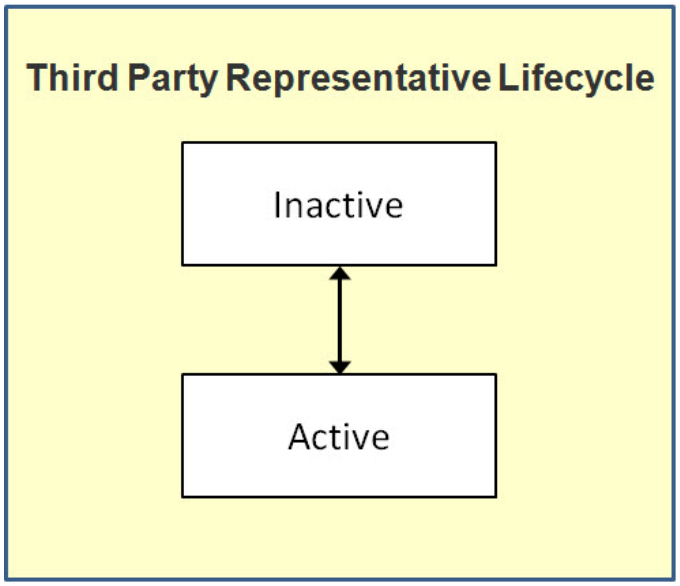
A third party representative is similar to a sales representative except that they are typically not internal employees and they have a different set of responsibilities.

Lead-related tasks may be outsourced to a third party representative who is better equipped to perform the work. These tasks may include pre-installation visits, energy audits, equipment installation, and equipment recycling. An initiative's lead event type profile defines whether or not lead-related work is sent to a third party representative.

Work is typically sent to a third party representative when a customer signs up for an initiative. The base product provides an online Sign Up action on active leads. This action creates a Third Party Lead Event that triggers the third party notification.

The third party representative is also responsible for providing updates to the system about the assigned leads. These updates can include event status updates, updates to important date/time information (e.g., completion date/time) and comments. This feedback enables users of the system to monitor the progress of leads and provide any necessary customer service.

Refer to the The Lifecycle of a Third Party Lead Event for more details on third party lead events.



The topics in this section provide additional information about Third Party Representatives.

- The Lifecycle of a Third Party Representative
- Third Party Representative Log

The Lifecycle of a Third Party Representative

The following diagram shows the possible lifecycle of a Third Party Representative:

Copyright © 2026, Oracle and/or its affiliates.

Active state: A Third Party Representative starts out in an active state.

Inactive state: A Third Party Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Third Party Representative either temporarily or permanently. A user can manually place the Third Party Representative back to the active state from the inactive state.

Refer to Maintaining Third Party Representatives for more information.

Third Party Representative Log

Every Third Party Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Third Party Representative is created.
- When a Third Party Representative's status changes (e.g. transitions to the inactive state).
- Users can manually add log entries as desired.

Maintaining Initiatives

An initiative defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.

Refer to The Big Picture of Initiatives for more information about initiatives.

- Initiative Portal
- How To Perform Common Initiative Functions

Initiative Portal

You use the Initiative portal to maintain initiatives.

The **Main** page contains the following zones:

- **Initiative:** Displays the basic information about the initiative.

Copyright © 2026, Oracle and/or its affiliates.

- **Initiative Eligibility Criteria Overview:** Displays initiative eligibility criteria associated with the initiative.
- **Related Object Criteria Overview:** Displays criteria for finding one or more related objects (such as, a premise) to link to a lead.
- **Initiative Hierarchy:** Displays the entire hierarchy of initiatives that the selected initiative is a part of.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Processing:** Allows you to submit the lead generation or lead disposition batch process.

The **Statistics** page contains the following

- **Lead Summary by Representative:** Displays the summary of leads for the initiative hierarchy, grouped by representatives.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Outcome Graph:** Displays the number of leads linked to the initiative hierarchy that entered the final state within the last 24 months.
- **Lead Statistics:** Displays statistics for the leads associated with the initiative.
- **Lead Monthly Statistics:** Displays statistics for the leads associated with the initiative on a monthly basis.
- **Unassigned Leads:** Displays leads that are not yet assigned to a sales representative and are not in a final state. (**Note:** Leads can be assigned to a sales representative in bulk.)

How To Perform Common Initiative Functions

The topics in this section describe how to perform common initiative functions from the Initiative portal.

- Creating Initiatives
- Maintaining an Initiative
- Viewing Initiative Hierarchy
- Creating Leads from an Initiative
- Managing Leads from an Initiative
- Viewing Initiative Statistics

Creating Initiatives

Use this procedure to create a new Initiative.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Add.**
2. Select the business object that will define the initiative and click **OK.**
3. Enter the initiative's name, (short) description, detailed description, start date, and end date.
4. Specify if the initiative is a master or a subsidiary initiative.
    - If the initiative is a **Subsidiary Initiative**, search for and select the initiative that is the parent to this initiative.

Copyright © 2026, Oracle and/or its affiliates.

5. Specify whether the master initiative will participate in demand-side analytics processing through Contract Option Participation Analysis.
6. Specify whether or not leads can be generated for the initiative.
    - If leads can be generated, complete the options regarding communication channel and related object creation.
7. In the Third Party Notification section, specify the Lead Event Type to use to notify a third party. This lead event type is used when creating a third party notification lead event, if applicable, when a customer signs up or enrolls into a program.
8. In the Lead Reassignment Notification section, indicate how the system should respond if a lead is reassigned to another sales representative.
9. In the Statistics Notification section, specify how often, in hours, the statistics for the initiative should be updated.

    A background process accumulates the statistics for an initiative when enough time has elapsed since the statistics were last updated. A user may also manually initiate the process to update the statistics for an initiative.
10. If this initiative will have leads, add lead event types in the Lead Event Type Profile section to define the events or actions that will occur during the lifetime of the lead to encourage the customer to participate in the initiative. To add lead event types in the Lead Event Type Profile section:
    a. Assign an **Event Sequence** to each list entry.
    b. Search for and select a **Lead Event Type** to indicate the type of lead event to generate for each list entry (for example send customer an email or create a customer contact).
    c. Specify the number of **Days After Lead Creation** that the related lead event will be triggered.
11. Click **Save.**

Maintaining an Initiative

The topics in this section describe procedures for maintaining an initiative:

- Allowable Record Actions on an Initiative
- Defining Eligibility Criteria for an Initiative
- Defining Related Object Criteria for an Initiative

Allowable Record Actions on an Initiative

Use this procedure to maintain an initiative using standard record actions.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Click the appropriate record action button:
    - **Edit** – Click the **Edit** button to edit the main attributes of an initiative. When you click **Save**, the system updates the record.

Copyright © 2026, Oracle and/or its affiliates.

- **Duplicate** – Click the **Duplicate** button to create a duplicate of the initiative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record.
- **Activate** – Click the **Activate** button to transition a pending or inactive initiative to the active state.
- **Deactivate** – Click to **Deactivate** button to transition an active initiative to an inactive state.
- **Refresh Statistics** - Click the **Refresh Statistics** button to manually initiate the accumulation of the statistics for the initiative.
- **Delete** – Click the **Delete** button and click **OK** to delete the initiative from the database. Before you delete an initiative, the system verifies that the initiative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete an initiative, the system ensures the initiative has not been referenced on a lead, etc.

Defining Eligibility Criteria for an Initiative

Use this procedure to define eligibility criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define eligibility criteria for the initiative.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative that you want to maintain. *(The selected initiative opens in the Initiative portal.)*
5. To define eligibility criteria for the initiative, click the **Add** link in the Initiative Eligibility Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.

   The base package provides a number of initiative eligibility criteria business objects. Each business object defines its valid comparison algorithm(s), operator(s), and value(s). Refer to the maintenance maps of these business objects for details. For more information about eligibility criteria types, refer to About Initiative Eligibility Criteria .
7. Enter a sequence number, description, detailed description, and criteria execution point for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm**, **Comparison Operator** and **Comparison Value**.

   Refer to the embedded help on the maintenance map for more details on these fields.
9. Complete the Comparison Results section. Specify the action for each possible comparison outcome - meaning, **If True**, **If False**, and **If Insufficient Data**.

   Refer to the embedded help on the maintenance map for more details on these fields.
10. Click **Save.**

Repeat steps 5 to 10 to add additional criterion for the initiative.

Copyright © 2026, Oracle and/or its affiliates.

Defining Related Object Criteria for an Initiative

Use this procedure to define related object criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define related object criteria for the initiative.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To define related object criteria for the initiative, click the **Add** link in the Related Object Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.

   The base package provides a number of related object criteria types that attempt to link an account's premise(s) to the lead. Each initiative criteria business object defines its valid comparison algorithm(s), operators and value(s). Refer to the maintenance maps of these business objects for details. For more information on eligibility criteria types, refer to About Related Object Criteria .
7. Enter a sequence number, description, and detailed description for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm**, **Comparison Operator**, and **Comparison Value**.

   Refer to the embedded help on the maintenance map for more details on these fields.
9. Complete the Comparison Results section. Specify the action to take for each possible outcome of the comparison - meaning, **If True**, **If False**, and **If Insufficient Data**

   Refer to the embedded help on the maintenance map for more details on these fields.
10. Click **Save**.

Repeat steps 5 to 10 to add additional criterion for the initiative.

Viewing Initiative Hierarchy

The Initiative Hierarchy zone on the Initiatives portal displays the hierarchy the selected initiative is a part of. By clicking on any initiative in the hierarchy, you will be navigated to the selected initiative.

Creating Leads from an Initiative

The topics in this section describe how to create leads from an Initiative.

- Bulk Creation of Leads
- Uploading Leads

Bulk Creation of Leads

Copyright © 2026, Oracle and/or its affiliates.

Use this procedure to create leads in bulk.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain.

   The selected initiative opens in the Initiative portal.
5. To create leads for the initiative, click **Lead Generation** on the Lead Generation and Disposition zone. This zone is displayed for initiatives in the active state, can have leads and allows a batch job to be submitted for the creation of leads.
   - Select the **Lead Status** to leave the created leads in. Valid values are Pending or Active. Creating leads in a pending state allows a user to confirm the lead population prior to activating these leads
   - Specify the **Number of Leads to Generate.** This may be used to create a sample set of leads to test the initiative's eligibility criteria.
   - Specify the **Email Address.** You may optionally specify an email address if you want to be informed when the batch job completes
6. Click **OK.**

Uploading Leads

> **Note**
>
> This functionality is to be used on small volume uploads.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To upload Leads for an initiative, click the **Lead Upload** link in the Initiative Leads zone title bar. This displays the Lead Upload page, which you can use to upload a CSV file containing account IDs for which leads will be generated.
6. Click **Submit.**

Managing Leads from an Initiative

The procedures in this section describe how to manage leads from an initiative.

- Viewing Initiative Leads
- Activating, Deleting, and Discarding Leads for an Initiative in Bulk

Viewing Initiative Leads

The Initiative Leads zone is displayed on both the Main page and the Statistics page.

Copyright © 2026, Oracle and/or its affiliates.

By default, the Initiative Leads zone is populated with all leads for the initiative (or initiative hierarchy group) for all sales representatives.

On the Statistics page, you can limit the set of leads using the Lead Summary by Representative zone. See Viewing Lead Summary by Representativefor details.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event.** You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event.** You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Activating, Deleting, and Discarding Leads for an Initiative in Bulk

Use the following procedure to activate, delete or discard leads for an initiative.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain.

   The selected initiative opens in the Initiative portal.
5. Scroll, as needed, to the Lead Processing zone.
6. To activate, delete or discard leads for the initiative, click **Lead Disposition**. This allows a batch job to be submitted for the activation, deletion or discarding of leads.
   - Select the **Pending Lead Disposition** to indicate the action to take on pending leads. The possible actions are: Activate (pending leads), Delete (in case of erroneous generation), Ignore.
   - Select the **Active Lead Disposition** to indicate to action to take on active leads. The possible actions Ignore and Discard.
   - Select the **Discard Reason** to be used for any active leads that get discarded. The values are maintained on the Status Reason control table.
   - Specify the **Email Address.** You may optionally specify an email address if you want to be informed when the batch job completes
7. Click **OK.**

Viewing Initiative Statistics

The Statistics page displays statistical information about the leads of the current initiative in context. It shows the following:

- Lead counts by sales representative and status
- List of leads

Copyright © 2026, Oracle and/or its affiliates.

- Graph of completed and discarded leads over a period of time
- Graph of leads by status
- Graph of active leads per sales representative
- Graph of open, completed and discarded leads over a period of time
- Graph of the top discard reasons over a period of time

The following sections describe these zones. You can also refer to each zone's embedded help for more details.

- Viewing Lead Summary by Representative
- Graphs and Statistics for an Initiative
- Displaying and Assigning Unassigned Leads

Viewing Lead Summary by Representative

The Lead Summary by Representative zone displays a summary of leads for the initiative (or initiative hierarchy group) by individual representative. If the Initiative is configured not have a sales representative, the zone will group those leads under 'Leads without Representative'.

To limit the summary of leads by sales representative:

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain.

   The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Lead Summary by Representative zone.
6. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
7. If **Include Inactive Leads** is set to No, leads for the initiative (or initiative hierarchy group) regardless of status are included.

The following is displayed in the result set:

- A summary line for the individual sale representative shows the total Lead Count.
- A breakdown is included beneath each sales representative summary line that shows a subtotal Lead Count by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Graphs and Statistics for an Initiative

The following zones display statistics for the initiative's leads.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The system periodically refreshes the statistics for an initiative when the time specified on an initiative has lapsed. A user may also manually initiate the refreshing of statistics if required.

Lead Outcome Graph

This Lead Outcome Graph zone shows the number of Leads linked to the initiative (or initiative group hierarchy) that entered the final state in the last 24 months starting from the most recent completed Lead.

The date shown on the X-axis will be the first day of the month. Note that the information displayed here is based on the most recent completed Lead as of the time the Initiative Statistics is accumulated.

Lead Statistics

The Lead Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chart shows the number of leads for each state in the lead's lifecycle as of the initiative's Statistics Date/Time. Each state can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to Program Management Master Configuration for setting up program management options for more information.
- **Active Leads by Representative:** The chart shows the top five individual sales representatives for the initiative (i.e. sales representatives with the largest number of active leads assigned to them as of the Statistics Date/Time). The top five sales representative can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to Program Management Master Configuration for setting up program management options for more information.

Lead Monthly Statistics

The Lead Monthly Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chronological graph highlights the number of open, completed and discarded leads over time for the initiative in context. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013. Each State can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to Program Management Master Configuration for setting up program management options for more information.
- **Active Leads by Representative:** The chronological graph highlights the top 4 discard reasons over time for the initiative in context. Statistics for all other discard reasons are accumulated in a catch-all bucket. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013.Each Discard Reason can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to Program Management Master Configuration for setting up program management options for more information.

Displaying and Assigning Unassigned Leads

Use the following procedure to review and assign, as appropriate, non-final and unassigned leads that are associated to the initiative in context.

Copyright © 2026, Oracle and/or its affiliates.

1. Select **Menu**, and then **Sales & Marketing**, and then **Initiative**, and then **Search.**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Unassigned Leads Zone.
6. Enter a Start Date and End Date range that encompasses the desired period.
7. Click **Refresh** to view unassigned leads that were created within the period specified.
8. (optional) Assign one or more leads from the result set:
    a. Select the unassigned leads from the results set.
    b. Enter the sales representative that will be assigned the leads.
    c. Press **Assign to Sales Rep**.
    d. Select the Sales Representative from the dropdown menu and click **OK**.

Maintaining Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program

The topics in this section describe the common functions associated with leads.

- My Leads
- Lead Portal
- How To Perform Common Lead Functions

My Leads

You can use the My Lead menu item to maintain leads.

- If your User ID is linked to a Sales Representative, you are navigated to the Sales Representative portal with the user in context.
- If your User ID is not linked to a Sales Representative, you are navigated to the Leads Query portal.

Lead Portal

You use the Leads portal to maintain leads. This portal contains the following zones:

- **Lead:** Displays the basic information about the lead.
- **Lead Events:** Displays the events associated with the lead in chronological order.
- **Related Leads:** Displays the leads that are related to the current lead's related objects (e.g. account).
- **Attachments:** Displays uploaded documents that are related to the lead.
- **Notes:** Displays all notes for the lead and its lead events.

Copyright © 2026, Oracle and/or its affiliates.

- **Third Party Event:** if a third party lead event exists, this zone displays the lead event's information, including the event steps

How To Perform Common Lead Functions

The topics in this section describe how to perform common lead maintenance functions from the Lead portal.

- Manually Creating a Lead
- Maintaining a Lead
- Adding New Lead Events to a Lead
- Adding Lead Notes
- Maintaining Lead Events
- Maintaining Third Party Lead Events

Manually Creating a Lead

Use this procedure to manually create a new lead.

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead** , and then **Add.**
2. Select the lead's Initiative and click **OK.**

   The Account Lead page displays so that you can complete the lead.
   Enter the following information as required by the Initiative:
3. Search for and select the **sales representative** for the lead.
4. Indicate how the customer requested information about the initiative in the **response channel**.
5. Indicate if the customer has **signed up** for the initiative.
6. Search for and select the **account** that will be associated to the lead.
7. Search for and select the **premise** that will be associated to the lead.
8. Click **Save**.

> **Note**
>
> Leads can also be created through the Initiative context menus and Account context menus.

Maintaining a Lead

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead**, and then **Search.**
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh.**
4. In the search results list (not applicable if Lead ID is specified in the search criteria), click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You may also navigate to the Lead portal by clicking on the appropriate lead from various portals and zones. Examples include:
>
> - Sidebar Portal: Alerts zone
> - Initiative Portal: Initiative Leads zone
> - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

5. Click the appropriate record action button:

   Buttons that appear when the lead is Pending:

   - **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead. When you click **Save**, the system updates the record.
   - **Delete** – Click the **Delete** button and click **OK** to delete a pending lead from the database. Before you delete a lead, the system verifies that the lead is not referenced anywhere in the system. If it is, you cannot delete it.
   - **Activate** – Click the Activate button to transition a pending lead to the active state. When a lead is activated, lead events for the lead are created to encourage the customers to participate in the initiative.

   Buttons that appear when the lead is Active:

   - **Edit** – *see the description above.*
   - **Discard** – Select the **Discard** button to inactivate an active lead. Select a **Status Reason** indicating why the lead is being inactivated and click **Save.** The values are maintained on the Status Reason control table
   - **Complete** – Click the **Complete** button to indicate that an active lead has been successful.
   - **Sign Up** – Click the **Sign Up** button to initiate a script that is defined on the Initiative's business object. The base package script **C1-IntvSignU** reevaluates the customer to determine if they are still eligible to participate in a program, indicates the customer has signed up or enrolled on the lead and creates a third party lead event (if applicable) to notify the relevant third party of the actions to be performed. The Response Channel on the lead is also updated for analytical purposes

6. Click the **Add Notes** button, in the Notes zone, to capture additional information for the lead.
7. The **Third Party Event Zone** displays third party lead event (if any) details along with the steps involved in the lead event

Adding New Lead Events to a Lead

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead**, and then **Search.**
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.
5. To add a lead event to the lead, click the **Add Lead Event** link in the Lead Events zone title bar.

Copyright © 2026, Oracle and/or its affiliates.

6. Search for and select the appropriate lead event type.
7. Specify the Trigger Date of when the lead event is to be executed.
8. Specify the Communication Channel to indicate what form the event will be sent.
9. Click **Save.**

Repeat steps 5 to 9 for add additional lead events.

Adding Lead Notes

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead**, and then **Search.**
2. Enter your search criteria in the Lead Query zone.

   The C1-owned base package search options include:

   - Name and address
   - Related object
   - Representative and initiative
   - Lead ID
3. Click **Refresh.**
4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.
5. Scroll, as necessary, to view the Notes zone.
6. Click the **Add Notes** link in the zone's title bar.
7. Enter the desired information in the **Add Notes for Lead** pop-up window and click **Save**.

Maintaining Lead Events

A lead event is an event or action in a lead to take place to encourage a customer to participate in a program. A lead may contain many lead events.

The Lead Event portal is used to maintain lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.
- **Notes:** Displays user-defined comments about this lead event

To maintain a lead event:

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead Event**, and then **Search.**
2. Enter your search criteria in the Lead Event Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:
>
> - Initiative Portal: Initiative Leads zone
> - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

5. Click the appropriate record action button:
   - **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
   - **Complete** – Click the **Complete** button to indicate a pending lead event is completed.
   - **Cancel** - Select the **Cancel** button to cancel a pending lead event.
6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Third Party Lead Events

A third party lead event represents an action within a lead to either encourage a customer to participate in a program, or perform an on-site service. A lead may contain one or more third party lead events.

The Lead Event portal is used to maintain third party lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.
- **Notes:** Displays user-defined comments about this lead event

To maintain a third party lead event:

1. Select **Menu**, and then **Sales & Marketing**, and then **Lead Event.**
2. Enter your search criteria in the Lead Event Query zone.

   The C1-owned base package search options include:
   - Name and address
   - Related object
   - Initiative and representative
   - Lead and lead event
3. Click **Refresh.**
4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

> **Note**
>
> You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:
>
> - Initiative Portal: Initiative Leads zone
> - Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

Copyright © 2026, Oracle and/or its affiliates.

5. Click the appropriate record action button:
    - **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
    - **In Progress** – Click the **In Progress** button to initiate the notification process and have the third party lead event sent to the representative.
    - **Cancel** - Select the **Cancel** button to cancel a pending lead event.
6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Sales Representatives

A Sales Representative is a user or group of users who can be assigned to follow up on leads and responsible for selling the initiatives product or service to the customer.

The topics in this section describe the common functions associated with Sales Representatives.

- Sales Representatives Portal
- How To Perform Common Sales Representative Functions

Sales Representatives Portal

You use the Sales Representative portal to maintain sales representatives. This portal contains the following zones:

- **Sales Representative:** Defines the basic information about the representative.
- **Initiative Lead Summary:** Lists initiatives and information about leads for each initiative for the representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
    - **Initiative Leads:** Displays leads for the initiative and representative.
    - **Initiative Lead Event Summary:** Displays lead event statistics for the initiative lead and representative.
    - **Initiative Lead Events:** Displays lead events for the initiative lead and representative.
- **Group's Representatives:** This zone is displayed for a representative group and lists the individual representatives who are members of the group.
- **Representative's Groups:** This zone is displayed for an individual representative and lists the representative groups of which this representative is a member.

How To Perform Common Sales Representative Functions

The topics in this section describe how to perform common sales representative functions from the Sales Representative portal.

- Creating Sales Representatives
- Maintaining Sales Representatives
- Displaying Leads and Lead Event Information for a Sales Representative
- Reassigning Leads for a Sales Representative

Copyright © 2026, Oracle and/or its affiliates.

Creating Sales Representatives

Use this procedure to create a new sales representative.

1. Select **Menu**, and then **Sales & Marketing**, and then **Sales Representative**, and then **Add.**
2. Select the sales representative type that will define the representative and click **OK.**
3. Enter the appropriate information for the representative:
   - For a Group Sales Representative:
     - Specify the Sales Representative name and description.
     - Search for and select Individual Sales Representative who will be a member of the group.
   - For an Individual Sales Representative:
     - Specify the Sales Representative name and description.
     - Search for and select User for the individual sales representative.
     - Search for and select Group Sales Representative that the individual sales representative will be a member of.
4. Click **Save.**

Maintaining Sales Representatives

1. Select **Menu**, and then **Sales & Marketing**, and then **Sales Representative**, and then **Search.**
2. Enter your search criteria in the Sales Representative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the sales representative you want to maintain. The selected sales representative opens in the Sales Representative portal.

> **Note**
>
> You may also navigate to the Sales Representative portal by clicking on the appropriate Sales Representative from various portals and zones. Examples include:
>
> - Initiative Portal: The Initiative Zone or the Lead Summary By Representative.
> - Lead Portal: Lead zone

5. Click the appropriate record action button:
   - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a sales representative. When you click **Save**, the system updates the record
   - **Duplicate** – Click the **Duplicate** button to create a duplicate of the sales representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record

Copyright © 2026, Oracle and/or its affiliates.

- **Deactivate** – Click the **Deactivate** button to transition an active sales representative to an inactive state
- **Delete** – Click the **Delete** button and click **OK** to delete the sales representative from the database. Before you delete a sales representative, the system verifies that the sales representative is not referenced anywhere in the system. If this is the case, you cannot delete the representative. For example, if you attempt to delete a sales representative, the system ensures the sales representative is not referenced on a lead, etc.

6. For an individual sales representative, you can add the sales representative to another group by clicking the **Add Rep to Another Group** link in the Representative's Group zones title bar. Select a group sales representative and click **Save**. You can remove the representative from a group (or groups) by selecting the group(s) and clicking the **Remove Rep from Group(s)** button.
7. For a representative group, you can add a representative to the group by clicking the **Add Rep To This Group** link in the Group's Representatives zone's title bar. Search for and select the individual sales representative to add to the group and click **Save**. You can remove representatives from a group by selecting the representatives and clicking the **Remove Rep(s) from Group** button.

Displaying Leads and Lead Event Information for a Sales Representative

From the Initiative Lead Summary zone on the Sales Representative portal, you can broadcast a representative, initiative, date range and lead state (if available) to other zones on the portal.

- Displaying Leads Associated Information for a Sales Representative
- Sales Representative Initiatives Leads Zone

Displaying Leads Associated Information for a Sales Representative

The Initiative Lead Summary zone on the Sales Representative portal displays the leads that have been assigned to the sales representative. If the representative is a group, leads are summarized for all individuals in the group.

To limit the summary of leads for the sales representative:

1. Select **Menu**, and then **Sales & Marketing**, and then **Sales Representative**, and then **Search.**
2. Enter your search criteria in the Sales Representative Query zone.
3. Click Refresh.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized. Otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh.**

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the individual or group rep.

Copyright © 2026, Oracle and/or its affiliates.

- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Sales Representative Initiatives Leads Zone

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Leads zone on the Sales Representative portal is populated with relevant lead information for the selected item. If the sales representative is a group, leads for all individuals in the group are shown.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event.** You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event.** You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the rep assigned to each lead.

For information about using this zone to reassign leads to another representative, see Reassigning Leads for a Sales Representative.

- Initiatives Lead Event Type Summary
- Initiatives Lead Events Summary

Initiatives Lead Event Type Summary

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Lead Event Type Summary zone is displayed. If the representative is a group, lead events are accumulated for all individuals in the group. The summary spans the 14 day period on/after the Start Date which defaults to current date if blank. If you want to specify the start date, click Refresh to update the zone.

The following is displayed in the result set:

- The **Event Count** shows the total number of events for a specific Event Type on each day within the 14 day period. You can click on the broadcast icon to see a list of events for the **Event Date** and **Event Type** on the Initiative Lead Events zone.
- The **Event Status** bar provides a breakdown of the total event count by status. Each color segment shown represents a different event status for pending, completed and canceled events. Colors used are defined on the program management master configuration.
  - Hover the mouse pointer over a segment of the bar to see the respective count and status represented by the segment.
  - Click on a segment of the bar to broadcast the event date, event type and event status. Broadcasting from the event status bar instead of the broadcast icon will limit the Initiative Lead Events zone to a particular status.

Initiatives Lead Events Summary

Copyright © 2026, Oracle and/or its affiliates.

By clicking on one of the broadcast items in the Initiative Lead Event Type Summary zone, the Initiative Lead Events zone is populated. This zone displays lead events for the initiative, representative, lead event type (if available) and status (if available). If the representative is a group, events for all individuals in the group are shown. Only lead events with a trigger date on or after the **Start Date** are displayed.

The following is displayed in the result set:

- **Event Date** and **Lead Event** information is shown for each event. You can navigate to a specific lead event by clicking on a lead event.
- **Lead** shows the lead information for the initiative's lead. You can navigate to the lead by clicking on a lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking customer information for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Reassigning Leads for a Sales Representative

To reassign leads from one sales representative to another sales representative:

1. On the Initiatives Leads zone, select the leads that you want to reassign and click **Reassign Rep.**
2. Select the Sales Representative to reassign the selected lead to and click **Save.**

Maintaining Third Party Representatives

A Third Party Representative is someone who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection or an installation. Refer to The Big Picture of Third Party Representatives for more information

The topics in this section describe the common functions associated with Third Party Representatives.

- Third Party Representatives Portal
- How To Perform Common Third Party Representative Functions

Third Party Representatives Portal

The Third Party Representative portal is used to maintain third party representatives. This portal contains the following zones:

- **Third Party Representative:** Defines the basic information about the third party representative.
- **Initiative Lead Summary:** Displays a summary of initiatives that have leads assigned for the third party representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
  - **Initiative Leads:** Displays leads for the broadcasted initiative and third party representative.
  - **Unassigned Leads:** Displays unassigned leads for the broadcasted initiative that are not yet assigned to a third party representative.

Copyright © 2026, Oracle and/or its affiliates.

How To Perform Common Third Party Representative Functions

The topics in this section describe how to perform common representative functions from the Third Party Representative portal.

- Creating Third Party Representatives
- Maintaining Third Party Representatives
- Displaying Leads Associated Information for a Third Party Representative
- Displaying and Assigning Leads to a Third Party Representative

Creating Third Party Representatives

Use this procedure to create a new third party representative.

> **Note**
>
> Before adding the third party representative, they must be added as a Person without an account in the system. For more information about this process, see How To Add A New Customer From Control Central.

1. Select **Menu**, and then **Sales & Marketing**, and then **Third Party Representative**, and then **Add.**
2. Enter the appropriate information for the representative:
   - Specify the Third Party Representative name and description.
   - Search for and select the Person record for the third party representative.
   - Select the External System that will be used to communicate to the third party representative.
3. Click **Save.**

Maintaining Third Party Representatives

1. Select **Menu**, and then **Sales & Marketing**, and then **Third Party Representative.**
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the third party representative you want to maintain. The selected third party representative opens in the Third Party Representative portal.
5. Click the appropriate record action button:
   - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a third party representative. When you click **Save**, the system updates the record
   - **Duplicate** – Click the **Duplicate** button to create a duplicate of the third party representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record

Copyright © 2026, Oracle and/or its affiliates.

- **Deactivate** – Click the **Deactivate** button to transition an active third party representative to an inactive state
- **Delete** – Click the **Delete** button and click **OK** to delete the third party representative from the database. Before you delete a third party representative, the system verifies that the third party representative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete a third party representative, the system ensures the third party representative is not referenced on a lead, etc.

Displaying Leads Associated Information for a Third Party Representative

The Initiative Lead Summary zone on the Third Party Representative portal displays the leads that have been assigned to the Third Party representative.

To limit the summary of leads for the sales representative:

1. Select **Menu**, and then **Sales & Marketing**, and then **Third Party Representative**, and then **Search.**
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized; otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh.**

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the third party representative.
- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the third party representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

The Initiative Leads zone on the Third Party Representative portal displays the leads that have been assigned to the third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Completed Step.** You can navigate to the lead event by clicking on the event/step information.
- For active third party lead events, the **Next Pending Step.** You can navigate to the lead event by clicking on the event/step information.
- The **Sales Representative** shows the representative assigned to the lead.

Copyright © 2026, Oracle and/or its affiliates.

The Unassigned Leads zone on the Third Party Representative portal displays active leads that are not yet assigned to a third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Sales Representative** shows the representative assigned to the lead.
- You can assign leads to the third party representative using the **Assign to Third Party** button.

See Displaying and Assigning Leads to a Third Party Representative for more information.

Displaying and Assigning Leads to a Third Party Representative

Use the following procedure to view leads that are not assigned to a third party representative, and assign one or more of those leads to the third party representative in context.

1. Select **Menu**, and then **Sales & Marketing**, and then **Third Party Representative**, and then **Search.**
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the third party representative you want to view. The selected third party representative opens in the Third Party Representative portal.
5. The **Initiative Lead Summary** zone shows the initiatives that have leads assigned to the third party representative in context. Click the broadcast button on an initiative to view its unassigned leads.
6. Scroll down to view the **Unassigned Leads** zone. This zone will display if there are active leads (for the broadcast initiative) that are not yet assigned to a third party representative.
7. To assign one or more leads to the third party representative in context:
   a. Select the unassigned lead(s) from the results set.
   b. Press **Assign to Third Party**.
   c. Click **OK**.

Rates

When you set up a customer in the system, you create a service agreement for every service that the customer uses. The most important information specified on a service agreement is the rate. The rate controls:

- How the service's charges are calculated.
- How the charges are described on the customer's bills.
- How the general ledger is affected by the charges.

It's important to understand that while *most* service agreements are associated to a rate, you may have service agreements that don't use a rate to calculate their charges; for example, you

Copyright © 2026, Oracle and/or its affiliates.

may have billable charge service agreements to bill a customer for charges that have been calculated in an external system. Whether or not a service agreement uses a rate and the list of rates that can be specified on a service agreement are controlled by the service agreement's SA Type.

In addition to calculating charges for service, your implementation can also use rates to calculate adjustments.

NOT_SUPPORTED

Refer to How Rates Affect The Information On A Bill for how billing uses the information in a rate to calculate a bill segment. Refer to Calculated Adjustments for how to use a rate to calculate an adjustment.

Note

Do not equate a rate in your legacy system with a rate in this system. You may find that the system's flexibility will result in fewer rates than you have today. For example, your current rate structure may have three rates for service because there are different prices based on the customer's geographic area. In this system, however, you can set up a single rate and vary the price based on where the customer lives.

This chapter describes the structure and process to configure rates.

Note

If you're using Oracle Utilities Rate Cloud Service, refer to the Oracle Utilities Rate Cloud Service chapter in the *Business User Guide*, and the Defining Oracle Utilities Rate Cloud Service Options chapter in the *Administrative User Guide* for information about how the rate functionality works in the context of that cloud service.

Rate schedules created using the new rate engine are referred to as **Calculation Rule-Based Rates** or, simply, **Rates**; and those created using the original rate engine are referred to as **Component-Based Rates**. This chapter focuses on Calculation Rule-Based Rates, unless stated otherwise.

Caution

Component-Based Rates, or classic rates, is not the recommended approach for new implementations. Component-Based Rates is intended for upgrading customers who currently use this rate structure and have not converted to Calculation Rule-Based Rates.

- Calculation Rule-Based Rates

Copyright © 2026, Oracle and/or its affiliates.

Calculation Rule-Based Rates

Calculation Rule-Based Rates (Rates) offer a flexible and reusable structure to calculate charges, centralize configuration, and reduce your development effort and time.

This chapter describes the structure and process to configure Rates.

- All Calculation Rule-Based Rates Share a Common Structure
- Control Tables That Must Be Set Up Before Creating a Rate Schedule
- Setting Up Bill Factors
- Rate Schedule Execution
- Understanding Calculation Groups and Rules
- Designing Calculation Groups and Rules
- The Big Picture of Calculation Rule Eligibility Rules
- Working with Calculation Groups and Rules
- Creating Rate Schedules
- Base Package Calculation Rule Descriptions
- Rate Check
- Effective Dates and Price Proration
- Setting Up Estimated Consumption for Items
- Setting Up Degree Days (and Average Temperatures)
- United Kingdom VAT and CCL

All Calculation Rule-Based Rates Share a Common Structure

The basic components used to calculate charges are **Calculation Rules**. Each calculation rule is configured to perform a specific type of calculation, such as calculating tax charges, the number of days in a billing period, or the amount of consumption used by a customer in a billing period.

Calculation rules are organized into **Calculation Groups**, which are logical collections of calculation rules that can be referenced by rate schedules. Calculation rules and groups are commonly "generic" and can be applied to multiple rates.

Furthermore, calculation groups can be nested within other calculation rules. When the parent rule is processed, it executes all the rules that are nested in its referenced group. This strategy allows a single rule to execute any number of nested rules. Nesting also allows common calculations to be encapsulated into a set of calculation rules that can be included in multiple rates.

Calculation groups are defined for a rate schedule in one of three ways:

- **Pre-Processing Calculation Groups** perform initial calculations in preparation for the rate version calculation group.

Copyright © 2026, Oracle and/or its affiliates.

- **Rate Version Calculation Groups** are effective-dated calculation groups that perform the main calculations of the rate schedule.
- **Post-Processing Calculation Groups** perform calculations after rate version calculation groups are executed.

  See About Calculation Groups for more information.

At the highest level, every rate has a single rate schedule that contains basic information that shouldn't change over time; such as, the billing frequency, currency, and the rate's proration strategy. This information combined with the calculations groups, and other high-level configuration, comprise the Rate Schedule

Control Tables That Must Be Set Up Before Creating a Rate Schedule

This section describes tables that must be set up before you can add a rate schedule.

- Master Configuration
- Defining Frequency Codes

Master Configuration

The **Rate Engine Configuration** master configuration can be used to define the behavior of the Rate Schedule portals used when creating rate schedules.

To edit this master configuration, select **Admin**, and then **Master Configuration,** and click the edit icon for the **Rate Engine Configuration.**

The **Rate Engine Implementation** dropdown list defines which rate engine(s) will be used by your organization.

- **Calculation-Rule Based** indicates that your implementation uses calculation rule-based rates, which require the configuration of rate schedules with calculation groups and calculation rules.
- **Component-Based** indicates that your implementation uses component-based rates, which require the configuration of rate versions with rate components, and rate schedules with SQ and register rules.
- **Both** indicates that your implementation uses both rate engines. If this applies to you, then the system will use this option to ease navigation as follows:
  - Select **Menu**, and then **Rates**, and then **Rate Schedule**, and then **Add** to launch the page to add a new rate schedule. *(A hyperlink is included to take the user to the component-based rate schedule maintenance page, if necessary.)*
  - Select **Menu**, and then **Rates**, and then **Rate Schedule**, and then **Search** to launch the **Rate Schedule Query** portal.
  - The query results attempt to highlight component-based rates by appending **"(Component-Based)"** to the rate schedule's description.
  - Once a rate schedule is selected from the result set, the system navigates the user to either the calculation rule-based **Rate Schedule portal** or the component-based **Rate Schedule page**.

The **External Communication** section is used when the rate engine needs to communicate with an external system. For example, service quantities are needed to test a rate on the **Rate Check** portal. These service quantities may be entered on the portal, retrieved from an existing

Copyright © 2026, Oracle and/or its affiliates.

bill segment, or (in the case of a service agreement that requires bill determinants) request service quantities from Oracle Utilities Meter Data Management.

- **Request Type** identifies the various data requests that can be made to an external system. Request types are defined in the RATE_EXT_REQ_TYPE_FLG lookup field. To introduce additional request types, add appropriate lookup values to this lookup field for each request type you wish to support.

  The base package includes the following business objects to be defined on the outbound message types created for such requests:

  – **Rate Check Usage**: C1-UsageRequestOutMsg (used to request bill determinants from MDM on the rate check portal)

- **External System** and **Outbound Message Type** are used when creating the outbound message for the data request.

Defining Frequency Codes

When you create a rate schedule, you must enter a code defining the frequency in which the prices are expressed, e.g., monthly, quarterly, biannual, etc. To set up frequency codes, open **Admin**, and then **Rates**, and then **Frequency.**

Description of Page

Enter a unique **Frequency** ID and **Description** for each frequency.

Before entering the remaining fields, you must analyze the "proration provisions" in your rates. For example, consider a rate used to calculate charges for a "month's worth of service". Assume this rate's charges will not be prorated when the customer's service period is anywhere between 27 and 33 days. This rate requires a frequency that indicates:

- 12 **Periods / Year** (because it's a monthly rate).
- **Minimum Days Offset** equal to 3.
- **Maximum Days Offset** equal to 3.

When the system creates a bill using a rate with this frequency, it compares the number of days of consumption on the bill to the minimum and maximum number of days inferred by the rate's frequency. In the example above, the minimum number of days would be 27 (365 days / 12 period per year - 3 offset for minimum days). The maximum number of days would be 33 (365 days / 12 periods per year + 3 offset for maximum days). Therefore, if a bill's consumption period is less than 27 days or more than 33 days, the bill's charges are prorated.

> **Note**
>
> **Overriding the system's standard proration logic.** If the standard proration logic does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation. For example, we have encountered companies who treat a year has have 360 days rather than 365 days. Such a company would need to develop an override proration algorithm and plug it on the Installation Record.

Where Used

Copyright © 2026, Oracle and/or its affiliates.

Every Rate Schedule must have a frequency. Refer to Defining Rate Schedules for more information.

Setting Up Bill Factors

This section describes bill factors and how they are used to levy the many charges referenced in a rate.

> **Warning**
>
> Most bill factors exist to support calculations performed by calculation rules. This means that you must design your calculation rules before you can design your bill factors. We strongly recommend that you design "on paper" how each rate's calculation rules look before attempting to set up bill factors.

- An Overview of Bill Factors
- The Structure of a Bill Factor
- An Illustration of a Bill Factor and Its Characteristics
- Deriving/Passing In Characteristic Values
- Defining Bill Factors
- Defining Bill Factor Values

An Overview of Bill Factors

The primary reason that calculation rules exist is to define how much to charge for the services sold by your company. When you create calculation rules, you have four ways to indicate how much to charge:

- Specify the value directly in the calculation rule.
- Define that the value is defined in a *bill factor*.
- Define that the value is calculated by a *for calculation purposes only* calculation rule.
- Tell the calculation rule to call an algorithm to get the price.

The remainder of this section describes the bill factor approach. The other methods are discussed in Case Study: Three Simple Rates .

Bill factors are used to pass a value to a calculation rule; such as specifying a tax rate. To further illustrate this, you could specify the current tax rate, say 6%, directly in every rate's calculation rules OR you could indicate every rate should levy the current state tax rate and have the system look up the applicable rate when it calculates bills. The latter approach involves using a bill factor to indicate that the amount to charge should be retrieved from someplace other than the calculation rule when a bill is calculated.

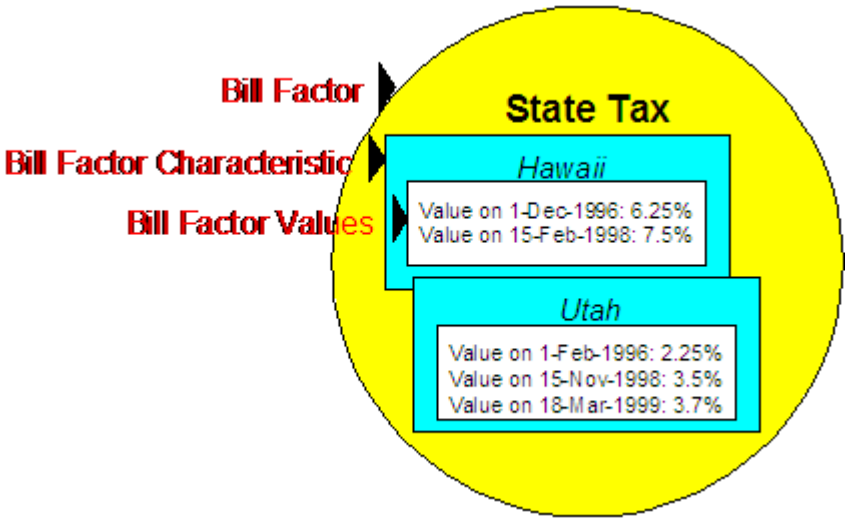
You can use bill factors to define any of the following types of charges:

- A flat amount. This would typically be used to define service charges, minimum charges, and asset charges.

Copyright © 2026, Oracle and/or its affiliates.

- An amount for a given unit of measure. This would typically be used to define the price for measured consumption (such as, the price per therm).
- A percentage. This would typically be used for tax rates and discount percents.

As a rule of thumb, you would use a bill factor (rather than specify the value in the calculation rule) when any of the following situations exist:



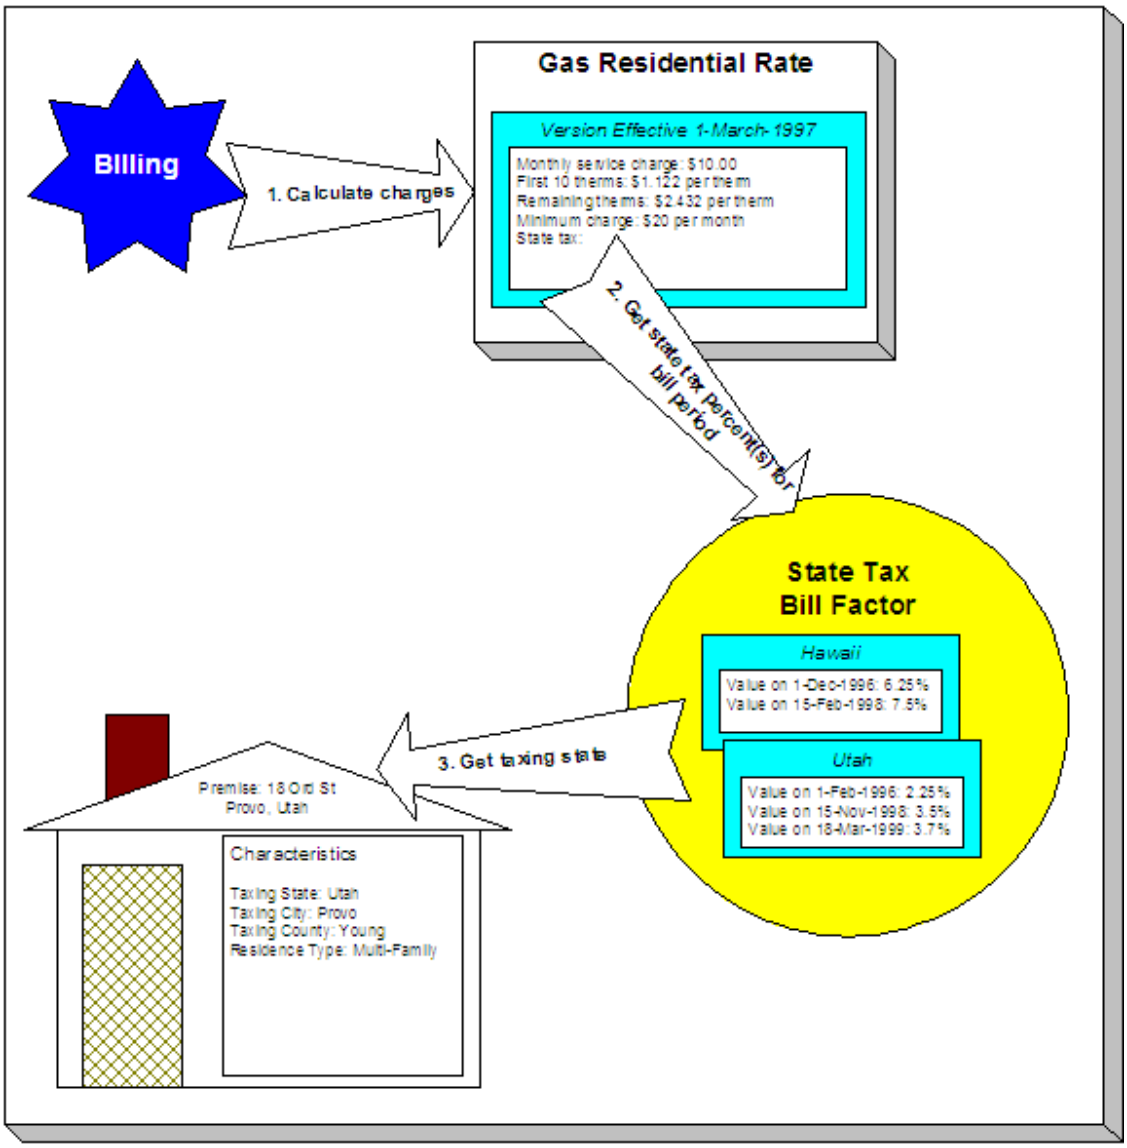
- The same charge exists in many rates. For example, if there are three rates that all contain the same service charge, it would make sense to use a bill factor to levy this charge rather than specify the same value on three calculation rules.
- The amount being charged is dependent upon some physical characteristic of the customer's equipment. For example, if the price differs depending on whether the customer owns the transformer, you would use a bill factor to specify the price.
- The amount being charged is dictated by some external organization and therefore can change independently from the rate. For example, tax percentages and use fees are set by taxing authorities and can be changed at any time (and you don't want to change the rate when these charges change).
- The amount being charged varies depending on WHERE the customer lives. If you have a rate where the price per gallon differs depending on where the customer lives, you should use a bill factor to levy this type of charge.
- A charge (or discount) is only levied for a subset of customers for defined periods of time. For example, if you have a discount that is only given to customers who have had service for more than two years, you would use a bill factor to specify the discount percent.
- The price differs per customer. For example, you may have a rate for large gas customers where the price per therm is different for every customer. In this situation, you would use a bill factor to specify the price.
- The price differs based on the number of weeks of consumption. This typically occurs in a deregulated environment when the price charge is based on the weighted average spot market price in effect during the bill period.

> **Warning**
>
> As you can deduce, bill factors are extremely flexible. While the flexibility makes for a very powerful rate engine, it also presents you a dizzying array of options. We have discovered that to take advantage of the flexibility, you need to gain an overall understanding of the pricing and taxation provisions in ALL of your rates. Only then can you make logical and pragmatic decisions in respect of the number and type of bill factors.

The Structure of a Bill Factor

All bill factors share a common structure as illustrated below:

Copyright © 2026, Oracle and/or its affiliates.



The above example shows a standard bill factor, which is made up of the following tables:

- **Bill Factor**. A **bill factor** contains descriptive information and attributes that control how the bill factor may be used in the system.
- **Bill Factor Characteristic**. All bill factors have the capability of having different values depending on some characteristic of the premise or service point. For example, a bill factor used to levy a state tax would have a different tax rate depending on the state in which the customer resides. A **bill factor characteristic** must exist for every state with a tax (states without a tax will not be linked to the state tax bill factor). At billing time, if the system cannot find a bill factor characteristic that corresponds with the customer's state of residence, the charge will be skipped.
- **Bill Factor Value**. Each bill factor characteristic may have many **bill factor values** over time. To continue with our state tax example, each state with a tax can have different tax rates over time. There are different ways in which a bill factor's values may be defined:
  - For bill factors whose values are applicable to many customers where only one value is effective on a given date (such as, a city tax) the values are defined using bill factor values. Refer to Defining Bill Factor Values for more information.
  - For bill factors whose value differs per customer, the value is defined in the customer's service agreement. Refer to Service Agreement - Contract Value for more information about bill factors in contract terms.
  - For bill factors whose values are applicable to many customers where more than one value is effective on a given date (such as, an interval price or a weighted average price) the values are defined on an interval value set. Refer to Defining Interval Values for more information about interval value sets.

An Illustration of a Bill Factor and Its Characteristics

The following picture illustrates how a bill factor and its characteristics are used to retrieve the relevant state tax at billing time:

Copyright © 2026, Oracle and/or its affiliates.

The following points describe the illustration:

- At billing time, the billing engine sends a request to a rate to calculate the charges for a customer's consumption.
- The rate calculates charges without bill factors until it encounters the calculation rule that levies state tax. This calculation rule references a bill factor. This means the rate must get the tax rate(s) in effect during the billing period from this bill factor.
- The state tax bill factor contains an attribute defining that the premise's taxing state characteristic controls the bill factor value. The bill factor therefore extracts the taxing state from the premise.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Deriving characteristic values.** Rather than have the system extract the characteristic value from an entity, you can setup the system to derive the characteristic value when the rate is calculated. For example, if all of your customers are located in a single state, you may not want to maintain the taxing state on every premise. To do this, you could setup the rate to "hard code" a taxing state of say Hawaii. This is an advanced topic, but it may prove useful for your implementation. Refer to Deriving / Passing In Characteristic Values for the details.

- The premise returns the taxing state and the bill factor extracts the tax rate(s) in effect during the bill period and returns them to the rate.
- The rate applies the tax percents and returns the charges to billing.

> **Note**
>
> **Some bill factors don't need a characteristic.** There are bill factors whose value does not differ based on a characteristic. For example, if your organization offers employee discounts, the discount percent is probably the same for all employees and therefore this bill factor doesn't need a characteristic to select the bill factor value at billing time. However, because of the relational design of the system, every bill factor value must reference both a bill factor and a characteristic value. Therefore, if you have bill factors whose value is not related to a characteristic, you must specify a characteristic type on the bill factor with a characteristic value that is exactly the same as the characteristic type.

> **NOT_SUPPORTED**
>
> For more information about setting up characteristics, see Setting Up Characteristic Types and Their Values .

Deriving/Passing In Characteristic Values

In An Illustration of a Bill Factor and Its Characteristics, we described how the system retrieves a characteristic value from a premise when a bill factor is encountered that uses a premise characteristic. This is a very common technique and is easy to understand. However, there are situations when an entity in Oracle Utilities Customer Care and Billing doesn't contain the appropriate characteristic value and therefore other techniques must be used. These techniques may not apply to your implementation, but they're worth understanding to help you form an intuitive understanding of rate application:

- There are implementations that only use the Oracle Utilities Customer Care and Billing rate engine. These implementations do not setup accounts, premises, etc. Rather, they simply setup their rate schedules, calculation rules, and bill factors. The rate engine is called from another application. This means the rate engine can't retrieve characteristic values from within Oracle Utilities Customer Care and Billing (because there are no objects where the characteristic values are defined). In this situation, the application that calls the rate engine

Copyright © 2026, Oracle and/or its affiliates.

must supply the characteristic types and values to be used when a bill factor requires this type of information.

- Assume you have a charge that is based on the account's customer class and the service agreement's revenue class. The characteristic value for this type of charge is not extractable through a single entity. Rather, the system must construct the characteristic value in real-time by concatenating information from the account and service agreement that is being billed. In this situation, you can use pre-processing calculation group to derive this characteristic type and value. This calculation group would create a characteristic type and value in real time by concatenating the account's customer class and the service agreement's revenue class. This characteristic type and value only exists in memory while the rate application executes.

When you setup a bill factor to use a characteristic whose value is derived or passed in, you need to define its characteristic source as Characteristics Collection. This source tells the system to extract the characteristic value from memory rather than extracting it from an object within the system.

> **Note**
>
> The plug-in spots on a calculation rule have access to the Characteristics Collection. You might find this useful if you have a calculation rule that needs to calculate characteristic values for subsequent calculation rules.

Defining Bill Factors

You create a bill factor for every type of charge whose value is not specified directly in a calculation rule.

It is recommended to use two windows to set up a bill factor. On the first, you define general information describing how the bill factor is used in the system. On the second, you define all the characteristic values for the bill factor.

- Defining General Bill Factor Information
- Setting Up Bill Factor Characteristics

Defining General Bill Factor Information

Begin to define a bill factor by selecting **Menu**, and then **Rates**, and then **Bill Factor**, and then **Add.**

Description of Page

Enter a unique **Bill Factor** code and a **Description** for the bill factor.

Use **Bill Factor Type** to indicate if this bill factor uses Regular, Interval (i.e., real-time), or Time of Use values.

- **Regular**. Indicates that this bill factor's values are specified on Bill Factor Value - Main or on Service Agreement - Contract Values.
- **Interval**. Indicates that this bill factor's values are specified on Defining Interval Values

Copyright © 2026, Oracle and/or its affiliates.

- **Time of Use**. Indicates that this bill factor's values are specified on Bill Factor TOU Values or on SA Interval Billing Info - TOU Contract Values (**Note:** This option is only applicable to Conponent-Based Rates).

Enter a **Currency Code** to define the bill factor's denomination, or currency. This field is disabled if the bill factor is referenced on a calculation rule.

> **Note**
>
> Bill factors referenced on a calculation rules must be denominated in the same currency as is the rate.

Select the **Value Type** to define the kind of value maintained by this bill factor. The Value Type options are:

- **Charge**. The value maintained in this bill factor is a fixed amount (e.g., a flat charge).
- **Percentage**. The value maintained in this bill factor is a percentage.
- **Unit Rate**. The value maintained in the bill factor is a price per service quantity.

This field is disabled if the bill factor is already referenced on a calculation rule or if the bill factor already has values

Turn on **Error If No Value** if the system should create a billing error when a bill factor value doesn't exist for the characteristic value linked to the customer. To clarify, understand that there are different types of bill factors:

- Those that should have a value for every customer whose rate references the bill factor. A bill factor used to levy the relevant state tax is a good example (assuming every state has a tax). For this type of bill factor, if the system cannot find a bill factor value for the taxing state, it must generate a billing error because data is missing from the system. You would turn on **Error if No Value** for this type of bill factor.
- Those that only have a value when the customer has a characteristic value that levies a charge. A bill factor used to levy the relevant city tax is a good example (because not all cities levy taxes). For this type of bill factor, if the system cannot find a bill factor value for the city in which the customer lives, the calculation rule will be skipped and no billing error will be generated. You would turn off **Error if No Value** for this type of bill factor

Bill factors used to levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for the tax exemption will have their tax obligation reduced (or nullified) at billing time. For bill factors that are eligible for tax exemptions, turn on **Tax Exemption**. If a service agreement is fully or partially exempt for the taxes defined by a given bill factor, the bill factor and the exemption information for the customer must be indicated on the Service Agreement page. This field will be disabled if the bill factor is referenced as being tax exempt in a service agreement.

> **NOT_SUPPORTED**
>
> For more information about how to make a customer tax exempt, refer to Service Agreement - Tax Exemptions.

Some types of bill factors do not have the same value for all customers. Rather, their value may be unique for every customer or it may be unique for some customers and common for

Copyright © 2026, Oracle and/or its affiliates.

others. For example, you may have rates where the price per kilowatt-hour is defined for every customer using the rate. You may have other rates where certain customers have their own price per kilowatt-hour defined and other customers who use the value defined on the bill factor. For any type of bill factor where a customer may have their own unique price, turn on **Value In Contract Term**. For any service agreement that has a unique value for a given bill factor, the bill factor and the service agreement's value must be indicated on the Service Agreement page. When applying the rate for a bill factor of this type, the system will first check for the existence of a contract value for the service agreement and if one is not found, it will use the value on the bill factor. This field will be disabled if a contract term referencing this bill factor exists.

> **Note**
>
> The **Error if No Value** switch also affects what happens if there is no contract term for the bill factor. If the error switch is on, a billing error will be generated. If the error switch is off, no billing error will be generated and the calculation rule will be skipped.

> **NOT_SUPPORTED**
>
> For more information about how to specify a bill factor value in a customer's contract, refer to Service Agreement - Rate Info.

Contract riders are used when the charge associated with the bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first 3 months of service, then a contract rider would be used. Turn on **Contract Rider Applicability** if the bill factor's applicability is contingent on the existence of a contract rider. This field will be gray if a contract rider referencing this bill factor exists on a service agreement.

> **NOT_SUPPORTED**
>
> For more information about how to establish a contract rider for a customer, refer to Service Agreement - Contract Riders.

The proration information tells the system how to handle changes to bill factor values and their optional contract riders that may occur during a customer's bill period. Turn on **Allow Proration** if changes to the bill factor's value and/or contract riders should be prorated. If the **Bill Factor Type** is not specified as Interval and if changes should **not** be prorated, indicate the **Rate Selection Date Algorithm** to use when the system retrieves bill factor values or determines if contract riders are applicable.

If you have sub service agreements, turn on **Use Sub SA Contract** terms if billing should access contract riders, values, tax exemptions from the sub SA rather than the master. If this switch is off, the system will use the master SA's riders, contract value, and tax exemptions when it creates bills for a sub service agreement. Refer to Sub Service Agreements for more information.

If the Contract Management module is not turned off, which includes umbrella agreement management, and you have checked either Tax Exemption, Value in Contract Term or Contract Rider Availability, indicate the **Terms of Service Usage**. Valid values are Check SA Only,

Copyright © 2026, Oracle and/or its affiliates.

Check TOS Only and Check TOS First, then SA. Refer to Overriding Rate Terms for details about how to set this value based on your business needs.

Bill Factor Tree

The right half of this page is dedicated to a tree that shows the bill factors characteristics and their respective values (for Regular bill factors) or interval value Sets (for Interval bill factors). You can use this tree to both view high level information about these objects and to transfer to the respective page in which an object is maintained by using the available Go To buttons.

Where Used

Many types of Rate Components may use a Bill Factor to define the price being charged. Refer to Designing Calculation Groups and Rules for more information.

The BILPC-TOTAL algorithm type that is used to levy late payment charges references the bill factor that defines the late payment charge percent. Refer to SA Type - Main for more information about this algorithm.

A Service Agreement references Bill Factors as follows:

- When a service agreement's Apply To calculation rule references tax exemptable bill factors AND the customer is tax exempt, the service agreement will define the bill factors from which the customer is exempt. Refer to Service Agreement - Tax Exemptions for more information.
- When a service agreement's rate references bill factors whose prices are customer-specific (i.e., specified on a contract term), the service agreement will contain prices for these bill factors. Refer to Service Agreement - Contract Values for more information.
- When a service agreement's rate references bill factors that are contingent on contract riders, the service agreement will define the rider period (if any) for these bill factors. Refer to Service Agreement - Contract Riders for more information.

Setting Up Bill Factor Characteristics

After defining general information about a bill factor, open **Menu**, and then **Rates**, and then **Bill Factor**, and then **Search** and navigate to the **Bill Factor Characteristics** page to define characteristic values where applicable. For example, a bill factor used to levy the applicable city tax would require the definition of every city that levies a tax.

> **Note**
>
> If all values for a bill factor are specified in contract terms, you do not need to set up Bill Factor Characteristics.

Description of Page

Enter a **Characteristic Type** to indicate the type of characteristic that controls how the bill factor's value is defined. This field will be disabled if Bill Factor Characteristics are specified in the following grid.

The **Characteristic Source** defines where the system retrieves the characteristic value at billing time. The Characteristic Source options are:

Copyright © 2026, Oracle and/or its affiliates.

Account	The characteristic type's value will be retrieved from the service agreement's account.
Characteristic Collection	Refer to Deriving / Passing In Characteristic Values for an explanation of this value.
Main Person	The characteristic type's value will be retrieved from the main person linked to the service agreement's account.
N/A	The characteristic type's value is the same for all customers using the rate. If this option is used, you must still choose a Characteristic Type. This Characteristic Type should have a single Characteristic Value. The ID of the characteristic value must be identical to the ID of the characteristic type.
Premise	The characteristic type's value will be retrieved from the service agreement's characteristic premise.
SA	The characteristic type's value will be retrieved from the service agreement.
SP	The characteristic type's value will be retrieved from the customer's service point. If multiple service points are linked to the service agreement, one will be chosen at random.

NOT_SUPPORTED

For more information about characteristics, see Setting Up Characteristic Types and Their Values and An Illustration Of A Bill Factor And Its Characteristics.

Use the add and remove buttons to define the **Characteristic Values** that are relevant for the bill factor's Characteristic Type. For example, if the bill factor is used to levy a city tax, you would define the city's that have a city tax in the above collection.

Use the **Minutes Per Interval** if your Bill Factor is of type Interval. This defines, for each characteristic value, the number of minutes expected between each record of interval data.

Use the **External ID** if the values for this characteristic are interfaced to the system from an external source and you want to record an identifier for the source.

Note

If the bill factor's value is the same for all customers, you still must link a "dummy" characteristic value to the bill factor. In other words, you'll have to create a characteristic type called "n/a" and define for it a characteristic value of "n/a". Then, on the bill factor, you reference the "n/a" characteristic type and on the above window, you indicate a characteristic value of "n/a".

Copyright © 2026, Oracle and/or its affiliates.

Defining Bill Factor Values

After the bill factor and its characteristic values are defined, you define the price / percent and GL distribution associated with each bill factor characteristic. The topics in this section describe the pages used to set up this information.

- Bill Factor Value - Main
- Bill Factor Value - GL Distribution

Bill Factor Value - Main

After the bill factor and its characteristic values are defined, select **Menu**, and then **Rates**, and then **Bill Factor Value** to define the price / percent applicable to each bill factor characteristic.

> **Important**
>
> You do not set up Bill Factor Values for bill factors whose values are specified in an interval value data set or if all the values are customer specific and are defined as contract terms. Refer to Defining Interval Values for more information about interval value sets. Refer to Service Agreement - Contract Value for more information about bill factors in contract terms.

Description of Page

Enter the **Effective Date** and respective **Value** for the bill factor and characteristic value. The first date should be the earliest date on which the bill factor's charges are effective. Subsequent effective dates and values are required whenever the value changes.

> **Note**
>
> **Default note.** A **Value** of 0, zero, will be defaulted.

Bill Factor Value - GL Distribution

Select **Menu**, and then **Rates**, and then **Bill Factor Value** and navigate to the **GL Distribution** page to define the GL account affected by the bill factor characteristic.

Description of Page

If the bill factor characteristic's charges are booked to a different GL account depending on the characteristic value, specify the appropriate **Distribution Code** for each **Revenue Class**.

Copyright © 2026, Oracle and/or its affiliates.

> **Important**
>
> Specifying distribution codes on a bill factor is optional. You would only do this if the GL distribution code differs based on the characteristic value (such as, the city tax payable GL account differs depending on the city). If you do not enter the above information, the distribution code will be used.
>
> The GL distribution code on the bill factor's value will not be used in the following cases:
>
> - Value derived solely on contract value or contract value in combination with contract rider and/or tax exemption, where characteristic value is no longer used to determine the bill factor value.
> - Value derived in calculate service quantity and math calculation rules where multiple bill factors may be configured in the rule resulting to multiple values contributing to the calculation of the line amount.

Rate Schedule Execution

When a rate schedule is executed, the system executes the calculation rules contained in the calculation groups defined for the rate schedule as follows:

1. First, the system executes the calculation rules defined within Pre-Processing Calculation Groups.

- The rate engine may create a bill segment calculation header for pre-processing calculations, if bill calculation lines are to be created.
- Calculation groups are executed in order according to the Sequence defined on the rate schedule.
- Calculation rules within each group are executed according to the Sequence configured within the group.

2. Next, the system executes the calculation rules within the Rate Version Calculation Groups. The system uses the Effective Date on each calculation group to determine which group(s) to execute. If more than one version of a calculation group is in effect during the billing period, the system may prorate the calculations, based on the configuration of the rate schedule.

- The rate engine creates a separate bill segment calculation header for each rate version calculation group.
- Calculation rules within each group are executed according to the Sequence configured within the group.

3. Finally, the system executes the calculation rules defined within Post-Processing Calculation Groups.

- The rate engine creates a separate bill segment calculation header for post-processing calculations.
- Calculation groups are executed in order according to the Sequence defined on the rate schedule.
- Calculation rules within each group are executed according to the Sequence configured within the group.

Additional Information.

Copyright © 2026, Oracle and/or its affiliates.

- After every rate version calculation group is processed, the rate application returns the calculation details to the process that called it. This point is important as it means that rate application executes in memory (i.e., it does NOT insert the calculation details on the database, rather, it returns them to whatever process called rate application). Because rate application executes in memory, it can be used to perform billing calculations in many parts of the system. For example:
- Both online and batch billing use rate application to calculate the charges that are eventually saved on the bill's bill segments.
- The Rate Check transaction calls rate application when you want to check a rate real-time. When you use this transaction, you enter the consumption that's passed into rate application and then rate application shows you the calculation details that result.
- Plug-ins exist that call rate application to estimate bill segments when adequate billing history doesn't exist. For example, the BUDCALC-PH budget recommendation algorithm calls rate application to calculate a budget amount for a customer without adequate history. Another example is the DEPRECOM-MBT deposit recommendation algorithm. This plug-in calls rate application to calculate a recommended deposit amount for a customer without adequate history.

Understanding Calculation Groups and Rules

This section provides descriptions of calculation groups and calculation rules, and describes how to identify components of rates that can be defined using calculation rules and groups.

- About Calculation Groups and Rules

About Calculation Groups and Rules

This section includes descriptions of calculation groups and calculation rules.

- About Calculation Groups
- About Calculation Rules

About Calculation Groups

Calculation groups are collections of calculation rules that are applied to calculate quantities for billing and billing charges for service agreements.

As noted previously, calculation groups are associated with specific rate schedules in one of three ways:

- **Pre-Processing Calculation Groups**: These are generally used to derive service quantities or massage measured quantities. The following illustrate some use cases of when a pre-processing calculation group might be needed:
  - When a rate contains prices for things that aren't measured directly by the customers' meters. For example, if the rate calculates a charge based on a service agreement's contracted quantity.
  - When a meter measures something in a unit of measure that has to be converted into a different unit of measure before it can be rated. For example, a meter measures gas in cubic feet, but the rate contains prices in therms.
    During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header

Copyright © 2026, Oracle and/or its affiliates.

is added if Pre-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header. Before invoking the rate's Pre-Processing Calculation Groups, the rate engine processor builds the initial service quantity (SQ) collection based on the item collection and final values in the read collection.

- **Rate Version Calculation Groups**: These are the calculation groups used to create a bill segment for the service agreement. Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, must be executed only in a rate version calculation group.
  When the system creates a bill segment for a service agreement, it checks if multiple Rate Version Calculation Groups are in effect during the bill period. If so, it uses the rate's **Allow RV Proration** and **RV Selection Date** values to determine if it should prorate the various Rate Version Calculation Groups, or if it should pick one of the Rate Version Calculation Groups effective during the bill period. Rate Version Calculation Groups are executed after the rate's pre-processing calculation groups.
  - **Effective Date**: defines the date on which each rate version calculation group becomes effective.
  - **Description on Bill**: Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to **How To Use Description on Bill** in the Defining Calculation Rules chapter for a discussion of the various substitution variables.
- **Post-Processing Calculation Groups**: These are similar to Pre-Processing Calculation Groups, except that these are executed after the Rate Version Calculation Groups. The intended types of functionality include applying taxes on calculated charges, or deriving more complex GL distribution.
  Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, are not designed to be executed in post and pre-processing calculation groups.

  During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header is added if Post-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header.

Calculation groups can also be referenced by "Execute Calculation Group" calculation rules. See "Execute Calculation Group Rules - Nesting Calculation Rules" in About Calculation Rules for more information.

About Calculation Rules

Calculation rules are standard and custom rules that perform calculations used when calculating quantities for billing and billing charges for a customer's service agreements.

Calculation rules are created for a specific calculation group. For example, if you were configuring two calculation groups and both included a specific calculation rule, you would need to create two instances of the calculation rule, one for each group.

Attributes used to define calculation rules typically include the following:

- **Basic Information**: Basic information about the calculation rule, including its name and description, the calculation group to which the rule belongs, the sequence of the rule within the group, the description that appears on the bill, and other information. This information is standard for most calculation rules.

Copyright © 2026, Oracle and/or its affiliates.

- **Parameters**: The parameters used by the rule. Parameters are specific to each rule. See Base Package Calculation Rule Descriptions for details about the calculation rules included with the base package.

Execute Calculation Group Rules - Nesting Calculation Rules

Execute Calculation Group rules are used to define business logic to allow reference to a separated specified calculation group. This allows rules that are used frequently to be bunched under a single calculation group, which can be referenced / called by other rules as needed. For example, if a set of standard rules should be applied to all rate schedules, this set of rules can be configured as part of a calculation group, which is referenced by a single calculation rule of this type. Execute Calculation Group rules use the following options:

- **Referred Calculation Group**: defines the calculation group referenced by the rule.
- **Characteristics**: defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calculation lines.

> **Note**
>
> There is a limit of 99 calculation groups that can be called from a calculation group defined directly on a rate schedule or via related child calculation groups when using Execute Calculation Group calculation rules.

Eligibility Criteria

Calculation rule eligibility criteria are user-definable conditions that could cause a given calculation rule to be applied or skipped. This can involve the evaluation of some attribute of the service agreement, or service point, or something else entirely.

A calculation rule can have multiple eligibility criteria for determining if the rule should be applied or skipped, based on a user-defined sequence. Each eligibility criteria uses the following settings:

- **Criteria Comparison**: defines the specific comparison for the criteria, based on the following:
  - **Criteria Field Type**: the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
  - **Comparison Operator**: the operator used in the comparison
  - **Comparison Value**: a user-specified value to which the retrieved value is compared (using the comparison operator)
- **Comparison Results**: defines how the rule should behave, based on the results of the comparison defined under Criteria Comparison:
  - **If True**: the action to take if the comparison is true
  - **If False**: the action to take if the comparison is false
  - **If Insufficient Data**: the action to take if there is insufficient data to perform the comparison

Copyright © 2026, Oracle and/or its affiliates.

Calculation Line Category Types

Calculation line category types are used to establish connections between calculation rules. Calculation rules can specify a member category and value to which they belong. When this same category and value are referenced as a "Target Category" by other rules (the rule is applied to the results of rate version calculation rules (defined in the same rate schedule) that belong to the category and value.

For example, calculation rules whose results are subject to taxes might belong to the "Subject to Tax" (TAXABLE) category and "County Tax" value. Apply To calculation rules defined for the same rate schedule with a target category of "Subject to Tax" and "County Tax" values are applied to "Subject to Tax" member rules.

Calculation Line Category Types are defined by the following:

- **Calculation Line Category Type**: The unique identifier of a calculation line category type definition
- **Description**: The description of the calculation line category type.
- **Category Values**: The valid category values for the calculation line category type.

Base Package Calculation Rules

Oracle Utilities Customer Care and Billing includes the following base package calculation rule types that can be used when creating calculation rules:

- **Apply To:** Used to create bill lines that levy charges based on amounts calculated on other bill lines.
- **Calculate Final Reading Values:** Used to determine the final values for readings based on user-defined UOM/TOU/SQI.
- **Calculate Service Quantity:** Used to derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection.
- **Copy Service Quantity From Master Bill Segment:** Used to copy all the entries from the master bill segment SQ collection to the sub bill segment SQ collection.
- **Execute Calculation Group:** Used to call and pass parameters to another calculation group.
- **Flat Charge:** Used to create bill lines that levy service charges and fees that aren't based on how much the customer uses.
- **Item Type:** Used to create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.
- **Math:** Used to derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities
- **Maximum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount.
- **Minimum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount.
- **Service Quantity:** Used to create bill lines that levy charges based on some type of consumption.
- **Simple Summary:** Used to create a "subtotal" on the bill, by summarizing bill lines produced by other calculation rules in the same calculation group.

Copyright © 2026, Oracle and/or its affiliates.

- **Stepped Service Quantity:** Used to create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are $0.43 per kWh, anything in excess of 50 kWh is charged at $0.71 per kWh)
- **Summary:** Used to create a "subtotal" on the bill. It exists purely for reporting and informational purposes.

See Base Package Calculation Rule Descriptions for details about each of these calculation rules.

Designing Calculation Groups and Rules

Before starting to design calculation groups and rules for your rates, please review the concepts outlines in the **Designing Rate Components** section in the Rates chapter. That section provides a good background for understanding how to break down rates into component pieces that can be modeled by calculation groups and rules.

This section provides guidelines for how to design and plan the calculation groups and rules you will need for your rates, and provides a simple case study of how to define the calculation rules and groups you might use for a set of rates for a small municipal electric company.

- Analyzing Your Rates and Identifying Calculation Rules and Groups
- Reusing Calculation Rules
- Leveraging Eligibility Criteria to Dynamically Apply Calculation Rules
- Case Study: Three Sample Rates

Analyzing Your Rates and Identifying Calculation Rules and Groups

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Best Practices

When designing calculation groups and rules, the following general rules apply:

- **Pre-Processing Calculation Groups**. Perform any initial processing or conversions that should occur before the rate version calculation group. This can include:
  - Calculating the number of days in a billing period (Calculate Service Quantity)
  - Calculating service quantities that are not measured (demand, kVa, etc.) (Calculate Final Reading Values, Calculate Service Quantity, Math)
  - Validating that consumption is within tolerances set by the rate (residential limits, etc.) (Calculate Service Quantity, with eligibility criteria)
- Calculations processed by calculation rules should be performed by **Rate Version Calculation Groups**. This includes most charge calculations, including:

Copyright © 2026, Oracle and/or its affiliates.

  - Charges based on service quantities (Service Quantity, Stepped Service Quantity)
  - Customer charges (Flat Charge)
  - Minimum/maximum charges (Minimum Charge, Maximum Charge)
  - Discounts (Apply To)
  - Taxes (Apply To)
  - Summaries (Summary, Simple Summary)
- Additional processing should be performed by **Post-Processing Calculation Groups**. This can include:
  - Allocating consumption/revenue (energy revenue vs. demand revenue) (Service Quantity)

Example Configurations

Let's look at a couple of different possible configurations for a simple electric rate that includes the following:

- Customer Charge
- Service Charge (price per kWh)
- Minimum Charge
- Discount

This rate could be set up in the following ways:

- A single Rate Version calculation group that contains a calculation rule for each of the above
- A set of Rate Version calculation groups as follows:
  - A calculation group for "flat" charges, such as the Customer Charge
  - A calculation group for consumption-based charges (including the Service Charge and Minimum Charge).
  - A calculation group for discounts or other charges applied to the total of other charges (which would include the Discount)

There are no hard and fast rules concerning how calculation rules should be grouped. How this is done should be based on the specific needs of the implementation but it's a good idea to look for ways to keep your configuration simple for maintenance and upkeep purposes. This includes changes to existing rates as well as adding/removing rates over time.

Reusing Calculation Rules

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Copyright © 2026, Oracle and/or its affiliates.

Identifying Calculation Rules that can be Shared/Reused

As you analyze the bill lines used by your rates, you should look for bill lines that utilize similar or identical variables or calculations. These calculations are candidates for reuse. For example, if all of your residential rates offer a discount for early payment, you would want to create a single rule to calculate that discount, and then use it each of the rates to which it applies.

How to Reuse Calculation Rules

There are two approaches that can be used to reuse calculation rules.

- **Encapsulating Rules in a Calculation Group**
  This approach involves grouping rules that can be applied to more than one rate into a single calculation group. You would use this approach when you identify charges and other components in your rates that apply to multiple rates, but that can be grouped together. Taxes for multiple types of jurisdictions (for example, State, County, and City) would be suitable for this approach.

  To use this approach, you simply create a calculation group that contains the rules to be applied to more than one rate. For the tax example, you might create the following group and rules:

  Calculation Group: Taxes, which includes:

  Calculation Rule: State Tax (Apply To)

  Calculation Rule: County Tax (Apply To)

  Calculation Rule: City Tax (Apply To)

  This "Taxes" calculation group can be included as a Rate Version Calculation Group in each of the rates to which the taxes apply. This calculation group could also be referenced by an "Execute Calculation Group" rule, as outlined below.

- **Using "Execute Calculation Group" Rules**
  This approach involves creating a calculation group that contains one or more rules, which is then referenced by another "Execute Calculation Group" rule. This approach can be used when you identify a charge or calculation that could be applicable within one or more calculation groups. For example, if multiple rates involve calculating peak demand (or some other quantity that is not measured by your customers' meters), you could create a "Calculate Demand" rule and include it in a group that is then referenced by an "Execute Calculation Group" rule.

  To use this approach, you create a calculation group that contains the calculation rules to be used within multiple calculation groups. You then create an "Execute Calculation Group" rule that references the group. Last, you include this "Execute Calculation Group" rule in the calculation groups to which it applies. For the calculate demand example, you might create the following:

  Calculation Rule: Calculate Demand (Execute Calculation Group), which references:

  Calculation Group: Calculate Demand, which includes:

  Calculation Rule: Calculate Demand (Calculate Service Quantity)

  The "Calculate Demand" Execute Calculation Group rule can be included in any calculation group used to calculate service quantities that includes calculating peak demand.

  "Execute Calculation Group" rules can be used with any calculation group. To return the taxes example from above, if you wanted to include your "Taxes" calculation group within other groups, you could use the following:

Copyright © 2026, Oracle and/or its affiliates.

Calculation Rule: Taxes (Execute Calculation Group), which references:

Calculation Group: Taxes, which includes:

Calculation Rule: State Tax (Apply To)

Calculation Rule: County Tax (Apply To)

Calculation Rule: City Tax (Apply To)

See "Execute Calculation Group Rules - Nesting Calculation Rules" in About Calculation Rules for more information about Execute Calculation Group rules.

Leveraging Eligibility Criteria to Dynamically Apply Calculation Rules

Another tool to consider when creating your calculation groups and rules is Eligibility Criteria. Eligibility criteria allow you to define rules that determine the conditions under which a calculation rule is applied or not.

For example, if you need to calculate demand for one or more of your rates, you might create separate calculation rules to calculate demand based on interval values of different units of measure (kWh vs kVarh for instance). You could create rules for each and include them in a single "Calculate Demand" calculation group, but assign eligibility criteria to each such that they are only executed when processing for the specified unit of measure.

See Eligibility Criteria in About Calculation Rules for more information about eligibility criteria and how they can be used with calculation rules. In addition, refer to **The Big Picture of Rate Component Eligibility Rules** in the Rates chapter for additional background on eligibility criteria.

Case Study: Three Sample Rates

Let's look at a sample set of rates, and how they might be implemented. We'll also look at which components of these rates can be shared.

Rates

The following rates are electric rates offered by a small municipal electric company.

Copyright © 2026, Oracle and/or its affiliates.

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
Cost of Service	Stepped charges, as follows: $3.08 for the first 10 kWh or less, plus 19.23 cents per kWh for the next 40 kWh, plus 15.44 cents per kWh for the next 150 kWh, plus 14.93 cents per kWh for the next 300 kWh, plus 14.71 cents per kWh for all kWh in excess of 500 kWh	Stepped charges, as follows: $2.95 for the first 10 kWh or less, plus 19.23 cents per kWh for the next 40 kWh, plus 18.85 cents per kWh for the next 50 kWh, plus 16.86 cents per kWh for the next 400 kWh, plus 15,45 cents per kWh for the next 3,000 kWh, plus 14.87 cents per kWh for all kWh in excess of 3,500 kWh.	1. Customer Charge:$52.00 2. Demand: $11.44 per KW 3. Energy: $11.28 cents per KWH **Billing Demand** The Billing Demand for any month shall be the greater of the following: 1. The maximum 15 minute measured demand during the month as measured in kilowatts, or 2. 70% of the maximum 15 minute measured demand as so determined during the preceding 11 months.
Discount	Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date. For qualifying elderly residents, an additional 10% discount is allowed on the basic rate if paid on or before the discount expiration date and no arrears exist on their accounts.	Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date.	Discount of 10% exclusive of purchased power and fuel adjustment charge paid on or before the discount expiration date.
Purchased Power and Fuel Adjustment	An upward or downward adjustment applied to all kWh sold, based on the total cost of purchased power and fuel compared to the portion of that cost contained in the base rate (11.615 cents/kWh). The purchase power and fuel adjustment shall be rounded to the sixth decimal place and shall be applied to all kilowatt-hours sold in the following month.	See Domestic Rate A	See Domestic Rate A
Misc.	N/A	N/A	**Minimum Bill** The Customer Charge
Taxes	State, County, and City Taxes	State, County, and City Taxes	State, County, and City Taxes

Copyright © 2026, Oracle and/or its affiliates.

Calculation Rules

Now let's look at these same rates in terms of how we might implement them using calculation rules. The table below lists the type of calculation rule used for each item on the rate.

Rate	Domestic Rate A	Commercial Rate B	Power Rate C
Cost of Service	Stepped Charges: • Stepped Service Quantity calculation rule • Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less)	Stepped Charges: • Stepped Service Quantity calculation rule • Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less)	Customer Charge: • Flat Charge calculation rule Demand: • Service Quantity calculation rule • Math calculation rule (to calculate demand from interval values)* Energy: • Service Quantity calculation rule *Could be included in either a Pre-Processing or Rate Version Calculation Group
Discount	Discount: • Apply To calculation rule Elderly Discount: • Apply To calculation rule	Discount: • Apply To calculation rule	Discount: • Apply To calculation rule
Purchased Power and Fuel Adjustment	PPF Adjustment: • Service Quantity calculation rule **Note:** The PPF adjustment rate would be defined as a Bill Factor, updated monthly based on the prior month's total cost.	PPF Adjustment: • Service Quantity calculation rule	PPF Adjustment: • Service Quantity calculation rule
Misc.	N/A	N/A	Minimum Bill: • Minimum Charge calculation rule
Taxes	State, County, and City Taxes: • Apply To calculation rule (one for each type of tax)	State, County, and City Taxes: • Apply To calculation rule (one for each type of tax)	State, County, and City Taxes: • Apply To calculation rule (one for each type of tax)

Shared Components

Now, let's look at the components of these rates that can be shared.

Discounts: Rates A and B both use the same discount, so we could create a single "AB Discount" calculation rule that could be used with both rates. Note: Either this could be in its

Copyright © 2026, Oracle and/or its affiliates.

own calculation group that is listed among the Rate Version Calculation Groups for each rate, or the group could be referenced by an "Execute Calculation Group" rule which in turn would be included in one of the other Rate Version Calculation Groups used in each rate.

Purchased Power and Fuel Adjustment: Rates A, B, and C all use the same adjustment for purchased power and fuel, so we could create a single "PPF Adjustment" calculation rule that could be used with all three rates. Again, this calculation rule could be in its own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

Taxes: Rates A, B, and C are all subject to the same taxes, so we could create calculation rules for each type of tax (State, County, and City) in a single group that could be used with all three rates. Again, these calculation rules could be in their own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

The Big Picture of Calculation Rule Eligibility Rules

You can use eligibility rules to define the criteria when a calculation rule should be applied (or skipped); for example,

- You may have a calculation rule that generates an employee discount. This calculation rule may have eligibility criteria that requires the person to have a given characteristic type and value (this assumes you use a person characteristic to identify employees) before the calculation rule is applied.
- You may have a calculation rule that applies a surcharge if the customer uses 25% more than they used in the same period in prior year.

> **Note**
>
> **Eligibility rules are optional.** If you add eligibility rules to a calculation rule, the calculation rule will be skipped or applied per the instructions in the rules. If you don't add eligibility rules to a calculation rule, however, the calculation rule will be executed – this is because calculation rules are eligible by default

The topics in this section describe eligibility rules.

- A Rate Component is Eligible by Default
- Defining Logical Eligibility Criteria
- Examples of Calculation Rule Eligibility Rules

A Rate Component is Eligible by Default

If you don't want to setup eligibility rules, you don't have to. If you don't specify eligibility rules on a calculation rule, it's eligible and will be processed by rate application.

Defining Logical Eligibility Criteria

Copyright © 2026, Oracle and/or its affiliates.

When you setup an eligibility criterion, you must define three things:

- The field to be compared
- The comparison method
- The comparison results

Criteria Comparison

You have the following choices in respect of identifying the **Criteria Field Type**:

- **Algorithm.** You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present an example later in this section to illustrate the power of this approach.
- **Bill Factor.** You can retrieve a bill factor value to use as a field value in the comparison.
- **Calc Line.** You can retrieve a calculation line amount to use as a field value. The value is derived by summing calculation lines defined as members of a target category.
- **Characteristic.** You can retrieve a characteristic value linked to any of the following:
  - The service agreement being billed
  - The service agreement's account
  - The main person linked to the service agreement's account
  - The characteristic premise linked to the service agreement
  - One of the service points linked to the service agreement
  - In addition, you can retrieve a characteristic value from the Characteristic Collection where values are derived while the rate is being calculated (characteristic values can be created by calculation rules)
- **Contract Quantity.** You can retrieve a contract quantity for the service agreement.
- **Service Quantity.** You can retrieve the value of a given service quantity from the SQ collection based on a specified UOM / TOU / SQI.
- **Historical Quantity.** You can derive a value based on the service agreement’s historical bill segment service quantities for the specified UOM / TOU / SQI.

You have the following choices in respect of identifying the **Comparison Method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value

Comparison Results

Once you have this information and have applied your comparison, you must define what action should be taken. You must specify what to do if the results are True, False, or Insufficient Data.

- **If True or False.** You have the option to apply the rule or not, or check the next condition.
- **If Insufficient Data.** You have the option apply the rule or not, check the next condition, or generate an error.

See Examples of Calculation Rule Eligibility Rules for illustrations of these rules.

Examples of Calculation Rule Eligibility Rules

The topics in this section provide examples about how to setup calculation rule eligibility rules.

Copyright © 2026, Oracle and/or its affiliates.

- A Calculation Rule with a Service Quantity Comparison
- A Calculation Rule with a Characteristic Lookup and Consumption Comparison
- A Calculation Rule with a Discount for Being on Autopay

A Calculation Rule with a Service Quantity Comparison

Imagine a calculation rule that is only eligible if the customer is a low-income customer and has used more than 1,000 kWh. This calculation rule would need the following eligibility rules:

- Customer is a low income customer
- The customer has used more than 1,000 kWh during the bill period

These rules will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Main person characteristic: Characteristic type = Low income indicator	= YES	Check next condition	Do Not Apply Rule	Do Not Apply Rule
20	SQ value: UOM = KWH	>= 1,000	Apply Rule	Do Not Apply Rule	Error

The criteria are similar - they retrieve a value and compare it to something:

The first criterion is fairly simple:

- **Field to Compare.** We indicate that the value of the Low Income Indicator characteristic is kept on the main person linked to the account should be retrieved. We assumed that this characteristic type has values of YES and NO.
- **Comparison Method and Results.** We indicate that if the person has a characteristic value of YES, then we should check the next condition; otherwise, we indicate if the eligibility rule is false or there is insufficient data, the calculation rule is skipped.

TThe second criterion works similarly:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KWH that should be retrieved.
- **Comparison Method and Results.** We simply compare the value to 1,000. If the SQ is greater than or equal to 1000, the eligibility rule is True and the calculation rule is applied. If the SQ is less than 1000, the eligibility rule is false and the calculation rule is skipped. If there is insufficient data, there is an error generated.

A Calculation Rule with a Characteristic Lookup and Consumption Comparison

Imagine a calculation rule that is eligible for customers who have signed up for a consumption reduction program and have low consumption. This would require the following criteria:

- Check that the customer has signed up for the reduction program.
- Check to see that the customer’s consumption is lower than the threshold.

Copyright © 2026, Oracle and/or its affiliates.

These rules will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Check if the customer has signed up for the reduction program	= Y	Check next condition	Do Not Apply Rule	Do Not Apply Rule
20	Check if consumption is less than the threshold	< = 100 Kilowatt	Apply Rule	Do Not Apply Rule	Do Not Apply Rule

The criteria are similar - they retrieve a value and compare it to something:

The first criterion works as follows:

- **Field to Compare.** We indicate the value of the reduction program characteristic type (CI_CLMSM) is found on the service agreement. We assumed that this characteristic type has values of Y and N.
- **Comparison Method and Results.** Comparison Method and Results. We indicate that if the service agreement has a characteristic value of Y, then we should check the next condition. If the condition is false or insufficient data, the calculation rule is skipped.

The second criterion works as follows:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KW that should be retrieved.
- **Comparison Method and Results.** We indicate that we want to compare the service quantity to the threshold (100 kW). If the service agreement's bill segment has a service quantity that is less than or equal to 100 kW, it is True and the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

A Calculation Rule with a Discount for Being on Autopay

Imagine a calculation rule that is only eligible if the current customer has signed up for Autopay. This calculation rule would need the following eligibility rule:

- Customer has Autopay

This rule will look as follows:

Seq	Field to Compare	Comparison Method	If TRUE	If FALSE	If Insufficient Data
10	Algorithm: check if customer has Autopay	= Y	Apply Rule	Do Not Apply Rule	Do Not Apply Rule

The criterion calls an algorithm that performs a logical comparison.

The criterion works as follows:

Copyright © 2026, Oracle and/or its affiliates.

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the account associated with the bill segment is on Autopay. If an autopay setup exists, then it returns a value of Y. If not, however, it returns N
- **Comparison Method and Results.** We simply compare the value returned by the algorithm to Y and indicate the appropriate response. If the condition is true, the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

> **Note**
>
> Refer to CI_CHK_APAY for more information about this algorithm.

Working with Calculation Groups and Rules

This section outlines how users work with calculation groups and calculation rules.

- Defining Calculation Groups
- Searching and Maintaining Calculation Groups
- Defining Calculation Line Category Types
- Maintaining Calculation Line Category Types
- Defining Calculation Rules
- Searching and Maintaining Calculation Rules
- Defining Calculation Rule Eligibility Criteria

Defining Calculation Groups

Use this procedure to define calculation groups.

- Select **Menu**, and then **Rates**, and then **Calculation Group**, and then **Add.**
- Enter a **Name** for the calculation group.
- Enter a short **Description** and **Detailed Description** for the group.
- Click **Save**.

> **Note**
>
> You can also add a calculation group directly from the Rate Schedule portal. The **Add Calculation Group** action on the Pre-Processing Calculation Groups, Rate Version Calculation Groups and Post-Processing Calculation Groups sections allows you to create the calculation group and link the new group to the Rate Schedule.

To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See Defining Calculation Rules for more information about creating calculation rules.

You can now create calculation rules for this group.

See About Calculation Groups for more information about calculation groups.

Copyright © 2026, Oracle and/or its affiliates.

Searching and Maintaining Calculation Groups

Use this procedure to search for and view a calculation group.

- Select **Menu**, and then **Rates**, and then **Calculation Group**, and then **Search.**
- Enter your search criteria.
  You can search by **Calculation Group** name or **Description**.
- Click **Refresh**.
- In the search results list, click the **Description** link for the calculation group you want to view or edit.
  The selected calculation group is displayed in the **Calculation Group** portal. You use this portal to maintain calculation groups. This portal includes the following zones:
  - **Calculation Group**: Defines basic information about calculation group
  - **Calculation Rules List**: lists the calculation rules belonging to the group. Eligibility criteria referenced by a calculation rule are listed indented beneath each rule. If a calculation rule in turn references a calculation group, the calculation group executed by the rule is displayed.
  - **Referencing Rates Schedules List**: lists the rates schedules that reference the group
  - **Referencing Calculation Rules List**: lists the calculation rules that reference the group

Use this procedure to maintain a calculation group:

- Select **Menu**, and then **Rates**, and then **Calculation Group**, and then **Search** to navigate to the Calculation Group Query portal.
- Search for and select the appropriate calculation group.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See Defining Calculation Rules for more information about creating calculation rules.
- To update the sequence values for all calculation rules in the group, click the **Resequence All Rules** link in the **Calculation Rules List** zone title bar.
  - Edit the sequence values for all rules by specifying new **Start Sequence** and **Increment By** values**.**
  - Click **OK** to update the calculation rules with new sequence numbers.
- To Edit or Delete a specific calculation rule in the group, select the **Edit** or **Delete** icon in the Calculation Rules List zone as appropriate.
- To Delete one or more of the calculation rules in the group:
  - Select one or more of the calculation rules you want to delete.
  - Click **Delete Calc Rules.**
  - Click **OK** to delete the selected calculation rules
- To update the bill print details for one or more of the calculation rules in the group:
  - Select one or more of the calculation rules for which you want to change the bill print details.

Copyright © 2026, Oracle and/or its affiliates.

- Click **Update Bill Print.**
- Edit the bill print details for the selected calculation rules.
- Click **Save** to update the selected calculation rules with the new bill print details.

- To change the sequence values for one or more of the calculation rules in the group:
  - Select one or more of the calculation rules for which you want to change the sequence values.
  - Click **Resequence Rules.**
  - Edit the sequence values for all the selected calculation rules.
  - Click **Save** to update the selected calculation rules with the new sequence values.

See About Calculation Groups for more information about calculation groups.

Defining Calculation Line Category Types

Use this procedure to define calculation line category types.

- Select **Menu**, and then **Rates**, and then **Calculation Line Category Type**, and then **Add.**
- Enter a **Category Type** name for the category type.
- Enter a short **Description** and **Detailed Description** for the category type.
- Define the **Category Value** and **Description** for each value for the category type.
- Click **Save**.

You can now reference this category and its values as either the Member Category or Target Category on calculation rules.

See "Calculation Line Category Types" in About Calculation Rules for more information about calculation line category types.

Maintaining Calculation Line Category Types

Use this procedure to search for and maintain calculation line category types.

- Select **Menu**, and then **Rates**, and then **Calculation Line Category Type**, and then **Search.**
  The **Calculation Line Category Type List** zone displays the calculation line category types defined in the system.
- Click the broadcast icon for the calculation line category type you wish to view and/or edit. The selected calculation line category type is displayed in the **Calculation Line Category Type** zone.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.

See "Calculation Line Category Types" in About Calculation Rules for more information about calculation line category types.

Defining Calculation Rules

Use this procedure to define calculation rules.

- Select **Menu**, and then **Rates**, and then **Calculation Rule**, and then **Add.**

Copyright © 2026, Oracle and/or its affiliates.

- Select the **Calculation Group** to which the rule will belong.
- Select the **Calculation Rule BO** for the calculation rule.
  Refer to Base Package Calculation Rule Descriptions for detailed descriptions of the available calculation rules and their associated business objects.
- Enter name for the **Calculation Rule**.
- Enter the **Sequence** for the rule. This designates the order in which the rule will be executed within its parent calculation group.
- Enter a short **Description** and **Detailed Description** for the rule.
- Enter or select other parameters for the rule as appropriate.
  Refer to Base Package Calculation Rule Descriptions for detailed descriptions of the available calculation rules and the parameters used by each.
- Click **Save**.

See About Calculation Rules for more information about calculation rules.

- How to Use Description on Bill

How to Use Description on Bill

Enter the verbiage to appear on the bill segment in the **Description On Bill**. Turn on **Print** if the verbiage should appear on the printed bill.

> **Note**
>
> **Suppressing calculation details on the printed bill.** Only calculation rules that are used to calculate intermediate values are typically suppressed on a bill. For these types of calculation rules, we recommend using **Description on Bill** to show users how the line was calculated, but select No from the **Print** dropdown menu. This way, users will see the calculation details on the Bill Segment - Calc Lines window, but the customer won't see it on their bill.

Many lines that appear on a bill do not contain static verbiage. Rather, the printed lines contain information from the calculation process. For example, the bill line for state tax would typically contain the tax percent.

You control exactly what is substituted in the bill line by entering one or more of the following substitution variables in the **Description on Bill** field:

> **Note**
>
> If none of the following substitution characters satisfy your need, there is a plug-in option on the calculation rule business object that allows customer modified variables. Algorithms can be attached to the business object as a Build Line Description system event.

Substitution Character	What It Does

Copyright © 2026, Oracle and/or its affiliates.

%A	Replaces the substitution character with the amount of the bill line. Please be aware of the following: • If the calculation rule isn't designated as being "for calculation purposes only" (FCPO), all trailing zeroes up to the decimal position of the rate's currency will be removed. If the calculation rule is designated as being "for calculation purposes only" (FCPO), the number of decimal places as defined in the calculation rule's precision will be shown. • All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place. • The Symbol on the Currency control table will prefix the value. • The position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process).
%B	Replaces the substitution character with the begin/start date covered by the bill calculation line. If the charge is proratable, %B may be used in conjunction with %E to display the period covered by the bill calculation line.
%C	Replaces the substitution character with the number of items being billed. Leading zeroes are suppressed.
%D	Replaces the substitution character with message 10101 from message category 11109. This message is maintained in the standard message table. We recommend this message be set to "(prorated for %1 of %2 days)" where %1 will be substituted with the number of days of prorated consumption charged on the bill line and %2 will be the "normal" days associated with the rate's prices. This message will only be substituted when the calculation rule is prorated. Note, neither %1 nor %2 are required. Either this character OR %F should be used when you desire to substitute the price / percent into the bill line. If the charge is proratable, %D should be used in conjunction with %R to print an appropriate message when the charges are prorated.
%E	Replaces the substitution character with the end date covered by the bill calculation line. If the charge is proratable, %E may be used in conjunction with %B to display the period covered by the bill calculation line.

Copyright © 2026, Oracle and/or its affiliates.

%F	Replaces the substitution character with message 10102 from message category 11109. This message is maintained in the standard message table. We recommend this message be set to "(prorated by %1)" where %1 will be substituted with the factor used to prorate the charge. This message will only be substituted when the calculation rule is prorated. Note, %1 is not required. If the charge is proratable, %F should be used in conjunction with %I to print an appropriate message when the charges are prorated.
%H	Replaces the substitution character with the high value defined on the calculation rule used to calculate the specific stepped charge on the bill line.
%I	Replaces the substitution character with the value specified in the calculation rule / bill factor. If the value is a percent, • all leading and trailing zeroes will be suppressed, • and a "%" will be suffixed to the resultant value. If the value is not a percent, • all trailing zeroes up to the decimal position of the rate's currency will be removed, • and all leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place, • and note that the position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process). Either this character OR %R should be used when you desire to substitute the price / percent into the bill line. Using %I will cause the value as specified in the calculation rule to be substituted regardless of whether the charges are prorated. If the charge is proratable, %I should be used in conjunction with %F to print an appropriate message when the charges are prorated.
%L	Replaces the substitution character with the low value defined on the calculation rule used to calculate the specific stepped charge on the bill line.

Copyright © 2026, Oracle and/or its affiliates.

%M	Replaces the substitution character with the item type defined on the calculation rule used to calculate the specific item type charge on the bill line. This is only applicable to calculation rule-based rates.
%O	Replaces the substitution character with the description of the time-of-use (TOU) code being billed on this line
%Q	Replaces the substitution character with the service quantity being billed. Leading zeroes are suppressed. The decimal places shown are specified in a field on the Unit Of Measure control table. If you wish to suppress trailing zeroes after the decimal, you must set up the Allow Consumption Zero Suppression In Bill Description option type on the Financial Transaction Options Feature Configuration.
%R	Replaces the substitution character with the value specified in the calculation rule / bill factor. Either this character OR %I should be used when you desire to substitute the price / percent into the bill line. Using %R causes the prorated price / percent to be printed in the bill line (%I causes the price / percent as specified in the rate to be printed during proration situations). If the charge is proratable, %R should be used in conjunction with %D to print an appropriate message when the charges are prorated.
%S	Replaces the substitution character with the summed amount. All trailing zeroes up to the decimal position of the rate's currency will be removed. All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place. The Symbol on the Currency control table will prefix the value. If the value is negative, a "-" will prefix the value. This character should only be used with Minimum, Apply To, and Summary calculation rules.
%T	Replaces the substitution character with message 10103 from message category 11109. This message is maintained in the standard message table. We recommend this message be set to "(%1% exempt)" where %1 will be substituted with the tax exemption percent as specified in the service agreement. This message will only be substituted when the calculation rule's bill factor is eligible for tax exemptions AND the customer is exempt from the tax. Note, %1 is not required.

Copyright © 2026, Oracle and/or its affiliates.

%V	Replaces the substitution character with the "C1-ADDSC" characteristic ad hoc value retrieved by the calculation rule used to calculate the charge on the bill line.
Lines that don't print	If the bill line is not printed (as defined by the Print option), message 10104 from message category 4 will be appended to the bill line. This message is maintained in the standard message table. We recommend this message be "NOT SEEN BY CUSTOMER!" This message appears in the bill line that appears in the billing windows but does not appear on the customer's bill.

The following are examples of the content of common **Description on Bills** along with how the line would look on the customer's bill:

Description on Bill On Calculation Rule	How It Looks On A Bill
%C lamp pole(s) at %I per pole %F	1,234 lamp pole(s) at $5.00 per pole (prorated by .3333)
%C lamp pole(s) at %R per pole %D	1,234 lamp pole(s) at $1.50 per pole (prorated for 10 of 30 days)
First %Q kWh at %I per kWh %F	First 100.32 kWh at $0.12349 per kWh (prorated by .3333)
First %Q kWh at %R per kWh %D	First 100.32 kWh at $0.12349 per kWh (prorated for 10 of 30 days)
%Q kWh at %I per kWh	100.32 kWh at $0.12349 per kWh
State sales tax %R %T	State sales tax 6.25% (50% exempt)
Minimum charge of %I %F	Minimum charge of $10.00 (prorated by .3333)
Subtotal of %S	Subtotal of $1,123.23
Charges for %O: %Q kW at %I per kW	Charges for Off Peak Winter: 234.43 kW at $0.05 per kW

The prorated references will only appear if the calculation rule's charges are prorated due to a short or long bill period.

Searching and Maintaining Calculation Rules

Use this procedure to search for and maintain calculation rules.

- Select **Menu**, and then **Rates**, and then **Calculation Rule**, and then **Search.**
- Enter your search criteria.
  Available query options include **Calculation Rule** and **Calculation Rule BO**.
  - When searching by **Calculation Rule**, you can search by **Calculation Group**, **Calculation Rule** name, or **Description**.
  - When searching by **Calculation Rule BO**, you can search by **Business Object**, or **Description**.
- Click **Refresh**.

Copyright © 2026, Oracle and/or its affiliates.

- In the search results list, click the **Description** link for the calculation rule you want to view or edit. To navigate to the rule's calculation group, click the **Calculation Group** link. The selected calculation rule is displayed in the **Calculation Rule** portal. You use this portal to maintain calculation rules. This portal includes the following zones:
  - **Calculation Rule**: Defines basic information about calculation rule
  - **Eligibility Criteria List**: Lists optional eligibility criteria for the current calculation rule. Eligibility criteria are used to determine whether a calculation rule should be applied (or skipped) during rate processing.

Use this procedure to maintain a calculation rule:

- Select **Menu**, and then **Rates**, and then **Calculation Rule**, and then **Search** to navigate to the Calculation Rule Query portal.
- Search for and select the appropriate calculation rule.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To define eligibility criteria for the rule, click the **Add** link in the **Eligibility Criteria List** zone title bar. See "Eligibility Criteria" in About Calculation Rules for more information.

See About Calculation Rules for more information about calculation rules.

Defining Calculation Rule Eligibility Criteria

Use this procedure to define eligibility criteria for a calculation rule.

Prerequisites: You must create a calculation rule before you can define eligibility criteria.

- Click the **Add** link in the **Eligibility Criteria List** zone title bar.
- Enter a **Sequence** number, **Description**, and **Detailed Description** for the criteria.
- Complete the **Criteria Comparison** section as follows:
  - **Criteria Field**: the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
  - **Comparison Operator**: the operator used in the comparison
  - **Value**: a user-specified value to which the retrieved value is compared (using the comparison operator)
- Complete the **Comparison Results** section as follows:
  - **If True**: the action to take if the comparison is true
  - **If False**: the action to take if the comparison is false
  - **If Insufficient Data**: the action to take if there is insufficient data to perform the comparison
- Click **Save**.

See The Big Picture of Calculation Rule Eligibility Rules for more information.

Creating Rate Schedules

This section outlines how users work with rate schedules.

- Defining Rate Schedules

Copyright © 2026, Oracle and/or its affiliates.

- Searching and Maintaining Rate Schedules

Defining Rate Schedules

Use this procedure to define rate schedules.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu**, and then **Rates**, and then **Rate Schedule**, and then **Add.**
  The Rate Schedule maintenance screen opens. To navigate to the Component-Based Rate Schedule page, click **Switch to Component-Based**.
- Enter a code for the **Rate Schedule**.
- Enter a short **Description** for the rate schedule.
- Select the **Service Type** (Electric Service, Gas Service, etc.) for the rate schedule.
- Select the **Frequency** (monthly, quarterly, etc.) for the rate schedule
- Select the **Currency Code** used with the rate schedule.
- Select whether or not the rate schedule will **Allow Estimates** when performing calculations.
- Select whether or not the rate schedule will **Allow RV Proration** when performing calculations.
- Select the **RV Proration Date**, used if the rate schedule does NOT allow RV proration. Valid options include Accounting Date, Bill End Date, and Bill Start Date.
- Define the **Pre-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

  For each pre-processing calculation group, specify:

  – **Sequence**: The sequence in which the group is executed when the pre-processing groups are processed.

  – **Description**: A description of the calculation group

  – **Calculation Group**: The calculation group.

  Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.
- Define the **Rate Version Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

  For each rate version calculation group, specify:

  – **Effective Date**: The date on which each rate version calculation group becomes effective

  – **Description on Bill**: Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to How To Use Description on Bill for a discussion of the various substitution variables.

Copyright © 2026, Oracle and/or its affiliates.

  - **Calculation Group**: The calculation group.

  Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define the **Post-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

  For each post-processing calculation group, specify:

  - **Sequence**: The sequence in which the group is executed when the post-processing groups are processed.
  - **Description**: A description of the calculation group
  - **Calculation Group**: The calculation group.

  Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define one more recommended **Meter Configuration Types** for meters linked to service agreements (by way of their service points) for the rate schedule.
- Define one or more **Bill Messages** that should appear on bills that use the rate schedule. For each message, specify
  - **Bill Message**: The message that should appear on the bill.
  - The **Start Date** and **End Date** when the bill message should appear on the bill. Leave **End Date** blank if the message should appear indefinitely,
- Click **Save**.

This rate schedule can now be referenced on service agreements.

Searching and Maintaining Rate Schedules

Use this procedure to search for and view a rate schedule.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu**, and then **Rates**, and then **Rate Schedule**, and then **Search.**
- Enter your search criteria.
  You can search by **Rate Schedule**, **Description**, or **Rate Engine** (Calculation Rule-Based or Component-Based).
- Click **Search**.
- In the search results list, click the **Description** link for the rate schedule you want to view or edit.

> **Note**
>
> Component-based rate schedules will be highlighted by having "(Component-Based)" appended to their listing in the search results.

Copyright © 2026, Oracle and/or its affiliates.

- The selected rate schedule is displayed in the (Calculation Rule-Based) **Rate Schedule** portal. You use this portal to maintain rate schedule. This portal includes the following zones:
  - **Rate Schedule**: Defines basic information about the rate schedule.
  - **Rate Schedule Tree:** Displays the hierarchy of Calculation Groups and Calculation Rules for the Rate Schedule. Only the most recent rate version calculation group is initially displayed. In this zone you can:
    - Click a calculation group or calculation rule link to go to the Calculation Group or Calculation Rule portal for the associated calculation group or calculation rule.
    - Click the Broadcast icon for a calculation rule to open the Cross Reference Rule zone. This zone displays the rate schedule's calculation rules that are members of the broadcast calculation rule's target category.
    - Click the **Show All Rate Versions** button to display all rate versions for the rate schedule. This will also display the **Show Effective Rate Version** button, which you can use to display the information for the most recent rate version.

Use this procedure to maintain a rate schedule:

- Select **Menu**, and then **Rates**, and then **Rate Schedule**, and then **Search** to navigate to the Rate Schedule Query portal.
- Search for and select the appropriate rate schedule.
  - The selected rate schedule is displayed in the (new) **Rate Schedule** portal.
    - Click **Edit**, **Delete**, or **Duplicate** as appropriate.

> **Note**
>
> If you select a component-based rate schedule, the selected rate schedule is displayed in the (component-based) **Rate Schedule** page.

Base Package Calculation Rule Descriptions

This section provides detailed descriptions of each of the base package calculation rules provided with Oracle Utilities Customer Care and Billing. The descriptions of the calculation rules below contain the following information

- **Rule Name**: The name of the rule
- **Base Package Calculation Rule Business Object**: The base package business object used by the rule
- **Apply Calculation Rule Algorithm Type / Algorithm**: The base package algorithm type and algorithm specified in the "Apply Calc Rule" system event for the rule
- **Rule Parameters**: Parameters used to define the rule (if applicable). Does not include common parameters used by all rules (see Common Parameters).
- **Example**: One or more example configurations of the rule. Note that all examples use default values for all Apply Calculation Rule Algorithm Parameters.
- Common Parameters

Copyright © 2026, Oracle and/or its affiliates.

- Calculation Rule Validation
- Calculation Rules

Common Parameters

All calculation rules use the following common parameters:

- **Calculation Group**: The calculation group to which the rule belongs
- **Calculation Rule**: The user-defined name given to the calculation rule
- **Sequence**: The relative position of the calculation rule in respect of the other rules in the calculation group. This controls the order in which the system performs the calculation.
- **Description**: A short description of the rule. This is used as the Information String for the rule in the user interface.
- **Detailed Description**: A detailed description of the rule.

In addition, several of the base package calculation rules also use the following parameters:

- **Description On Bill**: The text that appears on the bill line generated for this calculation rule. Variables can be used to dynamically generate text (such as, price and quantity) when billing calculates the charges. Refer to How To Use Description on Bill for more information about available substitution variables.
- **Print** (Yes or No): A flag that specifies if the bill line created by this calculation rule should appear on the customer's bill. All bill lines are shown on Bill Segment - Calculation Details. However, only those lines marked as Print are presented to the customer.
- **Print If Zero** (Yes or No): A flag that specifies if a bill line should be printed if the bill line's value is zero.
- **Rounding Type**: This flag specifies if the calculated value should be rounded Down, Up, or Nearest. Used with Precision to control how the system rounds the rule's calculated value.
- **Precision**: This field defaults to a value consistent with the decimal positions defined on the rate schedule's currency code. Used with Rounding Type to control how the system rounds the rule's calculated value.
- **FCPO** (For Calculation Purposes Only): A flag that indicates if this calculation rule exists purely to calculate a value used by another calculation rule. When set to Yes, the system does not include the calculated amount in the bill total. The following are required when FCPO is set to Yes:
  - **Create Bill Line**: Determines if a bill line should be created for the rule (if there is no need to show the results to the customer or a user, there is no need to create a bill line).
  - **FCPO Retention Rule**: If a bill line created, this defines if the FCPO amount should be set to zero on the bill line or whether the bill line's amount should be set equal to the FCPO amount.
- **Override Proration**: A flag that specifies if an override proration algorithm should be used. This is used in situations when the standard proration logic does not satisfy your requirements. In this case, you may plug in an override proration algorithm to calculate the proration factors required by your implementation. This algorithm can be specified on the calculation rule business object or on the parent calculation rule business object if the override proration applies to all rates.

Copyright © 2026, Oracle and/or its affiliates.

- **Seasonal** (Yes or No): A flag that specifies if charges associated with the calculation rule are only levied during a specific season. If set to "Yes", the following must be specified:
  - **Season Start**: Defines the start of the season for the calculation rule.
  - **Season End**: Defines the end of the season for the calculation rule.
  - **Seasonal Prorate Method**: Defines how the system should prorate a seasonal charge when a bill segment's period is not entirely within the seasonal period. The following options are available:
    * **Accounting Date**, **Consumption End Date** and **Consumption Start Date** options will not prorate the charge calculated by the calculation rule. Rather, it will only calculate the charge if the accounting date associated with the bill segment is within the seasonal period, or if the consumption period's end date is within the seasonal period, or if the consumption period's start date is within the seasonal period respectively.
    * **Prorate** will prorate the calculation rule charge based on number of days in the season that is included in the bill period.
    * The **Prorate Seasonal SQ** option is only pertinent if you have:
      * Seasonal service quantity (SQ) charges, AND
      * Meters that measure seasonal consumption on separate registers, AND
      * You have a bill that crosses seasonal boundaries, AND
      * You have multiple rate version calculation groups effective across the bill period.
        If the Prorate Seasonal SQ option is used, the system will prorate the charge calculated by a SQ calculation rule based on the number of days in the season that is included in the rate version calculation group's period.
- **GL Distribution**: If the charge calculated by the calculation rule impacts the general ledger, you must define the distribution code used to construct the GL account.
  - **Distribution Code Source**: Specifies the type of GL distribution to use for this calculation rule.
    If the calculation rule's charges should be booked to a single GL account regardless of the service agreement's SA Type's revenue class, select the **Specific Distribution Code** source and enter a **Distribution Code**.

    If the calculation rule's charges are booked to a different GL account depending on the service agreement's revenue class, select the **Revenue Class** source and insert the appropriate **Revenue Class** and **Distribution Code** for each that uses the rate.
- **Cross Reference**: Defines the calculation line categories that the resultant calculation details belong to. For example, for a rate that calculates city and state taxes on consumption and demand based charges, the following categories could be used to calculate these taxes:
  - A calculation line category type called "Taxable" with a category value for City Tax and another for State Tax.
  - Each of the rate's calculation rules used for consumption and demand based charges should define the Member Category(s) that it belongs to ("Taxable - City Tax" and "Taxable - State Tax"). In other words, these rules would be defined as a member of the city tax and state tax categories.
  - The Apply To rules used to calculate city tax and state tax should define the respective Target Category(s) ("Taxable - City Tax" and "Taxable - State Tax") that they are applied to.
    There are two types of cross-reference categories:

Copyright © 2026, Oracle and/or its affiliates.

  - **Target Category**: Specifies the category that the calculation rule targets. Used with Apply To, Maximum Charge, and Minimum Charge calculation rules.
  - **Member Category**: Specifies the category to which the calculation rule belongs.
- **Characteristics**: Defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calc lines. You can indicate that “C1-ADDSC” characteristic ad hoc value of a bill line should be substituted into the bill line's description by using the %V substitution variable in the calculation rule's **Description On Bill** field.

Calculation Rule Validation

All calculation rules are validated when created to ensure they contain proper data needed to perform their calculations. The algorithms used to perform these validations are performed by the algorithms specified in the “Validation” system event on the calculation rule’s business object.

Calculation Rules

This section provides descriptions for the base package calculation rules.

- Apply To
- Calculate Final Reading Values
- Calculate Service Quantity
- Copy Service Quantity from Master Bill Segment
- Execute Calc Group
- Flat Charge
- Item Type
- Math
- Maximum Charge
- Minimum Charge
- Service Quantity
- Simple Summary
- Stepped Service Quantity
- Summary

Apply To

Apply To calculation rules create bill lines that levy charges based on amounts calculated on other bill lines. Apply To calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges to which "Apply To" rules will be applied must be defined as members of the target category. See **Cross-Reference** under Common Parameters for more information about Member and Target categories.

- **Rule Name**: Apply To
- **Base Package Calculation Rule Business Object**: C1-ApplyTo

Copyright © 2026, Oracle and/or its affiliates.

- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-APPLYTO
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    * **Error If No Value**: Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
    * **Seasonal**: See Common Parameters.
    * **Value Type**: Defines if the price is a Charge, Percentage or Unit Rate.
    * **Value Source**: specifies the source of the price. Depending on the value source selected, either a Bill Factor, Value, or Value Algorithm is required.
- **Example**: The following calculation rule applies a county tax other calculation rules that belong the "Taxable - County Tax" category.
  Calculation Group: Taxes

  Calculation Rule: CNTYTAX

  Sequence: 530

  Description: County Tax

  Description On Bill: County sales tax %R %T

  Print: Yes

  Print if Zero: No

  Rounding Type: Nearest

  Precision: 0.01

  FCPO: No

  Override Proration: No

  Calculation Details:
  - **Error If No Value**: No
  - **Seasonal**: No
  - **Value Type**: Percentage
  - **Value Source**: Bill Factor
  - **Bill Factor**: County Tax
    GL Distribution:
  - **Distribution Source Code**: Specific Distribution Code
  - **Distribution Code**: Payable - County Tax
    Cross Reference:
  - **Target Category (Category Type / Value)**: Taxable / County Tax
  - **Member Category (Category Type/Value)**: Summary Item / Summary Line

Calculate Final Reading Values

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQI.

- **Rule Name**: Calculate Final Reading Values

Copyright © 2026, Oracle and/or its affiliates.

- **Base Package Calculation Rule Business Object**: C1-CalculateFinalValue
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-CALCFNVL
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Unit of Measure**: The unit of measure for the measured quantity.
    - **Time of Use**: The time of use for the measured quantity.
    - **Service Quantity Identifier**: The service quantity identifier for the measured quantity.
    - **Retain Measured SQ**: indicates whether to save the accumulated measured quantity entry in the SQ collection. If this value is set to No, it means the value will be removed from the SQ collection. Before any pre-processing rule is executed, the rate engine will place the sum / max value of the read details into the SQ collection. For example, if the read details contain entries for measured CCF, there will be an entry in the SQ collection for the total CCF from all read details. This might be what is needed, but it may be extraneous if a rule converts the measured quantity into therms. In this situation, the SQ collection only needs therms and the CCF entry can be removed.
    - **Formula**: Defines the formula used to calculate the final read quantity. Bill Factors (or scalar variables) to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Measured Quantity is referenced as MQ in the formula Mathematical operations supported include addition, subtraction, multiplication and division. For example: (MQ * V1) would be the formula to convert CCF to THERM.
  - **Scalar Variables**: Defines the scalar variables or Bill Factors to be used in the calculation. When referenced in the formula, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Note that only regular bill factors may be used in the formula. Interval and Time of Use bill factors are not supported.
    - **Sequence**: Designates the number of the variable (V1, V2, etc.)
    - **Bill Factor**: The Bill Factor used for the variable.
  - **Result**: Defines the type of data (**Unit of Measure**, **Time of Use**, and/or **Service Quantity Identifier**) to be used for the final quantity calculated by the rule.
- **Processing**: The following processing takes place:
  - The rule will process each read detail whose initial UOM matches the measured quantity UOM.
  - It substitutes the reference to MQ in the formula with each read's measured quantity and then calls the formula service passing the defined bill factors as variables 1 to n. The read's end date is passed as the effective date.
  - It then populates each read's final value with the results of the formula and it populates the final UOM / TOU / SQI with the values defined on the rule.
  - It populates the SQ collection with the results (this will either add a new value if the Final UOM / TOU / SQI is not present in the SQ collection, OR it will update the existing SQ quantity with the sum or max of the calculated value depending on the Final UOM's measure's peak value). Note, the initial and final values of such an SQ will be the calculated value.

Copyright © 2026, Oracle and/or its affiliates.

- It then removes the measured UOM / TOU / SQI from the SQ collection if the rule has been configured as such.

- **Example**: This calculation rule converts CCF (as recorded on the meter) to therms for billing purposes.
  Calculation Group: CCF to Therm Conversion (Calculate SQ - SQ and BF)

  Calculation Rule: CCF2TH

  Sequence: 10

  Description: Convert CCF to TH

  Calculation Details:

  - **Unit of Measure**: 100 cubic feet of gas
  - **Retain Measured SQ**: Yes
  - **Formula**: MQ*V1*V2
    Scalar Variables (Sequence / Bill Factor):
  - 1 / Pressure adjustment zone
  - 2 /Take point for therm conv.fac
    Result:
  - **Unit of Measure**: Thermal units

Calculate Service Quantity

Calculate Service Quantity calculation rules derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection. Calculate Service Quantity calculation rules are generally used to either manipulate measured consumption, or to derive quantities that are not measured by a meter.

- **Rule Name**: Calculate Service Quantity
- **Base Package Calculation Rule Business Object**: C1-CalculateServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-CALC-SQ
- **Rule Parameters**:
  - **Scalar Variable 1 (Scalar Variable 2, Scalar Variable 3, ... Scalar Variable 5)**: Defines one of the scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.).
    - **Type**: Defines the type of variable and can be one of the following:
      - **Algorithm**: an algorithm is responsible for retrieving the scalar variable value, e.g. calculate number of days in the bill period.
      - **Bill Factor**: the value for a specified bill factor that is in effect for the period.
      - **Calculated Line**: the value is derived by summing previously calculated lines defined as members of a target category.
      - **Characteristic Value**: the value is derived by summing characteristic values of a given characteristic type.
      - **Contract Quantity**: the value for a given contract quantity type specified on a service agreement.
      - **Historical Service Quantity**: the value is derived based on the SA's historical bill segment service quantities for the specified UOM / TOU / SQI. The

Copyright © 2026, Oracle and/or its affiliates.

Aggregate Function defines the calculation to perform on the set of historical service quantities retrieved to derive a single value. Average, Maximum, Minimum and Sum are supported.

        - **Service Quantity**: service quantities from the bill period's SQ collection, based on a specified UOM / TOU / SQI. This type of variable allows this rule to make use of values calculated by other rules.
        - **Previous Quantity**: the value is derived from the SA's most recent frozen bill segment service quantities for the specified UOM / TOU / SQI.
    - **Missing Value Action**: Defines what should take place if the system is unable to retrieve or derive a value for a particular scalar variable. Valid options are as follows:
        - Select **Error** to create an exception
        - Select **Skip** to exit the rule and process the next rule
        - Select **Use Default Value** if the scalar variable should be set to the default value specified
- **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Calculation Rule Processing**: Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
    - **Fail Action**: Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
    - **Calculation Rule Output**: Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
    - **Retain SQ**: Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of No should be used for SQ entries that do not have to be retained for audit or analytic purposes.
    - **Formula Source**: Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
    - **Formula**: Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: (V1*V2)/2.
        - **Conditional Formula**: this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
            - **Operand 1**: the first operand in the condition. Can reference an expression with one or more scalar variables (designated as Vn), e.g. [V1+V2] or [(V1/V2)*V3].
            - **Operator**: the operator used to compare Operand 1 with Operand 2.

Copyright © 2026, Oracle and/or its affiliates.

        - **Operand 2**: the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
        - **True Action**: indicates how to proceed if the comparison between the operands is true. Can be one of the following:
          Apply True Formula: indicates that the True Formula be executed.

          Check Next Condition: indicates that the next condition should be checked.
        - **True Formula**: the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as Vn), or a constant.
        - **False Action**: indicates how to proceed if the comparison between the operands is false. Can be one of the following:
          Apply False Formula: indicates that the False Formula be executed.
        - **Check Next Condition**: indicates that the next condition should be checked.
        - **False Formula**: the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IVn, where n is the number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as Vn).
    - **Result**: Define the **Unit of Measure**, **Time of Use** and/or **Service Quantity Identifier** to be used if this calculation rule inserts or updates a service quantity in the bill period's SQ collection.

- **Example**: This calculation rule calculates total kWh from On Peak and Off Peak service quantities.
  Calculation Group: Calculate KWH

  Calculation Rule: TOTKWH

  Sequence: 10

  Description: Total amount of KWH (On Peak + Off Peak)

  Scalar Variable 1:

  - **Type**: Service Quantity
  - **Missing Value Action**: Error
  - **Unit of Measure**: Kilowatt hour
  - **Time of Use**: On Peak
  - **SQ To Use**: Billable
    Scalar Variable 2:
  - **Type**: Service Quantity
  - **Missing Value Action**: Error
  - **Unit of Measure**: Kilowatt hour
  - **Time of Use**: Off Peak
  - **SQ To Use**: Billable
    Calculation Details:
  - **Calculation Rule Processing**: Always
  - **Fail Action**: Error

Copyright © 2026, Oracle and/or its affiliates.

- **Calculation Rule Output**: Service Quantity
- **Retain SQ**: No
- **Formula Source**: Simple Formula
- **Formula**: V1 + V2
  Result:
- **Unit of Measure**: Kilowatt hour

Copy Service Quantity from Master Bill Segment

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQI.

- **Rule Name**: Copy Service Quantity From Master Bill Segment
- **Base Package Calculation Rule Business Object**: C1-CopySQFromMasterBillSegment
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-CPY-MB-SQ
- **Rule Parameters**:
  - **Characteristics**: Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
    - **Characteristic Type:** Defines the characteristic type that is to be associated to the calculation rule.

      > **Note**
      >
      > Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to Defining Characteristic Types for information on how to set up characteristic types.

    - **Characteristic Value**: Defines the parameter value that will be associated to the characteristic type.

Execute Calc Group

Execute Calc Group calculation rules call another calculation group, and pass characteristics and their values to the referenced calculation group.

- **Rule Name**: Execute Calculation Group
- **Base Package Calculation Rule Business Object**: C1-CalcRuleReferredCalcGroup
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-ACALR-RFG
- **Rule Parameters**:
  - **Referenced Calculation Group**: Defines the calculation group that's being called.
    - **Calculation Group**: Defines the calculation group that's being called.
  - **Characteristics**: Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
    - **Characteristic Type:** Defines the characteristic type that is to be passed to the referenced calculation group.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to Defining Characteristic Types for information on how to set up characteristic types.

Characteristic Value: Defines the parameter value that will be associated to the characteristic type.

Flat Charge

Flat Charge calculation rules create bill lines that levy service charges and fees that aren't based on how much the customer uses. For example a flat charge calculation rule may be used to apply a monthly service charge of $10 to a customer's bill.

- **Rule Name**: Flat Charge
- **Base Package Calculation Rule Business Object**: C1-FlatCharge
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-FLAT-CHRG
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Seasonal**: See Common Parameters.
    - **Value Type**: Defines the type of value to use for the rule. For Flat Charge rules, this should be set to **Charge**.
    - **Value Source**: Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
- **Example**: This calculation rule levies a customer charge.
  Calculation Group: Customer Charge

  Calculation Rule: CSTCHG

  Sequence: 20

  Description: Customer Charge

  Description On Bill: Customer Charge

  Print: Yes

  Print if Zero: No

  Rounding Type: Nearest

  Precision: 0.01

  FCPO: No

  Override Proration: No

  Calculation Details:
  - **Seasonal**: No
  - **Value Type**: Charge
  - **Value Source**: Value

Copyright © 2026, Oracle and/or its affiliates.

- **Value**: 5
  GL Distribution:
- **Distribution Source Code**: Specific Distribution Code
- **Distribution Code**: Revenue - Energy
  Cross Reference:
  - **Member Category (Category Type / Value)**: Subject to tax / City taxable

Item Type

Item Type calculation rules create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.

- **Rule Name**: Item Type
- **Base Package Calculation Rule Business Object**: C1-ItemType
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-ITEMTYPE
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Seasonal**: See Common Parameters.
    - **Item Type**: Defines the types of items to which charges are applied. When defining more than one item type on a single calculation rule, you can indicate that the item type of a bill line should be substituted into the bill line's description by using the %M substitution variable in the calculation rule's **Description On Bill** field.
      - **Error If No Value**: A flag that indicates (Yes or No) if a bill error should be generated if the item type specified on the calculation rule was not supplied at billing time.
      - **Value Type**: Defines the type of charge. Valid options include Charge, Percentage, or Unit Rate.
      - **Value Source**: Defines the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
      - **Value/Bill Factor/Algorithm**: The specific Value, Bill Factor, or Algorithm that serves as the source of the price used to calculate the charge.
- **Example**: This calculation rule calculates charges for light poles.
  Calculation Group: Lamp Charges

  Calculation Rule: POLE CHARGE

  Sequence: 10

  Description: Pole Charge

  Description On Bill: %C lamp poles at %R per pole %D %I

  Print: Yes

  Print if Zero: No

  Rounding Type: Nearest

  Precision: 0.01

Copyright © 2026, Oracle and/or its affiliates.

FCPO: No

Override Proration: No

Calculation Details:

- **Seasonal**: No
- **Items**:
  - **Item Type**: Pole(s)
  - **Error If No Value**: No
  - **Value Type**: Unit Rate
  - **Value Source**: Value
  - **Value / Bill Factor /Algorithm**: 3
    GL Distribution:
- **Distribution Source Code**: Specific Distribution Code
- **Distribution Code**: Revenue - Area Lighting
  Cross Reference:
- **Member Category (Category Type / Value)**: Charges / Total Charges
- **Member Category (Category Type / Value)**: Charges / Lamp Charges

Math

Math calculation rules derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities.

- **Rule Name**: Math
- **Base Package Calculation Rule Business Object**: C1-Math
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-MATH
- **Rule Parameters**:
  - **Vector 1 (Vector 2, Vector 3, ..., Vector 5)**: Defines one of the vectors (Vector 1, 2, 3, ..., 5) to be used in the calculation. When used in formulas, interval values for vectors are designated as IV1, IV2, IV3, ..., IV5.
    - **Vector Type**: Defines the type of vector. Valid options include **Interval Bill Factor** and **Interval Service Quantity**.
    - **Bill Factor**: Defines the Interval Bill Factor from which interval values are derived for the vector.
    - **Unit of Measure/Time of Use/Service Quantity Identifier**: The UOM/TOU/SQI used to retrieve interval values from either the usage request service quantity entries given a usage request ID and usage period, or from the rate engine buffer populated prior to calling rate application.
    - **Missing Interval Data Action**: Defines the action to take (**Error** or **Skip**) if interval data is missing for the expected period
  - **Scalars**: Defines scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n is the number of the variable (based on the sequence in which they are defined in the list).
    - **Scalar Type**: Defines the type of variable. Can be one of the following:

Copyright © 2026, Oracle and/or its affiliates.

        - **Bill Factor**: The value for a specified bill factor that is in effect for the billing period.
        - **Set Function**: The result of applying a function to a set of interval measurement values (defined as a vector).
        - **Service Quantity**: Service quantities from the current SQ list, based on a specified UOM, TOU, or SQI. This type of variable allows this rule to make use of values calculated by other rules.
    - **Bill Factor**: Defines the bill factor used to retrieve the variable value (applicable only if Scalar Type is Bill Factor)
    - **Unit of Measure**: Defines the UOM for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
    - **Time of Use**: Defines the TOU for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
    - **Service Quantity Identifier**: Defines the SQI for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
    - **SQ to Use**: Every service quantity supplied to a rate has two quantities; the quantity initially measured, and the quantity that should be priced by the rate. Most of the time these two amounts will be the same, unless another rule has executed and caused the billable quantity to change. Each rule needs to know if it should use the **Initial** or **Billable** quantity.
        - **Set Function**: Defines the function used to calculate a scalar value from a set of interval values (defined as a vector). This is applicable only if Scalar Type is Set Function). Can be one of the following:
            - **Average**: calculates the average of the vector's interval measurement values.
            - **Count**: returns the number of interval measurements.
            - **Max**: returns the maximum value from the vector's interval measurement values.
            - **Min**: returns the minimum value from the vector's interval measurement values.
            - **Total**: calculates the total of the vector's interval measurement values.
        - **Vector**: the vector to be used for this variable (applicable only if Scalar Type is Set Function). Can be one of the following:
            - **FV** (Final Vector Interval Value): the vector containing the results of the formula defined in the Calculation Details section.
            - **IV1** (Vector 1 Interval Value): the vector defined as Vector 1.
            - **IV2** (Vector 2 Interval Value): the vector defined as Vector 2.
            - **IV3** (Vector 3 Interval Value): the vector defined as Vector 3.
            - **IV4** (Vector 4 Interval Value): the vector defined as Vector 4.
            - **IV5** (Vector 5 Interval Value): the vector defined as Vector 5.
    - **Missing Value Action**: Defines the action to take (**Error**, **Skip**, or **Use Default Value**) if data is missing for the scalar variable for the expected period
    - **Default Value**: The default value to use if data is missing for the scalar variable. Applicable only if Missing Value Action is Use Default Value.
    - **Calculation Details**: Details regarding how the calculation rule performs its calculations:

Copyright © 2026, Oracle and/or its affiliates.

* **Calculation Rule Processing**: Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
* **Fail Action**: Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
* **Calculation Rule Output**: Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
* **Retain SQ**: Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of No should be used for SQ entries that do not have to be retained for audit or analytic purposes.
* **Formula Source**: Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
* **Formula**: Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: (V1*V2)/2.
    * **Conditional Formula**: this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
        * **Operand 1**: the first operand in the condition. Can reference an expression with one or more scalar variables (designated as Vn), e.g. [V1+V2] or [(V1/V2)*V3].
        * **Operator**: the operator used to compare Operand 1 with Operand 2.
        * **Operand 2**: the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
        * **True Action**: indicates how to proceed if the comparison between the operands is true. Can be one of the following:
          Apply True Formula: indicates that the True Formula be executed.

          Check Next Condition: indicates that the next condition should be checked.
        * **True Formula**: the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as Vn), or a constant.
        * **False Action**: indicates how to proceed if the comparison between the operands is false. Can be one of the following:
          Apply False Formula: indicates that the False Formula be executed.
        * **Check Next Condition**: indicates that the next condition should be checked.
        * **False Formula**: the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IVn, where n is the

Copyright © 2026, Oracle and/or its affiliates.

number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as Vn).

- **Result**: Defines how service quantities are inserted into the SQ list. Math calculation rules can insert one or more entries into the SQ list.
  - **Result Source**: Defines the method to use to calculate for the service quantity. Can be one of the following:
    - **Set Function Against Derived Vector**: Applies a function to the derived interval values. The function to be applied is specified in the Set Function field.
    - **Scalar Formula Result**: Applies a user-defined formula. The formula is specified in the Scalar Formula field.
  - **Set Function**: the function to apply to the derived interval values (applicable only if Result Source is set to Set Function Against Derived Vector). Can be one of the following:
    - **Average**: Calculates the average of the derived interval measurement values.
    - **Count**: Returns the number of derived interval measurements.
    - **Max**: Returns the maximum value from the derived interval measurement values.
    - **Min**: Returns the minimum value from the derived interval measurement values.
    - **Total**: Calculates the total of the derived interval measurement values.
  - **Scalar Formula**: the formula to apply (applicable only if Result Source is set to Scalar Formula). Variables used in this formula must be defined in the Scalars section. When referenced in formulas, scalar variables are designated as Vn (where n is the number of the variable).
  - **Unit of Measure**: the UOM to be used when inserting service quantity entries
  - **Time of Use**: the TOU to be used when inserting service quantity entries
  - **Service Quantity Identifier**: the SQI to be used when inserting service quantity entries
  - **Apply TOU Map**: Indicates if a TOU map should be applied to the derived interval values. If TOU periods and values are returned as a result of TOU mapping, then service quantity entries are inserted.
  - **TOU Map**: Defines the TOU Map to apply to the derived interval values (applicable only if Apply TOU Map is set to Yes).
  - **TOU Mapping Function**: Defines the function to apply to the derived interval values when calculating for the time of use values (applicable only of Apply TOU Map is set to Yes). Can be one of the following:
    - **Max**: Returns the maximum value from the derived interval values for each TOU period.
    - **Sum**: Returns the sum of the derived interval values for each TOU period.

- **Processing**:
  Math rules derive interval values based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate billing quantities. Examples include the following:
  - Derive an interval data curve (vector) given a formula. For example, derive a power factor curve given a formula using kWh and kVarh curves.

Copyright © 2026, Oracle and/or its affiliates.

- Apply TOU mapping to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the result.
- Perform mathematical operations on SQ entries. For example, get total kWh consumption by adding "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" where "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" were calculated by a previous calculation rule.
  Each interval data curve is defined as a vector parameter (the rule can define up to 5 vectors). Mathematical operations defined by the "Vector Processing" parameters can be performed between vectors (e.g. IV1 * IV2) and between vectors and scalar variables (e.g. IV1 * V1).

- **Example**: This calculation rule calculates prices for interval usage by multiplying an interval service quantity times an interval price bill factor.

Maximum Charge

Maximum Charge calculation rules are used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount. Maximum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the maximum is levied on must be defined as members of the target category. See **Cross-Reference** under Common Parameters for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a maximum discount of $ -2.00 and previous calculation rules have calculated a discount of $ -3.00. You want a calculation rule to create a bill line for $1.00 to reduce the discount. A maximum charge calculation rule will not work in this case because -3 is considered less than -2. For this business scenario you should use a Minimum Charge calculation rule.

Note: Maximum Charge calculation rules are rare. You tend to only see them in deregulated markets where customers have agreed to pay the market rate but want a cap on the maximum they'll pay each bill period.

- **Rule Name**: Maximum Charge
- **Base Package Calculation Rule Business Object**: C1-Maximum
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-MAXIMUM
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Error If No Value**: Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
    - **Seasonal**: See Common Parameters.
    - **Value Type**: Defines the type of value to use for the maximum value for the rule. For Maximum Charge rules, this should be set to **Charge**.
    - **Value Source**: Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
- **Example**: This calculation rule sets a maximum charge for area lighting.
  Calculation Group: Customer-Owned Street & Highway Lighting

  Calculation Rule: MAXCHRGE

Minimum Charge

Minimum Charge calculation rules create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount. Minimum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the minimum is levied on must be defined as members of the target category. See **Cross-Reference** under Common Parameters for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a minimum discount of $ -2.00 and previous calculation rules have calculated a discount of $ -1.00. You want a calculation rule to create a bill line for $ -1.00 to apply a further discount. A minimum charge calculation rule will not work in this case because -1 is considered more than -2. For this business scenario you should use a maximum charge calculation rule.

- **Rule Name**: Minimum Charge
- **Base Package Calculation Rule Business Object**: C1-Minimum
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-MINIMUM
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Error If No Value**: Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
    - **Seasonal**: See Common Parameters.
    - **Value Type**: Defines the type of value to use for the minimum value for the rule. For Minimum Charge rules, this should be set to **Charge**.
    - **Value Source**: Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
- **Example**: This calculation rule defines a minimum charge for use with residential electric rates.

- **Member Category (Category Type / Value)**: Taxable - City Tab

Service Quantity

Service Quantity calculation rules create bill lines that levy charges based on some type of consumption.

Frequently the amount consumed is measured by a meter's registers and sometimes it's calculated using Pre-Processing calculation and sometimes it's derived based on the type of item (such as, lamps). Regardless of how the amount consumed is calculated, the charge for the consumption amount is levied using this type of calculation rule.

- **Rule Name**: Service Quantity
- **Base Package Calculation Rule Business Object**: C1-ServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-SQ
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    * **Unit of Measure**: The UOM used as the service quantity that the price is applied to.
    * **Time of Use**: The TOU used as the service quantity that the price is applied to.

Copyright © 2026, Oracle and/or its affiliates.

    - **Service Quantity Identifier**: The SQI used as the service quantity that the price is applied to.
    - **Error If No Value**: A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
    - **Measures Peak**: Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
    - **GL Statistical Qty**: A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
    - **Seasonal**: See Common Parameters.
    - **Value Type**: Defines the type of price to be used in the rule's calculations. Valid options include Charge, Percentage, or Unit Rate.
    - **Value Source**: Defines the source of the price used in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.

- **Example**: This calculation rule calculates charges based a customer's KWH consumption.

        - **Category Value**:
    - **Member Category (Category Type / Value)**: Revenue / Consumption Charge

Simple Summary

Simple Summary calculation rules create a "subtotal" on the bill by summarizing bill lines produced by other calculation rules in the same calculation group.

- **Rule Name**: Simple Summary
- **Base Package Calculation Rule Business Object**: C1-SimpleSummary
- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-SIMP-SUMM
- **Rule Parameters**:
    - **Referenced Calculation Rules**: Defines the calculation rules that should be included in the summary. Note that any calculation rules listed here must belong to the same calculation group as the Summary rule.
- **Example**: This calculation rule creates a summary of TOU-based charges (based on rules within the same calculation group as this rule).
  Calculation Group: Commercial TOU Electric Charges

  Calculation Rule: KWHTOT

  Sequence: 40

  Description: Consumption Subtotal

  Description On Bill: Consumption Subtotal

  Print: Yes

  Print if Zero: No

  Rounding Type: Nearest

  Precision: 0.01

  FCPO: No

  Referenced Calculation Rules:

    - Off Peak - kWh
    - On Peak - kWh
    - Shoulder Peak - kWh
      Cross Reference:
    - **Member Category (Category Type / Value)**: Taxable / State Tax

Stepped Service Quantity

Stepped Service Quantity calculation rules create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are $0.43 per kWh, anything in excess of 50 kWh is charged at $0.71 per kWh)

- **Rule Name**: Stepped Service Quantity
- **Base Package Calculation Rule Business Object**: C1-SteppedSQ

Copyright © 2026, Oracle and/or its affiliates.

- **Apply Calculation Rule Algorithm Type / Algorithm**: C1-STPD-SQ
- **Rule Parameters**:
  - **Calculation Details**: Details regarding how the calculation rule performs its calculations:
    - **Unit of Measure**: The UOM used as the service quantity that the price is applied to.
    - **Time of Use**: The TOU used as the service quantity that the price is applied to.
    - **Service Quantity Identifier**: The SQI used as the service quantity that the price is applied to.
    - **Error If No Value**: A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
    - **Measures Peak**: Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
    - **GL Statistical Qty**: A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
    - **Create Step Summary**: Stepped service quantity calculation rules may be configured with either a single step or multiple steps. The Create Step Summary flag is used to produce a summary bill segment calculation line if the calculation rule has multiple steps. Valid options include:
      - **Summarize Step Lines, Print**: Creates a stepped charge summary bill line that will appear on the customer's bill.
      - **Summarize Step Lines, Do Not Print**: Creates a stepped charge summary bill line that will be shown on Bill Segment - Calculation Details, but not appear on the customer's bill.
  - **Step Calculation Details**:
    - **Seasonal**: See Common Parameters.
    - **Step Multiplier Algorithm**: Specifies the algorithm that will be used calculate the step boundaries. Used only if step boundaries are dynamic and are calculated based on something that's only known at billing time.
    - **Values**: Defines the values associated with each of the ranges (steps) of consumption used by the rule. For example, if the charge is applicable to the first 300 kilowatt-hours, you would enter **Step Start** 0 and **Step End** 300. When multiple tiers exist, the **Step End** of the first tier is the **Step Start** of the second tier (and so on). To extend our example, the second tier would have a **Step Start** of 300; the **Step End** may be left blank (the system assumes a blank **Step End** means "to infinity"). When defining negative steps, the **Step Start** value must be higher than the **Step End**. For example, if a step ranged from -200 to -400, -200 is a higher value than -400 so the **Step Start** would be -200 and the **Step End** would be -400.
      - **Sqeuence**: Used by the rule (along with the **Step Start** and **Step End**) to order the evaluation of the billable service quantity against the tier. This is particularly important and should be set properly for negative steps which must be configured from high to low.

Copyright © 2026, Oracle and/or its affiliates.

        * **Step Start**: Defines the start value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999,999.9999).
          You can indicate that the **Step Start** of a bill line should be substituted into the bill line's description by using the %L substitution variable in the calculation rule's **Description On Bill** field.
        * **Step End**: Defines the end value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999,999.9999).
          You can indicate that the **Step End** of a bill line should be substituted into the bill line's description by using the %H substitution variable in the calculation rule's **Description On Bill** field.
        * **Value Type**: Defines the type of price to be applied to the consumption range in the rule's calculations. Valid options include Charge, or Unit Rate.
        * **Value Source**: Defines the source of the price to be applied to the consumption range in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
        * **Value/Bill Factor/Algorithm**: Specifies the Bill Factor, Value, or Algorithm used when calculating charges for the consumption range.

- **Example**: This calculation rule calculates charges for electric service based on stepped charges for kWh consumption during the Fall

Summary

Summary calculation rules create a "subtotal" on the bill. It exists purely for reporting and informational purposes. Summary calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges should be included in the summary must be defined as members of the target category. See **Cross-Reference** under Common Parameters for more information about Member and Target categories.

- **Rule Name**: Summary
- **Base Package Calculation Rule Business Object**: C1-Summary

Rate Check

This section describes the features and functionality of Rate Check.

- About Rate Check
- Performing a Rate Check
- Viewing the Results of a Rate Check

About Rate Check

The **Rate Check** feature allows you to test your rate schedules under different scenarios. For example, you can test your rates for an existing account using previous bill segments, or by providing user-specified bill period and service quantities.

Performing a Rate Check

> **Note**
>
> The Rate Check portal works with both calculation rule-based and component-based rate schedules.

Use this procedure to perform a rate check.

- Select **Menu**, and then **Rates**, and then **Rate Check.**
- Select the **Rate Schedule** for the rate check.
- Select the **Service Agreement** for the rate check.
- Select the **Bill Segment** for the rate check (if you wish to base the rate check on an existing bill segment).
- Enter the **Start Date**, **End Date**, and **Accounting Date** for the rate check.
- Select the **Revenue Class** for the rate check.
- If you are basing the rate check on user-specified **Service Quantities**, enter the following for each as applicable:

Copyright © 2026, Oracle and/or its affiliates.

  - **UOM**: The unit of measure applicable for the rate check (based on the specified rate schedule)
  - **TOU**: The time of use applicable for the rate check (based on the specified rate schedule)
  - **SQI**: The service quantity identifier applicable for the rate check (based on the specified rate schedule)
  - **Measured Quantity**: The amount of the service quantity specified.
  - **Service Point ID**: The service point which recorded the service quantities, if applicable Note: If you specified a Service Agreement with a Bill Segment and/or Start and End Dates, this section is populated based on the selected data, but can be manually updated.
- If you are basing the rate check on user-specified **Items**, enter the following for each as applicable:
  - **Item Type**
  - **Start Date**: The start date of the consumption period.
  - **End Date**: The end date of the consumption period
  - **Item Count**: The number of items for the specified Item Type.
  - Note: If you specified a Service Agreement with a Bill Segment and/or Start and End Dates, this section is populated based on the selected data, but can be manually updated.
- Specify characteristic types and values for any **Characteristics** are applicable to the rate check. Characteristic types and values are used to apply appropriate bill factor values during rate processing.
- If you are using a calculation rule-based rate schedule, specify if the system **Should Trace** the process. This produces logs that outline the calculation groups and rules used by the rate schedule.
- Perform the rate check:
  - If you wish to perform the rate check using a specified bill segment or service quantities or items, click **Check Rate**.
  - If you wish to execute the rate check using billing determinants retrieved from an external system (such as Oracle Utilities Meter Data Management), select the appropriate function from the **Select Function** dropdown list.

Refer to the Rate Check portal's embedded help, for more information.

Viewing the Results of a Rate Check

The outcome of the rate check process is displayed on the **Results** tab. This tab contains the following zones:

- **Main**: Displays results of the rate check, including:
  - **Rate Schedule**: The rate schedule used in the rate check
  - **Revenue Class**: The revenue class used for the rate check.
  - **Bill Period**: The start and end dates for the bill period used by the rate check.
  - **Consumption Period**: The start and dates for the consumption period used by the rate check.

Copyright © 2026, Oracle and/or its affiliates.

  - **Accounting Date**: The Accounting Date used by the rate check.
  - **Calculated Amount**: The calculated total for the rate check
- **Calculation Lines**: Displays the bill calculation headers and lines for the rate schedule.
- **Read Details**: Displays meter read details for the consumption used in the rate calculation.
- **SQ Details**: Displays a list of service quantities used in the rate calculation.
- **Characteristics**: Displays characteristics referenced by the rate calculation (if applicable).
- **Trace Log**: Displays logs that outline the calculation groups and rules used by the rate schedule. This zone is populated only if using a calculation rule-based rate schedule, and if the Should Trace dropdown list is set to "No".

Effective Dates and Price Proration

This section describes how proration applies to different types of calculation rules. Proration implies assessing charges proportionately.

The term "proration" describes two different issues:

- Prorating a charge whose value changes during a bill period. For example, if a tax rate changes during a bill period and you've indicated that such changes should be prorated, the system prorates the tax change (e.g., 20 days at 5% and 10 days at 6%).
- Prorating charges when the time period being billed is not in sync with the time period in which the charges were defined in the rate. For example, if a rate contains a flat monthly charge and the bill period spans two months, the flat charge must be prorated.

This is a complicated topic as it's possible for many proration issues to exist on a single bill. For example, on a single bill:

- The rate structure can change several times during the bill period (i.e., multiple rate versions are effective).
- The taxing authority changes the tax rate.
- The customer's tax exemption changes.
- The customer-specific price can change.
- etc.

Types of Proration

The following section describes the types of proration performed by applying a rate.

NOT_SUPPORTED

For more information on how prorated charges are presented on the printed bill, refer to How To Use Description On Bill.

- Consumption Period Proration
- Calculation Period Proration
- Bill Factor Proration
- A Service Agreement's Rate Changes Are Not Prorated

Consumption Period Proration

A rate schedule specifies its frequency. Bill segments generated using a rate are expected to have a consumption period that corresponds to this frequency. When a bill segment's consumption period falls outside of the rate frequency's normal period, proratable service quantities may be adjusted to match the normal period for calculation. The service quantities are then re-adjusted based on calculation period proration.

NOT_SUPPORTED

Refer to Service Quantity Proration for more information about these calculations.

Calculation Period Proration

There can be multiple versions of a given rate over time. Each version has an effective date. When the system detects that a rate schedule has multiple versions of a rate in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the rate schedule's proration parameters.

If multiple rate versions are effective during the consumption period and the rate schedule is configured to prorate the rate versions, a given bill segment will contain a set of bill calculation lines for each rate version. You should consider quite carefully how to handle this situation on your printed bills as rate version proration can confuse a customer.

NOT_SUPPORTED

Refer to Defining Calculation Rules for more information.

Copyright © 2026, Oracle and/or its affiliates.

Bill Factor Proration

A rate contains calculation rules. The primary reason a calculation rule exists is to define how much to charge for the services sold by your company. When you create calculation rules, you have two ways to indicate how much to charge:

- You can specify the value directly in a calculation rule.
- You can have the calculation rule use a bill factor that contains the value.

Bill factors are effective-dated (meaning, their values may change over time). When the system detects that a calculation rule's bill factor has multiple values in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

> **NOT_SUPPORTED**
>
> Refer to Defining Bill Factors and Bill Factor Value Proration for more information.

- Tax Exemption Proration
- Contract Value Proration
- Contract Rider Proration

Tax Exemption Proration

Bill factors that levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for tax exemptions will have their tax obligation reduced (or nullified) at billing time.

Whether or not a customer is tax exempt (and the percent exempt) is defined on the service agreement's tax exemption page. A customer's tax exemptability is effective-dated (it may change over time). If a customer's tax exemptability changes during a bill period, the system may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

Contract Value Proration

Some types of bill factors do not have the same value for all customers. For example, you may have rates where the price per kilowatt-hour can be different for every customer using the rate.

For bill factors whose value is customer-specific, the value is defined on the service agreement's contract value page. The contract value is effective-dated (it may change over time). If a customer's contract value changes during a bill period, the system may or may not prorate the changes. You control exactly how the system handles this situation using the bill factor's proration parameters.

Copyright © 2026, Oracle and/or its affiliates.

Contract Rider Proration

Contract riders are used when the charge associated with a bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first three months of service, then a contract rider would be used.

A customer's contract rider applicability period is defined on the service agreement's contract rider page. A rider's applicability may change during a customer's bill period. You control exactly what the system does when a rider's applicability changes during a bill period using the bill factor's proration parameters.

A Service Agreement's Rate Changes Are Not Prorated

A service agreement's rate is effective-dated (it may change over time). When the system calculates a service agreement's bill segment when multiple rates are effective during the bill period, it will use a single rate from the service agreement's rate history. The system chooses the rate as per the service agreement's SA type's rate selection date.

NOT_SUPPORTED

Refer to SA Type - Rate for more information.

Proration Factors

The purpose of calculation rules is to generate bill calculation lines. When rate application builds bill calculation lines, it may also prorate the charges.

There are multiple types of proration performed by rate application. Service quantities, step boundaries, rate values, and bill factor values may all be prorated as part of applying a rate.

We need to establish some terms in order to understand the calculations.

- Normal Days
- Consumption Period Factor
- Calculation Period Factor
- BF Value Period Factor

Normal Days

As mentioned previously, the rate schedule references a frequency that specifies the number of times per year that service agreements referencing the rate are expected to bill. The following formula dictates a rate frequency's normal days: 365 days / number of periods per year.

Example:

Copyright © 2026, Oracle and/or its affiliates.

- For a monthly frequency (12 periods per year), 365 / 12 = 30 days.
- For a quarterly frequency (4 periods per year), 365 / 4 = 91 days.

NOT_SUPPORTED

Refer to Defining Frequency Codes for more information.

Consumption Period Factor

Before applying a rate, the bill segment's consumption period is determined. The ratio of normal days to consumption period days is the consumption period factor.

The system uses the Minimum and Maximum Days Offset on the rate's Frequency to determine whether or not the calculation rule should be prorated due to a short or long consumption period.

If the number of days in the consumption period is within the tolerance of days determined by the specified on the rate's frequency, the consumption period factor is 1 (not applicable).

Example:

If the consumption period spans 60 days and the rate's normal days equals 30 days then the consumption period factor is:

- 30 days / 60 days = 0.5

If the consumption period spans 31 days and the rate's normal days equals 30 days and the maximum offset is 3 days, the consumption period factor is 1 (not applicable) because the consumption period days falls within the tolerance specified on the frequency.

NOT_SUPPORTED

For more information on how a bill segment's consumption period is determined, refer to How the System Requests How Much Was Consumed. For more information on specifying minimum and maximum offset days on frequency, refer to Defining Frequency Codes.

Calculation Period Factor

The calculation period is the date range where a rate version is effective during the consumption period. For each rate version that is effective during the consumption period, a bill segment calculation period is created. A set of bill calculation lines is created for each calculation period.

A calculation period factor is determined for each calculation period. The calculation period factor is the ratio of calculation period days to normal days. If the consumption period factor is 1 (not applicable), then the calculation period factor is the ratio of calculation period days to consumption period days.

Example:

Copyright © 2026, Oracle and/or its affiliates.

If the consumption period covers April 1 to April 30 and there was a new effective rate version as of April 21, there are two calculation periods.

- Calculation period April 1 to April 20, calculation period factor = 20 days / 30 days = 0.6666667.
- Calculation period April 21 to April 30, calculation period factor = 10 days / 30 days = 0.3333333.

BF Value Period Factor

The bill factor value period is the date range where a proratable bill factor value is effective during the calculation period.

When a bill factor value changes during the calculation period, the results is that multiple bill calculation lines are generated for the same calculation rule.

The ratio of the number of days within the calculation period that a distinct value is effective to the number of days in the calculation period determines the BF value period factor. When the bill factor is set up not to prorate, the BF value period factor is 1 (not applicable).

Example:

If the state tax rate changes from 6% to 6.5% on April 16 and the calculation period is April 1 to April 30, there are two bill factor value periods.

- Bill factor value period April 1 to April 15, BF value period factor = 15 days / 30 days = 0.5.
- Bill factor value period April 16 to April 30, BF value period factor = 15 days / 30 days = 0.5.

NOT_SUPPORTED

Refer to Defining Bill Factors for more information on specifying whether the bill factor allows proration.

Overriding Proration Factors

If the system logic for determining proration factors does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation.

- For Calculation Rule-Based Rates, the override proration algorithm is specified in the calculation rule's business object.
- For Component-Based Rates, the overriding proration algorithm is specified in the Installation record.

The system is delivered with an algorithm type that sets the proration factors to 1 (not applicable) when a predefined characteristic is specified on a calculation rule. Refer to OVPF-NOPROR for more information.

Copyright © 2026, Oracle and/or its affiliates.

Service Quantity Proration

When a bill calculation line is generated for a service quantity type calculation rule, the applicable service quantity is multiplied by the consumption period factor. That product is then multiplied by the calculation period factor to determine the prorated service quantity for the bill calculation line.

Example:

Customer's electricity bill segment's consumption period is from April 1 through May 15. A new rate version for the rate schedule is effective as of April 16. 100 kWh is consumed.

Assuming a monthly frequency, if the consumption period spans 45 days and the first calculation period spans 15 days, and the applicable service quantity is 100 kWh; then:

- Consumption period factor = 30 normal days / 45 days = 0.6666667.
- Calculation period factor = 15 days / 30 normal days = 0.5.
- Prorated service quantity = 100 kWh x 0.6666667 x 0.5 = 33 kWh.

The next calculation period extends to the end of the consumption period (30 days):

- Consumption period factor does not change = 0.6666667.
- Calculation period factor = 30 days / 30 days = 1.0.
- Prorated service quantity = 100 kWh x 0.6666667 x 1.0 = 67 kWh.

- Measures Peak
- Step Proration
- Step Multipliers

Measures Peak

If the calculation rule specifies that the service quantity measures peak, then service quantity proration is not performed. Although service quantities are not prorated if a calculation rule measures peak, calculation rule values (like price per kW) are prorated.

NOT_SUPPORTED

Refer to Calculation Rule Value Proration for more information.

Step Proration

If a calculation rule's charges are based on stepped pricing then the step boundaries are also prorated (as long as the calculation rule is not marked as measures peak). Step boundaries are multiplied by the calculation period factor to determine the adjusted steps boundaries.

Example:

Copyright © 2026, Oracle and/or its affiliates.

Assuming a monthly frequency, if the calculation rule's step boundaries are 100 kWh to 300 kWh, and the calculation period is 45 days; the step boundaries are prorated as:

- 45 days / 30 days x 100 kWh = 150 kWh.
- 45 days / 30 days x 300 kWh = 450 kWh.

Step Multipliers

If the calculation rule specifies that the steps be multiplied by the result value of another calculation rule, step proration is not performed. It is assumed that the result value from the referenced calculation rule has already been prorated, as the referenced step calculation rule is subject to Calculation Rule Value Proration.

Calculation Rule Value Proration

Except for summary type calculation rules (which are not prorated at all), a value is specified on the calculation rule. The value may be a unit rate, percentage or charge. The value may be specified directly on the calculation rule, derived from a bill factor, derived from another calculation rule, or calculated by an algorithm.

Regardless of where the calculation rule value comes from, it will be multiplied by the calculation period factor when determining the charge on a bill calculation line. Exceptions to this rule are:

- Unit rate values where the calculation rule's measures peak attribute is not checked.
- Percentage values.
- Calculation rule values derived from another calculation rule.

Even though the calculation rule values are not prorated for unit rate and percentage value types, if these rate values change during the calculation period due to a bill factor value change, bill factor value proration still applies.

Values derived from another calculation rule are not subject to rate value proration, as calculation rule value proration was already performed on the referenced calculation rule. Again, if the bill factor value changed on the referenced calculation rule, bill factor value proration still applies.

Example:

A calculation rule charges $2.00 per kW. The rate schedule's normal days equals 30, and the calculation period spans 15 days. The peak kW service quantity is 50 kW.

- The calculation period factor is 0.5 (15 days / 30 days).
- Calculation rule value proration yields $2.00 x 0.5 = $1.00 per kW.

NOT_SUPPORTED

For more information on bill factor value proration, refer to Bill Factor Value Proration.

Copyright © 2026, Oracle and/or its affiliates.

Bill Factor Value Proration

Bill factor value proration behaves the same way any time a bill factor value changes within a calculation period. This could be due to a change in a tax rate, a contract rider becoming effective, a tax exemption expiring, etc.

Multiple bill calculation lines are generated for a given calculation rule when a proratable bill factor value changes during the calculation period.

Example:

If the state tax rate changes from 6% to 6.5% on April 16, and the calculation period is April 1 to April 30.

- The first BF value factor period April 1 to April 15, so BF value period factor is 0.5.
- The value used in the first bill calculation line for state tax is 6% x 0.5 = 3%.
- The second bill factor value period is April 16 to April 30, so the BF value period factor is 0.5.
- The value used in the second bill calculation line for state tax is 6.5% x 0.5 = 3.25%.

Example of Generating Prorated Bill Calculation Lines

Let's say that 1200 kWh was consumed from March 17 to April 30. The peak kW for the consumption period is 20 kW.

A monthly rate schedule E-COM1 exists with two rate versions.

Rate version effective prior to April 1 has the following components:

- $0.05 per kWh.
- $1.00 per kW.

Rate version effective as of April 1 has the following calculation rules:

- $0.04 per kWh; as of April 16, $0.07 per kWh (new effective bill factor value).
- $1.50 per kW; as of April 16, $1.25 per kW (new effective bill factor value).

Calculation Period March 17 to March 31

The consumption period spans 45 days, so the consumption period factor is 30 normal days / 45 days = 0.6666667.

This calculation period spans 15 days, so the calculation period factor is 0.5.

Service quantity proration for the first calculation period yields:

- 1200 kWh x 0.6666667 (consumption period factor) x 0.5 (calculation period factor) = 400 kWh.
- 20 kW x 1 (not applicable) = 20 kW.

Calculation rule value proration for the first calculation period yields:

- $0.05 x 1 (not applicable) = $.05 per kWh.
- $1.00 x 0.5 (calculation period factor) = $0.50 per kW.

Copyright © 2026, Oracle and/or its affiliates.

First Set of Bill Calculation Lines

Bill calculation line 1: 400 kWh x $0.05 = $20.00.

Bill calculation line 2: 20 kW x $0.50 = $10.00.

Calculation Period April 1 to April 30

This calculation period spans 30 days, so the calculation period factor is 1.

Service quantity proration for the calculation period yields:

- 1200 kWh x 0.6666667 (consumption period factor) x 1 (calculation period factor) = 800 kWh.
- 20 kW x 1 (not applicable) = 20 kW.

Calculation rule value proration for the first calculation period yields:

- $0.04 x 1 (not applicable) x 0.5 (BF value period factor) = $0.02 per kWh.
- $0.07 x 1 (not applicable) x 0.5 (BF value period factor) = $0.035 per kWh.
- $1.50 x 1 (calculation period factor) x 0.5 (BF value period factor) = $0.75 per kW.
- $1.25 x 1 (calculation period factor) x 0.5 (BF value period factor) = $0.625 per kW.

Second Set of Bill Calculation Lines

Bill calculation line 1: 800 kWh x $0.02 per kWh = $16.00.

Bill calculation line 2: 800 kWh x $0.035 per kWh = $26.00.

Bill calculation line 3: 20 kW x $0.75 per kW = $15.00.

Bill calculation line 4: 20 kW x $0.625 per kW = $12.50.

Seasonal Proration

Seasonal proration adds another layer of complexity. If calculation rules are specified to prorate seasonally, the seasonal period specified on a given seasonal calculation rule dictates how a calculation rule's value or associated service quantity is prorated.

There are two proration methods, Prorate and Prorate Seasonal SQ, which may be specified on seasonal calculation rules. Both of these proration methods behave the same way with respect to calculation rule value proration. If a given seasonal calculation rule is eligible for Calculation Rule Value Proration, the ratio of days in the season that are applicable during the calculation period to the days in the calculation period determines the seasonal factor. When it comes to service quantity proration, the two proration methods are different. If a given seasonal calculation rule is eligible for Service Quantity Proration, it prorates the service quantities as follows:

- Prorate. A seasonal factor is calculated as the ratio of days in the season that are applicable during the calculation period to the days in the calculation period. This ratio is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.
- Prorate seasonal SQ. In this case, it is assumed that either the meter measures seasonal consumption on separate registers or the consumption has been split into separate service quantities by other means (like an SQ rule). To determine a prorated seasonal service quantity, the seasonal proration factor is calculated as for a Prorate seasonal calculation rule. The seasonal factor is then multiplied by another ratio of total consumption period

Copyright © 2026, Oracle and/or its affiliates.

days to days in the season that are applicable for the total consumption period. This modified seasonal factor is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.

> **Note**
>
> **Prorate seasonal SQ**. Specify this option only if you can determine the seasonal consumption as an independent service quantity for use by rate application. Because the service quantities themselves dictate the applicability of the calculation rule, a given service quantity need not appear in rate versions effective outside the season (i.e. a rate version effective on October 1 may not include calculation rules that charge for kWh/summer).
>
> **Override Seasonal Proration**. If the seasonal functionality provided with the system does not work for your organization, you may override the logic using the Override Seasonal Proration plug-in spot on the installation record. For example, perhaps the seasonal period is determined dynamically based on the scheduled meter read date of the bill cycle.

Example (Prorate):

Let's say that 600 kWh and 50 kW are the billable service quantities for a consumption period from April 1 to April 30. Prorate seasonal calculation rules are defined on a monthly rate that charge $0.05 per kWh and $0.75 per kW from January 1 to April 15. Prorate seasonal calculation rules are defined on the same rate version that charge $0.06 per kWh and $0.80 per kW between April 16 and December 31. Assume only one rate version is effective for the consumption period.

- The consumption period factor is 1 (not applicable).
- The calculation period factor is 1.0.
- The seasonal factor for the kWh calculation rule whose season is effective from January 1 to April 15 is 0.5 (15 season days in calculation period / 30 days in the calculation period).
- The resulting bill calculation line uses service quantity proration:
- 600 kWh x 0.5 (seasonal factor) x $0.05 = $15.00.
- The seasonal factor for the kW calculation rule whose season is effective from January 1 to April 15 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
- 50 kW x $0.75 x 0.5 (seasonal factor) = $18.75.
- The seasonal factor for the kWh calculation rule whose season is effective from April 16 to December 31 is 0.5.
- The resulting bill calculation line uses service quantity proration:
- 600 kWh x 0.5 (seasonal factor) x $0.06 = $18.00.
- The seasonal factor for the kW calculation rule whose season is effective from April 16 to December 31 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
- 50 kW x $0.80 x 0.5 (seasonal factor) = $20.00.

Example (Prorate seasonal SQ):

Copyright © 2026, Oracle and/or its affiliates.

Let's say that a given meter measures winter consumption separate from summer consumption. The meter itself measures kWh/summer on a register between June 21 and September 18, and measure kWh/winter on another register at other times of the year.

We are generating a bill segment with a consumption period from September 2 to October 30. A monthly rate schedule has two rate versions effective during the consumption period. The latest rate version is effective on October 1.

Each of the rate version calculation groups have Prorate seasonal SQ seasonal calculation rules defined. The first rate version's calculation rules charge $0.06 per kWh/summer and $0.05 per kWh/winter. The second rate version calculation group has a single calculation rule that charges $0.05 per kWh/winter.

Assume that the billable service quantities are 800 kWh/summer and 1600 kWh/winter.

First set of bill calculation lines (September 2 to September 30):

- The consumption period factor is 30 normal days / 60 consumption days = 0.5.
- The calculation period factor is 30 calculation days / 30 normal days = 1.0.
- calculation rule 1 ($0.06 per kWh/summer):
- The seasonal factor 17 seasonal days / 30 calculation days = 0.5666667.
- The modified seasonal factor is 0.5666667 x 60 consumption days / 17 seasonal days = 2.0.
- The resulting bill calculation line:
- 800 kWh/summer x 0.5 (consumption period factor) x 2.0 (modified seasonal factor) x $0.06 = $48.00.
- calculation rule 2 ($0.05 per kWh/winter):
- The seasonal factor is 12 seasonal days / 30 calculation days = 0.4.
- The modified seasonal factor is 0.4 x 60 consumption days / 42 seasonal days = 0.571428.
- The resulting bill calculation line:
- 1600 kWh/winter x 0.5 (consumption period factor) x 0.571428 (modified seasonal factor) x $0.05 = $22.86.

Second set of bill calculation lines (October 1 to October 30):

- The consumption period factor is 30 normal days / 60 consumption days = 0.5.
- The calculation period factor is 30 calculation days / 30 normal days = 1.0.
- Calculation rule 1 ($0.05 per kWh/winter):
- The seasonal factor 30 seasonal days / 30 calculation days = 1.0.
- The modified seasonal factor is 1.0 x 60 consumption days / 42 seasonal days = 1.428571.
- The resulting bill calculation line:
- 1600 kWh/winter x 0.5 (consumption period factor) x 1.428571 (modified seasonal factor) x $0.05 = $57.14.

NOT_SUPPORTED

For more information on specifying seasonal proration options, refer to Defining Calculation Rules.

Copyright © 2026, Oracle and/or its affiliates.

Price Changes and Interval Quantities

All of the above sections described situations where the service quantities will be prorated due to changes in the price during the billing period. The above sections assume that the bill contains a simple metering scenario, where reads will not exist on the date of the price break.

However, consider an interval billing example. There are two basic pricing scenarios for interval quantities:

- Interval prices are applied to interval quantities. In this case, proration is not applicable because the prices are changing at small intervals and the appropriate usage rules in Oracle Utilities Meter Data Management understand how to apply the prices to the interval quantities.
- Time of use prices. In this case, interval quantities are being mapped to time of use codes. Oracle Utilities Meter Data Management can compare interval quantities to a time of use map to create billing determinants for Oracle Utilities Customer Care and Billing. These will result in new entries in the bill segment's SQ collection when received by Oracle Utilities Customer Care and Billing. Calculation rules are then apply the appropriate price(s) for each SQ. In the time of use pricing scenario, it is possible for the prices to change during the usage or billing period. When usage requests are created by Oracle Utilities Customer Care and Billing, they will contain rate version date breaks to indicate to Oracle Utilities Meter Data Management to calculate the usage for each rate version period. Proration should not be necessary when the rate is applied for each usage (rate version) period. However, if prices are configured as bill factors and there are changes in bill factor values within the usage period, then proration may occur as the date breaks when bill factor values change are not included in the usage request from Oracle Utilities Customer Care and Billing.

Setting Up Estimated Consumption for Items

Some types of physical devices (such as, items) use power but a meter does NOT measure the power consumed. The most common example is a street light. If this situation exists for your company AND if the amount charged for the lamp varies based on the amount of estimated power used, then you will have to maintain estimated DAILY consumption for each type of item. The system uses this information at billing time to estimate how much power was used by the customer's items and then prices the estimated consumption as per the terms in the service quantity calculation rule.

Select **Admin**, and then **Rates**, and then **Item Type SQ Estimate** to define estimated consumption.

Description of Page

Select the **Item Type** using the search.

Enter the estimated daily consumption in the **Daily Service Quantity**. Each Service Quantity has an **Effective Date** so that changes in the estimated quantities may be recorded over time.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The unit of measure of the daily service quantity is displayed adjacent to the item type description. This value is defined on the item type table. Refer to Device Types for more information.

Where Used

This information is used when the system calculates a bill segment for a service agreement that references service points with items. If the items reference item types for which the system should estimate consumption, the system extracts the daily consumption amount from this table.

Setting Up Degree Days (and Average Temperatures)

Many organizations print degree-day and/or average temperature information on their customers' bills. Select **Admin**, and then **Billing**, and then **Degree Days**, and then **Search** to define these values for a given trend area.

Description of Page

The easiest way to define degree days is to select a **Trend Area** and **Month In Year** and tab out of the field. The system generates one row in the **Degree Days** collection for each day of the month. After the days exist in the collection, you should define the following for each day:

Degree Day This is a unit of measure used to express the extent to which temperatures vary from a specific reference temperature on a given date.

Maximum Temperature This is the maximum temperature on a given date.

Minimum Temperature This is the minimum temperature on a given date.

Average Temperature This is the average temperature on a given date.

Where Used

This information may be used by your bill print routines.

United Kingdom VAT and CCL

The topics in this section provide information about value added tax (VAT) and climate change levy (CCL) charges that are specific to non-domestic customers in the United Kingdom market.

> **Note**
>
> **Applicable for UK market**. This section is only relevant for the United Kingdom market. Other markets may disregard this section.

UK VAT Overview

Two rates of VAT, referred to as standard rate VAT and reduced rate VAT, are applicable to energy related charges in the UK. Domestic (i.e., residential) customers always pay VAT at the reduced rate. Non-domestic customers on the other hand normally pay standard rate VAT. However, part or all of the energy related charges for a non-domestic customer might be subject to reduced rate VAT. De minimis and VAT declarations affect the percentage of the energy related charges that is subject to each VAT rate:

- If average daily usage at a premise for a given service type does not exceed a certain threshold (the de minimis limit), all energy related charges at that premise / service type are taxed at the reduced rate.
- Some non-domestic customers, such as those with a mixed-use premise, may be eligible to pay reduced rate VAT on part or all of their energy related charges. Customers may file a VAT declaration specifying the percentage of their energy related charges that are eligible for reduced rate VAT - refer to Maintaining Declarations for more information. If the declared percentage exceeds a given threshold, the declared percentage is deemed to be 100% and the customer pays VAT at the reduced rate on all energy related charges at that premise. VAT declarations are non-transferable and must be filed for each account, premise, and service type combination.

In addition to the potential for different rates of VAT to be applicable on a bill, UK tax regulations require that excess credits are considered a prepayment of energy related charges together with VAT. Refer to Excess Credits and UK VAT for more information.

The system comes supplied with various algorithms types that can be used to perform the VAT calculations.

UK CCL Overview

The climate change levy (CCL) is based on the amount of energy used that is subject to standard rate VAT. Similarly to VAT declarations, customers may file for exemption from CCL. A CCL declaration specifies the percentage of the CCL charges that the customer is exempt from - refer to Maintaining Declarations for more information. CCL declarations are non-transferable and must be filed for each account, premise, and service type combination.

CCL charges themselves are subject to standard rate VAT.

UK VAT and CCL Bill Examples

The following examples show how a bill for a non-domestic customer is affected by de minimis, VAT declarations, and CCL declarations. In the examples, standard rate VAT of 17.5%, reduced rate VAT of 5%, a VAT declaration threshold of 60%, and a CCL charge of 0.43p per unit of energy are used.

Copyright © 2026, Oracle and/or its affiliates.

- Example 1 - Normal Account
- Example 2 - Account with Consumption Under the De Minimis Limit
- Example 3 - Account with VAT Declaration
- Example 4 - Account with VAT Declaration and CCL Declaration

Example 1 - Normal Account

This example shows the bill for a normal non-domestic account with no declarations and consumption above the de minimis limit. Standard rate VAT is applied to all energy related charges (the standing charge and the per unit charge) and to the CCL charge.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 2,000 units @ 0.43p	8.60
VAT @ 17.5% on 218.60	38.25
Total	256.85

Example 2 - Account with Consumption Under the De Minimis Limit

In this example, consumption does not exceed the de minimis limit and therefore reduced rate VAT is applied to all the energy related charges. There is no climate change levy because only units subject to standard rate VAT are subject to CCL.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
VAT @ 5% on £210.00	10.05
Total	220.05

Example 3 - Account with VAT Declaration

This example is for a non-domestic account with a VAT declaration of 20%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 1,600 units @ 0.43p	6.88
VAT @ 17.5% on £174.88	30.60

Copyright © 2026, Oracle and/or its affiliates.

VAT @ 5% on £42.00	2.10
Total	249.58

Example 4 - Account with VAT Declaration and CCL Declaration

This example is for a non-domestic account with a VAT declaration of 20% and a CCL declaration of 10%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. The customer gets a credit (CCL relief) for 10% of the CCL charges as a result of the CCL declaration. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge less the CCL reliefs are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

Bill Line	Amount
Standing Charge	10.00
2,000 units @ 10p	200.00
CCL on 1,600 units @ 0.43p	6.88
CCL relief	<0.68>
VAT @ 17.5% on £174.20	30.48
VAT @ 5% on £42.00	2.10
Total	248.78

Billing and UK VAT

The following sections describe how VAT rules are implemented when a bill is produced.

- Application of De Minimis
- Calculation of VAT
- Calculation of CCL

Application of De Minimis

The de minimis rule specifies that all energy related charges at a premise be subject to reduced rate VAT if the total usage at a premise does not exceed a certain threshold. To determine if de minimis applies, the total billed consumption for a premise must therefore be known. However, energy usage at a premise may be measured with several meters and billed by multiple service agreements. To ensure that the final billed consumption for the premise is used to determine if de minimis applies, all service agreements for an account of a given service type at a given premise should be billed together and de minimis should be checked after the bill segments have been generated. In addition, all bill segments on one bill for consumption at a given premise must be for the same bill period.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bill segments from different periods may not appear on the same bill.** If a bill segment is canceled, all bill segments associated with consumption at a given premise for the same service type must be canceled and re-billed together. You cannot re-bill the bill segment on a bill for a different period.

An **Apply De Minimis Rule** Customer Class – Pre Bill Completion algorithm type CPBC-DMCH is supplied with the base package that checks for de minimis at bill completion time. The base bill completion algorithm type checks that for any service agreement that was billed, bill segments for all the account's service agreements with the same service type and characteristic premise exist on the bill. It then calculates the total consumption for the premise and determines if de minimis applies. If de minimis applies, it sets a bill characteristic whose value is the premise ID to indicate that de minimis applies and regenerates the bill segment. Refer to the **Apply De Minimis Rule** algorithm type CPBC-DMCH for more information on how this type of algorithm operates.

For calculation rule-based rates, the **Apply VAT to Cross-Referenced Charges** calculation rule business object (**C1–ApplyVatToCrossRefCharge**) calculates standard and reduced rate VAT and applies the de minimis rule if the bill characteristic for de minimis is found. Refer to Calculation of VAT for more information. Note that during the initial generation of each bill segment, the characteristic will not exist and standard rate VAT will be applied. This means that if you look at a bill before it is complete, VAT may not be accurately reflected.

> **Note**
>
> **Batch billing cannot regenerate re-billed bill segments.** If you cancel and rebill a bill segment, you should complete the bill on-line so that the re-billed bill segments can be regenerated if de minimis applies.

Calculation of VAT

To calculate VAT, the percentages of energy related charges subject to standard rate VAT and reduced rate VAT must be determined. As these percentages vary from customer to customer and even from one bill to the next for the same customer, their calculation must take place at billing time and is handled by the following:

For calculation rule-based rates, the **Apply VAT to Cross Referenced Charges** business object (**C1–ApplyVatToCrossRefCharge**) is provided to calculate the percentages of energy related charges subject to standard rate and reduced rate VAT, taking into account de minimis and any VAT declaration that is in effect for the service type, account, and premise. The percentages can then be applied to the appropriate charges that are cross-referenced.

Calculation of CCL

CCL is a charge per unit of energy subject to standard rate VAT. It is therefore dependent on the same percentage of energy related charges subject to standard rate VAT determined during the calculation of VAT.

Copyright © 2026, Oracle and/or its affiliates.

For calculation rule-based rates, a **Calculate Climate Levy and Relief Charges** calculation rule business object (**C1–ApplyCCLCharges**) is provided to calculate CCL charges and CCL relief, taking into account any CCL declarations that are in effect for the service type, account, and premise.

Excess Credits and UK VAT

When a financial transaction that results in a credit balance for a service agreement is frozen, the amount of the excess credit must be accounted for as a prepayment of energy related charges and VAT. VAT is calculated at the reduced rate for domestic customers and at the standard rate for non-domestic customers. When the excess credit is used, the VAT liability is reversed.

A **Create Excess Credit GL Details** Customer Class FT freeze algorithm type CFTZ-VAT-GL is provided to create additional GL detail entries for unbilled revenue and VAT liability when the freezing of an FT results in a credit balance or a change to a service agreement's credit balance.

- Excess Credit GL Accounting Example

Excess Credit GL Accounting Example

The following example shows the additional GL details that are created when a service agreement's balance changes and the starting or ending balance is a credit. For this example, a single VAT rate of 10% is used simply to illustrate the principle.

The service agreement has a zero starting balance. Note the following:

- When the first payment is received, the overpayment results in a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.
- When the second bill segment is created, the credit balance is reduced and additional GL entries are created to back out the unbilled GL entries, up to the amount of the credit balance.
- When the bill segment is canceled, the service agreement again has a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.

Event	Normal GL Accounting	Additional GL Accounting	SA Balance
Bill segment for £110 created	A/R 110 Revenue <100> VAT <10>		110
Payment of £330 is received	Cash 330 A/R <330>	A/R 220 Unbilled Energy <200> Unbilled VAT <20>	<220>
Bill segment for £275 created	A/R 275 Revenue <250> VAT <25>	A/R <220> Unbilled Energy 200 Unbilled VAT 20	55

Copyright © 2026, Oracle and/or its affiliates.

Payment of £55 is received	Cash 55 A/R <55>		0
Bill segment for £275 is canceled	A/R <275> Revenue 250 VAT 25	A/R 275 Unbilled Energy <250> Unbilled VAT <25>	<275>

Setting Up The System For UK VAT and CCL

The following sections provide an overview of how to configure the system to apply UK VAT and CCL charges for non-domestic customers.

- Bill Segment Freeze Installation Option
- Customer Class
- Service Agreements
- Bill Factors for UK VAT and CCL
- Characteristic Type for De Minimis Amounts
- Distribution Code
- UOM / TOU / SQI
- Service Quantities
- Algorithms for UK VAT and CCL
- Calculation Rules to Charge VAT and CCL

Bill Segment Freeze Installation Option

Select Freeze at Bill Completion as the bill segment freeze option. The system determines if de minimis applies at bill completion time and has to regenerate the bill segments as necessary.

Customer Class

Create a separate customer classes for non-domestic customers.

Service Agreements

You must configure the system so that each service agreement that must be checked for de minimis is only linked to service points at a single premise. The service agreement must reference that premise as its characteristic premise. Refer to Application of De Minimis for more information.

Bill Factors for UK VAT and CCL

Copyright © 2026, Oracle and/or its affiliates.

- Standard Rate VAT
- Reduced Rate VAT
- VAT Declaration Percentage Threshold. Set up a separate bill factor for each service type as the thresholds differ based on service type.
- De Minimis Average Daily Amount Threshold. Set up a separate bill factor for each service type as the de minimis amounts differ based on service type.
- Climate Change Levy (CCL) Per Unit Price. Set up a separate bill factor for each service type as the CCL per unit prices differ based on service type.

Characteristic Type for De Minimis Amounts

Set up a characteristic type to use for the bill characteristic that indicates when de minimis applies. Define the type of characteristic value as a Foreign Key Value and specify a foreign key reference that points to the premise table. Specify this characteristic type as parameters to the algorithms that apply the de minimis rule and that apply VAT.

You need to define a characteristic type for every service type that is subject to the de minimis rule, as the de minimis limit may apply for one service type but not another on the same bill.

> **Note**
>
> A **De Minimis Premise** Characteristic Type is provided that may be used for a specific service type. For additional service types, additional characteristic types will need to be defined.

Distribution Code

Define the following distribution codes:

- Unbilled Prepaid Energy Related Charges
- Unbilled Prepaid VAT

These distribution codes are required as parameters to the algorithms to create the GL details for excess credit.

UOM / TOU / SQI

If using calculation rule-based rates, the calculation rule that calculates CCL requires the consumption that is subject to standard rate VAT as a service quantity.

Define the UOM / TOU / SQI used to store these service quantities.

Service Quantities

If using calculation rules-based rates, the algorithm that checks if the de minimis applies, requires a service quantity containing the total consumption. Unless you have registers that measure the total consumption independent of time of use or interval, you will need to set up a

Copyright © 2026, Oracle and/or its affiliates.

pre-processing calculation group with a calculation rule to aggregate the usage into one service quantity.

Algorithms for UK VAT and CCL

Add the following algorithms:

- Apply De Minimis Rule. Define an algorithm for each service type for which de minimis should be checked. Plug the algorithm(s) in on the customer class for the Pre Bill Completion system event. Refer to the CPBC-DMCH algorithm type for more information about the base package algorithm.
- Create Excess Credit GL Details. Plug this algorithm in on the customer class for the FT Freeze system event. Refer to the CFTZ-VAT-GL algorithm type for more information about the base package algorithm.
- Highlight Effective Declarations for Account and Premise. Plug this algorithm in on the installation option for the Control Central Alert system event. Refer to the CCAL-DECL algorithm type for more information about the base package algorithm.

Calculation Rules to Charge VAT and CCL

Four additional calculation rules are required to charge for VAT and CCL on non-domestic rates:

- Calculate standard rate VAT
  - Calculation Rule Type= Apply VAT to Cross Referenced Charges
  - VAT Calculation Type = Standard Rate
  - Specify the De Minimis Characteristic Type
  - Specify Declaration Percentage Threshold Bill Factor
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Note that the calculation rule overrides description on bill
  - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate reduced rate VAT
  - Calculation Rule Type = Apply VAT to Cross Referenced Charges
  - VAT Calculation Type = Reduced Rate
  - Specify the De Minimis Characteristic Type
  - Specify Declaration Percentage Threshold Bill Factor
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Note that the calculation rule overrides description on bill
  - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
  - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges

Copyright © 2026, Oracle and/or its affiliates.

  - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Note that the calculation rule overrides description on bill
- VAT on CCL
  - Calculation Rule Type = Apply To
  - Value type = Percentage
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Cross-reference the calculation line category for the total CCL and CCL Relief related charges

Setting up the calculation rules as above produces separate lines for VAT on energy related charges and on CCL (i.e., lines will be created for standard rate VAT on energy related charges, reduced rate VAT on energy related charges, and standard rate VAT on CCL charges).

You can set up rates to calculate standard rate VAT on energy related charges and CCL together as follows:

- Calculate standard rate VAT charges
  - Calculation Rule Type = Apply VAT to Cross Referenced Charges
  - FCPO = Yes
  - VAT Calculation Type = Standard Rate
  - Specify the De Minimis Characteristic Type
  - Specify Declaration Percentage Threshold Bill Factor
  - Value Source = Value
  - Value = 100
  - Note that the calculation rule overrides description on bill
  - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
  - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges
  - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Note that the calculation rule overrides description on bill
- Calculate standard rate VAT
  - Calculation Rule Type = Apply To
  - Value type = Percentage
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Cross-reference the calculation line category for the total CCL and CCL Relief related charges

Copyright © 2026, Oracle and/or its affiliates.

- Calculate reduced rate VAT:
  - Calculation Rule Type = Apply VAT to Cross Referenced Charges
  - VAT Calculation Type = Reduced Rate
  - Specify the De Minimis Characteristic Type
  - Specify Declaration Percentage Threshold Bill Factor
  - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
  - Note that the calculation rule overrides description on bill
  - Cross-reference the calculation line category for energy related charges that are subject to VAT

Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts a quote, one or more real service agreements are created.

NOT_SUPPORTED

Refer to Defining Quotation Options for how to setup the system to enable quotation functionality.

Note

Separate module. Please note that the quoting functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

The topics in this section describe the quotation functionality.

- The Big Picture Of Quotations
- Maintaining Quotes

The Big Picture Of Quotations

The topics in this section provide background information about a variety of quotation features and functions.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> If you are not familiar with the concepts described under Sales and Marketing, Billing, Rates the quotation functionality will be difficult to understand.

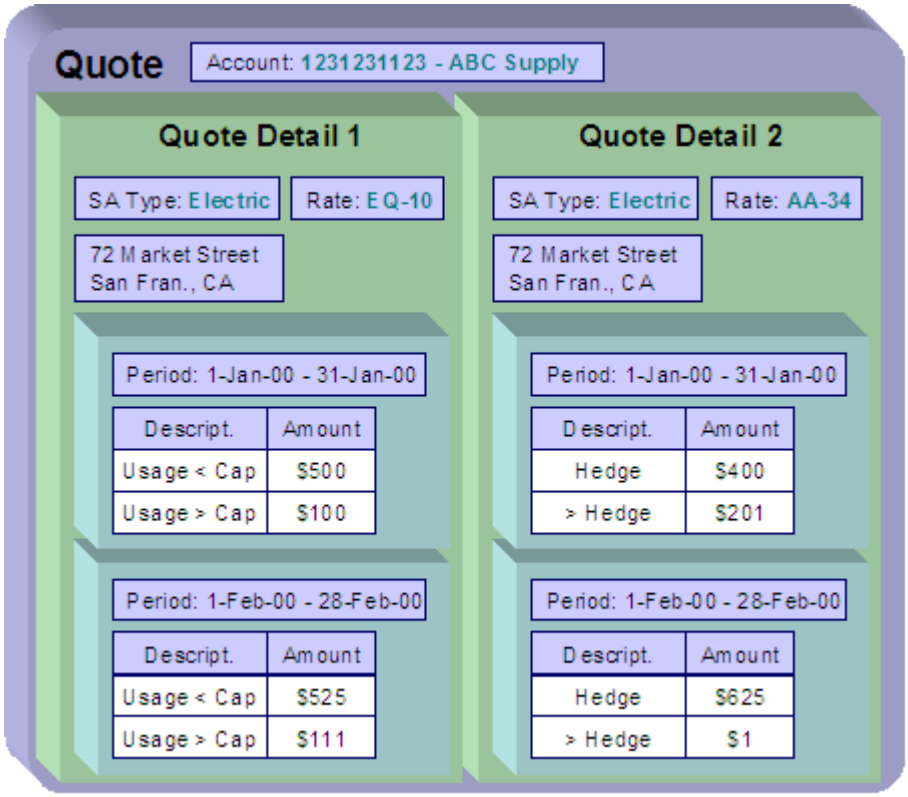
- Printing Quotes

Basic Quotation Concepts



The section describes basic quotation concepts.

- A Quote Shows How Bill Segments Might Look
- Proposal Service Agreements Must Exist
- Creating Quotes And Quote Details
- Completing A Quote Creates Quote Routings (And More)
- Accepting / Declining Quote Details
- Tinkering With Proposal SAs After Quote Generation
- Closing Quotes
- Alerts
- Trees

A Quote Shows How Bill Segments Might Look

A quote shows how a customer's bill segments will look if a given set of pricing terms is applied to a given amount of consumption. The following example illustrates how a quote might look that provides a customer with two different options for their electric service. If the customer elects either option, a new service agreement would be created.

Copyright © 2026, Oracle and/or its affiliates.

Please note the following about a quote:

- A quote is related to an account.
- A quote can contain many quote details. A quote detail shows how bill segments will look if a given set of pricing terms (e.g., rates, riders, contract quantities, contract options, etc.) is applied to a given amount of consumption.
- A quote detail may contain many simulated bill segments. For example, a quote detail could show the customer what their monthly bills would be if a given set of pricing terms were used over the course of several months (where each month has different consumption levels and different prices).
- A quote may contain multiple quote details for the same service. For example, a quote can contain four different pricing options for the same service (where each option is shown using a separate quote detail). The customer can then compare them and choose the optimum option.
- A quote may contain quote details for multiple premises and multiple services at each premise. For example, a quote can contain quote details for electric and gas service at multiple premises.

Proposal Service Agreements Must Exist

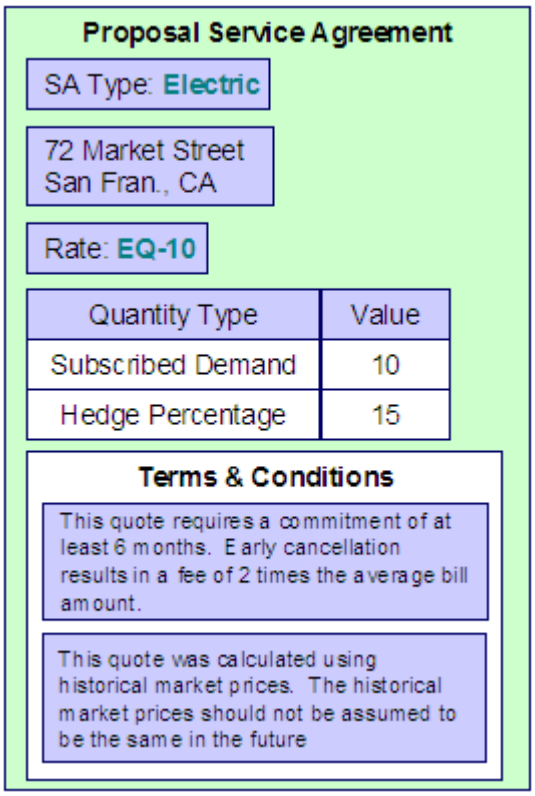
You cannot create a quote unless its account has at least one proposal service agreement (SA). A proposal SA contains the pricing terms, legal terms, and template consumption used to generate the simulated bill segments that appear on a quote. It might be helpful to view a proposal SA as special type of service agreement that is ignored when a bill is produced for an account.

The topics in this section provide detailed information about proposal SAs.

Copyright © 2026, Oracle and/or its affiliates.

- Proposal SAs Contain Pricing Terms
- Legal Terms and Conditions May Be Specified On Both Proposal And Real SAs
- Proposal SAs Contain Billing Scenarios And Template Consumption
- Proposal SAs Differ From Real SAs
- Proposal SA State Transition
- Orders Are Used To Create Proposal SAs
- Proposal SAs May Be Grouped Under An Umbrella Agreement

Proposal SAs Contain Pricing Terms



The pricing terms (e.g., rates, contract quantities, riders, bill factor values, etc.) used to generate a quote detail's simulated bill segments reside on a special type of service agreement (SA) referred to as a "proposal SA". Proposal SAs are like real SAs in many respects. In fact, you can view and change a proposal SAs pricing terms using the same transaction used to maintain real service agreements (i.e., service agreement maintenance).

> **Note**
>
> **Quote details are rather empty.** A quote detail doesn't contain the pricing terms or template consumption. Rather, a quote detail references a proposal SA and the proposal SA contains the pricing terms and template consumption.

Legal Terms and Conditions May Be Specified On Both Proposal And Real SAs

In addition to containing pricing terms, proposal SAs also contain the legal terms and conditions (T&Cs) that govern the proposal.

Copyright © 2026, Oracle and/or its affiliates.

Your master list of terms and conditions are defined when you setup your control tables. The system defaults a service agreement's T&Cs from the start option used to initially create it. You can change a SA's T&Cs at will.

> **Note**
>
> **Real SAs and proposal SAs can reference T&Cs.** Both proposal and real SAs can reference T&Cs. The T&Cs on a proposal SA are those that will apply if the customer accepts the related quote detail. The T&Cs on a real SA are those that apply while the SA is active.

Proposal SAs Contain Billing Scenarios And Template Consumption

In addition to the pricing terms and the legal terms and conditions, a proposal SA also contains billing scenarios. A billing scenario defines:

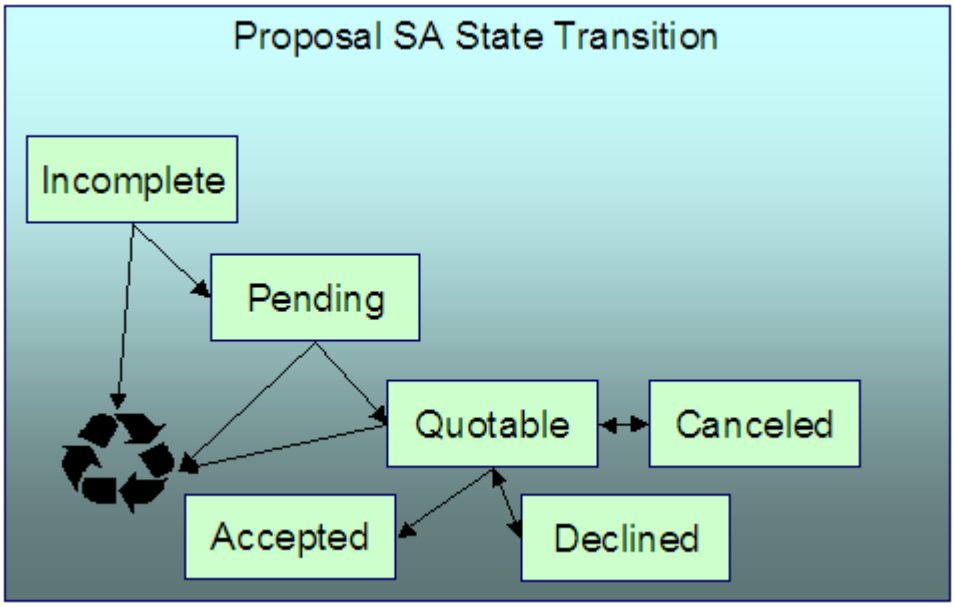
- The number of simulated bill segments that will be generated when a quote detail is produced for the proposal SA.
- The bill period of each simulated bill segment.
- The amount of consumption to be priced under each simulated bill segment. Note this statement is only true for non-interval consumption. *Note: Proposal SAs that use interval consumption are not supported in C2M. Load curves and TOU mapping are handled in Oracle Utilities Meter Data Management.*

A proposal SA's billing scenarios can be created as follows:

Copyright © 2026, Oracle and/or its affiliates.

- A plug-in spot exists on SA type called Proposal SA Creation. Algorithms plugged into this spot can setup billing scenarios. Refer to Enabling The Automatic Generation Of Billing Scenarios for more information about how to do this.
- A user can add / change / delete billing scenarios on a proposal SA using Service Agreement - Billing Scenario.

Proposal SAs Differ From Real SAs



A proposal SA is just like any other SA in that it contains the pricing terms that are used to generate how much the customer owes for service. In fact, the service agreement maintenance transaction is used to maintain both types of service agreements (however, you cannot use this transaction to create a proposal SA; proposal SAs can only be created using the order transaction).

However, there are differences between proposal SAs and real SAs:

- Billing ignores proposal SAs.
- Proposal SAs cannot have financial transactions.
- Proposal SAs are not subject to credit and collections.
- Proposal SAs do not appear on lists of "active" SAs in the system's various zones, grids and trees.
- Fieldwork is not performed for proposal SAs.
- A proposal SA's state transition is very different from a real SA. Refer to The Lifecycle Of A Service Agreement for an illustration of a real SAs state transition. Refer to Proposal SA State Transition for an illustration of a proposal SAs state transition.

Proposal SA State Transition

The following diagram shows the possible lifecycle of a proposal SA.

Copyright © 2026, Oracle and/or its affiliates.

You should never see an Incomplete proposal SA as this is a transitory state used when a proposal is first initiated using the Order transaction. The system always transitions such proposal SAs to the Pending state. Please note that when a proposal SA becomes Pending, the system executes any Proposal SA Creation algorithms plugged in on the proposal SA's SA type. You might use such algorithms to generate billing scenarios or initiate a workflow process that requests template consumption from the prospect.

A proposal SA exists in the Pending state while you are working on the proposal. For example, you might want to leave the proposal SA in this state while you wait for the prospect to send you their historical consumption.

A proposal SA is Quotable when a quote detail can be generated for it (at least one billing scenario must be linked to the proposal SA before it can become Quotable). Note, proposal SAs can be modified when they are Quotable.

> **Note**
>
> **Automatically transitioning a proposal SA to the Quotable state when it's first created.** As described earlier, you can setup a proposal SA creation algorithm to automatically create billing scenarios when a proposal SA is created. The base package algorithm can also automatically transition the proposal SA to the Quotable state (thus making it ready for quotation). Refer to Enabling The Automatic Generation Of Billing Scenarios for more information.

A proposal SA becomes Accepted when a customer accepts one of its quote details.

A proposal SA becomes Declined when a customer declines one of its quote details (or its quote expires). A Declined proposal SA can be "reopened" (by making it Quotable). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

A proposal SA becomes Canceled when a quote detail is withdrawn (or its quote expires). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

Incomplete, Pending and Quotable proposal SAs may be deleted.

Orders Are Used To Create Proposal SAs

Proposal SAs can only be created using the order transaction. This transaction allows a user to pose eligibility-oriented questions to a customer or prospect. The system determines which packages of goods and services for which they are eligible based on the answers to the questions. If the customer is interested in receiving a package, one or more SAs (real and/or proposal) are created using the SAs To Create information defined on the selected package.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **You must setup campaigns and packages before you can create an order.** If you are not familiar with the order transaction, you should take the time to form an intuitive understanding of the concepts described under Sales & Marketing. With this knowledge in place, you can design and set up the campaigns and packages necessary to allow an order to create proposal SAs. Keep in mind that a single switch controls whether real SAs or a proposal SAs are created when a package is selected on the order transaction. This switch resides on Package - SAs To Create.
>
> **A package could create a combination of real and proposal SAs.** When a customer elects to take a package of goods and services (via the order transaction), the system creates a service agreement for each SA type / start options defined on the package's SAs To Create. It is possible to setup a package to create both real and proposal SAs. For example, the customer may be calling you to start electric service, but they may also be interested in seeing a proposal for gas service.
>
> **You don't create special SA types for proposal SAs.** The SA type on a proposal SA is the same as the SA type on the real SA that's created when the proposal SA is accepted. This is because the business rules on your SA types govern both real and proposal SAs.
>
> **You don't need special start options for proposal SAs.** The start options that you setup to default information onto new, real service agreements are also referenced on the SA To Create information used to create proposal SAs.

Proposal SAs May Be Grouped Under An Umbrella Agreement

Each proposal SA may be part of a larger contract for multiple services that you are negotiating with a customer or group of customers. You may use an umbrella agreement and its collection of terms of service records to group together multiple proposal service agreements.

Creating Quotes And Quote Details

Once an account has quotable proposal SAs, you can generate a quote for the account using the quote maintenance transaction. When you generate a quote for an account, you can include quote details for any / all of the account's quotable proposal SAs.

The logic used to create a quote detail's simulated bill segments is not hard-coded. Rather, the system calls the algorithm plugged in on the proposal SA's SA type in the Proposal SA - Bill Segment Generation plug-in spot. Refer to Enabling The Generation Of Simulated Bill Segments for information about this plug-in spot.

The major difference between a bill segment linked to a quote detail and one linked to a bill is that a quote detail's bill segments are calculated using simulated consumption. This means that the financial information on quote details is not a guess - it's what the bill would be if a given amount of consumption was priced using the pricing terms (as long as you opt to use rate application to calculate the simulated bill segments).

In addition to this major difference, there are a few minor differences between a real bill segment and a simulated bill segment:

Copyright © 2026, Oracle and/or its affiliates.

- A quote detail bill segment does not have a foreign key to a bill. Rather, it references a quote detail.
- A quote detail bill segment's prime key is inherited from its quote detail (rather than its bill).
- A quote detail bill segment can never have a financial transaction linked to it.
- A quote detail bill segment doesn't have read details.
- A quote detail bill segment's state transition is simpler (it's either in the Error state or OK).

Completing A Quote Creates Quote Routings (And More)

When a quote's quote details are all OK, you change the status of the quote to complete to indicate the quote is ready to be sent to the customer or prospect.

When a quote is completed, the system creates a quote routing for each person who receives a copy of the account's quotes. When you indicate a person should receive a copy of the account's quotes, you define the routing method (e.g., email, fax, post) and the appropriate address.

> **Note**
>
> **Recipients of quotes.** You define who receives a copy of an account's quotes on the Account - Persons page. The system assumes (by default) that the main person linked to the account should receive the account's quotes. You can subsequently indicate any person linked to the account should receive its quotes (and turn off the creation of quotes for the main person). In addition, you can manually add additional quote routings to a quote if you need to send the quote to individuals not currently linked to the account. Refer to How To Reprint A Quote for more information.

The information that appears on the quote routing record is controlled by the quote route type specified on the respective account / person information:

- If the quote route type's routing method is email or fax and the system has been configured to use notification preferences for quote routing, a quote routing is created for each active contact preference whose notification type is associated with the **quote route type** specified on the respective account / person information. Refer to Bill and Quote Routing in *Designing Notification Types* for more information. Otherwise, quote routings are created as follows:
  - If the quote route type indicates the person's quotes are routed via fax, the person's fax number is used as the routing information. The system knows which of a person's person contacts is a fax number is by the contact routing or which of a person's phone numbers is a fax number by the phone type.
  - If the quote route type indicates the person's quotes are routed via email, the person's Email address is used as the routing information. The system knows which of a person's person contacts is an email or knows where to find the person email.
- If the quote route type indicates the person's quotes are routed via the postal service, the address constituents are populated with the address specified on the **bill** address source that is also specified on the account / person information. Note, if the person has a seasonal address effective on the business date, the seasonal address will be used regardless of the value of **bill address source**.

Copyright © 2026, Oracle and/or its affiliates.

Regardless of whether the quote is routed via fax, email or post; the routing record is also stamped with the batch process and run number that performs the download of the quote information. The batch process is defined on the quote route type. Refer to Printing Quotes for more information about this batch process.

In addition to creating routing information at completion time, the system executes any quote completion algorithms plugged in on the account's customer class. For example, you may want to create a workflow process to manage the processing of the quote. To do this, you plug in a Quote Completion Algorithm that creates a workflow process on the respective customer class .

Accepting / Declining Quote Details

A customer can accept or decline each quote detail on a quote.

When a quote detail is accepted, the system:

- Changes the state of the related proposal SA to accepted.
- Executes the Proposal SA - Acceptance algorithms plugged in on the proposal SA's SA type. The base package algorithm creates a real SA by copying the information from the proposal SA. The real SA is created in the pending start state. This new SA behaves similarly to a pending start SA that's created via the Order or Start/Stop transactions (e.g., field activities are initiated if the SA type has been setup accordingly).

When a quote detail is declined, the user must supply a decline reason. The system then changes the state of the related proposal SA to declined.

NOT_SUPPORTED

Refer to Proposal SA State Transition for more information about a proposal SA's states.

Note

Reopening a declined proposal SA. If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the service agreement maintenance transaction.

Rejecting an entire quote. If all details on a quote are being declined, you can simply change the state of the quote to closed rather than reject each quote detail. Refer to Closing Quotes for more information.

Tinkering With Proposal SAs After Quote Generation

The system allows a quotable proposal SA to be changed, EVEN IF QUOTE DETAILS HAVE BEEN GENERATED. This is intentional as otherwise you would have to create an entirely new proposal SA if you wanted to send another quote for slightly different terms. Your technical team could always introduce a user exit to prevent this from happening if you really didn't want this to take place.

Copyright © 2026, Oracle and/or its affiliates.

Because the system allows this, a potential issue is that the customer may end up accepting a proposal SA that differs from the terms on their quote (e.g., you could change the SA after the quote detail is generated). For this reason, we snapshot the version number of the proposal SA on the quote detail at the time it's generated. If a proposal SA is accepted and its version number differs from the value on its quote details, a warning is produced.

A warning is also issued if you change a proposal SA and a quote detail exists (reminding you to generate a new quote / quote detail).

In addition to the above, it's also important to understand that the system intentionally allows multiple quotes to reference a given proposal SA. This allows you to leave multiple quotes open that reference the same proposal SA(s).

Closing Quotes

Every quote has an expiration date. The CLOSEQTE background process closes quotes on their expiration date. This process changes the state of all related proposal SAs to canceled or declined (an input parameter of this process controls which state is used).

You can also close a quote real time using the quote maintenance transaction. When you do this, the system asks if the related proposal SAs should be left as quotable or if they should be changed to canceled or declined.

> **Note**
>
> **Reopening a declined proposal SA.** If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the service agreement maintenance transaction.

Alerts

The alert zone highlights if:

- The selected account has pending or complete quotes. Refer to Quote Lifecycle for more information.
- The selected account has pending or quotable proposal SAs. Refer to Proposal SA State Transition for more information.

Trees

The account tree highlights:

- The existence of non-closed quotes
- The existence of proposal SAs and their related quote details

Printing Quotes

Copyright © 2026, Oracle and/or its affiliates.

The contents of this section describe the technical implementation of printing quotes.

- Quote Routings Are Created For Each Recipient Of A Quote
- Quote Route Types Control The Information Merged Onto Quotes
- Technical Implementation Of Online Quote Display
- Technical Implementation Of Printing Quotes In Batch
- Reproducing The Quote Print Flat File
- How To Reprint A Quote (For The Original Recipients or For Someone New)
- The Quote Extract Records

Quote Routings Are Created For Each Recipient Of A Quote

Refer to Completing A Quote Creates Quote Routings for a description of how the system constructs the information used to route a quote to one or more recipients.

Quote Route Types Control The Information Merged Onto Quotes

Every quote routing references a quote route type.

The quote route type controls the following quote functions:

- It contains an algorithm that is responsible for extracting the information merged onto your quotes. Specifically, algorithms of this type create the "flat file records" that are passed to your quote-print software. Algorithms of this type are called under the following scenarios:
  - The background process that builds the flat file that's passed to your quote-print software calls these algorithms to construct the "flat file records" for each quote. Refer to Technical Implementation of Printing Quotes In Batch for the details.
  - If your quote-print software has the ability to construct a real-time image of a quote (in a PDF), you can plug in an Online Quote Display algorithm on the Installation Record. This type of algorithm calls the quote's dispatch group extract algorithm to extract the information that is merged onto the quote. Refer to Technical Implementation Of Online Quote Display for the details.
- Refer to The Quote Extract Records for examples of the record layouts passed to the document composition application.
- It contains the ID of the background process that builds the flat file that's passed to your quote-print software. The base package example of this background process (QUOTROUT) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file.

> **Note**
>
> CIS Division can override the extract algorithm and/or the background process found on the quote route type. The system processes first check the quote's account's CIS Division for an override specific for the quote route type.

Copyright © 2026, Oracle and/or its affiliates.

Technical Implementation Of Online Quote Display

Users can view an image of any quote if you set up the following:

- Plug in an Online Quote Display construction algorithm on the Installation Record. Refer to ONQD-DOC1 for an example of such an algorithm. Note if your quote-print software is not capable of producing a PDF containing an image of a quote, users will not be able to view images of quotes.
- Plug in the appropriate extract algorithm on each quote route type . Algorithms of this type format the records that contain the information that is passed to your printing software. Refer to QTEX-EX for an example of such an algorithm.

When you plug in these algorithms, a button appears on Quote - Main. When a user clicks this button, the following takes place:

- The installation record's Online Quote Display algorithm is executed.
- This algorithm calls the quote's route type's extract algorithm. This algorithm constructs the information that's merged onto the quote and returns it to the Online Quote Display algorithm. This algorithm, in turn, passes it to the quote-print software.
- The quote-print software renders an image of the quote in a PDF and returns it to the Online Quote Display algorithm.
- And finally, the Online Quote Display algorithm displays the PDF in a browser session. Note that the client must have Adobe Acrobat Reader installed to view PDF files.

Technical Implementation Of Printing Quotes In Batch

The batch process that extracts quote information reads all quote routing records in a given run number that are marked with its batch control ID. For each quote routing record, it creates numerous records on a flat file. These records contain the information that is merged onto your quotes.

The base package example of this process (QUOTROUT) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file. Refer to Quote Route Types Control The Information On Quotes for more information.

> **Note**
>
> **If your software doesn't support online quote display.** The algorithm that formats quote extract records that's plugged in on quote route type serves two purposes: 1) it formats the records used to construct online images of a quote, and 2) it formats the records downloaded to your quote print software in batch. If your quote printing software does not support the rendering of quote images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that both formats the extract records and downloads them (and then specify this batch process on your quote route type).

Copyright © 2026, Oracle and/or its affiliates.

Reproducing The Quote Print Flat File

You can reproduce the flat file at any time. Simply request the quote production background process and specify the run number associated with the historic run.

How To Reprint A Quote (For The Original Recipients or For Someone New)

A copy of a quote is sent to every individual / business specified in the quote's routing details. The system creates the routing details when a quote is completed. Refer to Completing A Quote Creates Quote Routings for more information about how this information is compiled during quote completion.

If you want to reprint a quote OR if you want to send a quote to someone other than the original recipients:

- Navigate to the Quote - Main page.
- Transfer to the Quote - Quote Routings tab.
- Insert a new row (click the + button). Note that you can only insert information on a quote that is Complete.
- Specify the name and address to which the quote should be sent. If you want to send the quote to someone other than the original recipient, specify the individual's name and address.
- Save the quote.

If a quote is Complete but the print process hasn't yet executed, you may change the name and address on the original routing details; you don't have to insert a new routing row.

The Quote Extract Records

Numerous different types of records are interfaced to the document composition application. However, they all share a common structure:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application quote template.
- The next X bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed quote appear in the correct order in the interface file.
- The next 12 bytes are called the **Mailing Key**. This field is used to control the order in which the formatted quotes are printed.
- The remaining bytes contain the **Quote Information** that appears on the printed quote. The type of information differs for each type of record.

The topics in this section describe each component.

- Printer Key (Record Types)
- Sort Key
- Mailing Key
- Quote Information

Copyright © 2026, Oracle and/or its affiliates.

Printer Key (Record Types)

The following table defines each printer key (i.e., record type) on the quote print flat file.

Record Type	Description	Notes
0010	Global extract information	Required. 1 per flat file
0100	Quote record	Required. 1 per Quote.
0200	Quote Detail record	1 per quote detail.
0300	Terms and Conditions record	1 per terms and conditions linked to the proposal SA.
0400	Bill segment record	1 per bill segment linked to the quote detail.
0500	Bill calculation header	1 per bill calculation header linked to the bill segment.
0600	Bill calculation line	1 per bill calculation line linked to the bill calculation header.
0700	End of record type 0500	1 for each bill calculation header
0800	Read detail	1 for each meter read detail linked to the bill segment.
0900	SQ detail	1 for each service quantity detail linked to the bill segment.
1000	End of record type 0400	1 for each bill segment.
1100	End of record type 0200	1 for each quote detail.
9999	End of record type 0100	1 for each quote.

Sort Key

The following table defines the structure of the sort key that appears on each quote print record. Please note that different components are filled in for each printer key.

Field Name	Format	Source/Value/Description
Quote ID	A12	
Sequence Number	N2	The sequence number of the account / person information associated with this quote routing information.
Quote record group	A2	10 Quote 20 Quote Detail 30 Quote end
Quote Detail ID	A12	

Copyright © 2026, Oracle and/or its affiliates.

Quote Detail record group	A2	10 Quote Detail record 20 SA Terms and Conditions 30 Bill Segment 40 Quote Detail record end
SA T&C Short Description	A60	
Bill Segment End Date	A10	
Bill Segment Id	A12	
Bill Segment Group	A2	10 Bill segment 20 Bill segment calculation group 30 Bill segment read detail 40 Bill segment SQ detail 50 Bill segment end
Bill Calc Header Sequence	N2	
Bill Calc Header Group	A2	10 Bill calculation header 20 Bill calculation line 30 Bill calculation end
Line Seq	N4	Defines order of rows for similar record types

Mailing Key

The following table defines the structure of the mailing key that appears on each quote print record.

Field Name	Format	Source/Value/Description
Postal code	A12	This is the postal code on the quote routing record.

Quote Information

The topics in this section describe the information that appears on each on each quote print record. The following links are provided so that you can move easily to specific topic within this section:

- Global Extract Information (0010) Record Definition
- Quote (0100) Record Definition
- Quote Detail (0200) Record Definition
- SA Terms and Conditions (0300) Record Definition
- Bill Segment (0400) Record Definition
- Bill Calculation Header (0500) Record Definition
- Bill Calculation Line (0600) Record Definition

Global Extract Information (0010) Record Definition

This is a "header" record that contains information about the extract run as a whole.

> **Note**
>
> Please be aware that if you do not sort your extract file by **CIS Sort Key** after it is produced, this record will physically be the last record on the extract file.

Field Name	Format	Source/Value/Description
BATCH_CD	A8	Batch Control Code of the extract process.
BATCH_NBR	N10	Batch Number of the extract process
BATCH_RERUN_NBR	N10	Batch Rerun number of the extract process.
QTE_CNT	N10	Count of quotes on this extract.
EXTRACT_DTTM	A26	System time of extraction.
QUOTE_ID_START	A12	This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract.
QUOTE_ID_END	A12	This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract.
THREAD_NBR	N10	This field is only used if quotes are extracted in batch. It contains the thread number in which the quote was extracted.
THREAD_CNT	N10	This field is only used if quotes are extracted in batch. It contains the total number of threads that were extracted.

Maintaining Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts the quote, real service agreements are created.

NOT_SUPPORTED

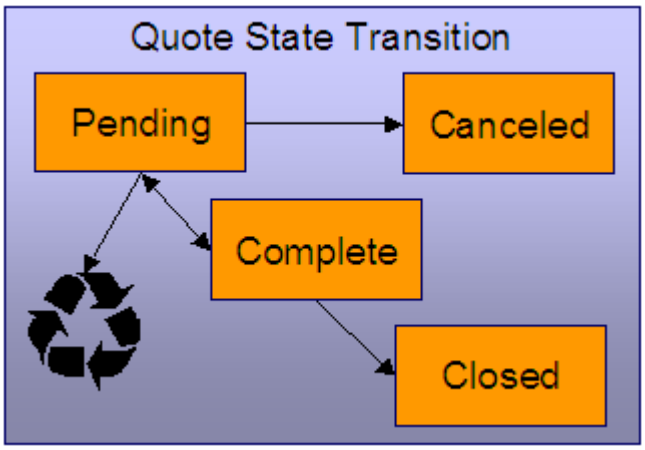
Refer to The Big Picture Of Quotations for background information about quotes.

The topics in this section describe how to maintain quotes.

- The Lifecycle Of A Quote And Quote Detail
- Quote - Main

The Lifecycle Of A Quote And Quote Detail

The topics in this section describe the lifecycle of the various quote objects.



- Quote Lifecycle

Copyright © 2026, Oracle and/or its affiliates.

- Quote Detail Lifecycle

Quote Lifecycle

The following diagram shows the possible lifecycle of a quote.

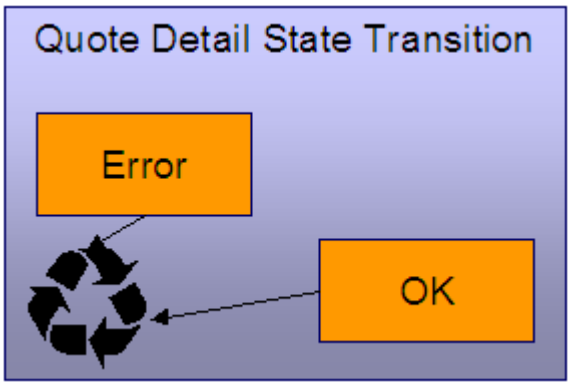
Pending A quote starts its life in the Pending state. Refer to Creating Quotes And Quote Details for more information.

A quote remains Pending until you Cancel or Complete it.

You may delete a Pending quote. Deleting a pending quote also deletes its quote details.

Canceled You cancel a quote if you want a record of a Pending quote that was never sent to a customer.

Complete A quote becomes Complete when it is ready to be sent to a customer. No changes may be made to a Complete quote. Refer to Completing A Quote for a description of what happens when a quote is completed.



A Complete quote may be reopened. You would only do this if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote details, and then recomplete the quote.

Closed A Complete quote becomes Closed when its terms are no longer valid. Refer to Closing Quotes for more information.

Quote Detail Lifecycle

The following diagram shows the possible lifecycle of a quote detail.

Copyright © 2026, Oracle and/or its affiliates.

When a quote detail is generated, it is placed in the Error or Ok state depending on whether the system successfully generated simulated bill segments for each billing scenario linked to the related proposal SA. A quote detail may be deleted if its parent quote is Pending. Refer to Creating Quotes And Quote Details for more information.

Quote - Main

This page is used to maintain quotes. This page provides many diverse functions:

- You can generate, complete, close, reopen, and cancel a quote.
- You can regenerate and delete quote details.
- You can accept, decline and cancel the proposal SAs that contribute a quote detail to the quote.

You should not attempt to use this transaction until you are comfortable with the concepts described under The Big Picture of Quotations.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Quote**, and then **Search.**

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

Account ID identifies the customer or prospect associated with the quote. The name of the account's main customer appears adjacent.

Quote Status contains the state of the quote. Refer to Quote Lifecycle for information about the valid values and the state transition rules.

If your system has been configured to display an online image of a quote, a **Display Quote** button appears adjacent to the quote's status. When clicked, an online image of the quote is displayed. Refer to Technical Implementation Of Online Quote Production for how to enable this feature.

Expiration Date / Time identifies when the quote's terms are no longer valid. Refer to Closing Quotes for how the system uses this information to automatically close a quote.

Refer to Quote Actions for a description of each **Quote Action** button.

This transaction has sophisticated logic that can be used to perform mass updates to the quote's quote details and their related proposal SAs. These mass update actions are executed by selecting quoted details (in the grid) and then clicking the desired action button at the

Copyright © 2026, Oracle and/or its affiliates.

bottom the page. The remainder of this section describes how to use this mass update functionality.

The **Select All** / **Clear All** buttons are used to select / unselect the quote details. These buttons are disabled when the quote is Closed.

> **Note**
>
> **100 quote details at a time.** Clicking **Select All** selects the first 100 quote details in the grid. If more than 100 quote details exist, you must select them in batches.

The grid that follows contains the quote details linked to the quote. The following information appears in the grid:

- Select box. Before you can perform any of the mass update actions at the bottom of the page, at least one quote detail must be selected. This field is disabled when the quote is Closed. You can use the **Select All** and **Clear All** buttons to change the value of the switch for all quote details in the grid.
- Click the go to button to transfer to the Quote - Quote Detail tab with the corresponding quote detail positioned in the scroll. On this page, you can see the details of the quote detail's simulated bill segments (and, from there, drill down into the details of each bill segment).
- The **Quote Detail Info** column contains a concatenation of a quote detail's division, SA type, start option, status, start date, and premise information (this information comes from the quote detail's proposal SA).
- The **Total Amount** column contains the sum of the quote detail's simulated bill segments.
- The **Remarks** column highlights special circumstances associated with the quote detail.
  - Proposal SA has been changed since the quote was created appears if the proposal SA was modified after the quote detail was generated. If you'd like to recalculate this quote detail, select this row and click the **Regenerate** button at the bottom of the page to regenerate the quote detail's simulated bill segments.
  - Quote detail contains bill segments in error appears if any of the simulated bill segments linked to the quote detail are in error . Click the adjacent go to button to transfer to the Quote - Quote Detail tab where the state of each simulated bill segment is shown. You can correct simulated bill segments that are in error by **Regenerating** the quote detail (and you do this by selecting the quote detail and clicking the Regenerate button at the bottom of the page).

The **Quote Detail Actions** and **Proposal SA Actions** can be used to perform mass updates to the selected quote details in the grid. Refer to Quote Detail Actions and Proposal SA Actions for the details.

Action Buttons On Quote Main

The topics in this section describe the various action buttons on the Quote - Main page.

Quote Actions

The topics in this section describe the **Quote Action** buttons on the Quote - Main page. The following links are provided so that you can move easily to specific topic within this section:

- Generate
- Complete
- Close
- Reopen
- Cancel (Quote)

Generate

The **Generate** button causes one or more quote details to be created for the account's Quotable proposal SAs. This button is enabled when there is at least one Quotable proposal SA linked to the selected **Account ID**.

When clicked, the **Generate Quote** window opens.

You must specify the following parameters to generate quote details:

- Indicate if quote details should be created for All Proposal SAs or for a Specific Proposal SA.
- If you indicated a quote detail should be generated for a Specific Proposal SA, also specify the **Proposal SA ID**.

After specifying the parameters, click **Generate** to create the quote details for quotable proposal SAs.

> **NOT_SUPPORTED**
>
> Refer to Creating Quotes And Quote Details for more information.

> **Warning**
>
> If the quote has existing quote details for the designated proposal SAs, they are deleted when you generate quote details (i.e., the system regenerates existing quote details). You can also regenerate quote details by selecting them on the Main page and clicking the **Regenerate** button.

Top of Page

Complete

Copyright © 2026, Oracle and/or its affiliates.

The **Complete** button causes the quote to become complete. This button is enabled when the quote is pending and all quote details linked to the quote are OK.

> **NOT_SUPPORTED**
>
> Refer to Completing A Quote Creates Quote Routings for a description of what happens during quote completion.

Top of Page

Close

A quote is closed when its terms are no longer valid (i.e., when the related proposal SAs can no longer be accepted). Most quotes are closed automatically by the system (refer to Closing Quotes for how this takes place).

If you want to close a quote real time, click the **Close** button. When this button is clicked, the system opens the **Close Quote** window and asks if anything should be done with the related proposal SAs.

In the resulting window, you must specify one of the following **Proposal SA Actions**:

- Choose No Action if you don't want to change the status of the related proposal SAs.
- Choose Decline if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to declined . You must also define a **Decline Reason**.
- Choose Cancel if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to canceled .

Top of Page

Reopen

The **Reopen** button causes a quote to return to the pending state. You would only reopen a quote if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote detail, and then recomplete the quote.

This button is enabled if the quote is complete.

Top of Page

Cancel (Quote)

The **Cancel** button causes the quote to become canceled. You would cancel a quote if you want a record of a pending quote that was never sent to a customer. This button is enabled when the quote is pending.

Canceling the quote does NOT cancel the related proposal SAs. If you want to cancel the related proposal SAs, you have the following options:

- You can click the Close button rather than the **Cancel** button. When you close a quote, you are given the option of also canceling the proposal SAs that contributed a quote detail to the quote.
- Before canceling the quote, you can select the quote details and click the Cancel button at the bottom of the page (in the Proposal SA Actions section). When you click this button, the system cancels the proposal SAs linked to the quote details.

Copyright © 2026, Oracle and/or its affiliates.

- You can transfer to the Quote - Quote Details tab and then drill down to the each proposal SA (using the SA context menu button). This transfers you to Service Agreement - Main where you can cancel the proposal SA.

Quote Detail Actions

The topics in this section describe the **Quote Detail Action** buttons on the Quote - Main page. These buttons are used to perform a given action to the quote details that are selected in the quote details grid.

- The **Regenerate** button is used to delete and recreate the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.
- The **Delete** button is used to delete the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.

Proposal SA Actions

The topics in this section describe the various **Proposal SA Action** buttons on the Quote - Main page. These buttons are used to perform a given action to the proposal SAs associated with the selected quote details.

The **Accept** button is used to accept the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

When you accept a proposal SA, you are asked to supply the **Start Date** of the real service agreement that will be created.

Refer to Accepting / Declining Quote Details for more information about how accepting a quote detail causes a real service agreement to be created.

Decline

The **Decline** button is used to decline the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected. When you decline a proposal SA, you are asked to supply a **Decline Reason**.

Refer to Accepting / Declining Quote Details for more information about declining a quote detail.

Cancel

The **Cancel** button is used to cancel the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

Quote - Quote Details

This page is used to view a summary of the simulated bill segments linked to a quote detail.

Copyright © 2026, Oracle and/or its affiliates.

Open this page using **Menu**, and then **Sales & Marketing**, and then **Quote**, and then **Search** and navigate to the **Quote Details** page to define this information. You can also display a quote detail by clicking the respective go to button in the quote details grid on the main tab.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Details** scroll contains one entry for every quote detail linked to the quote (a summary of these quote details also appears on the Main tab). The remainder of this section describes the information displayed for each quote detail.

> **Note**
>
> **You don't have to use the scroll.** If the quote has many quote details, you don't have to use the scroll to work through them. Rather, you can use the go to button in the quote details grid on the main tab to position the respective quote detail in the following scroll. Also note, you can use Alt - and Alt + to scroll to the next and previous quote details in the scroll.
>
> **You cannot maintain quote details on this page.** All maintenance functions (generate, delete, accept, decline and cancel) are performed on the **Main** tab.

Premise Info is the address of the main premise associated with the service agreement (as defined on the service agreement's characteristic premise). It's important to note that the service agreement may cover service at multiple premises, but only one may be defined as the main premise.

Quote Detail ID is the system-assigned unique identifier of the quote detail.

SA Info is a concatenation of the proposal SA's division, SA type, start option (if any), status and start date.

SA Version is a snapshot of the proposal SA's version number at the time the quote detail was generated. This information is used by the system to detect if the proposal SA was modified after the quote detail was created.

Total Amount is the sum of the quote detail's simulated bill segments.

Create Date / Time is the date and time the quote detail was generated.

Remarks highlight special circumstances associated with the quote detail. Please see the description of this field on the main tab for more information.

The grid contains a row for each simulated bill segment linked to the quote detail. The following information appears in the grid:

- The first go to button transfers you to the bill segment page where the details of the simulated bill segment are shown.
- **Bill Segment Period** defines the start and end dates of the simulated bill segment.
- **Amount** contains the amount of the bill segment.
- **Remarks** highlight special circumstances associated with the bill segment.

Copyright © 2026, Oracle and/or its affiliates.

- **Billing Scenario ID** allows you to go to the proposal SA's billing scenario where you can tinker with consumption and the bill segment period used to generate this bill segment. Refer to Proposal SAs Contain Billing Scenarios for more information.

Quote - Quote Routings

This page is used to view the recipients of a quote. Refer to Printing Quotes for a discussion of how this information is used to produce quote images.

This page is also used to request a new copy of a quote.

> **Note**
>
> **No routing information until completion.** A quote has no routing information until it is complete. At completion time, the system creates a routing detail for every person linked to the account that receives a copy of its quotes. Refer to Printing Quotes for more information about how this information is constructed.

Use **Menu**, and then **Sales & Marketing**, and then **Quote**, and then **Search** and navigate to the **Quote Routings** page.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status). **Quote ID** is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Routing Information** scroll contains an entry for each recipient of the quote. This information is disabled after the quote has been routed to the recipient. The remainder of this discussion describes the fields that can be defined for each recipient of the quote.

Person ID identifies the person who was originally associated with the routing record. You may change the **Person ID** to any person in the system as this information is only used to default the recipient's name and address information, below.

The **Quote Routing Parameters** area contains information explaining how and when the quote is routed to the recipient. This information is gray when the quote routing information has been extracted or if a quote is reopened:

- **Quote Route Type** is the method used to transmit the quote to the customer. This information defaults from Account - Person Information.
- **Batch Control** is the identifier of the batch of quotes in which the recipient's copy was downloaded. Embedded in this identifier is the batch control ID and the batch number. Note, this batch process is defined on the Quote Route Type or CIS Division.
- **Sequence** is the system-assigned identifier assigned to this quote routing.
- Turn on **Do Not Extract** if the quote should not be routed to the individual for whatever reason.
- **Reprint** is checked if an operator created this routing. This switch is populated by the system and is always protected.
- **Extract Date/Time** is the date and time the quote was downloaded. This information only appears after the download has commenced.

Copyright © 2026, Oracle and/or its affiliates.

The **Mailing Address Information** area contains the recipient's name and address.

- If the recipient has an override mailing name , **Name1**, **Name2** and **Name3** contain the person's override mailing name. Otherwise, **Name1** contains the recipient's primary name (this name might also include a prefix or suffix if the related Account - Person relationship has these fields defined).
- The remaining fields are the recipient's address. Refer to Completing A Quote Creates Quote Routings (And More) for information about how the system constructs the recipient's address
- If the recipient's address is a mailing address (as opposed to fax or email), the **Country** associated with the address controls the fields that appear in the address. Refer to Defining Countries for more information on the address constituents.
- If a user manually adds a routing record, the mailing address information defaults from the information on the current routing record.
- If a user specifies a **Person ID** that is linked to the quote's account, the **Quote Route Type** defined for this person on the account is defaulted.
- If a user specifies a **Person ID** that is not linked to the quote's account, the **Quote Route Type** on the installation record is defaulted. Note, if the quote route indicates the quote is routed via the postal service, the system will only be able to default the person's address if the person has an override mailing address on their correspondence information.
- If the user changes the **Quote Route Type** after the initial default, the system populates the address information as described above.

Service Credits

"Service credits" is a term used to describe a special program designed to reward a customer for service along with benefits related to such a program. For each program that a customer participates in, there is a service credit membership record. Service credit events are used to record the "points" earned and redeemed for the membership. The topics in this section provide further details related to the service credit functionality.

NOT_SUPPORTED

For information about designing and setting up your control tables for configuring service credit functionality, refer to Designing Your Service Credit Options.

Note

Service credits are optional. Service credits may not be set up in your system; they are only used if your company offers rewards programs to customers.

Penalty Points. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

- The Big Picture Of Service Credit Membership
- The Big Picture of SC Events
- Maintaining Service Credit Memberships and Their Events

The Big Picture Of Service Credit Membership

If a customer is participating in a rewards program, the customer has a service credit membership. The topics in this section provide background information about a variety of service credit membership features and functions.

- Who are the Members?
- Membership Application
- Creation of a Membership
- Membership Fees
- Stopping a Membership vs Inactivating a Membership

Who are the Members?

Each membership has one or more "members". The members are defined by the accounts linked to the membership and by the financially responsible person(s) linked to each account.

A typical membership is linked to only one account. However, in some cases more than one account is linked to the membership. For example, a customer may have one account for residential service and one for commercial service, but both accounts are part of the same membership. In this example, one person with multiple accounts is linked to the membership, so there is only one member.

For each account linked to the membership, the service related to the account may be used to calculate the accumulated credits for the membership. Refer to How Are Service Credits Earned? for more information.

> **Note**
>
> An account may not be linked to more than one membership of the SAME membership type at a given point in time. In other words, an account may not have two United Airlines frequent flier memberships (otherwise, the account would accumulate double miles). However, an account may be linked to more than one membership if they are of different membership types. For example, an account may have a capital credits membership and a United Airlines frequent flier membership.

When you find a customer's record on Control Central - Search, you are transferred to the Account Information portal. One of the zones on this page contains information about memberships for the customer.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Portal Preferences.** The service credit membership zone only appears if you have modified your preferences to display this zone. Refer to Portal Preferences for more information.

- Joint Membership
- Changing the Membership Accounts

Joint Membership

It is possible for more than one person to belong to the same membership. These persons may be linked to the same account or to different accounts. A typical scenario would be a married couple that shares in a membership. This is considered a "joint" membership.

The number of "members" for a membership is mainly for information purposes and typically has no bearing on the service credit amounts calculated for the membership. There may be legal restrictions or business practice restrictions controlling how you may set up your members. For example:

- In an airline's frequent flier program, a separate frequent flier account would exist for each customer. It is possible for you to create a frequent flier membership with more than one "member", but for the system, the important information is the external frequent flier miles number linked to the membership. The customer linked to this number accumulates the miles. For this case, your business practice may be that the person with the frequent flier account must be the only financially responsible person.
- For a capital credits membership, you may be required to distinguish between "single" memberships and "joint" memberships. If a single person gets married and would like the spouse to be added as a member, your practice may be to expire the single membership and to create a new "joint" membership to include both spouses.

> **Note**
>
> **Co-op Members**. Do not confuse the "members" of a co-op with the members linked to a service credit membership. At a cooperative, most customers are considered "members" of the co-op. However, in the system, separate membership records are created for each single or joint membership.

Changing the Membership Accounts

The link between the accounts and the membership is NOT effective dated. This means that if the list of accounts for a membership changes, you need to stop the membership and start a new one with the new list of accounts.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Stopping Memberships**. Stopping a membership does not necessarily prevent new service credits from accumulating. Refer to Stopping a Membership vs. Inactivating a Membership for more information.

Membership Application

Your business practice may dictate that the customer complete an enrollment form. Depending on your practice, the form may need to be received prior to starting membership or it may simply be a mechanism to gather supplemental information once the membership has begun.

Either way, you may consider setting up the system to handle forms as follows:

- Design your membership type to include a creation algorithm that generates a letter when the membership is created. The letter template could include the form to be filled out.
- Create the new membership in pending status. The letter and form are sent to the customer and the pending status indicates that you are waiting for the completed form. Refer to the Lifecycle of a Membership for more information.
- When the paperwork is received, change the status of the membership to active.

> **Note**
>
> **Membership Events for Pending Memberships**. The system allows events to be created for pending memberships assuming that paperwork is supplemental information that should not prevent service credits from accumulating. If your business practice dictates that the paperwork must be received prior to accumulating service credits, the algorithm or background process that creates events for memberships of this type should be coded to only create events for active memberships. Refer to How Events Are Created for more information.

Creation of a Membership

Memberships may be created using the membership page when a customer has signed up for a special program. In addition, it may be your business practice to automatically create a membership under certain circumstances when a customer has signed up for service.

For example, if you are a co-op, perhaps every new customer is automatically enrolled in a capital credits membership. Or perhaps signing up for cable service automatically entitles your customers to membership in the free pay-per-view movies program. For these cases, the recommendation is to use the order page to start service for your customer and to use questions and miscellaneous fields to record information needed to set up the new membership correctly. Refer to Using Campaigns & Packages to Create a Membership.

Copyright © 2026, Oracle and/or its affiliates.

Membership Fees

Some memberships may require a fee to be paid by the customer when joining. The behavior of this fee may differ depending on whether it is refundable or not.

- If the fee is nonrefundable, you create an SA with a simple adjustment or a one time billable charge to levy the fee. Refer to Defining Control Tables for a Nonrefundable Fee.
- If the fee is refundable, in addition to defining the SA to hold the fee, you need to put code in place to initiate the refund. Refer to Setting Up a Refundable Fee for more information.

Stopping a Membership vs Inactivating a Membership

You may stop a membership by entering an end date for the membership. However, depending on how events are created for your membership, stopping the membership may not prevent new events from being created. For example:

- If you stop a frequent flier membership on May 15th and a bill is subsequently created for the period May 1st through June 1st, your business rules may dictate that frequent flier miles should be accumulated for this bill because the membership was active for part of the period covered by the bill.
- For a capital credits membership, capital credit allocations are calculated for the prior year. If a membership stopped in the middle of the previous year, the membership should still get capital credits for the part of the year that the membership was still in effect.
- Capital credit retirements are calculated based on capital credit allocations accumulated in the past. If a membership has been expired, the members are still eligible for retirement amounts for the accumulated capital credit allocations. These retirements may continue for many years after a membership is stopped.

> **Note**
>
> **Membership Status**. For all the above scenarios, the system assumes that the status of the membership remains active.

You may have some circumstances where you do not want new events to accumulate after a membership is stopped. To prevent new events from being created, you must change the status of the membership to inactive.

If a customer moves away or otherwise stops service with your company, your business rules dictate whether or not the membership should be stopped or changed to inactive. The following issues must be considered:

- Will service credit events still get created for these memberships? If so, is that acceptable?
  - For frequent flier memberships, the miles are calculated based on new bill amounts for the membership's service agreements. If the SAs that contribute to the membership are expired, no new bills are generated so no new miles are accumulated.
- For capital credits, after a customer moves away, the capital credit allocation for the final year of the customer's service may still need to be calculated. In addition, this customer is

Copyright © 2026, Oracle and/or its affiliates.

eligible for the capital credit retirement amounts, even though they are no longer a customer.

- What happens if the customer returns to your company and signs on for service again? Assuming that the same account number is used, is it ok for the membership to be automatically reinstated? Or should the customer reapply? If the customer should reapply, you may consider updating the membership with a stop date when the customer originally stopped service.

> **Note**
>
> There is nothing in the system logic that automatically updates the membership stop date or the status when service agreements that contribute to the membership are stopped.

The Big Picture of SC Events

The service credit events record the accumulation and redemption of awards earned by the membership. The topics in this section provide background information about a variety of service credit event features and functions.

> **Note**
>
> **Events.** For convenience, this document often refers to service credit events simply as "events".

- Event Amounts May Contribute to a Balance
- Events May Indicate a Fiscal Year
- Events May Indicate a Subcategory
- An Event May Cause Other Actions to Occur
- Financial Transactions for an Event
- How Events Are Created
- Creating Pending Events
- Events May Be Transferred
- CPCRALOC - Allocating Capital Credits
- CPCRRETR - Capital Credit Retirement

Event Amounts May Contribute to a Balance

The event amount may be positive or negative, based on whether the event is accumulating points earned for the membership or redeeming points for the membership. For some types of memberships, these credit and debit amounts should be added together to produce the overall balance for the membership.

Copyright © 2026, Oracle and/or its affiliates.

For some types of memberships, a balance is not applicable. This is true for memberships where the redemption of the points does not occur within the system. For example, if the membership accumulates frequent flier miles on behalf of an airline, the customer redeems the earned miles with the airline, not with your company. As a result, there is no need to calculate a balance for the membership.

If you want the system to calculate a balance, you must set a switch on the membership type page. For memberships that calculate a balance, the balance may be viewed on the membership page.

Events May Indicate a Fiscal Year

For some types of memberships, the amount of each event is associated with a specific fiscal year. This is true for capital credit memberships where capital credit allocations are calculated for a fiscal year. When the capital credits are redeemed (also called retired), the retirement events must also indicate a fiscal year. Because all events for this type of membership are related to a fiscal year, the system can calculate the balance for the events by fiscal year.

If you want the system to require a fiscal year for every event in the membership, you must set a switch on the membership type page. For memberships that calculate a balance and indicate a fiscal year, the balance for each fiscal year may be viewed on the membership page.

Events May Indicate a Subcategory

For some types of memberships, the amount of each event is further grouped by a subcategory. This is common for capital credit memberships where multiple capital credit allocations are calculated. For example, each year, you may calculate allocations for generation and for transmission. Events for memberships of this type must indicate a subcategory.

Cooperatives that allocate capital credits for more than one subcategory, typically want to view the balance of the events over time broken down into these subcategories. When the capital credits are redeemed or retired, the retirement events must also indicate a subcategory. Because all events for this type of membership are related to a subcategory, the system can calculate the balance for the events by subcategory.

> **Note**
>
> **Partial Retirement**. For some cooperatives, it is common that certain capital credit allocations are never retired. Refer to Partial Retirement for more information.

If you want the system to require a subcategory for every event in the membership, you must define the valid subcategories on the membership type page. For memberships that calculate a balance and indicate a subcategory, the balance for each subcategory may be viewed on the membership page.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Calculating Subcategory Balances**. If events for your membership indicate a subcategory and fiscal year, balances for the membership are calculated for both groupings.

An Event May Cause Other Actions to Occur

When an event is generated, there are often other actions that need to take place. For example:

- If an event is created that allocates points for the customer, you may want to generate a temporary message on the customer's next bill.
- If a capital credit allocation event is created, the general ledger is affected so an adjustment must be created to post to the general ledger. Refer to Financial Transactions for an Event for more information.
- If an event is created to add frequent flier miles, the event must be marked for extraction so that the information is sent to the appropriate airline. Refer to Interface Membership Information to a Third Party for more information.
- If an event to retire capital credits is created, the customer's balance is affected so an adjustment must be created to transfer the capital credit to the members' service agreements. Refer to Financial Transactions for an Event for more information.

The system relies on algorithms linked to the event type to perform the actions described above and any other action that may be required by your business.

> **NOT_SUPPORTED**
>
> Refer to Service Credit Event Types for more information about the algorithms provided with the base product.

> **Note**
>
> **Event Cancellation Algorithms**. The event type also defines algorithms to be executed when an event is canceled.

Financial Transactions for an Event

An event may be related to financial transactions. There are two types of financial transactions that may be linked to the event:

- Financial transactions that contributed to the event. These are bills, payments or adjustments that caused the event to be created. For example, if you generate an event for frequent flier miles as a result of some amount billed for the customer, the bill segments

Copyright © 2026, Oracle and/or its affiliates.

associated with the billed amount are linked to the event. The FTs are linked to the event for audit purposes.

- Financial transactions that are created by the event. In an event may cause other actions to occur, we saw examples where an event completion algorithm may cause adjustments to be created. The FT ID for these adjustments is linked to the event as audit.

> **Note**
>
> **Automatically Canceling Event Financial Transaction**. The created by financial transactions may get canceled if the event is canceled AND you have plugged in an appropriate Event Cancellation Algorithm.

For financial transactions that are created by the event, the system must post the financial transactions to one or more appropriate service agreements. The service agreement to use depends on your business rules. For example:

- If the event affects the balance of accounts linked to the membership, the event completion algorithm may create adjustments for service agreements that contribute to the membership.
- If the event affects the general ledger and does not affect any balance for the account, the event completion algorithm simply needs a service agreement to use for the resulting adjustment. Rather than arbitrarily picking any service agreement in this case, a special miscellaneous service agreement should be linked directly to the membership for such adjustments.

How Events Are Created

Although a user may create an event manually on the service credit event page, most events are created automatically by an algorithm or by a background process. The following topics further describe these options.

- Events Created by an Algorithm
- Events Created as a Result of a Background Process

Events Created by an Algorithm

You would design an algorithm to create your events if the event should be triggered by an occurrence in the system, such as starting service or generating a bill. For example, perhaps every time you are billed for electric and/or gas service, the system adds one frequent flier mile for every $10 spent on service. Refer to How Are Service Credits Earned? for more information.

The base product provides a bill completion algorithm to create an event as a result of the amount billed for service agreements linked to the membership. Refer to CBCM-SC for more information.

Copyright © 2026, Oracle and/or its affiliates.

Events Created as a Result of a Background Process

You would use a background process to create the event if the calculation is done periodically or on an ad-hoc basis and does not get triggered by something occurring in the system. For example, the capital credit allocation and retirement processes are typically run once a year, when the business has determined that they are ready to calculate these amounts.

> **NOT_SUPPORTED**
>
> Refer to Allocating Capital Credits and Capital Credit Retirement for more information.

Creating Pending Events

Events may be created in pending or complete status. Only complete events cause the completion event algorithms to run and cause other actions to occur. You may use the status of pending if you want to review the calculated amount prior to completing the event.

For example, when a cooperative runs the background process to allocate capital credits, it may create the new events in the pending status. This allows the co-op to review the total amount of capital credits calculated for all members. If this total is in line with the co-op's expectations, they run the background process again creating the new events in complete status. Only at this point do the completion event algorithms run.

Events May Be Transferred

In some situations, you may want to transfer service credit events from one membership to another on the service credit event page. For example, if a member dies, you may decide to transfer earned service credits to the membership for a beneficiary. When transferring a service credit:

- The target membership must be of the same membership type as the original membership.
- The original service credit event is canceled and any event cancellation algorithms linked to the SC event type are executed.
- A new service credit event is created and completed and any event completion algorithms linked to the SC event type are executed.
- The new service credit event references the original event ID in the **Transferred From** event field.

> **Note**
>
> Contributed to FTs linked to the original event are not transferred to the new event. If you have created by FTs linked to the original event, the recommendation is to ensure that an event cancellation algorithm cancels this FT and that an event completion algorithm for the new event creates an appropriate new FT for the new membership.

Copyright © 2026, Oracle and/or its affiliates.

CPCRALOC - Allocating Capital Credits

The base product provides a background process (CPCRALOC) that allocates capital credits to members of a cooperative. The result of this process is the creation of new service credit events for capital credit memberships. This background process is typically run after the profits for the previous year are calculated. During that time, this job could be run a number of times for any of the following reasons:

- At the beginning of the allocation process, you may know the total amount to allocate to all members; however, you may estimate the allocation factor that determines the individual amounts that get distributed to the members. You may need to change your estimate and rerun the process until all the individual allocations add up to the desired total amount. To run the job with the estimated allocation factors, indicate that you want events created as pending. When you confirm the correct allocation factor, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type, subcategory and fiscal year. Refer to Creating Pending Events for more information.
- If the cooperative has more than one subcategory, the process must be run for each subcategory. In fact, the above trial-and-error process may need to be followed for each subcategory.

You must provide the service credit event type to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type. To calculate the capital credit allocation, the system finds all applicable bill segments for each service agreement that contributes to the membership.

Capital credit allocations are calculated for a specific fiscal year. The fiscal year is input to the background process and is stamped on any new events created by the process. The system also uses the fiscal year to determine the applicable bill segments for the membership's SAs. It uses the bill segment's accounting date and the accounting calendar to determine the fiscal year for each bill segment.

> **Note**
>
> **Canceled Bill Segments**. Any bill segments that were canceled in the fiscal year are included as well.
>
> **Accounting Calendar**. This process assumes that only one accounting calendar exists for the company. This is the case for companies that operate in a single jurisdiction, which is true for cooperatives.
>
> **Allocation Period**. If the membership was only effective for part of the fiscal year, the allocations are only calculated for the period of time that the membership was in effect.

For each applicable bill segment, the system determines the SQ total and the total sales amount for each segment. To calculate the totals correctly, a characteristic type and value to identify SQ bill lines must be provided to the background process and a characteristic type and value to identify bill lines contributing to the total sales amount must be provided to the background process.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Identifying SQ and Sales Information for Historical Bill Segments for more information.

If your membership type indicates subcategories to be used for the events, you must provide a subcategory as input. If you have multiple subcategories for your membership, this process must be run once for each subcategory.

The calculation of the capital credit allocation amount typically uses an allocation factor. This factor is often different for each subcategory. You will probably define a different bill factor for each subcategory and use the appropriate bill factor when submitting the process for each subcategory.

This process also assumes that the allocation factor differs by the customer's revenue class. It assumes that the bill factor's characteristic type is revenue class. Refer to Designing Bill Factors for Credit Allocation for more information. For each service agreement linked to the membership, the appropriate allocation factor is determined based on the revenue class for the SA type.

Capital credits for the input subcategory are calculated as follows:

Fiscal year sales amount - (fiscal year SQ amount * revenue class allocation factor) = Allocation Amount

The calculated amount is compared against a minimum amount, input to the background process. If the calculated amount is less than the minimum, no event is stored for this amount.

After determining the amount, a new service credit event is created for the membership. The event is stamped with the input subcategory, service credit event type and fiscal year.

The FTs for all the bill segments used to determine the allocation amount are linked to the event as contributed to FTs. Refer to Financial Transactions for an Event for more information.

Note

Rerunnable Process. This process is restartable and rerunnable. When running the process, for each membership the system checks whether there is already a complete event for the input service credit event type, subcategory and fiscal year. If so, it does not create a new event.

NOT_SUPPORTED

Refer to CPCRALOC for more information.

CPCRRETR - Capital Credit Retirement

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Calculation Method**. There are various calculations that different cooperatives may use when determining the amount to retire. The base product has provided one calculation method.

This background process is run when a cooperative is ready to pay out allocated capital credits to its members. This process is referred to as retirement. The result of this process is the creation of new service credit events for capital credit memberships. Capital credits are paid as the cooperative's financial position permits. During that time, this job could be run a number of times for any of the following reasons:

- You may choose to run the process and create pending events to review the results prior to finalizing the retirement. When you are happy with the results, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type and subcategory.
- If the cooperative has more than one subcategory, the process may be run separately for each subcategory. You may also run the process with no subcategory indicated and then all subcategories are processed.

> **Note**
>
> **Partial Retirement**. For some cooperatives there may be capital credits for some allocated amounts that are never retired. If that is the case, simply run this process for each subcategory whose amounts do get retired.

You must provide the service credit event type to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type.

This process receives a percentage to retire as input. It determines the current balance of all completed events for the subcategory. The retirement amount for the subcategory is calculated as the current balance * input percentage to retire. The process then determines the outstanding balance for each subcategory and fiscal year combination. For every combination that still has a balance, the process creates events to relieve the outstanding balance for the oldest fiscal year first. It creates events for subsequent fiscal years until the full retirement amount is used.

In order for the process to be rerunnable and restartable, a Control ID is used to mark retirement events that are created by the process. The Control ID is input to the routine and is determined by the user. When the process runs, it determines whether an event already exists for the subcategory / Control ID combination. If so, new events are not created for that subcategory. If you run the process multiple times for the reasons described above, you should use the same Control ID each time. This way the system knows that the process is being run again for the same retirement calculation.

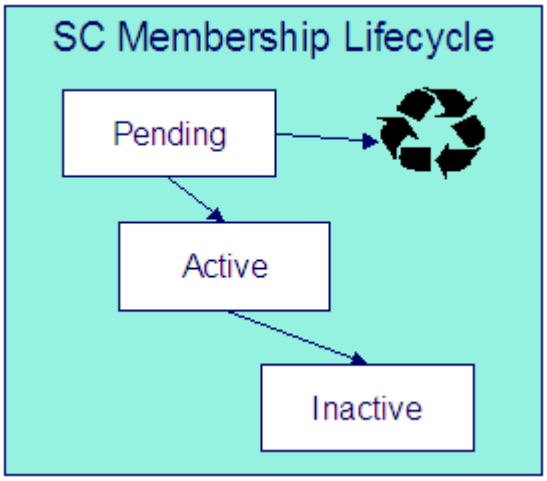
> Refer to The Big Picture Of Service Credits for background information about service credits.

- Service Credit Membership
- Maintaining Service Credit Events



Service Credit Membership

The topics in this section describe how to maintain service credit memberships. Refer to The Big Picture Of Service Credit Membership for background information about memberships.

- Lifecycle of a Membership
- Service Credit Membership - Main
- Service Credit Membership - Account
- Service Credit Membership - Characteristics
- Service Credit Membership - Membership Tree

Lifecycle of a Membership

The following diagram shows the possible lifecycle of a service credit membership.

Copyright © 2026, Oracle and/or its affiliates.

Pending A service credit membership may start out in the Pending state. A membership is typically created in this state if the creation of the membership requires approval or any manual step (e.g. waiting for paperwork) that needs to be completed prior to activation.

> **Note**
>
> **Events for Pending Memberships**. Service credit events may still be created for membership records in the Pending state.

Active A service credit membership is in the Active state when a customer is actively participating in a service credit membership. A membership may be created in the Active state or it may transition to the Active state from Pending when all the necessary approval or paperwork is complete.

> **Note**
>
> **Manual Activation Only**. There is no system functionality that automatically changes the status of a membership from Pending to Active. This is a manual step.

Inactive If a customer is no longer actively participating in a service credit membership, change the status to Inactive. This will prevent any new events from being created for the membership.

Service Credit Membership - Main

This page is used to maintain and display general information about a service credit membership. Open this page using **Menu**, and then **Customer Information**, and then **Service Credit Membership**, and then **Search**.

Description of Page

Membership Info and **Membership ID** are displayed on every page. These values only appear after the membership exists on the database. The **ID** is a system-assigned random number. The **Membership Info** is a concatenation of important details about the membership.

Membership Status defines the state of the membership.

> **NOT_SUPPORTED**
>
> Refer to Lifecycle of a Membership for more information about membership status.

Click the **Activate** button to activate a Pending membership. When this button is clicked, the system executes any Membership Activation algorithms that are linked to the service credit membership type.

Click the **Inactivate** button to transition an Active membership to Inactive. When this button is clicked, you are prompted to provide an **Inactive Reason** and the system executes any Membership Inactivation algorithms that are linked to the service credit membership type.

Copyright © 2026, Oracle and/or its affiliates.

Indicate the **SC Membership Type**. This field is important as it controls numerous aspects of the behavior of the membership and its events.

> **NOT_SUPPORTED**
>
> For more information about what the membership type controls, refer to Setting Up Service Credit Membership Types.

Indicate the **Start Date** and **End Date**, which define the period for which this membership is effective. Leave the end date blank if this membership is effective indefinitely. Refer to Stopping a Membership vs. Inactivating a Membership for more information.

If this membership is related to a record in an external system, use the **External ID** to indicate the unique identifier of the record in the external system.

If events linked to your membership may generate miscellaneous adjustments, indicate the **Service Agreement** to use for these miscellaneous transactions. The account for this service agreement must be one of the accounts linked to the membership.

The **Events** grid displays the events linked to the membership. To view any of the events use the drill down button.

If your SCM type indicates that the membership has a balance, the tree at the bottom displays information about the balance of the membership based on the amounts for completed events. If the SCM Type indicates subcategories and/or a fiscal year is required, subtotals for completed events are also displayed for each subcategory / fiscal year and by fiscal year / subcategory, if applicable. If any pending events exist, the tree includes a node with information about these events.

Service Credit Membership - Account

This page is used to maintain the accounts linked to a service credit membership. Open this page using **Menu**, and then **Customer Information**, and then **Service Credit Membership**, and then **Search** and navigate to the **Account** page.

Description of Page

Indicate the **Account ID** for each account linked to this membership. Typically a membership will be linked to only one account. However, if a person has multiple accounts and the service credits should span the accounts, multiple accounts are linked to the same membership.

The Service Credit Membership zone on the Account Information portal contains information about memberships for the current customer. (When you find one of the customer's records on Control Central - Search, you are automatically transferred to the Account Information portal.)

> **Note**
>
> **Portal Preferences.** The Service Credit Membership zone only appears if you have modified your preferences to display this zone.

Copyright © 2026, Oracle and/or its affiliates.

Service Credit Membership - Characteristics

The characteristics page contains information that describes miscellaneous information about the service credit membership. Open this page using **Menu**, and then **Customer Information**, and then **Service Credit Membership**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible on the service credit membership record. Refer to Setting Up Characteristic Types & Their Values for more information.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click + to insert a row then fill in the information for each field. The following fields display:

Effective Date Define the date on which the characteristic becomes effective. The effective date defaults from the Installation Record.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

> **Note**
>
> **Default Note.** A service credit membership's characteristics default from the service credit membership type.

Service Credit Membership - Membership Tree

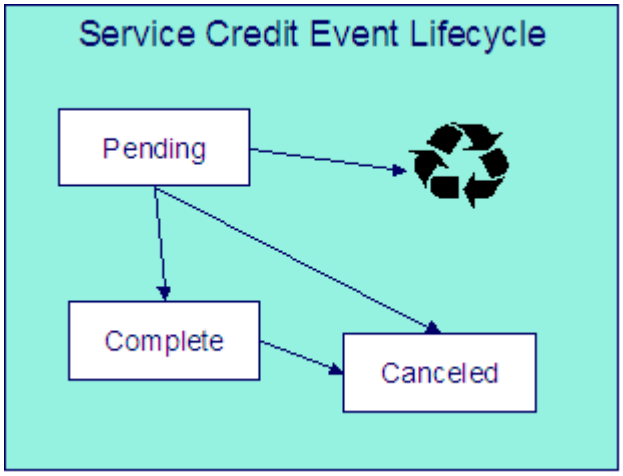
The membership tree page displays accounts, SAs and persons linked to the service credit membership. Open this page using **Menu**, and then **Customer Information**, and then **Service Credit Membership**, and then **Search** and navigate to the **Membership Tree** page.

Description of Page

The tree displays each account linked to the membership. For each account, a node exists for:

- Each service agreement whose SA type is included in the service credit membership type 's SA type collection.
- Each financially responsible person linked to the account. These persons are considered the members.

Copyright © 2026, Oracle and/or its affiliates.



Maintaining Service Credit Events

Service credit events record credits earned or redeemed for a given membership. The topics in this section describe how to maintain service credit events. Refer to The Big Picture of Service Credit Events for background information about memberships and their events.

- Lifecycle of a Service Credit Event
- Service Credit Event - Main

Lifecycle of a Service Credit Event

The following diagram shows the possible lifecycle of a service credit event.

Pending A service credit event may start out in the Pending state. An event is typically created in this state when a review of the event is desired before completing it. Refer to Creating Pending Events for more information.

Complete A service credit event is typically created in the Complete state. When an event is completed, the system executes any event completion algorithms indicated on the service credit event type.

Canceled If a service credit event is no longer valid, it may be Canceled. When an event is canceled, the system executes any event cancellation algorithms indicated on the service credit event type.

Service Credit Event - Main

Open this page using **Menu**, and then **Customer Information**, and then **Service Credit Event**, and then **Search.**

Description of Page

The **Service Credit Event Info** is a concatenation of important details about the service credit event. The **Service Credit Event ID** is a unique system-assigned random number. These values only appear after the service credit event exists on the database.

Copyright © 2026, Oracle and/or its affiliates.

Service Credit Event Status defines the state of the service credit event.

> **NOT_SUPPORTED**
>
> Refer to Lifecycle of a Service Credit Event for more information.

Click the **Complete** button to change a Pending event to Complete. When this button is clicked, the system executes any event completion algorithms that are linked to the service credit event type.

Click the **Transfer** button to transfer this event to another membership. When this button is clicked, you are prompted to provide the membership ID to transfer the event to. The new membership must have the same membership type as the original membership. Refer to Events May Be Transferred for more information.

Click the **Cancel** button to cancel this event. When this button is clicked, the system executes any event cancellation algorithms that are linked to the service credit event type.

The **Create Date/Time** captures the date and time that this event was created. This defaults to the system date/time.

Indicate the service credit **Membership ID** to which this event should be linked.

Indicate the **Service Credit Event Type**. This field may define algorithms to be executed when the event is completed or canceled. Refer to Setting Up Service Credit Event Types for more information.

If your service credit membership type indicates one or more subcategories to be associated with events for this type of membership, indicate the appropriate **Subcategory Name** for this event.

If your service credit membership type indicates that fiscal year is required, indicate the appropriate **Fiscal Year** for this event.

Enter the **Service Credit Event Amount**. If your service credit membership type indicates that your membership has a balance, this amount is used to calculate the overall balance for the membership as well as a balance for the subcategory and/or fiscal year, if applicable.

If this event was created as a result of a transfer from another membership, the **Transferred From Event** ID is displayed.

If the information about this event may be downloaded to a third party system, you should have an event completion algorithm that stamps the appropriate **Batch Control** and **Batch Number** onto the event.

The FT collection displays information about financial transactions related to this event. Two different categories of financial transactions may be linked to the event.

- FTs that contributed to this event. These financial transactions played a part in the creation of this event. For example, if frequent flier miles are earned as a result of newly created bill segments, the FTs related to these bill segments are linked to the event and marked as contributed to FTs. This information is purely for audit purposes. It is the responsibility of the algorithm or background process that creates the event to populate the collection of contributed to FTs. Refer to How Events Are Created for more information.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The amount of the contributed to FTs will not necessarily add up to the amount of the event. Refer to the algorithm or background process that calculates the amount of the event to understand how the event amount is calculated based on the amount of the contributed to FTs

- FTs that were created by this event. These financial transactions are created as a result of this event. For example, if you have generated a capital credit allocation event, perhaps you need to post information to the general ledger. An allocation event should therefore generate an adjustment to post the effect on the GL. The adjustment's FT is linked to the event as an audit. In order to create a financial transaction related to this event, you must plug in an appropriate event completion algorithm on your service credit event type.

> **NOT_SUPPORTED**
>
> Refer to An Event May Cause Other Actions to Occur for more information.

Loans

There are many reasons why your company may loan money to customers. For example, your company may loan money to:

- Finance service upgrades (e.g., to change to dual fuel)
- Support economic development (e.g., to extend a power line)
- Promote energy conservation (e.g., customers borrow to insulate their house)

> **Note**
>
> **Loans are optional.** You need only set up loans if your organization loans money to customers. For information on setting up the system to enable loans, refer to Defining Loan Options.

- The Big Picture Of Loans
- Loan Maintenance
- How To

The Big Picture Of Loans

The topics in this section provide background information about loans.

Copyright © 2026, Oracle and/or its affiliates.

- Loans Are Service Agreements
- Loan Interest Charges
- Loan Amortization Schedules
- Loan Overpayments
- The Lifecycle Of A Loan
- Finalizing And Closing A Loan
- Navigating To The Loan Maintenance Page

Loans Are Service Agreements

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA type) contains the loan's terms, including the loan amount, periodic payment amount, the number of amortization periods, the interest rate, and the periodicity of the bills. Loan service agreements are just like other service agreements in many ways:

- The system bills the customer for the periodic payment amount using information on the service agreement.
- The customer pays the billed amount.
- If the customer doesn't pay, credit and collections may start a collection process to encourage the customer to pay (depending upon how the loan debt class has been set up on your system).

Loan service agreements differ from other service agreements in the following ways:

- Loans have interest charges.
- Loans have amortization schedules.
- Loan SAs are maintained on a separate transaction (refer to Loan - Main for more information).

> **Note**
>
> **Loan service agreements are created using Start/Stop.** Loan service agreements are created using start/stop just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

Loan Interest Charges

When a bill is generated for a loan, the interest charge is calculated using an algorithm. The base package loan interest charge algorithm type (LINT-SI) calculates simple interest based on:

- Unbilled principal (i.e., the payoff balance minus the current balance)
- The number of billing periods covered by the bill

Copyright © 2026, Oracle and/or its affiliates.

- The interest rate

> **Note**
>
> **No interest on interest and no interest on past due amounts.** Just like a classic home loan, the base package algorithm does not calculate interest on interest, nor does it calculate interest on past due amounts. However, your system may be set up to levy a late payment charge.

After the interest charge is calculated, the bill segment FT algorithm generates the financial transactions for the bill. The base package FT algorithm generates a financial transaction that adds the interest charge to the payoff balance. In other words, if the customer wanted to pay off the loan, they would owe the principal balance plus the interest charge.

> **NOT_SUPPORTED**
>
> For more information, refer to Billing For Loans And Interest Calculation.

Loan Amortization Schedules

A loan's periodic payment amount is calculated such that the customer repays the loan in equal amounts over the term of the loan (with the exception of the first and last bill segments, which are typically for different amounts). The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

The amortization schedule is a theoretical projection of the future. The term theoretical is used because the customer's actual payments can cause the schedule to change. For example, if a customer overpays a bill, the loan's length decreases and the amount of principal and interest in each scheduled payment changes.

A loan's amortization schedule is calculated when you click the **Calculate** button on Loan - Main . When this button is clicked, an algorithm plugged in on the loan SA type actually calculates the amortization schedule.

You can view a loan's latest amortization schedule using Loan - Main . You can also change the loan's payment periods or periodic payment amount on this page and recalculate the loan's amortization schedule.

- Negative Amortization

Negative Amortization

The system does not allow you to use a periodic payment amount that is less than the periodic interest amount. If it did, the customer's payoff balance would increase over time (this is referred to as "negative amortization"). There are two methods you can use to specify a payment amount in the system. Depending on which method you use, the system informs you of negative amortization differently:

Copyright © 2026, Oracle and/or its affiliates.

- If you enter a payment amount that is too small on the Start confirmation page or in the **Renegotiate Future Payments** grid on Loan maintenance, you get an error message when you click the **Calculate** button. You must fix the payment amount before you can start the loan or save your changes.
- If you manually override the **Payment Amount** on Loan maintenance, you can save a payment amount that is too small to cover the interest charges. However, the system notifies you that it is not able to calculate the **Forecasted Schedule** because of negative amortization. Additionally, bill segments for the loan SA are produced in error until the payment amount is adjusted appropriately.

Loan Overpayments

Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan. When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Typically, loan service agreements should be set up so that the overpayment is applied to the principal balance.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to transfer the amount of the credit from the SA's current balance to its payoff balance, thus reducing the principal by the amount of the overpayment.

NOT_SUPPORTED

For more information about the adjustments created for loan overpayments, refer to Overpayments On Loans.

Note

Overpayments and interest. The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

The Lifecycle Of A Loan

Loans have the same lifecycle as other service agreements (e.g., pending start, active, pending stop). You should rarely have to manually change a loan service agreement's status. Why? Just like other service agreements, the system changes the status behind-the-scenes when various events take place. For example, loans in the pending start state are automatically activated by a system background process.

If you need to manually change a loan service agreement's status (e.g., you need to cancel a loan that was inadvertently started), you can do so from Service Agreement - Main.

Copyright © 2026, Oracle and/or its affiliates.

Finalizing And Closing A Loan

A loan SA is automatically stopped when the last bill segment is generated for the loan. If the remaining principal balance (plus accrued interest) is less than or equal to the loan payment amount, the SA status is changed to pending stop and the bill segment is marked as the closing bill segment. The SA can then be stopped by the user (manually using the SA page) or by the SA activation background process. When the customer pays the last bill, the loan SA is closed.

NOT_SUPPORTED

For more information about transitioning SAs from pending stopped, refer to Finalizing Pending Stops.

Navigating To The Loan Maintenance Page

Any of the following methods can be used to navigate to the Loan Maintenance transaction:

- A user can set up a favorite link associated with the loan transaction.
- Via any of the following menus:
  - Account context menu
  - Service agreement context menu
  - Menu

Note

Alerts and Loans. If the loan SA type is set up with an alert, the Alert Zone highlights if a loan exists for the current account. You are transferred to the SA maintenance transaction (not the loan maintenance transaction) if you drill down on the alert.

Loan Maintenance

You can use loan maintenance to view the loan's amortization schedule and financial history as well as to change the terms of a loan, including the loan amount (prior to SA activation only), interest rate, payment amount and number of payment periods.

Note

Starting Loans. You cannot start a loan from Loan - Main; you must use Start/Stop. Refer to How To Start A Loan Service Agreement for information.

Copyright © 2026, Oracle and/or its affiliates.

Open **Menu**, and then **Customer Information**, and then **Loan**, and then **Search** to maintain a loan.

Description of Page

The fields at the top of the page are informational only. The **Payoff Balance** is the total amount owed by the customer (excluding any interest that may have accrued since the last bill). The **Current Balance** is the amount currently owed by the customer. The **Principal Balance** is the total principal amount left unbilled. Refer to Payoff Balance and Current Balance for Loans for more information.

The **Loan Amount** is the amount originally loaned to the customer. The **Standard Interest Rate** is the standard interest rate defined on the loan's SA type. If the SA type allows, the standard interest rate may be overridden by a start option and/or manually. The **Next Payment Amount** is the effective periodic payment amount as of the next bill.

The **Payment(s)** shows the number of payments that were used to calculate the original loan schedule.

The **Override Interest Rate** grid is used to override the standard interest rate. The interest rate can only be modified if the loan's SA type allows it. Note that changing the interest rate changes the loan amortization schedule. To override the interest rate:

- Specify an **End Date** for the override rate in effect if there is one.
- Click + and specify the **Start Date** and the new **Interest Rate**. You can also specify the **End Date** of the new override rate, but this is not required.

The **Payment Amount** grid is used to maintain the effective periodic payment amount. Note that changing the payment amount changes the amortization schedule. To change the payment amount:

- Click + and specify the **Effective Date** and the new payment **Amount**.

> **Note**
>
> **Entering a payment amount that is too small.** If you save a payment amount that is too small to cover the periodic interest charges, this causes negative amortization. The system is not able to recalculate the amortization schedule and bill segments are produced in error until the problem is corrected.

The **History** grid shows the loan's financial history in reverse chronological order. The financial history grid displays the following information:

- The **Arrears Date** is used to compute how many days old the debt is. In the context of a loan, debt only refers to the billed amount (the amount the customer needs to pay to stay current).
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.
- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.
- **Payoff Amount** is the effect of the FT on the service agreement's payoff balance. The value is grayed out if it is the same as the current amount.
- **Payoff Balance** is the total amount owed by the customer. The value is grayed out if it is the same as the current balance.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> If you do not understand the difference between payoff balance and current balance, refer to Payoff Balance And Current Balance For Loans.

The **Forecasted Schedule** displays the loan amortization schedule. The first row of the schedule shows the current cumulative interest, current cumulative principal and the current principal balance. All other rows show the future amortization schedule based on the loan details. The forecasted schedule includes the following information:

- The **Loan Period** displays the forecasted payment period dates based on the billing frequency and the payment periodicity. The Loan Period is blank for the first row, which shows current cumulative amounts.
- The **Amount** displays the projected amount of that payment. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Interest** displays the projected amount of interest in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Principal** displays the projected amount of principal in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Cumulative Interest** is the total interest amount that would theoretically be billed at that loan period.
- The **Cumulative Principal** is the total principal amount that would theoretically be billed at that loan period.
- The **Principal Balance** is the remaining principal balance that would theoretically be remaining at the loan period.

> **Note**
>
> **Forecasted schedule.** The loan schedule algorithm calculates the values in the forecasted schedule. Depending on the algorithm set up for your installation, the values may have a different meaning.

The **Renegotiate Future Payments** area allows you to change the terms of the loan. You can modify the following options:

- You can modify the **Loan Amount** only if the SA has not been activated. After the SA is activated, this field is for information only.
- The **Interest Rate** allows you to change the interest rate. When changing the interest rate, specify either the number of payment amounts or the payment amount and click Calculate to recalculate the amortization schedule.
- The **Number of Payment Periods** allows you to change the number of periods remaining in the loan's term. The **Frequency** displays the periodicity of the payments. If you change the number of payment periods, use the Calculate button to recalculate the payment amount.
- The **Payment Amount** allows you to change the amount of individual payments. If you change the payment amount, use the Calculate button to recalculate the number of periods.

Copyright © 2026, Oracle and/or its affiliates.

- The **Calculate** button recalculates the payment amount (when you specify the interest rate and the number of payment periods) or the number of payment periods (when you specify the interest rate and the payment amount) and recomputes the loan amortization schedule based on these new terms.

> **Note**
>
> **Implementing New Loan Terms.** The changes that you make using **Override Interest Rate**, **Payment Amount** and **Renegotiate Future Payments** do not take effect until you save the loan. Changes made to the **Renegotiate Future Payments** section are only valid for save after you click Calculate, and they override any other changes.
>
> **Saving Renegotiated Future Payments.** When you save a loan that has renegotiated payments, the system may add new records for the override interest rate, payment amount, or both. It uses the start date of the next loan period as the start date of the new interest rate and/or as the effective date of the new payment amount. If the loan has not yet been billed, the system updates the interest rate and/or payment amount created when the loan was started.

How To

The topics in this section describe how to perform common loan functions.

- How To Start A Loan Service Agreement
- How To Modify The Terms Of A Loan
- How To Adjust Loans
- How To Stop A Loan Service Agreement

How To Start A Loan Service Agreement

Loan service agreements are created using start/stop just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above.

Creating a loan service agreement involves the following steps:

- Select the account on Control Central then open Start/Stop.
- Enter a **Start Date** and a **Start Method** of Start a SA.
- Indicate the **CIS Division** / **SA Type** of the loan service agreement and click the **Start** button.

> **Note**
>
> If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag sis set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

Copyright © 2026, Oracle and/or its affiliates.

- After you click **Start**, the Start Confirmation page appears. When you select a loan service agreement type, the Start Confirmation page displays special fields that allow you to specify the loan's terms.
- Select a loan **Start Option**. The start option includes the adjustment type for booking the principal amount, and can also include defaults for the initial loan amount, periodic payment amount, payment periods, and interest rate. The system uses the information on the start option to populate the service agreement's default parameters. You can manually override these parameters:
  - Enter the **Loan Amount** (the amount that the customer is borrowing). Note that the label for the Total Amount To Bill (e.g., Loan Amount) may appear differently depending on how the SA type was defined.
  - The system can automatically calculate either the payment amount (based on the loan amount and the payment periods) or the payment periods (based on the loan amount and the payment amount). Enter either the **Payment Amount** or the **Payment Periods** and click **Calculate**. Note that the label for the Recurring Charge (e.g., Payment Amount) may appear differently depending on how the SA type was defined.
  - Once the loan parameters are populated, click **Start**.

The loan is created in the pending start state. The next time the SA activation process runs, it will activate the loan SA. If you want to activate the loan immediately, navigate to the service agreement page and click **Activate SA**.

> **Note**
>
> **Overriding the Interest Rate.** The **Interest Rate** is a display only field. The interest rate is taken from the value of the interest bill factor defined on the SA type or the contract value of the interest bill factor on the start option if one is defined. After starting a loan, you can manually override the interest rate using Loan - Main if the SA type allows it.
>
> **Changing The Loan Amount.** You can use loan maintenance to change the loan amount for an SA as long as the SA has not yet been activated. It may be helpful to transfer to Loan - Main , and verify the amortization schedule before activating the SA.

How To Modify The Terms Of A Loan

After a loan is active, you may want to modify its terms. You can change number of payment periods, the payment amount, and the interest rate (if allowed by the SA type). To modify the terms of a loan:

- Navigate to the Loan maintenance page.
- If you used the account context menu, the loan you want to modify may be displayed. If not, use the search dialog that appears to search for and select the loan you want to modify.
- In the **Renegotiate Future Payments** section, change the interest rate (if allowed), the number of payments, or the payment amount. Note that either the number of payments or payment amount must be blank.
- Click **Calculate**. The **Forecasted Schedule** is recalculated along with either the new payment amount or the new number of payments (depending on which was left blank).

Copyright © 2026, Oracle and/or its affiliates.

- If the renegotiated payments are satisfactory to the customer, save the changes.

When you save the changes, appropriate entries are made in the **Override Interest Rate** and **Payment Amount** grids.

> **Note**
>
> **Saving Loan Modifications.** You must save the renegotiated payments after clicking Calculate for the loan modifications to be effective.

How To Adjust Loans

You issue ad hoc adjustments if you need to change a loan's principal and/or current balance outside of the normal billing and payment functions.

An adjustment can:

- Change a loan's payoff balance.
- Change a loan's current balance (i.e., how much the customer thinks they currently owe).
- Change both the loan's payoff and current balance.

> **NOT_SUPPORTED**
>
> For details about the adjustment types to apply, refer to Adjusting Loan Amounts. For information about creating adjustments, refer to Adjustments.

How To Stop A Loan Service Agreement

Normally, a loan SA is automatically stopped when the bill segment for the last payment in the amortization schedule is generated for the loan (refer to Finalizing And Closing A Loan).

If a customer decides to payoff a loan before the term is complete, you can:

- Transfer to the SA maintenance page for the loan service agreement, specify an **End Date** for the loan, and click Save. This transitions the loan SA to pending stop.

> **Note**
>
> **End Date.** The loan SA cannot be stopped until the specified end date is reached, so do not specify an end date that is in the future unless you do not want to stop the loan until that date.

Once the loan is in pending stop and the end date has been reached, the system transitions the loan SA to stopped. On the service agreement's normal bill cycle, the system final bills the SA for any outstanding balance plus accrued interest charges.

Copyright © 2026, Oracle and/or its affiliates.

If you want to stop the loan and create the final bill immediately, complete these additional steps:

- On the loan's SA maintenance page, click the Stop SA button to transition the loan SA to stopped.
- Manually, create a bill for the loan service agreement. Remember that if you only want to generate a bill segment for a specific service agreement (e.g., the loan service agreement), transfer to the bill segment page. From there, you can generate and freeze a bill segment for a specific service agreement. When finished, return to the bill page and complete the bill.

When the customer pays the final bill, the loan SA is closed by the system.

NOT_SUPPORTED

For more information about SA states, refer to The Lifecycle Of A Service Agreement.

Non-Billed Budgets

A Non-Billed Budget (NBB) is a payment plan used to level out a customer's payments over time. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. For example:

- Rather than receive a bill once a quarter, a customer could set up an Non-Billed Budget to pay fortnightly
- Rather than pay two large bills a year, the customer could set up an Non-Billed Budget to pay 10 out of 12 months (sparing themselves during the holiday season)

Non-Billed Budgets can cover one or more service agreements linked to the same account. You can have multiple active Non-Billed Budgets for an account, but any given service agreement can only be covered by a single Non-Billed Budget at any point in time.

Note

Non-Billed Budgets are optional. The business processes described in this section are only relevant if your organization offers Non-Billed Budgets to its customers.

NOT_SUPPORTED

For information about setting up non-billed budget functionality for your system, refer to Defining Non-Billed Budget Options.

- How To

The Big Picture Of Non-Billed Budgets

The following topics provide background information about Non-Billed Budgets.

- Non-Billed Budget Service Agreements
- Which SAs Are Covered By A Non-Billed Budget?
- Non-Billed Budgets Versus Other Plans For Payment
- There Are Two Types Of Non-Billed Budgets
- Navigating To The Non-Billed Budget Maintenance Page
- Recommending Scheduled Payments

Non-Billed Budget Service Agreements

Non-Billed Budgets are initiated by creating a Non-Billed Budget service agreement for a customer. The Non-Billed Budget SA and its SA type maintain the details of the Non-Billed Budget, such as recommendation rules, covered SAs, scheduled payments and credit balance. Non-Billed Budgets are just like other service agreements in some ways:

- Non-Billed Budgets have a current and a payoff balance.
- If the customer doesn't pay a monitored Non-Billed Budget, credit & collections may start a collection process to encourage the customer to pay (depending upon how the debt class has been set up on your system).

Non-Billed Budgets differ from other service agreements in the following ways:

- Non-Billed Budgets have a special role of Non-Billed Budget.
- Non-Billed Budgets have scheduled payments.
- Non-Billed Budgets maintain a list of covered SAs (utility and other service agreements to which the Non-Billed Budget applies)
- Non-Billed Budgets are started and maintained on a separate transaction (refer to Non-Billed Budget - Main for more information).

Which SAs Are Covered By A Non-Billed Budget?

A Non-Billed Budget can apply towards one or more of the account's billable SAs whose SA type is flagged as Eligible for Non-Billed Budget. SAs can be added to or removed from a Non-Billed Budget at any time. Additionally, an SA can be linked to more than one Non-Billed Budget as long as the Non-Billed Budgets to which it is linked do not have overlapping start and end dates.

A list of the SAs covered by a non-billed budget is maintained with the Non-Billed Budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budgets Versus Other Plans For Payment

Unlike a regular budget but like a payment plan, a Non-Billed Budget has one or more scheduled payments. However, unlike payment plans, bills are not produced for the scheduled payment amounts. Instead, customers are simply notified of the payment schedule and it is their responsibility to make the scheduled payments. In general, the following statements highlight the differences between Non-Billed Budgets and other payment plans.

- There is a payment schedule that is not dependent on billing, unlike budget plans.
- Non-Billed Budgets are not limited to SAs of a single debt class, unlike pay plans.
- Debt is not transferred from regular SAs to the non-billed budgets, unlike payment arrangements.

> **Warning**
>
> Non-Billed Budgets and Budget Plans! An SA should not be on a Non-Billed Budget if it is on a budget plan . A Non-Billed Budget overrides any budget functionality in most cases. However, placing an SA that is on a budget on a Non-Billed Budget may result in indeterminate results. For example, when the Non-Billed Budget is broken, the stop algorithm for the Non-Billed Budget syncs current and payoff balances for those utility SAs that were covered by the Non-Billed Budget.

There Are Two Types Of Non-Billed Budgets

There are two types of Non-Billed Budgets: monitored and unmonitored. As the terms suggest, the difference between monitored and unmonitored Non-Billed Budgets is whether they are monitored by the account debt monitor. However, this also means that monitored and unmonitored Non-Billed Budgets receive different financial treatment by the system.

In general, monitored Non-Billed Budgets have their current balances monitored by the account debt monitor while the current balances of any covered SAs are zero (and therefore don't violate any debt collection criteria). With monitored Non-Billed Budgets, customers make required prepayments that are applied towards their utility bills (until the Non-Billed Budget is stopped). They are responsible for making sure the payments on their Non-Billed Budget are up to date, but they do not have to payoff any balances on covered SAs.

Unmonitored Non-Billed Budgets do not have their current balances monitored by the account debt monitor while the current balances of any covered SAs are maintained and therefore subject to the account debt monitor. When customers are set up on an unmonitored Non-Billed Budget, the payments that they make towards the budget are optional. They are, however, financially responsible for paying the current balances of any covered SAs.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Financial Transactions For Unmonitored Non-Billed Budgets for detailed information about the financial differences between monitored and unmonitored Non-Billed Budgets.

Note

SA Type Determines Monitored Status. The SA type that you select when setting up a Non-Billed Budget determines whether it is monitored or unmonitored (i.e., it's a setting on the SA type). Your company may choose to implement only monitored non-billed budgets, only unmonitored Non-Billed Budgets, or both.

Navigating To The Non-Billed Budget Maintenance Page

Any of the following methods can be used to navigate to the Non-billed Budget Maintenance transaction:

- An alert in the Alert Zone highlights if a Non-Billed Budget exists for the current account. You are transferred to the non-billed budget transaction if you drill down on the alert.
- You can setup an order's campaign to automatically transfer a user to the Non-Billed Budget transaction whenever an order is completed for a given SA. This might be useful for campaigns that are associated with services that are typically on a Non-Billed Budget.
- A user can setup a favorite link associated with the Non-Billed Budget transaction.
- Via any of the following menus:
  - Account context menu
  - Service agreement context menu
  - Menu menu

Recommending Scheduled Payments

When creating a Non-Billed Budget, you must select a recommendation rule. The recommendation rule establishes the amount to be paid and the dates on which the payments are due. In other words, the recommendation rule creates a recommended payment schedule.

The recommendation rules that you can use are specific to your implementation. The recommendation rule that you select can have default values for its parameters. If your implementation allows, you can manually override one or more of these default values. For example, you may be able to specify the period covered by the Non-Billed Budget and the day of the month on which the payments are due.

If your implementation allows, you can manually modify the recommended payment schedule to suit the needs of a particular customer.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Designing Recommendation Rules for more information.

Maintaining Non-Billed Budgets

Non-Billed Budget service agreements are started and maintained on a different transaction than other SAs. The topics in this section explain how to start and maintain Non-Billed Budgets.

- Non-Billed Budget - Main
- Non-Billed Budget - History

Non-Billed Budget - Main

The Main page contains basic information about the Non-Billed Budget. Open **Menu**, and then **Customer Information**, and then **Non-Billed Budget**, and then **Search** to maintain this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The **SA ID** is a system assigned random number that stays with a service agreement for life. The **Non-Billed Budget SA** information is a concatenation of important details about the service agreement and its account.

The **Account ID** is identification of the account that is financially responsible for the service agreement.

Indicate the **CIS Division** and **SA Type**. These fields control aspects of the service agreement's behavior, such as whether the Non-Billed Budget is monitored or unmonitored. These fields are gray when the status is not Pending Start.

Note

If the service agreement’s account’s CIS Division’s **Restrict to Account CIS Division** flag sis set to *Restricted*, the CIS Division is set to the account’s CIS Division and cannot be changed.

NOT_SUPPORTED

For more information about Non-Billed Budget SA types, refer to Defining Non-Billed Budget Options.

Copyright © 2026, Oracle and/or its affiliates.

If **Sched**uled **Payment Auto Pay** is Included in Auto Pay and the account is set up for automatic payment, the scheduled payments are covered by auto pay. If Excluded from Auto Pay, the scheduled payments are excluded from auto pay if it is set up for the account.

Recommendation Rule is used to create a recommended payment amount and payment schedule. The SA type controls which recommendation rules are allowed for the Non-Billed Budget SA.

Current Balance indicates the amount the customer currently owes on the Non-Billed Budget. If the Non-Billed Budget is unmonitored, the current balance is always zero.

Payoff Balance displays the total amount the customer would owe if they wanted to close the service agreement. For Non-Billed Budgets, the payoff balance typically represents an accumulated credit that has not yet been distributed to the covered SAs (at bill completion time or when the Non-Billed Budget is stopped).

The **Start Date** defines when the financial relationship begins. The **End Date** is a display only field that indicates when the financial relationship terminates. The **Expiration Date** is the date on which the SA expires. The **Renewal Date** is the date on which the SA is scheduled to be renewed by the SA renewal background process. If the SA is not renewed by the expiration date, the stop process is initiated.

The **Recommendation Rule Parameter Values** grid specifies the parameters and their values to use for the selected recommendation rule:

- **Parameter** is the name of the parameter from the recommendation rule algorithm type.
- **Value** is the value used for the parameter. If the recommendation rule allows, you can override the default values by specifying your own.

> **Note**
>
> The recommendation rule's payment schedule algorithm type (NBPS-MON) controls the number and type of parameters. The recommendation rule controls the default values and whether they can be overridden.

The **Covered Service Agreements** grid lists the utility and other SAs that are on the Non-Billed Budget. You must create the list of covered SAs before the recommendation rule can recommend a payment amount and list of scheduled payments. The grid displays the **SA ID**, **SA Information**, **Current Balance** and **Payoff Balance** for covered SAs.

The scheduled payments grid displays the scheduled payments created by the recommendation rule (after you click the Recommend NBB button). You can manually create or modify the **Scheduled Date** and or **Scheduled Amount** of any scheduled payment in the list. The **Total of Scheduled Payments** shows the total of all scheduled payments in the list.

> **NOT_SUPPORTED**
>
> Refer to Scheduled And Actual Payments On The Non-Billed Budget for more information on what occurs when the base Non-Billed Budget scheduled payment background process processes scheduled payments that are due.

In the Action grid:

Copyright © 2026, Oracle and/or its affiliates.

- Click **Recommend** to create a recommended payment schedule based on the recommendation rule.
- Click **Renew** to manually renew the Non-Billed Budget. This executes the SA renewal algorithm for the SA type and returns new renewal and expiration dates for the SA.
- Click **Break** to manually cancel the Non-Billed Budget. This executes the break Non-Billed Budget algorithm defined for the SA type, and changes the status of the SA to pending stop.

Non-Billed Budget - History

The Financial History page displays the Non-Billed Budget's historical financial transactions. Open **Menu**, and then **Customer Information**, and then **Non-Billed Budget**, and then **Search** and navigate to the **History** page to view this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The SA ID is a system assigned random number that stays with a service agreement for life. The Non-Billed Budget SA information is a concatenation of important details about the service agreement and its account.

The **Account ID** identifies who is financially responsible for the service agreement.

The grid shows the Non-Billed Budget's financial history in reverse chronological order, including:

- The **Arrears Date** is used to compute how many days old the debt is. For monitored Non-Billed Budgets, debt refers to the scheduled payment amounts (i.e., the customer only owes the scheduled payment amounts up to the most recent scheduled payment date). The arrears date for a schedule payment is the scheduled payment date.
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.
- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.

How To

The topics in this section describe how to perform common Non-Billed Budget functions.

- How To Start A Non-Billed Budget Service Agreement
- How To Cancel / Stop Non-Billed Budget SAs
- How To Renew Non-Billed Budgets
- How To Set Up Automatic Payment For A Non-Billed Budget

How To Start A Non-Billed Budget Service Agreement

Copyright © 2026, Oracle and/or its affiliates.

To set up a new Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account is not already specified, select the **Account** for which you want to start the Non-Billed Budget.
- Define the **CIS Division** and **SA Type** to use for the Non-Billed Budget service agreement.
- If necessary, change the **Start Date** (the current date is defaulted).
- Select the **Recommendation Rule** to use and modify any of the default parameters to meet the needs of the customer.
- Verify the list of **Covered Service Agreements**. All the account's SAs that are eligible for Non-Billed Budget are listed. Click to remove unwanted SAs from the list.
- Click **Recommend**.
- On the pop-up dialog, specify the **Schedule Start Date** and click **Recommend**.
- Make any necessary changes to the expiration date, renewal date and scheduled payments grid and click Save.

How To Cancel / Stop Non-Billed Budget SAs

To stop a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to stop is not specified, select the **Account** of the Non-Billed Budget you want to stop.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to stop.
- Click **Break**.

How To Renew Non-Billed Budgets

Most Non-Billed Budgets are renewed automatically by a background process. However, you may manually renew Non-Billed Budgets that are eligible for renewal if desired.

To renew a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to renew is not specified, select the **account** of the Non-Billed Budget you want to renew.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to renew.
- If desired, change the recommendation rule or any of the parameters.
- Click **Renew**.

The new expiration and renewal dates are calculated and the new payment schedule is appended to the list of scheduled payments.

Copyright © 2026, Oracle and/or its affiliates.

How To Set Up Automatic Payment For A Non-Billed Budget

If a customer wants to pay their non-billed budget scheduled payments automatically:

- Set up the account for automatic payment (as described under How To Set Up A Customer To Pay Automatically).
- Navigate to the Non-Billed Budget Maintenance page and select the Non-Billed Budget for the account.
- Set the **Sched**uled **Payment Auto Pay** field to indicate that the scheduled payments are Included in Auto Pay.

Case Management

> **Note**
>
> **Separate module.** The Case Management functionality is associated with a separate Case Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

Your organization can use case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

> **Note**
>
> **Your implementation controls how your cases behave.** Since virtually all aspects of case management functionality are controlled by your implementation, you can use it to handle a myriad of business requirements. Refer to Defining Case Management Options for the details.

- Background Topics
- Maintaining Cases

Copyright © 2026, Oracle and/or its affiliates.

Background Topics

The topics in this section provide background information about case management functionality.

- Case Type
- Creating Cases
- Log Information
- Alerts
- To Do's and Cases
- Reports

Case Type

A case is controlled by the case type that it references. Some aspects of the case that are controlled by the case type include:

- The lifecycle of the case
- The applicability of a person, account, and/or premise on the case
- Which fields are required during the various stages of a case's life
- Which users can access cases of a given type
- Additional processing that should take place when a case enters or leaves a given state

Refer to Case Type Controls Everything for a description of the business rules that you control when you set up your case types.

Creating Cases

To create a case, open the case management page in add mode, select the appropriate case type, fill in the other necessary fields, and click save. Oracle Utilities Customer Care and Billing also includes scripts that can help create cases. Refer to Scripts and Cases for more information.

You can also develop plug-ins and user exits to so that the system will create cases when specific events take place. For example, you could set the system to create a case when an umbrella agreement is ready for renewal or when a quote is created.

Please refer to Maintaining Cases for a detailed description of the case page and field descriptions.

Log Information

A case log contains an entry for every recorded event during the lifecycle of the case. There are two types of log entries:

Copyright © 2026, Oracle and/or its affiliates.

- **Automatic entries.** The system automatically creates an entry in the log when a case is created or there is a status change. Users cannot modify or delete these log entries.
- **Manual entries.** Users can add manual entries to record significant events at their discretion.

Refer to Case - Main for the page used to view the log.

Refer to Case Statistics for a Given Status for information about a report that uses the log to provide productivity statistics.

Alerts

The alert zone will highlight if the person / account / premise in context have cases in a state that is configured as "alertable" if you plug-in the appropriate algorithm on the installation record. Refer to Alert Info Is Controlled By An Installation Plug-In for the details.

To Do's and Cases

You can configure the system to inform users of cases that require their attention. Refer to To Do's and Cases for the details.

Reports

Several reports summarize case information. Refer to the Reports chapter for the details.

Maintaining Cases

Your organization can use the case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Since an implementation can configure virtually every aspect of a case, the look and feel of the case management page are dynamic based on how case types have been configured.

- Case - Main
- Case - Log

Case - Main

Open the case management page by selecting **Menu**, and then **Customer Information**, and then **Case**, and then **Search**.

Main Information

Case Info contains a concatenation of important information about the case. **Case ID** is the system-assigned unique identifier of the case. These values only appear after the case is added to the database.

> **Note**
>
> **Formatting may be performed by a plug-in.** Refer to Case Info May Be Formatted By An Algorithm for more information.

Case Type defines the type of case. This field is protected after the case has been added. Refer to Case Type Controls Everything for more information.

> **Note**
>
> Available case types can be restricted by CIS Division. The restriction of case type by CIS division is dynamic. It is based on the account in context, the premise in context, or the current user. The restriction of case type is applied using these rules in sequence.
>
> - If there is an account in context and that account has a CIS Division, that CIS Division is used to restrict the case types that appear.
> - If there is a premise in context and that premise has a CIS Division, that CIS Division is used to restrict the case types that appear. Note: If there are both an account and premise in context, the account CIS Division is used.
> - If there is no account or premise in context with a CIS Division and the current user is associated with CIS Division(s) those CIS Division(s) are used to restrict the case types that appear. See Users and CIS Division for more information.

Status shows the current state of the case. Refer to Case Lifecycle for more information.

Copyright © 2026, Oracle and/or its affiliates.

If the case has any To Do entries associated with it, a hyperlink will appear summarizing the number and status of the entries. You can select the link to view these entries. Refer to To Do's and Cases for more information.

Date / Time Opened shows when the case was created. If the case is in a final state, the **Date / Time Closed** will also be shown. Refer to One Initial State and Multiple Final States for more information.

Script references the business process assistant script that can help you work on the case. You can click on the hyperlink to execute this script. This field is hidden if no script is associated with this case's current Status. Refer to Scripts and Cases for more information.

The **Actions** section contains buttons you can use to action the case. This area is suppressed if no actions can be performed for the case given its current status. A button will be gray if you do not have security rights to the action. Refer to Buttons Are Used To Transition A Case for more information.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. If the case has been automatically transitioned to its current state the following message area appears right after the action area. If an error is encountered in the process a corresponding error message is displayed in the Auto-transition Message Area. Refer to Automatic Transition Rules for more information.

> **Note**
>
> The Auto-transition Message Area only appears when a case has just been automatically transitioned to its current state online. It only remains visible until the data for the case is refreshed.

Use the **Comments** area to describe anything interesting or unusual about the case.

Person references the person associated with this case. This field is suppressed if the Case Type indicates that a person is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Person currently displayed in the Sidebar.

Account references the account associated with this case. This field is suppressed if the Case Type indicates that an account is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Account currently displayed in the Sidebar.

Premise references the premise associated with this case. This field is suppressed if the Case Type indicates that a premise is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Premise currently displayed in the Sidebar.

> **Note**
>
> The case type controls the relationship validation among person, account, and premise.

Copyright © 2026, Oracle and/or its affiliates.

Responsible User references the user who has overall responsibility for the case. This field is suppressed if the Case Type indicates that a responsible user is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final).

The **Contact Information** area is used to define how to contact the individual who initiated the case. These fields are suppressed if contact information is not allowed on cases of this type. The fields cannot be modified if the case is in a closed status. The following information can be defined.

Contact Person references the person who should be contacted. This defaults to the Person defined above.

Preferred Contact Method indicates how the person prefers to be contacted. The following options are available:

- Not Applicable. If the person doesn't want to be contacted (or the contact method is unusual), use this option. You might want to consider describing the situation in the Contact Instructions.
- Person Contact. If this method is selected, select a person contact related to the Person link to the customer contact. The customer contact must contain a Person to use this method.
- Postal. If this method is selected, the Contact Person's address appears. Refer to Where Does The Address Come From for a description of which address the system displays.

The following methods appear when the Legacy Person Phone and Email **Option Type** on the Customer Information Options Feature Configuration has been enabled.

- Email. If this method is selected, the Contact Person's email address appears adjacent.
- Phone. If this method is selected, the Contact Person's phone number appears.
- Fax. If this method is selected, the Contact Person's fax number appears (the system knows which of a person's phone numbers is a fax number by the phone type).
- SMS. If this method is selected, the Contact Person's short message service (SMS) information displays.

> **Note**
>
> While on a case, users can add a person contact by selecting Add Person Contact from a Person Context menu. This will open a portal-based page that allows a person contact to be added. This process will not lose context or information that has been added to the case. The new person contact can be used within the case.

Contact Instructions indicates any special instructions indicated for when or how to return a call.

Callback Phone Type, Callback Phone Number, and Extension indicate the actual phone number and phone type that should be used to call.

Characteristics

The **Characteristics** grid contains fields that contain important information about the case. This grid is suppressed if the Case Type does not use characteristics. This grid is protected if the case is closed (i.e., if its status is defined as being final).

You can only choose **Characteristic Types** defined as permissible for this case type. Refer to Additional Information for more information. If you attempt to use an **Action** to transition a case

Copyright © 2026, Oracle and/or its affiliates.

into a status that requires additional information, a pop-up will prompt you for the additional fields. Refer to Required Fields Before A Case Enters A State for more information.

Case - Log

To view the log entries associated with a case, open by selecting **Menu**, and then **Customer Information**, and then **Case**, and then **Search** and navigate to the **Log** page.

Description of Page

The **Log** grid displays log entries (in reverse chronological order) that audit the progress of the case. Please note the following about the entries in this grid:

- The system automatically creates log entries when a case is created, every time its status changes, or whenever an error occurs during the transition of a case. Algorithms plugged into a case type state can also be configured to create log entries. You cannot modify or delete the log entries.
- You can manually add a log entry by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
- **Log Date/Time** contains the date and time the log entry was created.
- **Details** contains user-specified or system-generated information about the log entry.
- **Related Object** is populated on log entries that were created to record the creation of some other object. For example, if a case plug-in creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
- **Log User** contains the user who caused the log entry to be created.
- **Log Type** indicates how the log entry was created. The possible values are:
- Created. Only one entry per case will be of this type. This entry is automatically created by the system when the case is created.
- User Details. A user creates this type of entry manually.
- Status Transition. This type of entry is created by the system each time the case's status is changed (as a result of pressing one of the Action buttons).
- System. An algorithm on the case type state may be designed/configured to create this type of entry when it does something auditable. For example, an algorithm that creates a customer contact could insert a log entry to show that it did this (it will also populate the FK to the customer contact, which will appear in the **Related Object** column).
- Transition Error. The background status transition process creates an entry of this type if an error occurs when automatically updating a case to a subsequent status (as directed by either an Enter Status algorithm or an Auto-Transition algorithm). An entry of this type lists the case states involved with the failed transition, and the algorithm in which the error was generated.
- Exception. The background status transition process creates an entry of this type under the same circumstances as a Transition Error. A log entry of this type indicates why the background transition failed.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CASE_LOG_TYPE_FLG.

Premise Management

> **Note**
>
> **Separate module.** The Premise Management functionality is associated with a separate Premise Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

The premise management functionality facilitates the following:

- Grouping premises together under a single parent premise
- Quick & efficient setup and maintenance of apartment complexes and high-rises
- A single view of properties for a landlord, including service status
- Ability to change the landlord or service status for a group of premises in one transaction
- And more...

The topics in this section describe premise management functionality.

- Overview
- Premise Management Page

Overview

The topics in this section provide background information about premise management functionality.

- Define Premise Hierarchy
- Manage Premises for a Landlord
- Manage Groups of Premises

Define Premise Hierarchy

Premise management allows you to define premise hierarchy. For example, you could also have the notion of

Copyright © 2026, Oracle and/or its affiliates.

- A building
- Multiple floors
- Multiple apartments per floor

To define this hierarchy you must create a premise for each level in the hierarchy and for each "child" premise, indicate its appropriate parent premise. Once you have set up your premise hierarchies, you may view the hierarchies on trees on the premise page and on the control central premise tree.

In addition, the system provides the following alerts:

- When viewing a parent premise, an alert indicates how many child premises exist
- When viewing a child premise, an alert indicates that it is linked to a parent premise.

Manage Premises for a Landlord

The premise management page provides the ability to view all the premises for the landlord along with information about the accounts linked to each premise.

You may use this page to assign, change or remove the landlord agreement for multiple premises in a single action. For example if a landlord sells their properties to another person, this page facilitates updating all premises with one action rather than changing the landlord for each premise separately. For example, if the landlord sells only a portion of their properties.

This page may also be used to start or stop service for one or more premises for the landlord. For example, a landlord plans to sell a high-rise apartment complex with 100 apartments. Imagine that 8 of these apartments are vacant and the landlord's account is currently paying for any usage to these apartments. In addition to changing the landlord agreement for all 100 apartments to the new landlord, the service for the vacant apartments should be transferred to the new landlord. A user can go to premise management, use the search criteria to view all premises for this landlord in a given apartment complex whose service is currently being paid for by the landlord and start service for these premise for the new landlord. (Using the back-to-back start/stop functionality, service will be stopped for the old landlord.)

Manage Groups of Premises

The powerful search criteria on the premise management page allows you to view different groups of premises based on any combination of account information, landlord information, parent premise address information and general geographic type information. You may also define search criteria such as "premises **not** linked to account 1234567890" or "premises linked to **any** landlord" or "premises **not** linked to any parent premise". For example, you could display all premises in a given latitude / longitude that are not linked to any parent premise.

Once your search results display the desired list of premises, you could perform mass updates such as assigning a parent premise or starting service. Following are examples of situations where this page would be helpful:

- The developer of a high-rise condominium complex is ready to start service for a group of condos. A user uses the premise management search criteria to display the premises linked to a give parent premise (representing the condo complex) that are not linked to any account. The user selects the premises in this list that the developer would like to start and starts service for all premises at once.

Copyright © 2026, Oracle and/or its affiliates.

- There is a shopping mall in your service territory and each store in an individual premise. You may decide to define a parent premise for the entire shopping mall and link each store's premise to the parent. Once the parent premise is defined, a user navigates to the premise management page and displays the individual premises based on a similar address or based on a similar geographic type. The user then assigns the parent premise for all the individual premises using a single action.

Premise Management Page

This page allows you to display a list of premises using a combination of search criteria. In addition, you can perform actions on one or more of the resulting premises, including:

- Assigning a parent premise to one or more premises
- Removing the link to a parent premise from one or more premises
- Assigning a landlord to one or more premises
- Removing the link to a landlord from one or more premises
- Start service for one or more premises
- Stop service for one or more premises

Open this page using **Menu**, and then **Customer Information**, and then **Premise Management.**

Description of Page

The top half of the page is where you enter the criteria used to search for premises.

> **Note**
>
> **Multiple search criteria may be specified.** You can search for premises using a combination of search criteria. For example, if you enter both a **Parent Premise Filter** of Linked To Any Premise and an **Account Filter** of Not Linked to Any Account; only those premises that have a parent premise but are not linked to an account will be displayed.
>
> **At least one positive criterion is required**. You may not define your search criteria to only use filter values that start with "Not Linked...". At least one "positive" filter value is required.

The following table describes each of the different search methods.

Search Method	Description

Copyright © 2026, Oracle and/or its affiliates.

Landlord Filter	Use this filter to narrow down your search based on landlord. Enter one of the following values: Not Applicable Linked To This Landlord - for this option, you must enter a **Landlord Agreement** Not Linked To This Landlord - for this option, you must enter a **Landlord Agreement** Linked To Any Landlord Not Linked To Any Landlord. A filter value of Not Applicable defaults.
Parent Premise Filter	Use this filter to narrow down your search based on parent premise. Enter one of the following values: Not Applicable Linked To This Parent Premise - for this option, you must enter a **Premise ID** for the parent premise Not Linked To This Parent Premise - for this option, you must enter a **Premise ID** for the parent premise Linked To Any Parent Premise Not Linked To Any Parent Premise. A filter value of Not Applicable defaults.
Account Filter	Use this filter to narrow down your search based on account. Enter one of the following values: Not Applicable Linked To This Account - for this option, you must enter an **Account ID** Not Linked To This Account - for this option, you must enter an **Account ID** Linked To Any Account Not Linked To Any Account. A filter value of Not Applicable defaults.
Premise Filter	Use this filter to narrow down your search based on account. Enter one of the following values: Located At This Address - for this option, you must enter address constituents Located At This Geographic Type / Value - for this option, you must enter a **Geo Type** and **Value** Not Applicable Show This Specific Premise - for this option, you must enter a **Premise ID** A filter value of Not Applicable defaults.

The **Select All** / **Clear All** buttons are used to select premises if you plan on issuing any of the mass update actions at the bottom of the page. Refer to the description of the "mass update" actions below for more information.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **50 premises at a time.** Clicking **Select All** selects the first 50 premises in the grid. If more than 50 premises exist, you must select them in batches.

The grid that follows contains the premises that match your search criteria. The following information appears in the grid:

- Select box. Use this checkbox to select premises for mass update actions.
- The **Premise Information** column shows information about each premise. Click the hyperlink to transfer to the Premise page where you can update information about the premise in question.
- The **Account Information** column shows information about all accounts linked to the premise, if any. Only accounts with non-canceled, non-closed service agreements linked to this premise are displayed. The column displays the name of the customer's main person followed by a list of status values for any of the account's service agreements linked to this premise. For example, you may see Customer A (pending stop), Customer B (pending start). If multiple service agreements linked to the account & premise have the same status, the status is only displayed once.
- The **Parent Premise Information** column displays information about the premise's parent premise, if one exists.
- The **Landlord Information** column displays the landlord agreement description for the premise's landlord, if there is one.

This transaction has sophisticated logic that can be used to perform "mass updates" to the premises that appear in the grid using the buttons at the bottom of the page. The buttons are enabled if you select at least one row from the premise grid. The following points describe these mass update actions:

- Start Service
- Stop Service
- Determine The Different Start Options That Exist For Each Type Of Service Agreement
- Remove Parent Premise
- Assign Landlord
- Remove Landlord

Start Service

The **Start Service** button is used to start service for one or more premises. When clicked, the **Start SA Groups Confirmation** window opens.

> **Note**
>
> **Similar to Start/Stop**. This page is similar to the Start SA Confirmation page that appears on start/stop. The differences are to accommodate starting multiple premises.

Copyright © 2026, Oracle and/or its affiliates.

In order to start service for the selected premises, select the **Account ID**.

The **Start Date** is the date on which the service is scheduled to start.

Use **Start Requested By** to indicate the name of the person who requested the start.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also be started for this account.

Click **Show SA Groups** to populate the remainder of the page.

The **Service Points** section summarizes the service points that exist for all the chosen premises. A row is displayed for each different **SP Type** along with a **Count** of the number of service points of that type. By default, all rows are checked, assuming that you want to start service for all service points (and the SA Groups To Start scroll below displays proposed SAs to start for each SP type). You may uncheck any SP Type row if you do not wish to start service for that SP type. Click **Show SA Groups** to rebuild the SA Groups To Start information.

> **Warning**
>
> This page displays summary information about the service agreements and service points that are being turned on. It is recommended that you start groups of premises that have similar service point configurations. If you attempt to start service for many premises, each with different service point configurations, the start logic may be very complicated to verify on this page.

The **SA Groups To Start** scroll contains an entry for every service agreement that will be created if you click the **Start** button. If you do not want a service agreement to be created, click the - button or uncheck **Start this SA Group**. If you would like to start service agreements that are not SP-based service agreements (for example a deposit or a connection charge), click the + button to add a new SA group. The system assumes that you want to create a new service agreement for each selected premise.

Turn on the **Start this SA Group** switch if you want service agreements of this type to be created. If this is the first customer at the selected premises, this switch is checked for all service agreements that appear in the scroll. For each premise that was linked to a previous customer, this switch is on only for those types of service agreements used by the previous customer(s). (We assume the new customers only want the services used by the previous customers). Service agreements that are possible, but were not used by the previous customers, appear in the scroll with this switch turned off.

If Start This SA Group is checked, the system displays a message indicating the number of service agreements (for the number of service points) that will be created if you choose Start.

For a description of the remaining fields, refer to Start/Stop - Start Confirmation.

Click **Start**. Standard start logic is followed when clicking start.

> **Note**
>
> The start button is disabled if changes are made to fields on the page that may impact the SA Groups To Start collection. You must click **Show SA Groups** to rebuild the SA groups and enable the start button.

Copyright © 2026, Oracle and/or its affiliates.

Stop Service

The **Stop Service** button is used to stop service for one or more premises.

> **Note**
>
> that this functionality stops service for any account linked to the selected premises. If you want to stop service at the selected premises for only certain accounts, use the account filter criteria to narrow down the selection of premises prior to clicking Stop Service.

When clicked, the **Stop SA Group Confirmation** window opens.

In order to stop service for the selected premises, enter a **Stop Date**.

Enter a **Restrict to Account** if you want to stop only service agreements linked to this account. If not specified, all active services agreements for the premise are stopped regardless of the account.

Use **Stop Requested By** to indicate the name of the person who requested the stop.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be stopped.

Click **Show SA Groups** to populate the remainder of the page.

The system builds a collection of service agreements currently linked to the service points for the selected premises. The grid contains the **CIS Division** and **SA Type** for each SA "group" and displays the number of service agreements in the **SA Group Summary**.

By default, the system checks each SA group assuming that you want to stop service for all SAs. You may uncheck any of the SA groups to not stop service for those SAs.

Click **Stop**. Standard stop logic is followed when clicking stop.

> **Note**
>
> The stop button is disabled if changes are made to fields on the page that may impact the SA collection. You must click **Show SA Groups** to rebuild the SA collection and enable the stop button.

Determine The Different Start Options That Exist For Each Type Of Service Agreement

After you know which SA types are going to be created, determine the potential start options that can be used for each SA type. In our example campaign, several start options are possible for the E-RES (electric residential service):

Copyright © 2026, Oracle and/or its affiliates.

SA Type	Start Option
E-RES	Senior
E-RES	Single-Elec Heat
E-RES	Single-Gas Heat
E-RES	Multi-Family

Remove Parent Premise

The **Remove Parent Premise** button is used to remove the parent premise from one or more premises. When clicked, the parent premise ID of all selected premises is reset.

Assign Landlord

The **Assign Landlord** button is used to assign a landlord to one or more premises. When clicked, the **Assign Landlord** window opens.

Specify the **Landlord** agreement ID.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be assigned this landlord.

Click **Assign**.

Remove Landlord

The **Remove Landlord** button is used to remove the landlord agreement from one or more premises. When clicked, the **Remove Landlord** window opens.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also have their landlord agreement removed.

Click **Remove**.

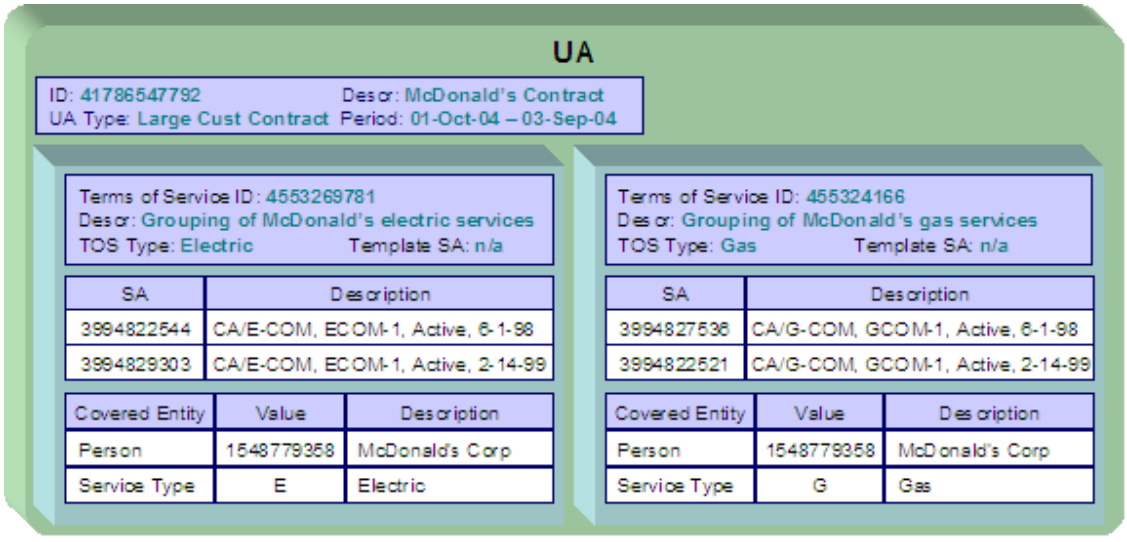
Umbrella Agreement Management

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts

Copyright © 2026, Oracle and/or its affiliates.

- Applying override rate terms to one or more service agreements for a given effective period
- more...



> **Note**
>
> **Separate module.** The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

- Overview Of Umbrella Agreement & Terms Of Service
- Umbrella Agreements & Proposals
- Additional Umbrella Agreement Topics
- Umbrella Agreement Maintenance
- Terms Of Service Maintenance

Overview Of Umbrella Agreement & Terms Of Service

An umbrella agreement is used to group together terms for a contract. It contains high level information about the contract such as the effective dates, the renewal date, if applicable and an account management group, if applicable. You may also define characteristics and contacts for the umbrella agreement.

The terms of the umbrella agreement are defined using one or more terms of service (TOS) records. For each TOS record, you must link one or more service agreements to indicate the services covered under the TOS.

The Terms of Service may point to a 'template service agreement' as a way to specify the rating terms and conditions to be used by all service agreements linked to the TOS. If a TOS does not define a template SA, then the TOS is used largely as a grouping mechanism rather than a billing mechanism.

Copyright © 2026, Oracle and/or its affiliates.

Umbrella agreements and their terms of service records are used to support specific business scenarios that your organization supports.

- TOS Covered Entities
- Rate Terms Overridden By Terms Of Service
- Umbrella Agreement Renewal

TOS Covered Entities

Your implementation may configure a Terms of Service type to require that entities "covered" by the terms of service record be referenced on the TOS. For example, imagine that you define an umbrella agreement to provide special discounts to all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement, you may link the person record representing the McDonalds corporate entity as a covered entity for the TOS.

> **Note**
>
> that there is no base product functionality that uses this collection. However, your implementation may use this information in an algorithm, for example, it could be used in a campaign / package eligibility algorithm.

Refer to Terms Of Service Covered Entities for information about defining covered entities for a terms of service type.

Rate Terms Overridden By Terms Of Service

Your organization may require rate information to be temporarily overridden for a service agreement that is linked to a TOS. In order to do this, the TOS record must reference a template SA. Refer to Overriding Rate Terms for information about defining your Terms of Service types to support template service agreements.

The topics in this section further describe the possible rate term overrides that may occur when a service agreement is linked to a terms of service record.

- Rate Schedule Override by TOS
- Override Of Other Rate Terms By TOS

Rate Schedule Override by TOS

If a service agreement is linked to a terms of service, you may configure the system to use the rate schedule from the terms of service record's template SA rather than the one from the customer's service agreement. The customer's SA type controls this option.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Configure SA Types for Umbrella Agreements for more information.

If a service agreement is linked to a terms of service record, the rate information tree on the service agreement's rate info tab tells the user whether the rate from the service agreement or from the template SA on the TOS is currently applicable.

If a given service agreement's rate schedule is being taken from the terms of service record's template SA, then the override rate schedule is used not just in bill calculations, but for any logic that requires the service agreement's rate schedule. For example, one of the recommended budget amount algorithms may estimate consumption and apply the service agreement's rate. In this case, the rate used by the algorithm is the one linked to the terms of service record's template SA.

Override Of Other Rate Terms By TOS

There are other terms associated with a rate that may change when linking a service agreement to a terms of service record that has a template SA. These include contract riders, contract terms and tax exemptions.

When applying the rate to create the customer's bill segment, if a bill factor on any of the calculation rules indicates that it is eligible for tax exemptions, contract terms or contract riders, a flag on the bill factor indicates where the system should look for the appropriate value. The Terms of Service Usage flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

NOT_SUPPORTED

Refer to Configure Bill Factors for Umbrella Agreements for more information.

Note

Independent of rate source. The flag values on the bill factors are independent of the rate source setting for the SA type. For example, your implementation may configure the SA type's rate source to indicate that rate should be taken from the TOS template SA. However, if a bill factor is eligible for tax exemptions, your implementation may configure the bill factor to indicate that the exemption information should be taken from the customer's SA, not the template SA.

Umbrella Agreement Renewal

Although umbrella agreement records require an end date, your organization probably allows for renewal of agreements. A renewal may involve full re-negotiation of all terms, or may be as simple as extending the current terms. If umbrella agreements of a given type are eligible to be

Copyright © 2026, Oracle and/or its affiliates.

renewed, you configure the UA type to indicate how to calculate the renewal date and which algorithm to execute when the renewal date is reached.

- Umbrella Agreement Renewal Background Process

Umbrella Agreement Renewal Background Process

The UA renewal background process (UARENEW) finds complete umbrella agreements whose renewal date has arrived and executes the renewal algorithm for the associated UA type.

> **Note**
>
> It is the responsibility of the renewal algorithm to update the renewal date as per the business practice. Refer to Renewable Umbrella Agreements for more information.

Umbrella Agreements & Proposals

Umbrella agreements and their terms of service records may reference proposal service agreements. This functionality allows you to create the full contract for your customer during the quoting stage.

Additional Umbrella Agreement Topics

The following topics describe additional functionality related to umbrella agreements.

- Umbrella Agreement Alerts
- Orders And Umbrella Agreements
- Umbrella Agreement Reports

Umbrella Agreement Alerts

The alert zone will highlight if any of the account's SAs are linked to an effective umbrella agreement (via a non-canceled terms of service record).

Orders And Umbrella Agreements

When starting new service for a given account and premise, you may know ahead of time that the new service should be linked to an existing umbrella agreement. For example, perhaps all the service in a specific low income housing area qualifies for a special negotiated contract for the next year.

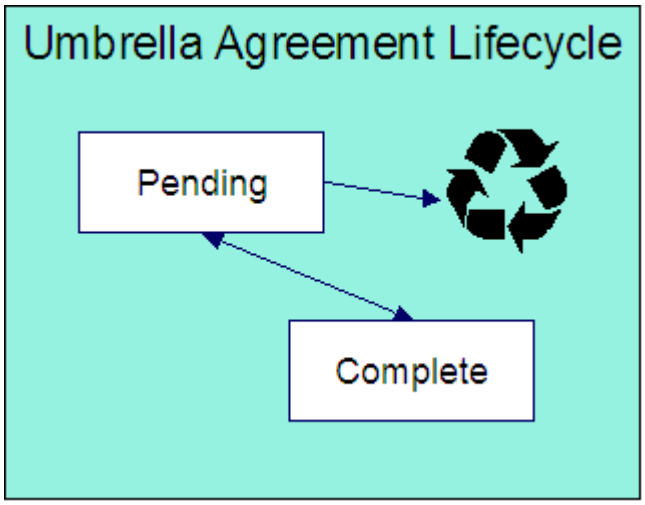
Copyright © 2026, Oracle and/or its affiliates.

The system provides algorithms to allow you to add a new service agreement to an existing terms of service record when using the Order transaction to start service.

Refer to Configure A Campaign To Link An SA To A Terms Of Service for more information.

Umbrella Agreement Reports

The system supplies a Report providing umbrella agreement information for one or more umbrella agreements.



Umbrella Agreement Maintenance

Umbrella agreements help you manage your contracts by allowing you to group together service agreements for the contract with one or more terms of service records for the umbrella agreement.

- Lifecycle Of An Umbrella Agreement
- Umbrella Agreement - Main
- Umbrella Agreement - Contacts
- Umbrella Agreement - Characteristics

Lifecycle Of An Umbrella Agreement

The following diagram illustrates the lifecycle of an umbrella agreement.

Pending The umbrella agreement is created in pending status.

You may delete a pending umbrella agreement. Deleting a UA also deletes its terms of service records.

Complete Only complete umbrella agreements are considered effective. You may transition a UA to complete if there is at least one terms of service record linked to it and if none of its TOS records are in pending status.

Copyright © 2026, Oracle and/or its affiliates.

Under unusual circumstances, a complete umbrella agreement may be changed back to pending to correct errors.

Umbrella Agreement - Main

Open this page using **Menu**, and then **Umbrella Agreement Management**, and then **Umbrella Agreement**, and then **Search.**

Description of Page

Umbrella Agreement Info contains a concatenation of important information about the umbrella agreement. **Umbrella Agreement ID** is the system-assigned unique identifier of the umbrella agreement. These values only appear after the UA is added to the database.

Umbrella Agreement Status shows the current state of the UA. The buttons adjacent to the status allow you to transition the UA's status.

- Click **Complete** to change the status of a pending umbrella agreement to complete.
- Click **Reopen** to change the status of a complete umbrella agreement back to pending.

> **NOT_SUPPORTED**
>
> Refer to Lifecycle of an Umbrella Agreement for more information.

Enter a **Description** for the umbrella agreement.

The **Umbrella Agreement Type** defines the type of umbrella agreement. Refer to Setting Up Umbrella Agreement Types for more information.

The **Start Date** and **End Date** define the effective dates of the contract. If the UA type is renewable, the **Renewal Date** indicates the date the umbrella agreement is processed by the renewal background process.

You may assign an **Account Management Group** to this umbrella agreement. The AMG controls the roles assigned to To Do entries associated with the umbrella agreement. Refer to Setting Up Account Management Groups for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

This bottom of this page contains a tree that shows the various objects linked to the umbrella agreement. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Umbrella Agreement - Contacts

The contacts page defines persons associated with the umbrella agreement. Open this page using **Menu**, and then **Umbrella Agreement Management**, and then **Umbrella Agreement**, and then **Search** and navigate to the **Contacts** page.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

The contacts collection allows you to define persons that are associated with the umbrella agreement. For each contact, define the **Person ID** for the person record that contains the demographic information for the contact. For each contact, use the **Comments** to define information about the contact.

Umbrella Agreement - Characteristics

The characteristics page contains information that describes miscellaneous information about the umbrella agreement. Open this page using **Menu**, and then **Umbrella Agreement Management**, and then **Umbrella Agreement**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined on umbrella agreement's umbrella agreement type .

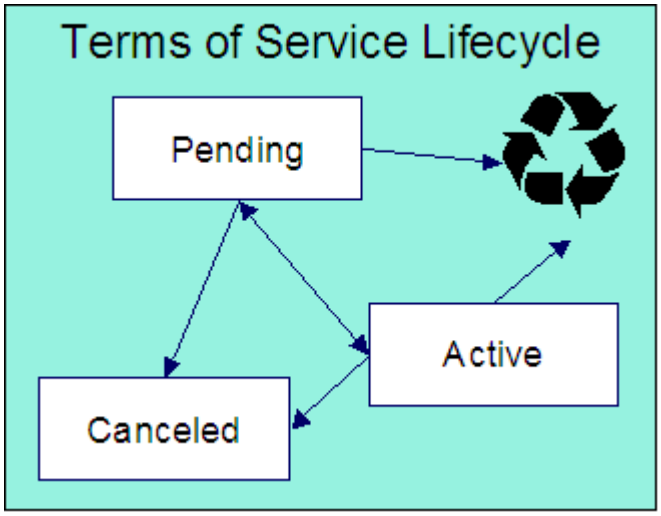
The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

> **Note**
>
> **Default Note.** An umbrella agreement's characteristics default from the umbrella agreement type.

Terms Of Service Maintenance



A terms of service (TOS) record defines one or more service agreements participating in a given umbrella agreement. The TOS record may also reference a template SA that could be used to override rate terms for the participating service agreements.

- Lifecycle Of Terms Of Service
- Terms Of Service - Main
- Terms Of Service - SAs

Lifecycle Of Terms Of Service

The following diagram illustrates the lifecycle of a terms of service record.

Copyright © 2026, Oracle and/or its affiliates.

Pending The terms of service record is created in pending status. You may delete a pending TOS. If you want to keep a record of the TOS, you may cancel it rather than deleting it.

Active Only active terms of service records are considered effective. Change the status to active when you have entered all the desired information for this TOS. You may delete an active terms of service if the umbrella agreement is still pending. (Otherwise you must cancel the TOS.)

Canceled You may cancel a pending or active terms of service if it should no longer be used. Canceling a terms of service record unlinks all its service agreements.

Terms Of Service - Main

Open this page using **Menu**, and then **Umbrella Agreement Management**, and then **Terms of Service**, and then **Search.**

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of Service ID** is the system-assigned unique identifier of the terms of service record. These values only appear after the TOS is added to the database.

The **Umbrella Agreement ID** defines the umbrella agreement to which this terms of service is linked.

Status shows the current state of the terms of service record. The buttons adjacent to the status allow you to transition the TOS record's status.

- Click **Activate** to change the status of a pending terms of service record to active.
- Click **Pend** to change the status of an active terms of service record back to pending.
- Click **Cancel** to change the status of a pending or active terms of service record to canceled.

NOT_SUPPORTED

Refer to Lifecycle Of Terms of Service for more information.

Copyright © 2026, Oracle and/or its affiliates.

Enter a **Description** for the terms of service record.

The **Terms of Service Type** defines the type of terms of service record. Refer to Setting Up Terms of Service Types for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

The **Characteristics** collection contains information that describes miscellaneous information about the terms of service record.

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined on the terms of service record's terms of service type .

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

> **Note**
>
> **Default Note.** A terms of service record's characteristics default from the terms of service type.

The **Covered Entities** collection allows you to define specific entities that are "covered" by this terms of service record. Refer to TOS Covered Entities for more information.

> **Note**
>
> **Characteristic Types.** You can only choose covered entity characteristic types defined on the terms of service record's terms of service type.

The following fields display:

Covered Entity Characteristic Type Indicate the type of characteristic used to define this covered entity type.

Characteristic Value Indicate the value of the characteristic used to define the covered entity value.

> **Note**
>
> **Default Note.** A terms of service record's covered entity types default from the terms of service type.

Copyright © 2026, Oracle and/or its affiliates.

Terms Of Service - SAs

This page is used to maintain the service agreements linked to the terms of service record.

Open this page using **Menu**, and then **Umbrella Agreement Management**, and then **Terms of Service**, and then **Search** and navigate to the **SAs** page.

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of Service ID** is the system-assigned unique identifier of the terms of service record.

The filters control the service agreements that appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:
  - Account. Use this option to restrict service agreements to those linked to a given **Account ID**.
  - Address. Use this option to restrict service agreements to those linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
  - All. Use this option if you do not wish to restrict service agreements based on service agreement attributes.
  - All Proposals. Use this option to restrict service agreements to only proposal service agreements.
  - All Real SAs. Use this option to restrict service agreements to only "real" service agreements (i.e., not proposal SAs).
  - Geographic Type. Use this option to restrict service agreements to those linked to service points associated with a given **Geographic Type** and **Geographic Value**.
  - SA Type. Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.
  - Specific SA. Use this option to reference a specific **SA ID**.
- Use **Status Filter** to restrict the service agreements based on their status. Status values for both proposal service agreements and regular service agreements are included in the filter. The following options are available:
  - All. This option shows all service agreements, including proposal service agreements, regardless of status.
  - Refer to Service Agreement Lifecycle for the various status values for real service agreements.
  - Refer to Proposal SA State Transition for more information about status values for proposal service agreements.

Don't forget to click the search button after changing the filters.

The grid that follows contains the **Service Agreement**s that match your search criteria along with its **Account Info**.

Use the "+" to link new service agreements to the terms of service record.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Link SA Using Order**. You may also link a service agreement to a TOS through orders if you have configured an appropriate campaign and package.

Note you may remove a service agreement from the TOS using the delete button as long as the change has not been committed to the database. As soon as the SA's link to the TOS has been committed to the database, you must use the **Remove** action to unlink the service agreement.

The **Select All** / **Clear All** buttons are used to select service agreements if you plan on issuing the mass update action **Remove** at the bottom of the page. Clicking **Remove** removes the service agreement from the terms of service record.

Overdue Financial Obligations

The system periodically monitors how much your customers owe to ensure they haven't violated your overdue rules. When a violation is detected, the system creates an overdue process. The overdue process contains the events meant to prod the customer to pay (e.g., letters, disconnect field activities, To Do entries, write-off outstanding debt, etc.). This section describes how to manage your overdue (i.e., collections) processing.

> **Note**
>
> The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with the algorithms that support collecting on overdue bills. If your organization practices balance-forward accounting (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under Credit and Collections.

- Overdue Processing Background Information
- Overdue Process Maintenance
- Cut Process Maintenance
- Payment Arrangement for Bills

Overdue Processing Background Information

In the section, The Big Picture Of Overdue Processing, we describe how overdue processing works and how to set up the control tables that automate most functions. You will find that many of your questions regarding when and how overdue and cut processes are created and canceled are described in this section.

Copyright © 2026, Oracle and/or its affiliates.

Overdue Process Maintenance

An overdue process is a series of events (e.g., letters, To Do entries) meant to encourage an account to pay its delinquent debt. The topics in this section describe the pages on which overdue processes are maintained.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture Of Overdue Processes for background information.

- Overdue Process - Main
- Overdue Process - Events
- Overdue Process - Log
- How To Perform Common Overdue Process Functions

Overdue Process - Main

The Main page contains core overdue process information. Open this page using **Menu**, and then **Credit & Collection.**, and then **Overdue Process**, and then **Search**

Description of Page

> **Note**
>
> Refer to How To Perform Common Overdue Process Functions for more instructions describing how to use this page.

Overdue Process contains a concatenation of important information about the process. **Overdue Process ID** is the system-assigned unique identifier of the process. These values only appear after the overdue process is added to the database.

> **Note**
>
> **Summary information may be overridden.** Refer to Overdue Process Information Is Overridable for how your implementation can override the summary information that appears throughout the system.

Account ID identifies the overdue process's account.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Multiple overdue processes may be linked to an account.** It's important to be aware that it's possible for multiple, active overdue processes to be linked to an account. The Alert zone will contain a summary of the account's overdue processes.

Status defines the state of the overdue process. The following values may exist:

- Active, Events Pending. Overdue processes are initially created in this state. An overdue process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. An overdue process will exist in this state when it's been manually canceled by a user. Navigate to the **Log** tab to see when this happened and who did it.
- Inactive, Canceled by System. An overdue process will exist in this state when it's been canceled by the system (typically because the overdue obligations were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. An overdue process will exist in this state when the system completes its last event. Navigate to the **Log** tab to see when this happened.

The **Cancel** button appears if the overdue process is Active, Events Pending and the process's **Overdue Process Template** has a Cancel Logic plug-in. Click this button to cancel the process.

The **Trigger Events** button appears if the overdue process is Active, Events Pending. Click this button to activate all pending events that are ready for activation.

> **Note**
>
> **If you can't wait for the Overdue / Cut Event Manager to run.** The Overdue / Cut Event Manager is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

Overdue Process Template defines the template that was used to create the overdue process's events. You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

> **Note**
>
> **Changing the template.** If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the overdue process. This field is protected after the overdue process is saved on the database. This field is used to derive the trigger date of some overdue events when the process is first created. Subsequent changes to the start date change the trigger dates on the events accordingly.

Copyright © 2026, Oracle and/or its affiliates.

Inactive Date/Time is the date and time that the overdue process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the **Log** tab.

Base Date is reserved for future releases. This field is protected when the overdue process is Inactive.

Enter any **Comments** about the overdue process. This field is protected when the overdue process is Inactive.

The **Collecting On** grid holds the overdue objects. For example, if this process manages overdue bills, the grid contains a list of the bills being collected on by this process. This grid is unprotected when the process is Active . The following points describe the columns that appear in the grid:

- Press the + button to add a new overdue object to the process.
- Press the - button to remove an overdue object to the process.
- The next column contains the unique identifier of the overdue object. For example, if this process manages overdue bills, this column will contain the bill ID. The type of object that's specified in this column is control by the overdue process template.
- **Original Amount** contains the original amount of the overdue object.
- **Unpaid Amount** contains the unpaid amount of the overdue object.

The Trees at the bottom of the page shows a variety of information about the overdue process including its events and cut processes. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Overdue Process - Events

This page contains the activities that are performed to persuade the customer to pay the outstanding debt. Open this page using **Menu**, and then **Credit & Collection**, and then **Overdue Process**, and then **Search** and navigate to the **Events** page.

Description of Page

> **Note**
>
> Refer to How To Perform Common Overdue Process Functions for more instructions describing how to use this page.

Refer to the first tab for a description of **Overdue Process** and **Overdue Process ID**.

The **Overdue Events** scroll contains the process's overdue events. Refer to Overdue Processes Are Created From Templates for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the state of the event.
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Overdue Event Type** has a Cancel Logic plug-in. Click this button to cancel the event.

Copyright © 2026, Oracle and/or its affiliates.

- The **Overdue Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
  - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0, this event will be activated immediately after the dependent events are completed / cancelled. Refer to Calendar vs Work Days for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled , you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

> **Note**
>
> **If you can't wait for the Overdue / Cut Event Manager to run.** The Overdue / Cut Event Manager is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Overdue Process - Log

This page contains log entries that highlight significant events in the process's life. Open this page using **Menu**, and then **Credit & Collection**, and then **Overdue Process**, and then **Search** and navigate to the **Log** page.

Description of Page

Please note the following about the entries in this grid:

- The system automatically creates log entries when significant events occur. Refer to Overdue Log for more information.
- You can manually add a log entry to an Active process by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
  - **Date/Time** contains the date and time the log entry was created.
  - **Details** contain the user-specified or system-generated information about the log entry.
  - **Relate Object** is populated on log entries that were created to record the creation of some other object. For example, if an overdue event creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
  - **Related Process / Event** appears if the log entry was created by an overdue event, a cut process or a cut event. It references the unique identifier of the process / event.

Copyright © 2026, Oracle and/or its affiliates.

- **Log User** contains the user who caused the log entry to be created.
- **Log Type** indicates how the log entry was created. The possible values are:
  - User. A user manually created this entry.
  - System. This system created this entry.

How To Perform Common Overdue Process Functions

The topics in this section describe how to perform common overdue process maintenance functions. Refer to The Big Picture Of Overdue Processing for high-level information about overdue processing.

- How To Create An Overdue Process
- How To Change Overdue Events
- How To Cancel An Overdue Process

How To Create An Overdue Process

99.9% of all overdue processes are created by the Overdue Monitor and require no human intervention. The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new overdue process.
- After the account is populated on Control Central, choose the **Overdue Process +** option on the account context menu to transfer to the overdue process transaction in add mode for the account.
- After the Overdue Process - Main page appears, specify the appropriate **Overdue Process Template**. The template is used to default the process's events (the template also controls numerous business rules, for example, when it will be canceled, how it will be canceled, etc). Refer to How To Change Overdue Events for a description of how you can override these events.
- Enter the overdue object(s) in the **Collecting On** grid. You must define at least one object.
- Save the overdue process.

How To Change Overdue Events

When an overdue process is first created, it has one or more overdue events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when an overdue process is initiated are defined on the overdue process's overdue process template. The following points describe how to add / change / delete events on an overdue process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the overdue process whose events need to be changed.

Copyright © 2026, Oracle and/or its affiliates.

- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. Note, an account's Active overdue processes can be selected from the Alerts zone.
- To add a new event, transfer to the Overdue Process - Events tab and press the + button in the **Overdue Events** scroll. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
  - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
  - Choose a **Status** of Pending.
  - Choose the desired **Overdue Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
  - specify the sequences of the dependent events in **Event Dependencies** and
  - specify the how many days after the completion of the last dependent event that the new event should be triggered.
  - If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on Overdue Process - Main. This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.
- To change an existing event, click on the event in the tree on Overdue Process - Main. This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the overdue process.

How To Cancel An Overdue Process

The system will cancel an overdue process when the cancel criteria defined on the overdue process are satisfied. The following points describe how to manually cancel an overdue process.

- Use **Control Central** to choose the account with the overdue process to be cancelled.
- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. A list of all overdue processes associated with the account appears. If only one overdue process exists, it is automatically selected for you. Note, an account's Active overdue processes can be selected from the Alerts zone.
- On the **Main** tab, click Cancel and answer any prompts.

Cut Process Maintenance

A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is

Copyright © 2026, Oracle and/or its affiliates.

created for each service agreement. The topics in this section describe the pages on which cut processes are maintained.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture Of Cut Processes for background information.

- Cut Process - Main
- Cut Process - Events
- How To Perform Common Cut Process Functions

Cut Process - Main

The Main page contains core cut process information. Open this page using **Menu**, and then **Credit & Collections**, and then **Cut Process**, and then **Search.**

Description of Page

> **Note**
>
> Refer to How To Perform Common Cut Process Functions for more instructions describing how to use this page.

Cut Process contains a concatenation of important information about the process. **Cut Process ID** is the system-assigned unique identifier of the process. These values only appear after the cut process is added to the database.

> **Note**
>
> **Summary information may be overridden.** Refer to Cut Process Information Is Overridable for how your implementation can override the summary information that appears throughout the system.

Overdue Process and **Overdue Event** define overdue event that created the process. Refer to Cut Processes Exist Under An Overdue Process for more information.

Service Agreement identifies the service agreement being cut.

Premise identifies the service agreement's characteristic premise (if any).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Multiple cut processes may be linked to an overdue process / event.** It's important to be aware that it's possible for multiple, active cut processes to be linked to the overdue event. You can see all cut processes associated with an overdue process on the tree of Overdue Process - Main. The Alert zone will contain a summary of the account's cut processes.

Status defines the state of the cut process. The following values may exist:

- Active, Events Pending. Cut processes are initially created in this state. A cut process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. A cut process will exist in this state when it's been manually canceled by a user. Navigate to the overdue process's Log tab to see when this happened and who did it.
- Inactive, Canceled by System. A cut process will exist in this state when it's been canceled by the system (typically because the overdue obligations on the overdue process were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. A cut process will exist in this state when the system completes its last event. Navigate to the overdue process's Log tab to see when this happened.

The **Cancel** button appears if the cut process is Active, Events Pending and the process's **Cut Process Template** has a Cancel Logic plug-in. Click this button to cancel the process.

The **Trigger Events** button appears if the cut process is Active, Events Pending. Click this button to activate all pending events that are ready for activation.

> **Note**
>
> **If you can't wait for the Overdue / Cut Event Manager to run.** The Overdue / Cut Event Manager is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Cut Process Template defines the template that was used to create the cut process's events. You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

> **Note**
>
> **Changing the template.** If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the cut process. This field is protected after the cut process is saved on the database. This field is used to derive the trigger date of some cut events when the process is first created. If you need to subsequently change the trigger date on the events, navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

Copyright © 2026, Oracle and/or its affiliates.

- Change the **Cut Process Template** to something (anything). Doing this causes the **Start Date/Time** to become unprotected.
- Specify the base date of the cut events in the newly unprotected **Start Date/Time**.
- Change the **Cut Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Start Date/Time**.

Inactive Date/Time is the date and time that the cut process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the overdue process's Log tab.

Enter any **Comments** about the cut process. This field is protected when the cut process is Inactive .

The tree at the bottom of the page shows a variety of information about the cut process including its events. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Cut Process - Events

This page contains the activities that are performed to cut the service agreement. Open this page using **Menu**, and then **Credit & Collection**, and then **Cut Process**, and then **Search** and navigate to the **Events** page.

Description of Page

> **Note**
>
> Refer to How To Perform Common Cut Process Functions for more instructions describing how to use this page.

Refer to the first tab for a description of **Cut Process** and **Cut Process ID**.

The **Cut Events** scroll contains the process's cut events. Refer to Cut Processes Are Created From Templates for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the state of the event.
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Cut Event Type** has a Cancel Logic plug-in. Click this button to cancel the event.
- The **Cut Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
  - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0 (zero), this event will be activated immediately

Copyright © 2026, Oracle and/or its affiliates.

after the dependent events are completed / cancelled. Refer to Calendar vs Work Days for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled , you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

> **Note**
>
> **If you can't wait for the Overdue / Cut Event Manager to run.** The Overdue / Cut Event Manager is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

How To Perform Common Cut Process Functions

The topics in this section describe how to perform common cut process maintenance functions. Refer to The Big Picture Of Cut Processing for high-level information about cut processing.

- How To Create A Cut Process
- How To Change Cut Events
- How To Cancel A Cut Process

How To Create A Cut Process

Cut processes are created when an overdue event is activated. You cannot create an ad hoc cut process.

How To Change Cut Events

When a cut process is first created, it has one or more cut events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when a cut process is initiated are defined on the cut process's cut process template. The following points describe how to add / change / delete events on a cut process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the cut process whose events need to be changed.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menus to transfer to the cut process transaction in update mode. Note, an account's Active cut processes can be selected from the Credit and Collections zone.
- To add a new event, transfer to the Cut Process - Events tab and press the + button in the **Cut Events** scroll. At this point, the event has not been added to the database; rather, it

Copyright © 2026, Oracle and/or its affiliates.

just exists in memory. Before you add the event to the database, you must specify the following information:

  - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
  - Choose a **Status** of Pending.
  - Choose the desired **Cut Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
  - specify the sequences of the dependent events in **Event Dependencies** and
  - specify the how many days after the completion of the last dependent event that the new event should be triggered.
- If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on Cut Process - Main. This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.
- To change an existing event, click on the event in the tree on Cut Process - Main. This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the cut process.

How To Cancel A Cut Process

The system will cancel a cut process when the cancel criteria defined on the overdue process are satisfied. The following points describe how to manually cancel a cut process.

- Use **Control Central** to choose the account with the cut process to be cancelled.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menu to transfer to the cut process transaction in update mode for the account. A list of all cut processes associated with the account appears. If only one cut process exists, it is automatically selected for you. Note, an account's Active cut processes can be selected from the Credit and Collections zone.
- On the **Main** tab, click Cancel and answer any prompts.

Payment Arrangement for Bills

A payment arrangement is an agreement with a customer to payoff severely overdue debt in installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

Organizations that practice open-item accounting who collect on overdue bills may allow customers to pay off their overdue bills in installments by setting up a payment arrangement for one or more bills. This transaction is used to maintain bill-oriented payment arrangements.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Bill-Oriented Payment Arrangements for background information.

Open this page using **Menu**, and then **Credit & Collection**, and then **Payment Arrangement for Bills**, and then **Search** page.

Description of Page

The **SA** (service agreement) **Info** is a concatenation of important details about the payment arrangement service agreement (PA SA). The **SA ID** is the unique identifier of the PA SA. These values only appear after the PA SA exists on the database.

The **Current Balance** that appears beneath **SA Info** contains the PA SA's current balance. When you initially set up a PA SA this balance will be zero. It is only non-zero if the customer has not paid a billed installment.

Payoff Balance beneath **SA Info** contains the PA SA's payoff balance. The payoff balance is the total amount to be paid off over the PA SA's life. It is only non-zero after delinquent funds have been transferred to the PA SA. This balance is only displayed when it differs from the **Current Balance**.

NOT_SUPPORTED

Refer to Current Amount versus Payoff Amount for more information.

Account ID is the account associated with the PA SA.

The occurrences of **Current** and **Payoff Balance** beneath **Account** are the account's respective balances. These values are displayed to help you confirm exactly how much the customer currently owes versus how much they will have to payoff over time (remember, after you transfer funds to a payment arrangement, the amount transferred is reduced from the account's current balance).

The **Unpaid Bills** grid contains a row for each of the account's unpaid bills.

Adjacent to each Unpaid Bill is its **Unpaid Amount** and a check box used to select the bill. Every selected bill's unpaid amount will be transferred to the PA SA when you click the **Create** button.

Warning

The system automatically indicates that all unpaid debt should be transferred to the payment arrangement. It does this by checking each bill by default.

Total Candidates is the sum of ALL unpaid bills (not just the selected bills).

New Payoff Balance contains the PA SA's payoff balance. This is the total amount of debt that will be paid off over the lifetime of the PA SA. This value equals the current payoff balance on the PA SA plus all selected debt from the **Candidate SAs** scroll.

The next fields work in unison.

Copyright © 2026, Oracle and/or its affiliates.

- If you want to define the number of future bills that the customer has to payoff the selected unpaid amount, enter the number of **Installments**. When you tab out of the field, the system sets the **Arrange Amount** equal to **New Payoff Balance** / **Installments**.

> **Note**
>
> **Arrange Amount may not add up.** The **Arrange Amount** is rounded up so that if you multiply the number of installments by the calculated installment amount, the result will be greater than the PA SA's payoff amount. Don't worry - only the actual dollar amount of the PA SA's total debt will be billed by the system. The last installment will be slightly lower than the other installments.

- If you want to define the amount charged on future bills to payoff the unpaid amount, enter the **Arrange Amount**. For example, if the customer agrees to pay off their delinquent debt by paying an additional $50 on each bill, you'd enter "50" in this field. Note - If you enter a dollar amount in this field and tab out, the system will calculate the number of installments and display the number in the **Installments** field.

Define the **CIS Division** and **SA Type** of the payment arrangement service agreement.

> **Note**
>
> **Payment arrangement SA types.** There is a field on SA type called Special Role. Only those SA types with a role of Payment Arrangement may be selected.

Clicking the **Create** (or **Change**)button causes the system to perform the following:

- It creates / updates a payment arrangement service agreement (PA SA). It sets the installment amount on this service agreement equal to the installment amount specified on the page.
- It transfers unpaid debt from the selected bills to the PA SA. The adjustment type used to transfer these funds is defined on the PA SA's SA type.
- It links the "transfer from" adjustments to the unpaid financial transactions on the bills. This will cause the unpaid FT's to be linked to Balanced match events. This means that any Active Overdue Processes for the bills should Inactivate (i.e., cancel) because the bills will no longer be consider unpaid. Refer to How Are Overdue Processes Cancelled for more information..
- It reduces the current balance on the PA SA by the amount of debt transferred to the PA SA. Why? Because when delinquent debt is transferred to the PA SA, its current balance increases. Because current balance contains the amount the customer currently owes, this balance must be reduced because the customer is going to pay off the debt in installments (and therefore they don't currently owe anything). The adjustment type used to transfer these funds is defined on the PA SA's SA type.

Clicking **Break** causes the PA SA to become broken. Please refer to the note below for what transpires when a PA is broken.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Break logic is in a plug-in.** Please be aware that the logic that is executed when a payment arrangement is broken exists in a plug-in algorithm (plugged-in on the account's Collection Class Overdue Rules). The base package algorithm performs many functions (refer to Breaking A Bill Oriented Payment Arrangement for the details). The bottom line is that when a PA SA is broken, the originating bills will have their debt reinstated and this will again be subject to the Overdue Monitor. Because this logic is in a plug-in, you can develop alternative logic and plug it in if the base package logic is not satisfactory.

Clicking **Cancel** causes the PA SA to become canceled. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken.

- How To Set Up A Payment Arrangement
- How To Add Additional Debt To A Payment Arrangement
- How To Break A Payment Arrangement
- How To Cancel A Payment Arrangement

How To Set Up A Payment Arrangement

To set up a new payment arrangement:

- Open Payment Arrangement for Bills in add mode.
- Select the **Account** in question.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills**).
- Enter the number of **Installments** or the **Arrange Amount**.
- Define the **CIS Division** and **SA Type** of the new payment arrangement service agreement.
- Click the **Create** button.

How To Add Additional Debt To A Payment Arrangement

To transfer additional debt to an existing payment arrangement:

- Open Payment Arrangement for Bills in update mode.
- Select the existing payment arrangement in the search.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills** amounts).
- Enter the number of **Installments** or the **Arrange Amount**.

Copyright © 2026, Oracle and/or its affiliates.

- Click the **Change** button.

> **Note**
>
> **After transfer.** After transferring the funds to the payment arrangement service agreement, confirm the account's payoff and current balances make sense (the payoff balance is the total amount of debt that the account will eventually have to payoff, the current balance is how much they currently owe. The account's payoff and current balances are displayed in the page's second section. If you do not understand the difference between payoff balance and current balance, refer to Current Amount versus Payoff Amount.

How To Break A Payment Arrangement

You would break a payment arrangement when a customer doesn't make the agreed payments. Typically, your overdue processes will break a payment arrangement behind-the-scenes if a customer doesn't pay. Refer to Breaking A Bill Oriented Payment Arrangement for information about how the system monitors payment arrangements.

If you want to manually break a payment arrangement,

- Open Payment Arrangement for Bills in update mode.
- Select the existing payment arrangement in the search.
- Click the **Break** button.

How To Cancel A Payment Arrangement

You would cancel a payment arrangement if you made a mistake and never intended to set up the payment arrangement in the first place. To cancel a payment arrangement

- Open Payment Arrangement for Bills in update mode.
- Select the existing payment arrangement in the search.
- Click the **Cancel** button.

Rebate Claims

The Rebate Claims feature allows you to search, view, and maintain rebate claims submitted as part of a conservation program.

> **NOT_SUPPORTED**
>
> For more information about conservation programs, see Conservation Programs.

Copyright © 2026, Oracle and/or its affiliates.

- Rebate Claim Query Portal
- Rebate Claim Portal

Rebate Claim Query Portal

You use the Rebate Claim Query Portal to search for rebate claims. Use the following procedure to search for rebate claims:

- Select **Menu**, and then **Customer Information**, and then **Rebate Claim**, and then **Search** to open the Rebate Claim Query portal.
- Enter search criteria in the Rebate Claim Search zone and click **Refresh**. You can search by:
  - Customer Name
  - Account ID
  - Conservation Program
  - Start and End Dates
- A list of rebate claims matching the search criteria appears, displaying the following for each:
  - Claim Date
  - Rebate Claim (Status, Claim Date, Conservation Program, and Total Amount)
  - Account (Name, Customer Class, Current Balance, and Account ID)
  - Total Rebate Amount
- To view a rebate claim, click the **Rebate Claim** link. The selected rebate claim opens in the Rebate Claim portal.

Rebate Claim Portal

You use the Rebate Claim portal to view, edit, and maintain rebate claims. To add a rebate claim, open **Menu**, and then **Customer Information**, and then **Rebate Claim**, and then **Search.**

The topics in this section describe the base-package zones that appear on the Rebate Claim portal.

- Rebate Claim Zone
- Adding Rebate Claims
- Rebate Claim Line Zone
- Rebate Claim Log Zone

Rebate Claim Zone

You use the Rebate Claim zone to view the details of rebate claims. The Rebate Claim zone opens when you first create a new rebate claim, or when you select a rebate claim on the

Copyright © 2026, Oracle and/or its affiliates.

Rebate Claim Search zone. The Rebate Claim zone displays the following information about the selected rebate claim:

- Basic Information: information about the claim, including:
  - Conservation Program
  - Status (Pending, Issue Detected, Approval in Progress, Receipt Verification, Complete, or Canceled)
  - Rebate Claim number
  - Claim Date
  - Total Rebate Amount
- Customer Details: details about the customer who submitted the claim, including:
  - Person
  - Account
  - Premise
  - Mailing Address
- Contact Details: contact information for customer who submitted the claim, including:
  - Name
  - Phone Number
  - Fax Number
  - Email Address
- Premise Information: information about the physical premise of the customer who submitted the claim, including:
  - Premise Property Type
  - Residential Property Type
  - Building Vintage
- Payment Release Authorization Details: details about the person to whom the rebate payment should be made, including:
  - Authorized By
  - Authorization Date
  - Payee Name
  - Phone Number
  - Mailing Address
- Issue Details: issues related to the rebate claim, including manually submitted issues as well as those detected through the Verify action.
- Approval Details: details related to users assigned to approve the rebate claim, including:
  - Current Approver
- Reject Details: details related to why a claim was rejected, including:
  - Reject Reason
  - Date Rejected
  - Rejected By

Copyright © 2026, Oracle and/or its affiliates.

To view a different rebate claim, select the rebate claim from the **Select a Rebate Claim** drop-down list and click **Go.**

- Rebate Claim Status
- Rebate Claim Actions
- Editing Rebate Claims
- Verifying Rebate Claims
- Approving Rebate Claims
- Rejecting Rebate Claims
- Noting Issues Related to a Rebate Claim
- Canceling Rebate Claims

Rebate Claim Status

Rebate claims are assigned a status to indicate the current state of the claim within the system. Valid statuses include:

- **Pending** indicates the claim is pending. This is the initial state of a rebate claim when first created.
- **Issue Detected** indicates that one or more issues have been detected with the claim. Issues can include those manually created as well as issues detected through the Verify action.
- **Approval in Progress** indicates the claim is awaiting approval.
- **Receipt Verification** indicates that receipts associated with the rebate claim's claim lines need verification.
- **Complete** indicates the claim was approved and is complete.
- **Rejected** indicates the claim was rejected.
- **Canceled** indicates the claim has been canceled.

Rebate Claim Actions

You can perform a number of actions on a rebate claim, including:

- **Edit:** Used to edit the details of the rebate claim.
- **Verify:** Used to verify the supplied details of the rebate claim, and change its status to either Approval in Progress (if the claim passes the verification) or Issue Detected (if any issues are detected). This helps ensure the rebate claim has been properly set up.
- **Approve:** Used to approve a submitted rebate claim, and change its status to Complete or Receipt Verification (if receipts had not been previously verified).
- **Reject:** Used to reject a submitted rebate claim, and change its status to Complete.
- **Issue Detected:** Used to note an issue related to the rebate claim, and change its status to Issue Detected.
- **Cancel:** Cancels a rebate claim, changing its status to Canceled.

Copyright © 2026, Oracle and/or its affiliates.

The actions available are based on the current status of the rebate claim. The table below summarizes the actions available at each status.

Status	Valid Action
Pending	Edit, Verify, Issue Detected, Cancel
Issue Detected	Edit, Verify, Cancel
Approval in Progress	Approve, Reject, Issue Detected
Receipt Verification	Issue Detected
Completed	None
Rejected	Issue Detected
Canceled	None

Editing Rebate Claims

Use the following procedure to edit a rebate claim:

- Click **Edit.**
- Edit the details of the rebate claim as needed.
- Click **Save.**

Verifying Rebate Claims

To verify a rebate claim, click **Verify.**

Approving Rebate Claims

To approve a rebate claim, click **Approve.**

Rejecting Rebate Claims

Use the following procedure to reject a rebate claim:

- Click **Reject.**
- Select the **Reject Reason** on the Reject Rebate Claim dialog.
- Click **OK.** To close the dialog without rejecting the claim, click **Cancel.**

Noting Issues Related to a Rebate Claim

Use the following procedure to note an issue related to a rebate claim:

- Click **Issue Detected.**
- Enter details about the issue in the Comments field of the Issue Comments dialog.

Copyright © 2026, Oracle and/or its affiliates.

- Click **OK.** To close the dialog without saving the comment, click **Cancel.**

Canceling Rebate Claims

Use the following procedure to cancel a rebate claim:

- Click **Cancel.**
- Select the **Cancel Reason** on the Cancel Rebate Claim dialog.
- Click **OK.** To close the dialog without cancelling the rebate claim, click **Cancel.**

Adding Rebate Claims

You can also add rebate claims from the **Rebate Claim Query** portal. Use the following procedure to add a rebate claim:

- Select **Menu**, then **Customer Information**, then **Rebate Claim**, then **Add** or click **Add** on the title bar of the **Rebate Claim Search** zone. The user is navigated to **Control Central** to select the customer filling the rebate claim. Click **Continue** once the correct account is in context.
- Select the Conservation Program associated with the rebate claim and click **OK.**
- Complete the Rebate Claim details, including:
  - Claim Date for the rebate claim
  - Customer Details
  - Contact Details
  - Premise Information
  - Payment Release Authorization Details
- Click **Save**. The rebate claim is displayed on the Rebate Claim portal.
- Edit the claim as needed in the Rebate Claim zone.
- Add claim lines to the claim using the Rebate Claim Line zone.

Rebate Claim Line Zone

You use the Rebate Claim Line zone to add, view, and edit rebate claim lines associated with a rebate claim. A rebate claim can have one or more claim lines, one for each item for which a rebate is requested. For example, if a customer purchases new energy efficient appliances (such as a washing machine and dryer), the rebate claim they submit would have a rebate claim line for each appliance. The Rebate Claim Line zone displays the following details for each claim line:

- Rebate Definition
- Manufacturer/Model
- Rebate Amount
- Icons to Edit, Delete, and Verify claim lines
- Adding Rebate Claim Lines

Copyright © 2026, Oracle and/or its affiliates.

- Deleting Rebate Claim Lines
- Editing Rebate Claim Lines
- Verifying Rebate Claim Lines

Adding Rebate Claim Lines

Use the following procedure to add a rebate claim line to a rebate claim:

- Click **Add Rebate Claim Line** in the title bar of the Rebate Claim Line zone.
- Select the **Service Agreement** associated with the claim line from the dropdown list.
- Select the **Rebate Definition** for the claim line from the dropdown list. This list is filtered based on the Conservation Program associated with the rebate claim.
- Select the **Manufacturer/Model** for the claim line from the dropdown list. This list is filtered by the Rebate Definition selected.
- Enter the **Install Date** for the claim line.
- Enter the **Number of Units** being claimed.
- Click **Save.** To return to the Rebate Claim Line zone without adding the claim line, click **Cancel.**

Deleting Rebate Claim Lines

Use the following procedure to delete a rebate claim line from a rebate claim:

- Click the delete icon for the claim line you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the claim line, click **Cancel.**

> **Note**
>
> You can delete a rebate claim line only when the rebate claim is in Pending status.

Editing Rebate Claim Lines

Use the following procedure to edit an existing rebate claim line on a rebate claim:

- Click the edit icon for the claim line you wish to edit.
- Edit the details of the claim line as appropriate.
- If you are revising the data based on updated information, check the **Data Revised** checkbox and select the reason for the revision from the **Data Revised Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.

Copyright © 2026, Oracle and/or its affiliates.

- If the claim line contained bad data, check the **Bad Line** checkbox and select the reason for the revision from the **Bad Line Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.
- Click **Save.** To return to the Rebate Claim Line zone without changing the claim line, click **Cancel.**

> **Note**
>
> You can edit a rebate claim line only when the rebate claim is in Pending status. In addition, you cannot edit a rebate claim line after it has been verified.

Verifying Rebate Claim Lines

Use the following procedure to verify a rebate claim line on a rebate claim:

- Click the **Verify** button for the claim line you wish to verify.
- Verify that the details of the claim line match the submitted receipts.
- Click **Verify.** To return to the Rebate Claim Line zone without adding the claim line, click **Cancel.**

> **Note**
>
> You cannot edit a rebate claim line after it has been verified.

Rebate Claim Log Zone

This is a standard log zone. You use the Rebate Claim Log zone to view logging details associated with a rebate claim.

- Adding Rebate Claim Log Entries

Adding Rebate Claim Log Entries

Use the following procedure to add a rebate claim log entry:

- Click **Add Log Entry** in the title bar of the Rebate Claim Log zone.
- Enter the log entry details in the Add Rebate Claim User Log dialog.
- Click **OK.** To close the dialog without saving the log entry, click **Cancel.**

Device Events

- About Device Events
- Processing Device Events

About Device Events

Device events are developments that have taken place relative to a device, and can include power outages, power restorations, tampering alerts, command completions, among others.

Attributes used to define device events include the following:

- **Device Event Date/Time**: the date and time of the event. This date/time is flexible in its interpretation. For single events it is the moment the event took place. For events that are paired, like a power up and a power down, it will represent the start of the event when received with the first of the pair and the end of the event when received with the second of the pair. For an event that includes the duration, where the device event end date/time is also supplied, this date/time represents the start date/time.
- **Device Event End Date/Time**: the end date and time of events with durations. This will only be populated if the device event date/time is also populated.
- In addition, device events also reference details specific to the head-end system that sent the event, including the following:
- **Sender**: the head-end system (defined as a service provider in Oracle Utilities Smart Grid Gateway) from which the event was sent.
- **External Sender ID**: the external ID for the head-end system that sent the event.
- **External Event Name**: the external, head-end-specific name for the event. This name is translated into a "standard" event name within Oracle Utilities Smart Grid Gateway.
- **External Source Identifier**: an identifier for the source of the event.

Standard Event Names

When the system is loading a device event, it first determines which head-end system sent it, and then determines which device produced it. The system then maps the device event name sent by the head-end system to a standard event name that corresponds to the event. Standard event names are beneficial because the event names sent by head-end systems vary, even when the events are essentially the same. What one head-end system calls "Primary Power Down," another system may call "Last Gasp." Creating a standard event name, such as "Power Outage - Device," makes it easier to send the device events to an external system such as Oracle Utilities Network Management System. In this way, the external systems that receive the events do not need to be configured to accept all of the possible names for a single type of event.

Refer to Understanding Device Event Types for additional information about how the device events are mapped using standard event names.

Copyright © 2026, Oracle and/or its affiliates.

Processing Device Events

Device Events received from external systems are processed through two major stages:

- **Device Event Seeder**: This is the common interface point that receives all device event information and performs critical validations and conversions. During this process the device event seeder identifies the appropriate specific device event business object for further processing. The choice is made based on the originating external system and the type of event being received. For example, a device event for a "Last Gasp" would result in the paired event first device event being selected.
  If for some reason the device event seeder encounters an error an instance of the device event eeder will be created to manage the resolution of that error.
- **Specific Device Event**: Each specific device event has the appropriate logic for the type of event that has been received. A tamper event might create a service issue monitor while a "Last Gasp" might create an outage activity.

Device Event Seeder Processing

The device event seeder receives device event data in a common structure, however, the content of the data (identifiers, date/times, etc) can vary depending on the system and the particular device that generated it. To accurately translate the external content to values understood by the system the device event seeder leverages the configuration of the service provider (aka head end or external system) and the device.

The service provider specifies the following inputs into device event seeder processing:

- **Identifier Types:** Each device event must identify the device the event has been generated from. The system supports a multitude of identifiers for the device. The service provider configuration specifies which identifier type is used for the device which enables the device event seeder to search for the correct destination for the device event. For example, a service provider might indicate that devices are identified by a serial number.
- **Date/Time Format:** The service provider configuration will identify whether the date/times that were sent included specific time zone designations. This allows the system to accurately handle any time zone conversions that may be necessary.
- **Processing Methods:** A service provider has the following processing methods that are used in the evaluation of the device event:
- **Device Event Mapping :** Maps a given external device event name to a standard event name. That standard event name is eventually used to identify the appropriate device event for specific processing.
- **Time Zone Translation:** Identifies the extendable lookup to be used in mapping the service provider specific time zone to the interval time zone.

The device specifies the following inputs into IMD Seeder processing:

- **Incoming Data Shift:** This value is either specified directly on the device or can be defaulted via fallback on the device type. It identifies whether the incoming date/time information has is "Shifted" meaning it has been adjusted for Daylight Savings Time (DST) when in effect, or it is "Not Shifted" which means it will never be adjusted for DST. This plays an important role in the date/time processing since all incoming device event date/times will be stored without an adjustment for DST.

With these inputs the device event seeder is able to translate the external identifiers into the appropriate identifiers to tie the device event to the originating device in the system..

Copyright © 2026, Oracle and/or its affiliates.

Device Event Seeder Critical Validations

For device events to continue on to specific device event processing they must pass the critical validations:

- The device must be identified.
- The device event must have an event date/time.

If either of the critical validations fails the device event processing will be halted and an instance of the device event seeder will be created

Note: There is special logic that exists for handling the situation where either the device event date/time or the device event end date/time falls on the duplicate hour that occurs when a time zone transitions out of daylight savings time.

Device Event Seeder Time Zone Translation and Conversion

To provide the most accurate tracking of device events all device event data is stored in a single time zone without an adjustment for Daylight Savings Time (DST). As utilities can have multiple head end systems that each send date/time information in different ways and some utilities operate in multiple time zones the device event seeder contains functionality to convert incoming date/times from a source time zone into the time zone of Oracle Utilities Meter Data Management (as indicated by the base time zone)

There are three components to identifying the source time zone of the incoming device event:

- **Service Provider IMD Import Date/Time Format:** When the device event date/times are sent in a format that identifies the time zone for each date/time the date/times will be delivered to the device event seeder already converted.
- **Incoming Data Shift:** This indicates whether the date/times will be adjusted for DST while it is in effect. A value of "Always in Local Time" indicates that the date/times are adjusted for DST. A value of "Always in Standard Time" indicates that the date/times are not adjusted for DST
- **Time Zone**: The time zone of the incoming data is identified using the follow order of precedence:
    1. The time zone as indicated by the device event data
    2. The service point time zone
    3. The device configuration time zone
    4. The base time zone

Once the time zone and the data shift of the incoming date/times is identified all date/times will be converted from that time zone and shift into the base time zone in standard time.

Specific Device Event Processing

Types of Device Events

Standard

Momentary device events, such as a tamper alert, are processed using the standard device event. These device events do not provide any special processing.

Copyright © 2026, Oracle and/or its affiliates.

Paired Device Events

Device events with a duration are defined using paired event device events: paired event first and paired event last. With the first of the pair representing the start of the event, and the last of the pair representing the end of the event. Events of this type can be configured to create or complete activities that represent the event. For example, a "Last Gasp" event might create an outage activity that is completed when "Power Restoration" event is received.

When pairs of events arrive in rapid succession (such as a last gasp followed quickly by a power restoration), these "paired event" business objects are designed to prevent them from being sent to subscribing applications.

Communication Response

The communication response is a special type of event used for head end systems that respond to smart meter commands with device events. When received these events create a communication in that will initiate the completion of the originating smart meter command.

Refer to About Communication In for more information on a communication in.

Sending Device Events to Subscribing Systems

When device events are received, they are typically passed onto to another subscribing system, such as Oracle Utilities Meter Data Management, a customer information system (such as Oracle Utilities Customer Care and Billing), an outage system (such as Oracle Utilities Network Management System), or some other application.

The means of sending device event information to subscribing system is defined in the "How to Send Device Event Related Information" processing method for the service provider representing the subscribing system. Device event information can be sent via outbound communication business object, outbound communication, or batch process.

The method for sending device events to subscribing systems (business object, outbound message, or batch process) can be defined for each device event category, and can be overridden for individual device event types (including the ability to exclude specific device event types within a category. In addition, a default event processing method can be also be configured that applies when methods of transmission aren't specified at the individual category level.

The "Subscribe to Device Event" business service is used to process device event subscription requests, and allow external applications to manage the categories of events they receive.

Refer to About Device Event Notification Suppressions for more information on a suppression device event notifications.

Creating Service Issue Monitors and Service Investigative Orders

Device events can be configured to create service issue monitors and service investigative orders. The service issue monitor type to create is defined on the device event type. When a device event is received, an Enter algorithm on the device event's Processed state creates the service issue monitor, based on the Service Issue Monitor Type specified for the device event type.

Refer to Understanding Service Task Types for more information on configuring service issue monitor types.

Copyright © 2026, Oracle and/or its affiliates.

Device Event Prioritization

By default, device events are created and/or received into the system in an initial state is "Pending" and are transitioned to subsequent states via the batch processing. This batch processing can be skipped by setting the Execution Method flag on the device event to "Real Time" (D1RT), in which case an Enter algorithm transitions the device event to the next state in its lifecycle immediately. This feature can be used to prioritize processing of certain types of device events.

The Execution Method flag can be set in in unsolicited device events sent from the head-end system, or can be inserted during Oracle Utilities Smart Grid Gateway Adapter processing.

Oracle Utilities Smart Grid Gateway Adapters set this flag to "Real Time" on all device events created as the result of smart meter commands.

Activities

- About Activities
- Maintaining Activities

About Activities

Activities cover a range of functional process within the system from smart meter commands, synchronization of consumption between related measuring components, service order management activities, and statistics and aggregations.

The table below provides the full list of activity type categories supported and a brief description of how they are used:

Activity Type Category	Activities of this type category are used to
Bulk Activity	Initiate a smart meter command for a group of meters using Oracle Utilities Smart Grid Gateway
Command Request	Initiate a smart meter command for an individual meter using Oracle Utilities Smart Grid Gateway
Consumption Sync	Trigger related measuring component estimation synchronization
Device Event Activity	Represent a device event. These are used when viewing usage and events with the Oracle Utilities Meter Data Management 360 Degree View.
Dimension Scanner	Trigger dimension scanning when aggregating usage, statistics, and other data.
Error Activity	Represent errors in activity processing.
Extract Request	Retrieve usage and device events from a head-end system using Oracle Utilities Smart Grid Gateway
Field Activity	Initiate field work via a message to an external field work system. Activities of this type are most often created by a request orchestration activity.

Copyright © 2026, Oracle and/or its affiliates.

Meter Read Download Activity	Download a list of meters to be read.
Multi Device Command Request	Initiate a smart meter command for multiple meters (for head-end systems that support multi-device commands) using Oracle Utilities Smart Grid Gateway
Non-Dispatchable Activity	Represent steps or stages in a larger process in which the system is waiting for a resolution from another system. Examples include "Wait for Measurement" or "Wait for Scheduled Read."
Orchestration Maintenance	Update or cancel an active service order activity.
Payload Statistics	Calculate processing statistics for usage and device event import processing
Request Orchestration	Orchestrate the steps necessary to fulfill a service request, based on the current state of the service point related to the request.
Suppression	Suppress sending of device events to subscribing systems (such as Oracle Utilities Network Management System)
Usage Transaction Correction Processor	Trigger correction processing for usage transactions when corrected usage is received that would impact an existing usage transaction

Maintaining Activities

You use the **Activity** portal to view and maintain activities.

Refer to About Activities for additional functional information.

You can access the portal by selecting **Main**, **Communication**, **Activity**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When creating new activities using this portal, if the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal will be available.

This portal includes the following zones:

- **Activity**: defines the basic attributes of the activity
- **Field Activity Attachments**: lists attachments related to the activity (displayed only if the current activity is a field activity)
- **Activity Hierarchy**: a tree that displays the activity and related activities (including field activities and smart meter commands), inbound and outbound communications, and completion events

Copyright © 2026, Oracle and/or its affiliates.

- **Activity Related Completion Event**: lists completion events (if any) related to the activity

Manually Completing Service Order Field Activities

Service order field activities in the "Communication in Progress" state can be manually completed or canceled by clicking **Complete** in the **Record Actions** section of the **Activity** zone. This opens the **Field Activity Manual Completion** page where the user can enter appropriate details to manually complete the field activity (such as completion information, service point information, device information, and so on). When submitted, this page creates an inbound communication and transitions the field activity to the next state as appropriate.

Note: Implementations can define custom service scripts for each field task type in the **Manual FA Completion Controls** section on the Field Task Type extendable lookup to customize the sections displayed on the **Field Activity Manual Completion** page.

Communications

- About Communication Out
- About Communication In
- Maintaining Communications

About Communication Out

These transactions are typically created from an activity and are tasked with sending a message to an external system. They follow one of two communication patterns:

- Two-way: these messages are sent to the external system without an expectation of an immediate response, or a response is received but it is only an acknowledgement of a successful receipt of the message. The true response to the message is expected to be received in a process detached from the communication out. For the full lifecycle of the communication to be complete a communication in must be received.
- One-way: these messages are sent to the external system and responded to in full within a single transaction. No communication in will be received.

The format of the message sent to the external system is typically driven by a processing method for that external system and the transportation method is controlled by the external system's message options.

If an error is encountered sending the message to the external system the communication out can perform automated retry of the messages for a configurable rate of retry and number of retry attempts.

For one-way communications the communication out will be responsible for creating the completion event.

Once the message has been communicated and a response received the outbound communication will update the initiating activity with the result.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Refer to the following topics for additional information on communications functionality:
>
> - Understanding Processing Methods for additional information on how processing methods are configured.
> - See About Completion Events for details on completion events.
> - See External Systems in the Oracle Utilities Application Framework *Administrative User Guide* for additioal information on configuring communication between your system and external systems.

About Communication In

These transactions represent a message sent from an external system and are received in two situations:

- In response to a communication that had been sent to the external system. This is the most common usage of the communication in.
- An unsolicited message received from an external system such as a real time event. Note: this is not a common pattern.
- Upon receipt the communication in will link itself to the communication out that initiated it. The response message will then be validated to ensure that it is technically and functionally correct.
- For many smart meter commands and field activities executed by service order management the communication in is responsible for creating the appropriate completion events. For example, if the response was for the On Demand Read smart meter command a completion event will be created that will generate the appropriate initial measurement data.
- Similar to the communication out a communication in that encounters an error can perform an automated retry with a configurable rate of retry and number of retry attempts.

Maintaining Communications

The Communication portal is used to maintain communication in and communication out records.

Refer to About Communication Out and About Communication In for additional functional information.

You can access the portal from the **Main > Communication > Communication**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Communication**: defines the basic attributes of the Communication
- **Communication Hierarchy**: a tree that displays the communication and related activities (including field activities and smart meter commands), inbound and outbound communications, and completion events.

Copyright © 2026, Oracle and/or its affiliates.

Completion Events

- About Completion Events
- Maintaining Completion Events

About Completion Events

Completion events are used to implement the outcome of an activity. They are created by either the communication out (for one-way communication) or the communication in (for two-way communication). Completion events are executed by the activity orchestrating the communication with the external system.

Some examples of the tasks a completion event will perform are:

- Commissioning, decommissioning, connecting, disconnecting a smart meter
- Installing or Removing a meter or item
- Creating initial measurement data
- Updating a device or service point

Maintaining Completion Events

The Completion Event portal is used to maintain completion events.

Refer to About Completion Events additional functional information.

You can access the portal from the **Main > Communication > Completion Event**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Completion Event**: defines the basic attributes of the Completion Event
- **Completion Event Related Objects**: displays data related to the completion event such as a device, service point, or initial measurement.

Notification Suppressions

- About Device Event Notification Suppressions
- Maintaining Notification Suppressions

About Device Event Notification Suppressions

When a device event is processed by the system it can be sent to one or many external applications interested in being notified about the event. A prime example of this is the Outage Management System subscribing to any device events related to a meter either losing power or regaining power.

Copyright © 2026, Oracle and/or its affiliates.

There are situations, such as a field worker performing maintenance on a meter or on a node that impacts many meters, that will result in a large amount of device events being created, processed, and distributed to subscribers.

Device event notification suppressions provides a way for a subscribing system, in anticipation of scheduled maintenance, to suppress notification of certain device events (power down, power up, tamper, etc) from one or more meters.

Maintaining Notification Suppressions

The **Activity** portal is used to maintain notification suppressions records.

Refer to About Device Event Notification Suppressions for additional functional information.

You can access the portal from the **Main > Communication > Notification Suppression**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Activity**: defines the basic attributes of a notification suppression activity

Integrations

- Business Flags
- Analytics Integrations

Business Flags

- About Business Flags
- Maintaining Business Flags

About Business Flags

Business flags provide a view into the status of a service point across applications (such as Oracle Utilities Customer Cloud Service, Oracle Utilities Meter Data Management, Oracle Utilities Customer Care and Billing and so on). Business flags are currently available in two forms:

- **Service Point Business Flags**: are often informational in nature but also allow for manual investigation to be taken.
- **Service Point Monitor Business Flags**: are seen as symptomatic of an issue that needs to be investigated. These business flags feed into a service issue monitor and may result in a service investigative order being created.

For additional details see About Business Flags in the Oracle Utilities Application Framework *Administrative User Guide*.

Copyright © 2026, Oracle and/or its affiliates.

Business Flag Allowed Actions

Allowed actions are implemented presented to the user as selectable options that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity**: This will initiate a field activity associated to the business flag's service point. The type of field task will be selected by the user. Note: this option requires Oracle Utilities Service Order Management.
- **Request Customer Notification:** This will initiate a message to the appropriate external system (e.g. Oracle Utilities Customer Care and Billing) that will identify a notification to be sent to the customer. The type of communication will be determined by the notification type selected by the user.

Note: not all business flags support allowed actions and not all business flags that support allowed actions support all allowed actions.

Maintaining Business Flags

Information for this functionality is available in the Business Flags section in the Oracle Utilities Application Framework *Administrative User Guide*.

Analytics Integrations

- Using the Meter Insights Investigation Viewer

Using the Meter Insights Investigation Viewer

The Meter Insights and Investigations functionality leverages the Oracle Utilities Analytics Insights business flag integration to support receipt of revenue protection events (referred to as "insights") from Oracle Utilities Analytics Insights for research and investigation using Oracle Utilities Meter Data Management (or Oracle Utilities Meter Solution Cloud Service). Revenue protection insights sent from Oracle Utilities Analytics Insights for investigation are events that suggest potential theft or loss of revenue such as unexpected consumption from an inactive meter, evidence of meter tampering, discovery of an improperly installed meter (such as a meter installed upside down or in reverse), and so on. Insights received from Oracle Utilities Analytics Insights create business flags, which in turn create related Meter Insight Investigation service tasks (referred to as “investigations”). Business users can use the **Meter Insights Investigations Viewer** portal to search, view, and investigate these investigations. This portal is intended to provide as much investigative information as possible so as to allow the user to complete as much work as possible without leaving the portal.

Searching

Use the following procedure to search for investigations:

1. Navigate to the portal by selecting **Main**, then **Insights**, then **Meter Insights Investigation Viewer**.

   By default the **Investigations** zone displays search results for unassigned records and records assigned to the current user.

Copyright © 2026, Oracle and/or its affiliates.

2. To search by specific search criteria or display the search criteria and filters, click the **Show Filters** link or icon. The **Investigations** zone expands to display the available search filters, including:
    - Business Flag Type
    - Address (including City and Postal Code)
    - Average Daily Usage
    - Priority
    - Service Type
    - Service Point Type
    - Assigned to User ID
    - Flags to include Unassigned records, and investigations with current active field activities.
3. Enter your search criteria and click **Search**.

The **Investigations** zone displays a default set of data about each investigation. To select the information to display for each, click the **Display** link or icon, select or deselect the data you wish to view or hide, and click **Display**.

Viewing Service Issue Monitors and Consumption

To view additional information about an investigation, click the **Expand Section** icon in the far left column. The section expands to display:

- Comments
- Service Point Information
- Field Work Information
- A list of insights (business flags) related to the investigation
- Consumption (a section similar to the **Final Values Overlay** zone in the **360 Degree View** portal)

To view additional information about the investigation, service point, or field activity, click the icon at the end of its information string. A new browser window will open displaying the **Service Task**, **Service Point** tab of the **360 Degree View** portal or **Activity** portal (respectively). This allows the user to investigate the issue in more detail as needed without having to navigate away from the **Meter Insights Investigations Viewer** portal.

To expand the **Consumption** section, click the **Expand Section - Consumption** icon on the far right side of the **Consumption** section heading. The section expands to display the following:

- **Parameters**: The default parameters used to display consumption for the service point. This includes **Measuring Component**, **Value Identifier Type**, **Start Date/Time**, **End Date/Time**, **Final Values Overlay Profile**, and **Event Bar Profile**. These values are based on the **Consumption Data Source** parameters on the investigation's **Investigation Type** (Service Task Type). The measuring component and value identifier type is based on service point type, interval/scalar flag, and UOM/TOU/SQI combination, and the date range is based on the start and end dates of the investigation and the **Days Before to Graph** and **Days After to Graph** parameters.
- **Values to Graph**: A list of measuring components to graph, including measuring components defined in the current **Final Values Overlay Profile**, as well as other measuring components selected by the user.

Copyright © 2026, Oracle and/or its affiliates.

- **Measurement Data**: A graph and tabular display of the consumption and values to graph, and event bars based on the current **Event Bar Profile**.

To change the displayed consumption, adjust the **Parameters** and **Values to Graph** and click **Load** (in the **Parameters** section).

Working With Investigations

Users can also add comments, assign a recipient for To Do entries, and change the status of investigations from this portal.

- To add or edit a comment, click the **Edit** icon in the second column from the left. The **Edit** icon is replaced by a checkmark icon and an "X" icon, and a **Comments** box opens. Enter or edit the comment text and click the checkmark icon. To delete a comment, click the "X" icon.

  Comments are saved on the Investigation, and can be viewed from the **Log** tab on the **Service Task** portal.
- To assign a recipient for To Do entries, click the **Edit** icon in the second column from the left. The **Edit** icon is replaced by a checkmark icon and an "X" icon, and the **Assigned To** column displays a drop-down list. Select the user to which To Do entries should be assigned, and click the checkmark icon.
- To change the status of the investigation, click the icon in the **Action** column. A popup menu will open displaying available options including:
  - Initiate Field Work: Select this to create a field activity to investigate the issue from the field (this transitions the investigation to the Waiting for Field Work state).
  - Issue Resolved: Select this if the issue has been resolved (this transitions the investigation to the Issue Resolved state).
  - No Issue: Select this if there is no issue (this transitions the investigation to the No Issue state).
  - Inconclusive: Select this if/when the investigation is inconclusive (this transitions the investigation to the Inconclusive state).
  - Discarded: Select this to discard issue (this transitions the investigation to the Discarded state).

See Meter Insights and Investigation Processingin the *Administrative User Guide* for more information about what happens when the investigation enters one of these states.

Aggregations

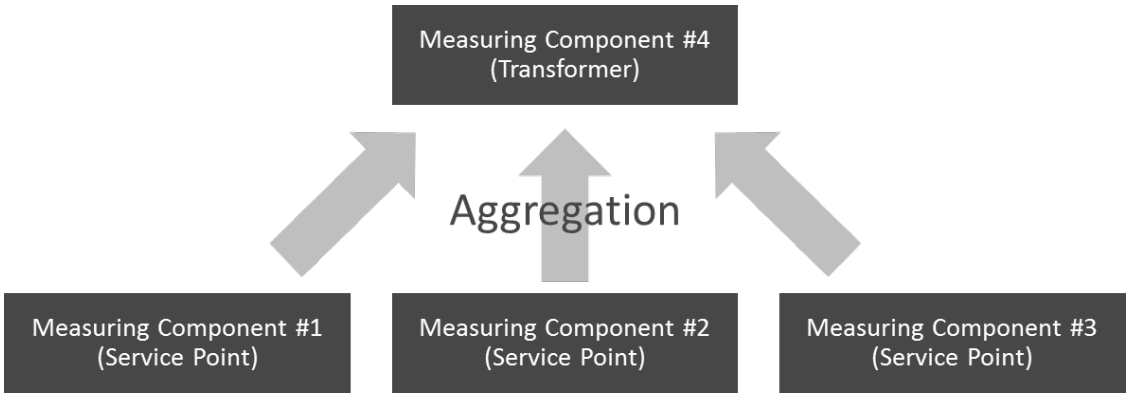
- Base Product Aggregators

Copyright © 2026, Oracle and/or its affiliates.



- Maintaining Aggregations

About Aggregations

Aggregations are measurements that represent a summarization of other measurements from a set of devices, items, and/or measuring components. For example, an aggregation may be based on the sum of the electric consumption of all residential customers in a particular postal code within the utility's service territory. The group of related measuring components for which measurements are summarized are referred to as constituent measuring components.

Every type of aggregation has one or more dimensions. For example, an aggregation might be defined with three dimensions as follows:

- Substation
- Feeder
- Transformer

Aggregations are defined by aggregator measuring components. A separate aggregator measuring component should be defined for every distinct combination of dimensions for a given type of aggregation. For example, the transformer aggregation described above would require an aggregator measuring component for every distinct combination of substation / feeder / transformer found among the electric Service Points.

Aggregations can also be aggregated. For example, the aggregator measuring components for each substation / feeder / transformer combination can in turn be used to aggregate consumption at each substation / feeder combination. In this case, a distinct aggregator measuring component would be defined for each unique substation / feeder combination. Likewise, the aggregator measuring components for each substation / feeder combination could be used to aggregate consumption at each substation, in which case, distinct aggregator measuring components would be defined for every unique substation. Finally, the aggregator measuring components for each substation can be used to aggregate total consumption for all substations, with an aggregator measuring component defined to represent the entire service area.

Aggregation Calculations

The system periodically aggregates consumption via batch process, using a deferred monitor on the aggregator measuring components. In addition, users can re-aggregate data in real-time if they don't wish to wait for the batch process, or if the original aggregation needs to be re-calculated due to incorrect data. Users can also create ad hoc aggregations "on the fly" and these will persist in the database in the same manner as other aggregations.

Copyright © 2026, Oracle and/or its affiliates.

Understanding Aggregation Periods

The start and end dates and times for aggregation calculations are based on the following:

- Aggregation Horizon
- Aggregation Lag
- Aggregation Cut Off Time

Whenever aggregation is performed for an aggregator measuring component, consumption is aggregated for every day in its "Aggregation Horizon." The "Aggregation Horizon" is the number of days during which there's a potential change in measurement data for one or more of the measuring components associated an aggregator measuring component.

Aggregation calculations typically lag behind the current date by a few days to give the system time to upload and perform validations and create final measurements. The amount of lag time is referred to as the "Aggregation Lag" and is the number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the end of the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.

Aggregation is always performed through a given "through time" (such as 12:00 AM) rather than through the actual time of the aggregation calculation. This time is referred to as the "Aggregation Cut Off Time." For example, the stop time for aggregation calculations with an Aggregation Lag of 2, and an Aggregation Cut Off Time of 10:00 PM will always be 10:00 PM 2 days prior to the date on which the calculations are performed. In the above examples, aggregations performed on January 9 would have an end date/time of 10:00 PM on January 7, and aggregations performed on January 10 would have an end date/time of 10:00 PM on January 8.

Aggregation and Re-Aggregation

The use of the aggregation horizon means that aggregated totals for some days will be re-aggregated until those days are no longer covered by the aggregation horizon. For example, with an aggregation horizon of 5 days and an aggregation lag of 2 days, on the night of January 9 the aggregation period would be January 3 through January 7 (as in the above example).

On the night of January 10, the horizon will shift 1 day (to January 4 through January 8, again as above). This means the following:

- The totals for January 3 calculated on January 9 will be untouched (January 3 now falls outside the aggregation horizon)
- The totals for January 4 through January 7 will be re-derived because corrections may have occurred (and they still fall within the aggregation horizon)
- The totals for January 8 will be calculated for the first time (because it now is within the aggregation horizon).

Copyright © 2026, Oracle and/or its affiliates.

Manually Read Meters and Aggregation Lag

Aggregations that include manually read meters often have much longer aggregation lags than those for automatically read meters. This allows more time for manual meter readings to be imported into the system for use in aggregations.

For example, suppose a situation where manual meter reads arrive approximately 1 month after the date of the reading. In this case, it wouldn't be until a meter read upload on February 7 that the last manual reads including consumption from January 6 will exist. Since we don't want to perform aggregations for January 6 until there's a decent chance that all consumption for that date exists, an aggregation lag of 32 days ensures that the data for January 6 is in the system when the aggregation is performed on February 7.

When An Aggregator Measuring Component Contains Both Manual and AMI Measuring Components

The previous section suggests that if an aggregator measuring component contains both manually read and AMI measuring components, the aggregator measuring component should have a long lag time rather than the short time shown in the earlier example.

While this is one possible approach, an alternative approach could allow users to see timely aggregations of the AMI channels and only lag the manual channels. To do this they could configure the system as follows:

- Create an aggregator measuring component that only aggregates manual measuring component types (horizon: 5 days, lag: 31 days)
- Create a separate aggregator measuring component that only aggregates interval measuring component type: 5 days types (horizon: 5 days, lag: 2 days)
- Create a third aggregator measuring component that aggregates the above aggregator measuring component types (horizon: 5 days, lag 31 days)

Expanding The Aggregation Horizon Periodically

Even with a 30-ish day aggregation lag, it's possible for an account with several months of estimated consumption to have its consumption "invalidated" when real readings arrive whose dial readings are less than the estimated readings (or when major retroactive data change takes place). Another similar situation is when a user manually corrects consumption after the aggregation horizon has moved forward.

To address situations like these, the use of ad-hoc aggregations with a user-specified aggregation horizon supports the notion of periodically (such as once a month or once a week) aggregating with a long aggregation horizon (up to 90 days) to catch as many retroactive changes as possible.

A Note About Using Non-Effective Dated Dimensions

Be aware that whenever aggregation takes place, the system uses master data that exists as of that date. For example, if an aggregation is performed using non effective-dated master data attributes (for example, aggregating by measuring component type) and a measuring component's type is changed, all days in the aggregation horizon will reflect the change regardless of when the user makes the change, because the measuring component type relationship is not effective-dated.

The impact of this depends on the nature of the change:

Copyright © 2026, Oracle and/or its affiliates.

- If the master data was wrong, this provides a way to re-aggregate the data to accurately reflect the master data.
- If the change occurred effective as of a given date (but there's no effective dated attribute), this can result in incorrect aggregation values.

Because of this, it is recommended that where possible dimensions used in aggregations be effective-dated.

For information on configuration, reference the related section for Aggregations in the Administration Guide.

Creating Aggregators

There are two ways in which aggregator measuring components are created:

- Automatically: The system will periodically create new aggregator measuring components when new "dimensional values" are detected. For example, if a new substation is added to the system, a new aggregator measuring component will be created for the substation.
- Manually: An end-user can create an aggregator measuring component at their discretion

Automatic Creation of Aggregator Measuring Components

The system automatically creates aggregator measuring components when it detects new instances of the dimension(s) being aggregated. This activity is referred to as dimension scanning. For example, if the system is configured to aggregate individual substations, a user will NOT have to manually set up an aggregator measuring component when a new substation if referenced on a service point. Rather, the system will create the new aggregator when it detects a substation on a service point that doesn't have an aggregator measuring component.

Similarly, if is configured to aggregate distinct combinations of rate class (on usage subscription type) and postal code (on service point), the system will create an aggregator measuring component when it detects new combinations of rate class and postal code.

The periodic monitoring to ensure sufficient aggregation measuring components exist is implemented via monitoring algorithms on a related activity business object that references a corresponding measuring component type. This means that there must be a separate activity type / activity combination for every type of aggregation performed. These monitor algorithms include:

- A Monitor algorithm on the Active state that simply transitions the activity to the transitory Scan state. Users can manually transition the activity to the Scan state by clicking the "Scan" button on the activity.
- An Enter algorithm on the Scan state finds the distinct combinations of dimensional values for this type of aggregation and checks that an aggregator measuring component that references the activity's aggregator measuring component type exists for every instance and creates new aggregator measuring components as appropriate. The algorithm also populates the dimensional values on the new measuring components (mapped to searchable characteristics), and sets the Consumption Aggregated Through Date/Time field on the new aggregator measuring components to the current date and the Aggregation Cut Off Time on the aggregator measuring component type.

Hard-Wiring Service Types for Aggregations

If the dimensions used for aggregation do not include at least one service type-specific dimension (for example, in the case of aggregating by postal code only) AND the aggregation should not commingle measurements of different service types, it's important to:

Copyright © 2026, Oracle and/or its affiliates.

- Declare the specific service type for the aggregation on the dimension scanner activity instance
- Declare the desired service type-specific measuring component types on the aggregator measuring component type

For example, if an electric and gas implementation aggregates consumption by postal code, they will need 2 activities: one will reference the Electric service type and the desired aggregator measuring component type, the other will reference the Gas service type and its aggregator measuring component type. The aggregator measuring components will have two dimensional attributes: postal code and service type.

Manual Creation Of Aggregator Measuring Components

Users can also create aggregator measuring component manually. This is useful when an ad hoc aggregation for an ad hoc time period is required, or when there is no activity that automatically creates instances of a given combination of dimensions. To do this, the user simply clicks the "Add" link on the Aggregator Search zone title bar. The BPA script:

- Prompts the user to define the type of aggregation (this will present a list of measuring component types whose measuring component category is aggregator)
- Prompts the user to define the dimensional value(s), the desired aggregation time, and if this aggregation should be performed indefinitely or if it is a "one time"

Base Product Aggregators

A number of standard aggregation processes are delivered as part of the base product. These provide a means of aggregating measurement data by postal code and service type for both physical meters and items.

Aggregator Name	Description
Aggregator - Postal and Service Type	Aggregates measurement quantities for constituent measuring components from physical meter based on postal code and service type dimensions.
Item Aggregator - Postal and Service Type	Aggregates measurement quantities for constituent measuring component from items based on postal code and service type dimensions.

Aggregators Used With Analytics

Other aggregators shown below are delivered for use by Oracle Utilities Analytics and Oracle Utilities Analytics Visualization (OUAV). These aggregate measurement data (including quantities and counts) for constituent measuring components based on the following dimensions: Postal, City, Head-End, Device Type, Usage Calculation Group, Market and Service Provider, and Service Type.

Aggregator Name	Description
Measurement Measured Quantity Aggregator OUAV Subject Area: Meter - Aggregated Measurement Quantity	Aggregates measurement quantities and distributes the constituents' measurements across Value Identifiers based on condition codes.

Copyright © 2026, Oracle and/or its affiliates.

Measurement Quality Count Aggregator OUAV Subject Area: Meter - Aggregated Measurement Count	Aggregates measurement counts and distributes the constituents' counts across Value Identifiers based on condition codes.
Measurement Timeliness Count Aggregator OUAV Subject Area: Meter - Aggregated Timeliness Count	Aggregates measurement counts that arrived on time or are late.
Measurement Timeliness Quantity Aggregator OUAV Subject Area: Meter - Aggregated Timeliness Quantity	Aggregates measurement quantities that arrived on time or are late.

See the Oracle Utilities Analytics Visualization User Guide for more information about the OUAV Subject Areas.

Maintaining Aggregations

This portal is used to display and maintain Aggregations.

Refer to About Aggregations for additional functional information.

You can access the portal from the **Main > Totals and Trends > Consumption Statistics**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component**: defines the basic attributes of the aggregator measuring component.
- **Measuring Component Attributes:** displays attributes that describe the dimensions and criteria for the aggregation measuring component (applies to dynamic aggregation measuring components only)
- **Measurements — Interval**: displays aggregated measurement data for the selected aggregator measuring component.
- **Interval - Audit View**: allows users to view an interval measurement curve for a given period overlaid with the count of audit records for each individual measurement.
- **Final Values Overlay**: displays final measurements for a measuring component, and provides the ability to overlay the graphed data with final measurements from other measuring components.
- **Time of Use Overlay**: displays an overlay of the TOU periods on a final interval measurement along with totalized TOU consumption based on a user-defined time period and TOU map
- **Related Measuring Component Sets**: lists measuring components sets of which the aggregator measuring component is a member (applies to dynamic aggregation measuring components only)
- **Usage Subscriptions Directly Linked to MC**: lists usage subscriptions that are directly linked to current measuring component

A few functions are available in many of these zones that allow you to interact with the measurement data. For more information of these functions refer to the Applying Measurement Functions section.

Dynamic Aggregation

- Dynamic Aggregation Overview
- Understanding Dynamic Aggregation Execution
- Aggregation Measuring Components

Dynamic Aggregation Overview

Standard aggregation processing uses specific algorithms configured to work with a specified set of dimensions. For example, the base package Service Type and Postal aggregation uses specific algorithms for dimension scanning and finding constituent measuring components. In contrast, dynamic aggregation uses dynamic queries for the dimension scanning, find constituents, and aggregation processes.

Dynamic aggregation can be used for analysis (to view aggregated data to understand load demand, for instance) as well as settlement processing performed by Oracle Utilities Market Settlements Management.

Dynamic aggregation results can be viewed using Oracle Utilities Analytics Visualization. See Viewing Dynamic Aggregation Results Using Oracle Utilities Analytics Visualization and the Oracle Utilities Analytics Visualization User Guide for more information.

Understanding Dynamic Aggregation Execution

This section provides an overview of how dynamic aggregation processing is executed, including descriptions of the different types of dynamic aggregation processing and the different types of data that can be aggregated.

Dynamic Aggregation Execution: Aggregation Groups and Aggregation Group Runs

Aggregation processing is managed via aggregation groups. Aggregation Groups outline the sequence of aggregations that must occur for a given aggregation process. Each aggregation group includes a set of Measuring Component Sets, each of which has one or more related Aggregation Measuring Components.

When processing is initiated for an aggregation group, the system creates an Aggregation Group Run record to track the status and progress of the aggregation processing. This record is used to manage the aggregation process for each group and track which Measuring Component Sets should be executed next and when the aggregation is complete.

The following steps outlines the aggregation process:

1. The Dimension Scan and Aggregation monitor batch control (D1-DSAEM) initiates processing for all Aggregation Groups. This should be scheduled at least once per day. This monitor process runs all monitor algorithms on each aggregation group. The base package aggregation group has two monitor algorithms:
    - Aggregation Group Run Maintenance (D1-AGRM)
2. The Aggregation Group Run Maintenance algorithm verifies if the Aggregation Group is ready to aggregate by looking at the processing timetable defined for the aggregation group and the last scheduled execution. If it is time for the next aggregation then the

Copyright © 2026, Oracle and/or its affiliates.

algorithm creates a pending Aggregation Group Run which will then be used to track the status of the Measuring Component Sets for the aggregation.

3. At the completion of the Dimension Scanner and Aggregation monitor batch process, the Submit Dimension Scanner Batch (D1-SUBDIMSCN) post-processing algorithm searches for any Aggregation Group Run entries that are in progress where the next Measuring Component Set is not manual. If at least one is found then it will initiate the Aggregation Group Dimension Scanner batch process (D1-AGDS).
4. The Aggregation Group Dimension Scanner batch process identifies the next Measuring Component Set for each Aggregation Group Run that is in progress. If that next Measuring Component Set is not manual then it will retrieve each Aggregation Measuring Component for the Measuring Component Set and execute the monitor algorithms for that Aggregation Measuring Component. These include an aggregation algorithm (specific to the type of data to be aggregated such as interval, billed quantities, etc.) and in some cases a value derivation algorithm.
5. For each Aggregation Measuring Component that is monitored by the Aggregation Group Dimension Scanner batch process, the aggregation process:
    a. Executes the appropriate Find Constituents algorithm to find the list of constituents that are to be aggregated
    b. Extracts the data for those constituents that should be aggregated
    c. Executes the appropriate aggregation algorithm against that data and store the results
    d. Executes validation algorithms if applicable
    e. Executes value derivation algorithms if applicable
6. The Aggregate Next Measuring Component Set (D1-AGGNXMCS) post-processing algorithm on the Aggregation Group Dimension Scanner batch process updates the Aggregation Group Run the batch information for each Measuring Component Set that was aggregated, and requests the Dimension Scan and Aggregation monitor batch process to run again.
7. This again executes the monitor algorithms for all the Aggregation Groups which will do one of several things:
    - If the Aggregation Group Run is in progress and the next Measuring Component Set is Automatic then nothing will happen.
    - If the Aggregation Group Run is in progress and the next Measuring Component Set is Manual it will create a To Do.
    - If the Aggregation Group Run does not have a next Measuring Component Set, it will set the Aggregation Group Run to Complete

    > **Note**
    >
    > The Dimension Scanner algorithm will be executed again but since there will not be a pending Aggregation Group Run it will not do anything.

8. Once all Measuring Component Sets are complete the Aggregation Group Run Maintenance algorithm marks the Aggregation Group Run as complete.

Aggregation Scheduling

Refer to Understanding Aggregation Periods for basics about aggregation periods.

Copyright © 2026, Oracle and/or its affiliates.

Aggregation Scheduling for Aggregation Groups can be based on either a Defined Lag, or a Processing Timetable.

- **Defined Lag** scheduling uses the following parameters:
  - **Aggregation Cut Off Time**: The end time for aggregation calculations performed for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This is used to ensure a consistent end time for aggregation periods. This is especially useful when aggregating other aggregations.
  - **Aggregation Lag**: The number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.
  - **Aggregation Horizon**: The number of days in the aggregation period for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This reflects the time period during which there's a potential change in measurement data for one or more of the measuring components associated with Aggregation Measuring Components. This together with the Aggregation Lag is used to determine the start and end dates of an aggregation period.
- **Processing Timetable** scheduling uses a Processing Timetable Type to drive aggregation schedule.

With dynamic aggregation, the aggregation period is consistent for all members of an Aggregation Group when an aggregation is performed. This is despite the fact that there may be differences between Measuring Component Sets and even Measuring Components within an Measuring Component Set as to how far the data has been aggregated through. In addition, individual Aggregation Measuring Components all use the same aggregation period when aggregation is performed.

Anchor Time

Dynamic aggregation processing supports calculations based on an "Anchor Time". The Anchor Time is specified on dynamic aggregation measuring component types and defines the start and end time of the business day for purposes of aggregation processing. When processing aggregation for dynamic aggregation measuring components whose type specifies an **Anchor Time**, the Start Time and End Time of the calculation period should match the **Anchor Time** on the dynamic aggregation measuring component type.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> When processing calculations for measuring components whose type specifies an **Anchor Time**, if the Start Time and End Time of the calculation period do NOT match the **Anchor Time** on the measuring component type, the Start and Stop Time are shifted to align with the closest time to the **Anchor Time** that aligns with the interval size of the measurement data being processed. The Start Time is shifted backwards (to an earlier time) and the End Time is shifted forwards (to a later time). In the case of hourly intervals with Start Times and End Times on the hour, no shift occurs. In the case of daily intervals, the shift is to the nearest Anchor Time. For example, in the Anchor Time is 07:00AM but the Start Time and End Time are both 12:00, the Start Time would be shifted to the previous 07:00AM, and the End Time would be shifted the next 07:00AM.

- Dynamic Aggregation Processing
- Types of Aggregations

Dynamic Aggregation Processing

This section provides additional details around the specific types of processing used with dynamic aggregation.

Similar to standard aggregation, dynamic aggregation processing comprises three primary types of processes:

- **Dimension Scanning**: a process that searches for unique combinations of dimensions that are not yet represented by an Aggregation Measuring Component.
- **Find Constituents**: a process that finds all source data to be aggregated for a given Aggregation Measuring Component, based on the Aggregation Measuring Component's dimensions.
- **Aggregation**: a process that aggregates source data that corresponds to the Aggregation Measuring Component's dimensions.

Dynamic aggregation processing is driven by the following types of administrative data:

- **Data Sources** define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or other sources of data.
- **Aggregation Measuring Component Types** define the most important properties of aggregation measuring components used to store aggregated data.
- **Aggregation Groups** define the ordering of a series of related aggregations and the schedule of aggregation.
- **Measuring Component Sets** define the dimensions and criteria by which aggregation will be performed.

Refer to Dynamic Aggregation Configuration Overview for more information about configuration of this data.

- Dynamic SQL
- Dimension Scanning
- Find Constituents
- Aggregation Calculation

Copyright © 2026, Oracle and/or its affiliates.

- Foundation and Composite Aggregation

Dynamic SQL

Dynamic aggregation uses dynamic SQL queries to perform dimension scanning, find constituents, and aggregation processing. These dynamic queries are based on configuration of:

- Data Sources
- Aggregation Measuring Component Types
- Measuring Component Sets

The Source of Dynamic SQL

Data sources provide template SQL that is used as the basis for dynamic queries. This template SQL is extended by additional SQL generated from the data source configuration as well as configuration defined for measuring component sets, measuring components, and measuring component types that reference the data source. The ways in which the template SQL is extended is based on the type of process:

- **Dimension Scanning**: The data source template SQL is extended by the criteria, dimensions, and individually managed items configured on the measuring component sets being processed.
- **Find Constituents**: The data source template SQL is extended by attributes defined on the aggregation measuring components being processed.
- **Aggregation**: The data source template SQL is extended by the value identifiers defined on the measuring component type of the aggregation measuring components being processed.

Dimension Scanning

The dimension scanning process analyzes master data to identify unique dimension combinations and create an aggregation measuring component for each. Several objects play a role in this process:

- The Aggregation Group holds the monitor algorithm that performs the scanning
- The Data Source defines the template SQL for identifying dimensions
- Measuring Component Sets define the dimensions and criteria for identifying the dimension combinations

See Dynamic SQL for more about the role of data sources and measuring component sets in generating dynamic SQL queries for dimension scanning.

This process is executed when aggregation is initiated for an Aggregation Group. This process should be run on a frequent basis (daily or more frequent) and should be executed prior to aggregation processing being run. Each time it is executed the dimension scanning process takes the following high level steps:

1. Identifies all Measuring Component Sets for the Aggregation Group that are not imported from an external source
2. Identifies all yet to be represented dimension combinations
3. Creates an Aggregation Measuring Component based on the Measuring Component Set's Measuring Component Type for each dimension combination identified in step 2.

Copyright © 2026, Oracle and/or its affiliates.

4. Adds Attributes for each Aggregation Measuring Component created to describe the dimensions and criteria for that Measuring Component
5. Adds an entry in the Measuring Component Set participants table for each Aggregation Measuring Component created

This processing is performed by a monitor algorithm (Aggregation Group Dimension Scanner: D1-AGDS) on the Finalized status of the Aggregation Group business object.

Find Constituents

The Find Constituents process finds all source data to be aggregated for a given aggregation measuring component, based on the Aggregation Measuring Component's dimensions. The queries used for this process are based on data source template SQL extended by attributes defined on the Aggregation Measuring Components being processed.

The Find Constituents process is initiated by the aggregation algorithm on the Aggregation Measuring Component (each type of Aggregation Measuring Component — interval, item, billed quantities — has its own aggregation algorithm), and is performed by algorithms defined for the Find Constituents system event on the Aggregation Measuring Component business object.

This process differs slightly when finding constituents for interval and scalar measurements stored on measuring components, item data, and billed quantities.

Measuring Components

The Find Constituents process for measuring components uses the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm which retrieves data based on the following:

- Attributes on the Aggregation Measuring Component based on the Measuring Component Set configuration
- Measuring Component Types on the Data Source

Measuring component constituents are inserted into a global temporary table (GTT1) with the following information:

- Measuring Component ID
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

> **Note**
>
> The aggregation period for each is adjusted by the source Measuring Component's installation history.

Items

The Find Constituents process for items uses the Find Constituents for Items (D1-FICONITEM) algorithm which retrieves data based on the following:

- Attributes on the Measuring Component based on the Measuring Component Set configuration

Copyright © 2026, Oracle and/or its affiliates.

- Item Types / Service Point Types on the Data Source (for badged vs. unbadged items, respectively)

Item constituents are inserted into a global temporary table (GTT3) with the following information:

- Maintenance Object (Device or Service Point)
- Device Type: Item Type
- Item Count
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

> **Note**
>
> The aggregation period for each is adjusted by the source Item's installation history.

Billed Quantities

The Find Constituents process for billed quantities uses the Find Constituents for Billing Data (D1-FINDCONSB) algorithm which retrieves data based on the following:

- Attributes on the Aggregation Measuring Component based on the Measuring Component Set configuration
- Usage Subscription Types on the Data Source

Billed quantity constituents are inserted into a global temporary table (GTT5) with the following information:

- Usage Subscription ID
- Usage ID
- Horizon Start Date/Time
- Horizon End Date/Time
- Time Zone

> **Note**
>
> The aggregation period for each is adjusted by the source Usage Subscription's installation history.

Aggregation Calculation

The aggregation calculations process aggregates source data that correspond to the Aggregation Measuring Component's dimensions. The queries used for this process are based on data source template SQL extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Components being processed.

The aggregation calculation process is initiated by Aggregation by MC Set Monitor batch process (D1-AMCS), and is performed by monitor algorithms defined on the Active state of the

Copyright © 2026, Oracle and/or its affiliates.

Aggregation Measuring Component business object. The algorithms used by each type of Aggregation Measuring Component are as follows:

Aggregation Measuring Component Business Object	Aggregation Algorithm
Dynamic Aggregator - Billed Quantities (D1-AggBilledServiceQuantities)	Aggregate Billed Service Quantities (D1_AGGBSQ)
Dynamic Aggregator - Composite (D1-AggregatorComposite)	Aggregate Interval Measurements (D1_AGGINT)
Dynamic Aggregator - Customer Quantities (D1-AggregatorCustomerQuantity)	Aggregate Customer Specific Quantities (D1_AGGCSQ)
Dynamic Aggregator - Interval (D1-AggregatorInterval)	Aggregate Interval Measurements (D1_AGGINT)
Dynamic Aggregator - Items (D1-AggregatorItems)	Aggregate Item Data (D1_AGGITEM)
Dynamic Aggregator - Scalar (D1-AggregatorScalar)	Aggregate Scalar (D1_AGGSCLR)

See Types of Aggregation for more information about aggregation calculations for each type.

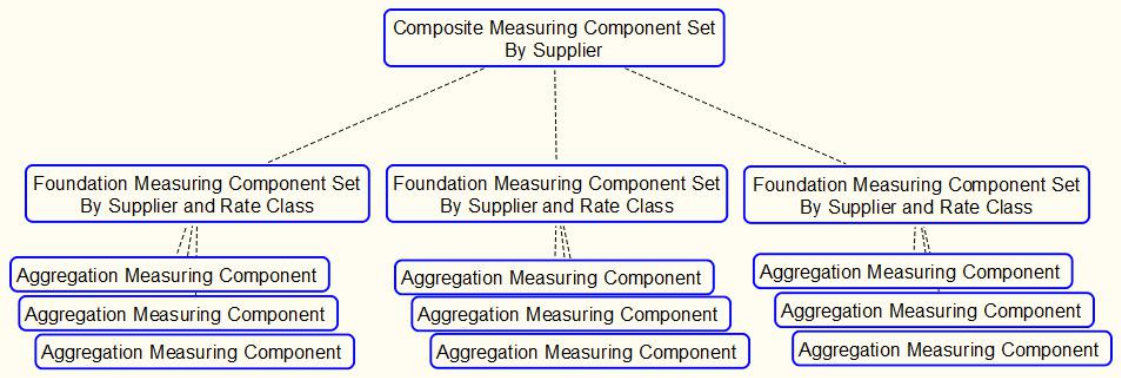
Other Calculations

In addition to basic aggregation processing, other calculations can be performed on aggregated measurements as needed. For instance, a common step in aggregating date for use in market settlements is applying a loss factor to aggregated data to reflect system losses (line loss, etc.) between generation-level quantities and end consumption quantities.

These types of calculations can be performed by value derivation algorithms. These are algorithms based on the Derive Aggregated Quantity Using a Formula (D1-DERAGGQTY) algorithm type which apply a configured formula to aggregated measurement values. For instance, to apply a loss factor, an algorithm can retrieve effective-dated factor values for a loss factor and multiply each aggregated measurement value by the appropriate factor value.

The Execute Aggregation Value Derivation (D1-EAGGVALD) algorithm on Aggregation Measuring Components executes any value derivation algorithms specified for Value Identifiers on the Aggregation Measuring Component Type.

Aggregation Calculation and Anchor Time



Dynamic aggregation processing supports calculations based on an "Anchor Time". The Anchor Time is specified on dynamic aggregation measuring component types and defines the start and end time of the business day for purposes of aggregation processing. When processing aggregation for dynamic aggregation measuring components whose type specifies an **Anchor Time**, the Start Time and End Time of the calculation period should match the **Anchor Time** on the dynamic aggregation measuring component type.

Foundation and Composite Aggregation

Dynamic aggregation supports two “levels” of aggregation. Aggregating source data, from measuring components, items, or billed quantities is referred to as “Foundation” aggregation. Aggregation of aggregated data is known as “Composite” aggregation. Composite aggregation provides the ability to aggregate data from a set of other aggregations.

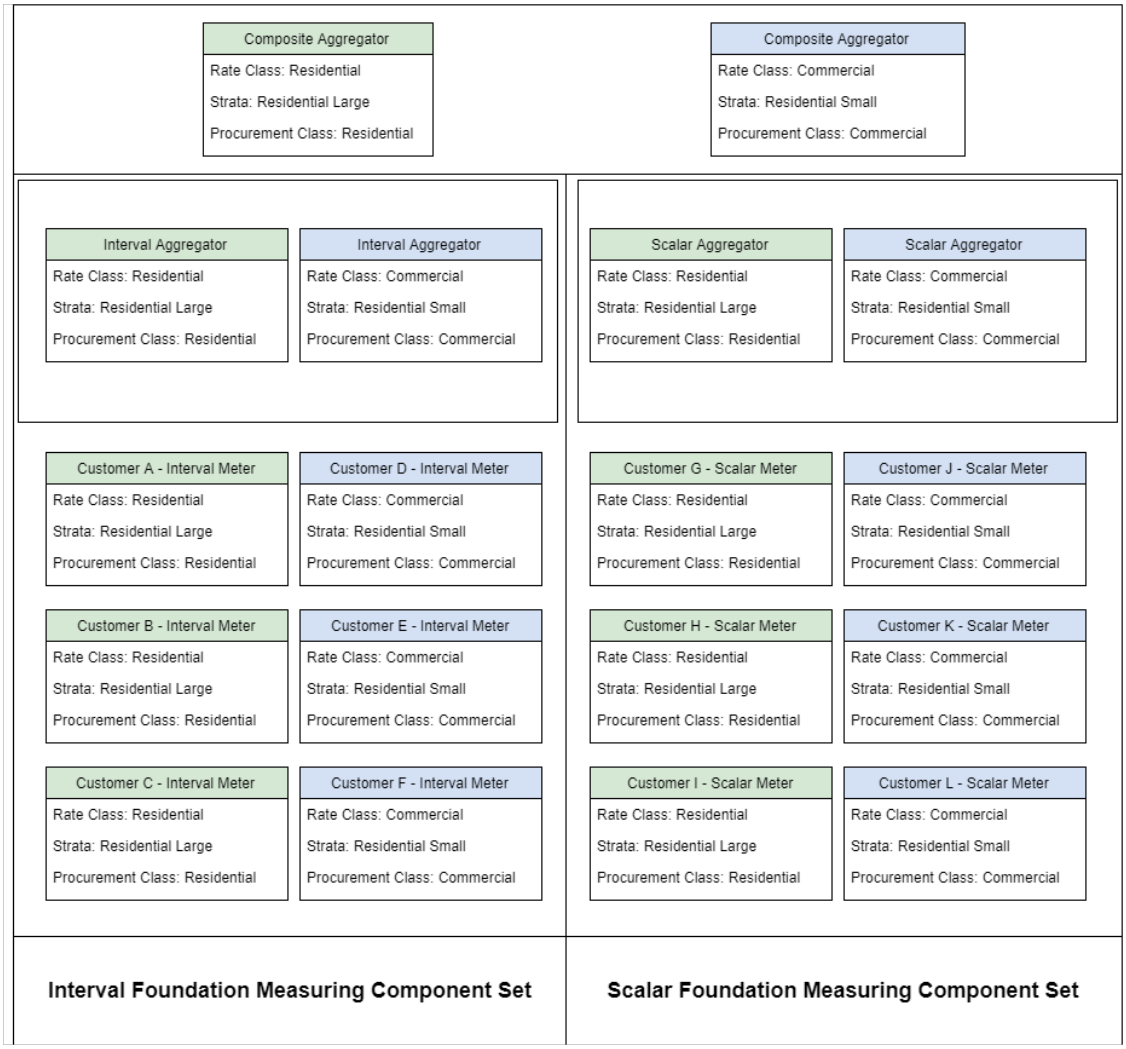
The diagram below illustrates a simple example of the relationship between foundation and composite measuring component sets. Each of the three foundation measuring component sets has a number of aggregation measuring component participants that aggregate data based on a set of dimensions and a particular supplier and rate class. Those in turn are participants in the composite measuring component set that aggregates based on the supplier (including data for all rate classes).

Copyright © 2026, Oracle and/or its affiliates.

A common scenario where composite aggregation would be used is to consolidate data across several foundation aggregation measuring component sets that pulled data from a set of data sources ordered by precedence such that the best data was sourced when available and when not the aggregations fell back to a lesser quality data source:

- Foundation: Interval measurements from usage subscriptions and / or service points
- Foundation: Scalar measurement from usage subscriptions and / or service points
- Foundation: Interval measurements from estimations (backcasted using actual weather)
- Composite: Aggregation by supplier

In this example the goal of the first aggregation would be to retrieve as much interval data as possible where that interval data covered the entire period being settled for. The second aggregation would take scalar data for those instances where interval data was not available and apply a profile to produce the appropriate intervals. The third aggregation would fill in any remaining gaps that were not covered by interval or scalar data with estimations based various forecasting models.



At the completion of those first three aggregations there would be the full resolution of data for the customer base. However, the values would be spread out across many aggregation measuring components tied to those measuring component sets. This is where the composite aggregation functionality comes into play. The composite aggregation measuring component would reference the first three foundation aggregations and sum together the data from each aggregation into a single instance that represents the total usage for the period being settled.

Let’s look at a slightly more involved example. The diagram below illustrates a set of foundation aggregations based on:

- Rate Class
- Strata
- Procurement Class

This shows how the physical measuring component data (designated by Customer A, Customer B, etc.) will be aggregated into separate aggregation measuring components based on source of data (interval or scalar). Then it shows how those aggregations are then aggregated to produce a total number that represents all 3 aggregation sources merged together.

Types of Aggregations

This section describes the processing used by different types of aggregations, including:

- Aggregating Measurement Data (Interval and Scalar)
- Aggregating Item Data
- Aggregating Billed Service Quantities
- Aggregating Aggregated Data (Composite Aggregation)

- Aggregating Measurement Data
- Aggregating Item Data
- Aggregating Billed Quantities
- Aggregating Aggregated Data

Aggregating Measurement Data

Aggregating measurement data involves identifying constituent measuring components for an Aggregation Measuring Component, identifying the measurement data that falls within the

Copyright © 2026, Oracle and/or its affiliates.

aggregation period, and aggregating that data. The process varies slightly between interval and scalar measuring components.

Interval Measuring Components

Aggregation of interval measurements is handled by the Aggregate Interval Measurements (D1_AGGINT) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm and populates the GTT1 global temporary table (see Find Constituents for more details about this process).
- It deletes any constituents from the GTT1 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT1, the algorithm inserts its measurements for the aggregation period into the GTT2 global temporary table. If the SPI and UOM are different from that of the Aggregation Measuring Component, the measurements are converted to a common SPI using Axis Conversion.
- It performs aggregation calculations on the measurement data in the GTT2 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Scalar Measuring Components

Aggregation of scalar measurements is handled by the Aggregate Scalar Measurements (D1_AGGSCL) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm and populates the GTT1 global temporary table (see Find Constituents for more details about this process).
- It deletes any constituents from the GTT1 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT1, the algorithm inserts its measurements for the aggregation period into the GTT2 global temporary table. If the UOM is different from that of the Aggregation Measuring Component, the measurement is converted to a common UOM before being inserted into GTT1.
- It performs aggregation calculations on the measurement data in the GTT2 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It applies a profile to the aggregated scalar values to create interval measurements with the same SPI as the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.

Copyright © 2026, Oracle and/or its affiliates.

- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Item Data

Aggregating item data involves identifying constituent items for an Aggregation Measuring Component, calculate item measurement data for the aggregation period, and aggregating that data.

Aggregation of interval measurements is handled by the Aggregate Item Data (D1_AGGITEM) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Items (D1-FICONITEM) algorithm and populates the GTT3 global temporary table with groups of device types (for badged items) and/or service point types (for unbadged items) (see Find Constituents for more details about this process).
- It deletes any constituents from the GTT3 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT3, the algorithm calculates measurements for the aggregation period and inserts them into the GTT4 global temporary table by applying the item counts for each group to the item interval (profile) data. If the SPI and UOM are different from that of the Aggregation Measuring Component, the measurements are converted to a common SPI using Axis Conversion.
- It performs aggregation calculations on the measurement data in the GTT4 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Billed Quantities

Aggregating billed service quantities involves identifying constituent usage transactions for an Aggregation Measuring Component, retrieving the service quantity data that falls within the aggregation period, and aggregating that data.

Aggregation of billed quantities is handled by the Aggregate Billed Service Quantities (D1_AGGBSQ) algorithm. The algorithm performs the following steps:

- It calls the Find Constituents for Billing Data (D1-FINDCONSB) algorithm and populates the GTT5 global temporary table (see Find Constituents for more details about this process).
- It deletes any constituents from the GTT5 table that do not have 100% coverage for the dates in the aggregation period.
- For each remaining constituent in GTT5, the algorithm retrieves billing data for the aggregation period (based on the service quantity configuration on the data source) and inserts it into the GTT6 global temporary table. If the UOM is different from that of the Aggregation Measuring Component, the service quantities are converted to a common UOM.

Copyright © 2026, Oracle and/or its affiliates.

- It performs aggregation calculations on the measurement data in the GTT6 table, using data source template SQL, extended by the value identifiers defined on the measuring component type of the Aggregation Measuring Component.
- It applies a profile to the aggregated values to create interval measurements with the same SPI as the Aggregation Measuring Component.
- It either inserts or updates the results to the appropriate measurement table (the standard Measurement table, or the Aggregation Measurement table)
- If there is no data for any dates in the aggregation period and previously aggregated measurements exist, those measurements are deleted to indicate the absence of data.
- It updates the **Most Recent Measurement Date/Time** and **Latest Measurement Date/Time** values on the Aggregation Measuring Component.

Aggregating Aggregated Data

Aggregating aggregated data, also known as composite aggregation, involves identifying constituent aggregation measuring components for a composite Aggregation Measuring Component, identifying the measurement data that falls within the aggregation period, and aggregating that data.

Composite aggregation is very similar to aggregating interval measurement data, and uses the Aggregate Interval Measurements (D1_AGGINT) Find Constituents for Dynamic Aggregation (D1-FINDCONST) algorithm.

Aggregation Measuring Components

- About Aggregation Measuring Components
- Maintaining Aggregation Measuring Components

About Aggregation Measuring Components

Aggregation Measuring Components are measuring components used to store aggregated data. Aggregation measuring components do not use initial measurements. Aggregated measurements are stored in the Measurement or Aggregation Measurement table (based on the Measurement Business Object defined for the aggregation measuring component's type).

Aggregation Measuring Components are defined by the following:

- **Initiating Measuring Component Set**: The measuring component set that triggered creation of the aggregation measuring component via the Dimension Scanning process (see Dimension Scanning for more information).
- **Processing Information**: Details of aggregation processing for the aggregation measuring component, including the date and time through which aggregation has been performed.
- **VEE Groups**: The VEE groups used when performing validation, editing, and estimation for the aggregation measuring component.
- **Measuring Component Attributes**: Attributes that describe the dimensions and criteria for the aggregation measuring component (identified by the Dimension Scanning process)

The base package includes the following aggregation measuring component business objects for use with dynamic aggregation:

Copyright © 2026, Oracle and/or its affiliates.

- Aggregator Interval (D1–AggregatorInterval): Used to aggregate interval measurements from interval measuring components
- Aggregator Scalar (D1–AggregatorScalar): Used to aggregate scalar measurements from scalar measuring components
- Aggregator Items Measuring Component (D1–AggregatorItems): Used to aggregate item data
- Aggregator Billed Service Quantities (D1–AggBilledServiceQuantities): Used to aggregate billed service quantities from usage transactions
- Aggregator Customer Quantities (D1–AggregatorCustomerQuantity): Used to aggregate specific types of customer quantities such as Peak Load Contribution (PLC) and usage factors
- Aggregator Composite (D1–AggregatorComposite): Used to aggregate aggregated data from aggregation measuring components (composite aggregation)

These business objects define the Find Constituents and Aggregation algorithms used for aggregation calculations.

Maintaining Aggregation Measuring Components

You use the **Totals and Trends View** portal to maintain aggregation measuring components.

Refer to About Aggregation Measuring Components for additional information.

You can access this portal by selecting an aggregation measuring component from the **Measuring Component Set Participants** zone in the **Measuring Component Set** portal. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

This portal includes the following zones:

- **Measuring Component**: This zone displays the basic attributes of the aggregation measuring component
- **Measuring Component Attributes:** This zone displays attributes that describe the dimensions and criteria for the aggregation measuring component
- **Related Measuring Component Sets**: This zone displays the measuring component sets related to the aggregation measuring component
- **Final Values Overlay**: This zone graphs final measurements for a measuring component, and provides the ability to overlay the graphed data with final measurements from other measuring components. The zone also permits overlaying data from the same measuring component for different time periods, as well as data from measuring components that measuring different quantities, such as temperature.
- **Interval - Audit View**: This zone allows users to view an interval measurement curve for a given period overlaid with the count of audit records for each individual measurement. It also allows users to magnify a portion of the curve and see how the measurements looked at different points in time.
- **Measurements - Interval**: This zone displays measurement details for the aggregation measuring component
- **Usage Subscriptions Directly Linked to MC**: This zone displays usage subscriptions that are directly linked to the aggregation measuring component

Copyright © 2026, Oracle and/or its affiliates.

- **Time of Use Overlay**: This zone displays an overlay of the TOU periods on measurement data along with totalized TOU consumption based on a user-defined time period and TOU map

Master Data Synchronization

The synchronization of master data in Customer To Meter is covered in detail in the Customer To Meter Master Data Synchronization section of the *Oracle Utilities Customer to Meter Administrative User Guide*.

Outage Storm Mode

- About Outage Storm Mode
- Reviewing Widespread Outages

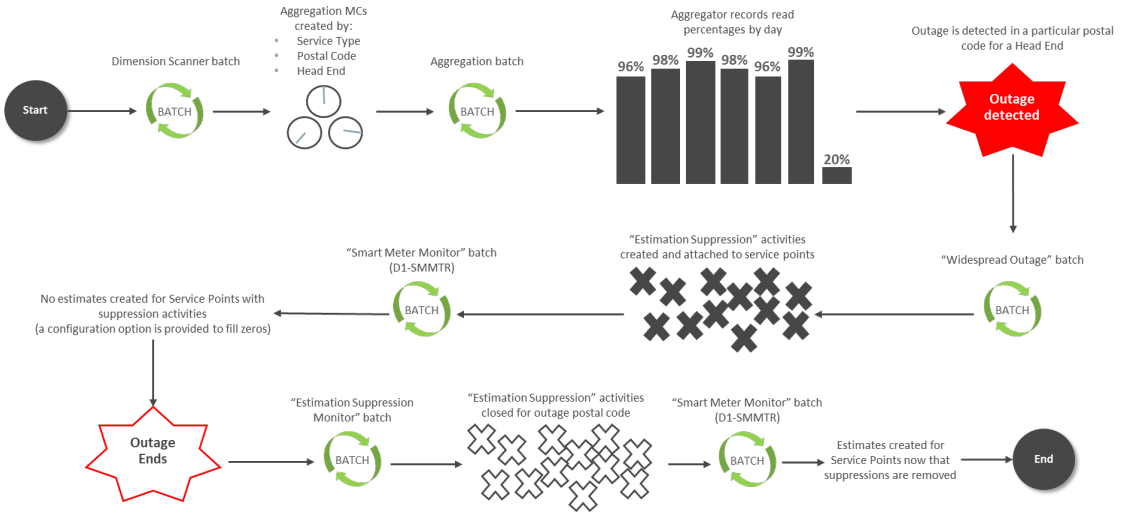
About Outage Storm Mode

Unfortunately, utilities and their customers are often subject to natural disasters that cause disruptions to AMI networks. These outage events can be related to hurricanes, tornadoes, ice storms, earthquakes, tsunamis, etc. During these severe outages, AMI systems do not always provide outage and restoration events from the devices. Without these outage and restoration events, Oracle Utilities Meter Data Management processes could estimate measurements that would be billed by the CIS. This will lead to unhappy customers, potentially bad press, and lots of manual cleanup work after the fact.

While this is a problem for major outage events, this can also occur with smaller outages (smaller blackouts, planned outages, etc.). This can potentially become an issue anytime the AMI network has a significant number of devices failing to communicate.

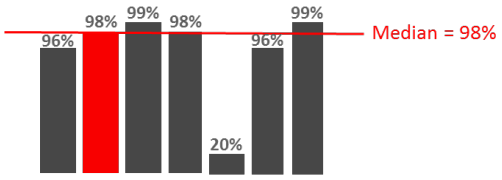
This module includes outage processing to improve estimation accuracy during major outages. The system will automatically stop estimations when the number of meter readings coming is less than a user defined tolerance. This tolerance is based on a significant drop in the read percentage for all devices in a similar postal code, service type, and Head End. Estimations will automatically resume when the device returns to normal operation. This can occur through a number of actions: read percentage for the surrounding area returns to normal, regular data is received from the device, or a power restoration device event is received from the device.

Oracle Utilities Meter Data Management also includes the ability to manually override "storm mode". This override will allow estimations to resume even if the outage hasn't been fully resolved. This will be useful if network fixes take too long and the utility has decided that customers should be billed on an estimate after a few days pass.

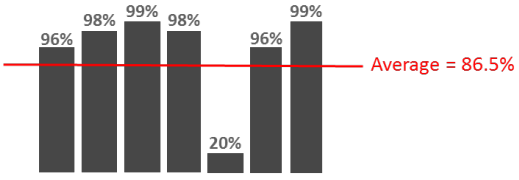


> **Note**
>
> For information on configuration, reference the related section for Outage Storm Mode in the Administrative User Guide.

Copyright © 2026, Oracle and/or its affiliates.



The diagram below illustrates the primary flow for Outage Storm Mode processing. The steps include:



1. The **Dimension Scanner** batch (D1-ADS) monitors the **Meter Communication Tracking Dimension Scanner** business object. New Aggregator Measuring Components will be created for every applicable Service Type, Postal Code, and Head End in the system.
2. The **Aggregation Monitor** batch (D2-AGG) runs to execute the logic for the **Meter Communication Tracking Aggregator** Measuring Component. This logic will aggregate all meters for the defined Service Type, Postal Code, and Head End. Once the read percentage is found for that day then a measurement will be created for the Aggregator Measuring Component.
3. The **Widespread Outage** batch (D2-WSO) runs to determine if any of the "Meter Communication Tracking Aggregator" Measuring Components have dropped below the defined threshold on the MDM Master Configuration. If it has dropped enough, then an **Estimation Suppression** Activity is created for each of the affected Service Points and the "Meter Communication Tracking Aggregator" Measuring Component is set to an "Active Outage" indicator.
4. If the **Device Periodic Estimation** batch (D1-DVCPE) runs to generate estimates while an Estimation Suppression Activity is active for a Service Point, then the Service Point will either be skipped for estimation or will have zero consumption filled for all data with a condition code of "No Read - Outage Fill".
5. There are a number of methods available to resume normal operation and close out the Estimation Suppression Activity. These include the following:
    a. The read percentage reaches a "normal level" again as defined in the MDM Master Configuration. This will be detected by the **Widespread Outage** batch (D2-WSO).
    b. When non-estimated data is received from a device, this will close out an open Estimation Suppression Activity.
    c. If the **Standard Event Name** Extendable Lookup is configured with the End Estimation Suppression algorithm (D2-EN-ESTSUP), then any Power Up event this is configured for will close out an open Estimation Suppression Activity.
    d. Estimation Suppression Activities can also be closed manually be a user by navigating to the Activity, using the "Edit" button", and add an End Date.
6. The **Estimation Suppression Monitor** batch (D2-ESTSU) runs for all Estimation Suppression Activities to determine if the related "Meter Communication Tracking Aggregator" Measuring Component is no longer in a state of "Active Outage". If the widespread outage has ended, then the Estimation Suppression activity will be set with an end date.
7. The next time the **Device Periodic Estimation** batch (D1-DVCPE) runs it will generate estimated data as normally configured.

Copyright © 2026, Oracle and/or its affiliates.

In order to determine if an area is experiencing a widespread outage, the median read percentage of prior days is used as the basis for comparison. The median was chosen instead of the average to help reduce the impact of outlier values. This is illustrated in the example below.

Reviewing Widespread Outages

Anytime a **Meter Communication Tracking Aggregator** Measuring Component is marked with an indicator of "Active Outage", a To Do will be generated for user review. The base To Do Type for this is "Widespread Outage" (D2-WSOTD). This To Do is meant to serve as a warning to users that one of the areas in the service territory is experiencing a widespread outage.

If there is a desire to continue processing as normal and not have estimation suppressed, then you can override the Meter Communication Tracking Aggregator by hitting the "Force Complete Outage" button while reviewing the To Do. This will mark the Widespread Outage Indicator as "User Override" and will allow estimation to continue normally.

Dashboards

- About Dashboards
- Using the Customer Operational Dashboard
- Using the Meter Operational Dashboard
- Using the Service Order Operational Dashboard

Copyright © 2026, Oracle and/or its affiliates.

- Using the Service Order Trends Dashboard

About Dashboards

Dashboards provide a broad view of numerous metrics used with Oracle Utilities Customer To Meter. The data presented on each dashboard is tailored to provide operational as well as analytical information for management. On some graphs, drill down options are provided to retrieve more detailed information about the metrics provided.

For information on configuration, reference the related section for Defining Dashboard Options in the *Oracle Utilities Customer To Meter Administrative User Guide*.

Using the Customer Operational Dashboard

This portal is used to display the Customer Operational Dashboard.

You can access the portal from the **Main > Dashboards > Customer Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The **Billing** tab displays the following zones:

- **Billing Trend**: displays bill completion counts and billed amounts by date.
- **Bill Print Trend**: displays bill print counts by date.
- **Open Bill Issues Trend**: displays open bill issue counts by date.

The **Payment** tab displays the following zones:

- **Payment Trend - All Sources**: displays payment counts and payment amounts from all sources.
- **Payment Trend - Upload**: displays upload payment counts and payment amounts.

The **To Do** tab displays the following zones:

- **To Do Completion By User**: displays To Do completion counts by user.
- **To Do Work Time By User**: displays average To Do work time by user.

The **Batch Performance** tab shows a series of zones related to any defined Performance Targets for batches. More information on Performance Targets can be found in the Framework guide.

Refer to About Dashboards for additional functional information. For information on configuration, refer to the related section for Configuring the Customer Operational Dashboard in the *Oracle Utilities Customer To Meter Administrative User Guide*.

Refer to each zone's embedded help for more information.

Using the Meter Operational Dashboard

This portal is used to display the Meter Operational Dashboard.

You can access the portal by selecting **Main , Dashboards, Meter Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

Copyright © 2026, Oracle and/or its affiliates.

The **Meter Operational Dashboard** contains three tabs:

- Operations
- Batch Performance
- System Health Check

Using the Operations Tab

The **Operations** tab displays the following zones:

- **IMD Loading Trend**: displays the count of initial measurement data that's loaded each day by Head End system.
- **Device Event Loading Trend**: displays the count of device event data that's loaded each day by Head End system.
- **Incomplete IMDs by Status**: displays a set of counts for initial measurement data by status.
- **Incomplete IMDs Trend**: displays a set of counts for initial measurement data for each day by status
- **VEE To Dos by Exception Type**: displays a set of counts for VEE Exceptions by Exception Type that also still have a To Do that's incomplete.
- **VEE To Dos Trend**: displays a set of counts for VEE Exceptions by Exception Type for each day that also still have a To Do that's incomplete.
- **Usage Transactions by Status**: displays a set of counts for usage transactions by status.
- **Usage Transactions Trend**: displays a set of counts for usage transactions for each day by status.
- **Usage Transaction To Dos by Exception**: displays a set of counts for Usage Transaction Exceptions by Exception Type that also still have a To Do that's incomplete.
- **Usage Transaction To Dos Trend**: displays a set of counts for Usage Transaction Exceptions by Exception Type for each day that also still have a To Do that's incomplete.

Click **Configure** to navigate to the MDM Operational Dashboard Configuration master configuration. See **Configuring the Meter Operational Dashboard** in the *Administrative User Guide* for information regarding configuration of the dashboard.

Filtering by Division

Data displayed in the zones on the **Operations** tab (except the **IMD Loading Trend** and **Device Event Loading Trend** zones) can be filtered by Division. To enable filtering by Division set the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration to "Yes". If this is set to “No” the zones display data for all divisions.

When filtering is enabled, the **Division** drop-down list allows the user to select the Division for which they wish to view data. Available divisions are based on the divisions assigned to the user in the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal. The division marked “Use As Primary” is the default.

- Using the Batch Performance Tab
- Using the System Health Check Tab

Using the Batch Performance Tab

Copyright © 2026, Oracle and/or its affiliates.

The **Batch Performance** tab shows a series of zones related to any defined batch-based Performance Targets

Click **Configure** to navigate to the **Performance Target** portal. See Measuring Performance in the *Administrative User Guide* for information.

Using the System Health Check Tab

The **System Health Check** tab includes a set of zones displaying data related to initial measurement processing and quality. These include:

- IMD Processing Trend
- IMD Processing Detail
- IMD Quality Trend
- IMD Quality Detail
- IMD Control Seeder Overview
- IMD Control Seeder Trend

Click **Configure** to navigate to the System Health Check Dashboard Configuration master configuration. See **Configuring the System Health Check Dashboard** in the *Administrative User Guide* for information regarding configuration of the dashboard.

IMD Processing Trend

The **IMD Processing Trend** zone displays the number of initial measurements and calculated numbers of constituent measurements for each day in the selected time period. The x-axis displays individual dates during the selected period. The left y-axis shows the average and maximum number of measurements per initial measurement. The right y-axis shows the number of initial measurements. The graph shows the following:

- **IMD Records**: The number of initial measurements processed on each day in the selected time period.
- **Average Measurements**: The average number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.
- **Maximum Measurements**: The maximum number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the largest number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.

You can filter the data displayed using the following controls:

- **Period View**: Specifies the range of data displayed. Options include Thirty Days, Seven Days, Three Days, or One Day. The default is "Seven Days".
- **Division**: Specifies the division of the initial measurements displayed in the graph. The default is "Show All".
- **Interval/Scalar**: Specifies whether the graph should display only interval initial measurements, scalar initial measurements, or both. The default is "Show All".

Copyright © 2026, Oracle and/or its affiliates.

- **Business Object**: Specifies the initial measurement business object(s) related to the initial measurements displayed in the graph. The default is "Show All".
- **Status**: Specifies the status (Pending, VEE Ready, Exception, Error, Finalized, and so on) of the initial measurements displayed in the graph. The default is "Show All".
- **Data Source**: Specifies the data source (if any) of the initial measurements displayed in the graph. The default is "Show All".

Click on the labels on the legend below the graph to hide/show specific metrics.

This zone displays data from statistics snapshots based on the IMD Processing Snapshot - Hourly (D1-IMDProcessingHourly) business object. The **Snapshot Date/Time** drop-down list (in the lower right corner of the zone) lists all currently available snapshots based on this business object. Filtering options are based on data available in the snapshot. For example, if all of the initial measurements processed for a specific snapshot are all interval initial measurements, the "scalar" option wouldn't appear in the **Interval/Scalar** drop-down list.

Other metrics, including File Count (the number of payload files processed) and Total Measurements, Average Age, and Maximum Age can be viewed from the statistics snapshot.

Click **Capture** (next to **Snapshot Date/Time** in the lower right corner of the zone) to navigate to the **Statistics Control** portal where you can view a list of snapshots for the statistics control, view details of a specific snapshot, and create a new snapshot if needed.

IMD Processing Detail

The **IMD Processing Detail** zone displays details from the most recent snapshot based on the IMD Processing Snapshot - Hourly (D1-IMDProcessingHourly) business object. By default this zone displays a tabular view of the data from the snapshot, with each row in the table representing a unique combination of business object, interval/scalar flag, and status. This table includes the following:

- **Date Time**: The date and time on which the initial measurements captured in the row were processed
- **Business Object**: The business object of the initial measurements captured in the row
- **Interval/Scalar**: A flag designating if the data captured in the row is interval (D1IN) or scalar (D1SC)
- **Status**: The status of the initial measurements captured in the row
- **Description**: A description of the initial measurements captured in the row
- **IMD Records**: The number of initial measurements processed for the unique combination of business object, interval/scalar, and status captured in the row
- **Average Measurements**: The average number of measurements (Total Measurements divided by IMD Records) per initial measurement captured in the row
- **Maximum Measurements**: The maximum number of measurements per initial measurement captured in the row
- **Total Measurements**: The total number of measurements values in the initial measurements captured in the row

To view a bar chart version of this data, click the **Bar** icon (to the upper right of the table).

IMD Quality Trend

The **IMD Quality Trend** zone displays the number of Validation, Editing, and Estimation (VEE) exceptions and calculated numbers of measurements for each day in the selected time period. The x-axis displays individual dates during the selected period. The left y-axis shows the

Copyright © 2026, Oracle and/or its affiliates.

average and maximum number of measurements per initial measurement. The right y-axis shows the number of VEE exceptions. The graph shows the following:

- **VEE Exceptions**: The number of VEE exceptions processed on each day in the selected time period.
- **Average Measurements**: The average number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.
- **Maximum Measurements**: The maximum number of measurement values (for example, individual interval values) per initial measurement on each day in the selected time period. This is calculated by dividing the largest number of measurements in all of the initial measurements on the day in question by the number of initial measurements on the day in question. The number of measurements is based on the Start Date/Time, End Date/Time, and the interval size of each initial measurement.

You can filter the data displayed using the following controls:

- **Period View**: Specifies the range of data displayed. Options include Thirty Days, Seven Days, Three Days, or One Day. The default is "Seven Days".
- **Division**: Specifies the division of the initial measurements displayed in the graph. The default is "Show All".
- **Interval/Scalar**: Specifies whether the graph should display data for only interval initial measurements, scalar initial measurements, or both. The default is "Show All".
- **Business Object**: Specifies the initial measurement business object(s) related to the data displayed in the graph. The default is "Show All".
- **Excepti0on Type**: Specifies the exception type (Insufficient Input Data, Device Identifier Discrepancy, and so on) of the VEE exceptions displayed in the graph. The default is "Show All".
- **Data Source**: Specifies the data source (if any) of the the data displayed in the graph. The default is "Show All".

Click on the labels on the legend below the graph to hide/show specific metrics.

This zone displays data from statistics snapshots based on the IMD Quality Snapshot - Hourly (D1-IMDQualityHourly) business object. The **Snapshot Date/Time** drop-down list (in the lower right corner of the zone) lists all currently available snapshots based on this business object. Filtering options are based on data available in the snapshot. For example, if all of the VEE exceptions processed for a specific snapshot are all based on interval initial measurements, the "scalar" option wouldn't appear in the **Interval/Scalar** drop-down list.

Other metrics, including File Count (the number of payload files processed) and Total Measurements, Average Age, and Maximum Age can be viewed from the statistics snapshot.

Click **Capture** (next to **Snapshot Date/Time** in the lower right corner of the zone) to navigate to the **Statistics Control** portal where you can view a list of snapshots for the statistics control, view details of a specific snapshot, and create a new snapshot if needed.

IMD Quality Details

The **IMD Quality Detail** zone displays details from the most recent snapshot based on the IMD Quality Snapshot - Hourly (D1-IMDQualityHourly) business object. By default this zone displays a tabular view of the data from the snapshot, with each row in the table representing a

Copyright © 2026, Oracle and/or its affiliates.

unique combination of business object, interval/scalar flag, and status. This table includes the following:

- **Date Time**: The date and time on which the VEE exceptions captured in the row were processed
- **Business Object**: The business object of the initial measurements on which the VEE exceptions captured in the row are based
- **Interval /Scalar**: A flag designating if the VEE exceptions captured in the row are based on interval (D1IN) or scalar (D1SC) initial measurements
- **Exception Type**: The exception type of the VEE exceptions captured in the row
- **Description**: A description of the VEE exception type captured in the row
- **VEE Exceptions**: The number of VEE exceptions processed for the unique combination of business object, interval/scalar, and exception type captured in the row
- **Average Measurements**: The average number of measurements (Total Measurements divided by VEE Exceptions) per initial measurement on which the VEE exceptions captured in the row are based
- **Maximum Measurements**: The maximum number of measurements per initial measurement on which the VEE exceptions captured in the row are based
- **Total Measurements**: The total number of measurements values in the initial measurements on which the VEE exceptions captured in the row are based

To view a bar chart version of this data, click the **Bar** icon (to the upper right of the table).

IMD Control Seeder Overview

The **IMD Control Seeder Trend** zone displays details from the most recent snapshot based on the IMD Control Seeder – Hourly (D1-IMDCtrlSeeder) business object. By default this zone displays a pie chart of the data from the snapshot, with each segment in the chart representing a unique combination of business object, interval/scalar flag, and message category and number.

To view a table version of this data, click the **Grid** icon (to the upper right of the table). The tabular version of this data can also be seen in the **IMD Control Seeder Trend** zone.

IMD Control Seeder Trend

The **IMD Control Seeder Trend** zone displays details from the most recent snapshot based on the IMD Control Seeder – Hourly (D1-IMDCtrlSeeder) business object. By default this zone displays a tabular view of the data from the snapshot, with each row in the table representing a unique combination of business object, interval/scalar flag, and message category and number. This table includes the following:

- **Date Time**: The date and time on which the initial measurements captured in the row were processed
- **Business Object**: The business object of the initial measurements captured in the row
- **Interval/Scalar**: A flag designating if the data captured in the row is interval (D1IN) or scalar (D1SC)
- **Message Category**: The message category for the exceptions associated with the IMD seeders captured in the row
- **Message Number**: The message number for the exceptions associated with the IMD seeders captured in the row

Copyright © 2026, Oracle and/or its affiliates.

- **Message Text**: The message text for the exceptions associated with the IMD seeders captured in the row
- **IMD Records**: The number of initial measurements processed for the unique combination of business object, interval/scalar, and status captured in the row
- **Average Measurements**: The average number of measurements (Total Measurements divided by IMD Records) per initial measurement captured in the row
- **Maximum Measurements**: The maximum number of measurements per initial measurement captured in the row
- **Total Measurements**: The total number of measurements values in the initial measurements captured in the row

To view a bar chart version of this data, click the **Bar** icon (to the upper right of the table).

Using the Service Order Operational Dashboard

This portal is used to display the Service Order Operational Dashboard.

You can access the portal from the **Main > Dashboards > Service Order Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The following zones may appear as part of the portal's **Main** tab page:

- **In-Flight Activities By Type**: shows the distribution of in-flight Activities (in progress or in error) by Activity Type.
- **In-Flight Activity Trend**: shows the number of activities that are in-flight on a given day.
- **In-Flight Activities with Issues**: presents a bar chart that indicates the number of activities with issues.
- **In-Flight Activity Status Distribution**: presents a pie chart that displays the distribution of statuses of in-flight activities.
- **Efficiency Trend for In-Flight Activities**: presents a stacked bar chart that displays the distribution of in-flight activity processing efficiency relative to configurable tolerance.
- **Service Order To Do Summary**: this zone uses horizontal bars to highlight the relative number of open To Dos for a set of To Do Types related to Service Order Management.

Refer to About Dashboards for additional functional information. For information on configuration, refer to the related section for Configuring the Service Order Operational Dashboard in the Administrative User's Guide.

Filtering by Division

Data displayed in the zones on this dashboard can be filtered by Division. To enable filtering by Division set the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration to "Yes". If this is set to "No" the zones display data for all divisions.

When filtering is enabled, the **Division** drop-down list allows the user to select the Division for which they wish to view data. Available divisions are based on the divisions assigned to the user in the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal. The division marked "Use As Primary" is the default.

Using the Service Order Trends Dashboard

Copyright © 2026, Oracle and/or its affiliates.

This portal is used to display the Service Order Operational Dashboard.

You can access the portal from the **Main > Dashboards > Service Order Trends Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The following zones may appear as part of the portal's **Main** tab page:

- **Orchestration Issues Trend**: contains a stacked bar chart showing issues by category and Activity Type.
- **Issue Distribution Over Time**: contains a pie chart showing the distribution of activity issues over a range of days.
- **Activity Success Trend**: shows successful activities over a range of days.
- **Activity Creation Trend**: shows activities created over a range of days.
- **Activity Completion Efficiency Over Time**: shows the efficiency of activity completion over a range of days.

Refer to About Dashboards for additional functional information. For information on configuration, refer to the related section for Configuring the Service Order Trends Dashboard in the Administration Guide.

Filtering by Division

Data displayed in the zones on this dashboard can be filtered by Division. To enable filtering by Division set the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration to "Yes". If this is set to “No” the zones display data for all divisions.

When filtering is enabled, the **Division** drop-down list allows the user to select the Division for which they wish to view data. Available divisions are based on the divisions assigned to the user in the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal. The division marked “Use As Primary” is the default.

Totals and Trends

- Processing Statistics
- Consumption Statistics

Processing Statistics

- About Processing Statistics
- About Head-End System Processing Statistics

About Processing Statistics

Upload statistics (or upload stats) are statistics related to the uploading of initial measurement data and device events sent from a head-end system.

Upload statistics are defined as activities in Oracle Utilities Smart Grid Gateway.

There are three types of upload statistics activities:

Copyright © 2026, Oracle and/or its affiliates.

Payload Statistics: Contains statistics related to a specific payload (file) containing one or more initial measurements or device events. Payload Statistics activities contain:

- Basic information about the payload (head-end system, file name, and status
- Middleware statistics including specifics about the file, the total number of initial measurements or device events processed, the number of initial measurement or device events errors, and total processing time
- Initial measurement statistics including the number of initial measurements processed
- Device event statistics including the number of device events processed

Payload Error Notification: Contains details concerning processing errors encountered in an individual payload (file) containing one or more initial measurements or device events. Payload Error Notification activities are related to Payload Statistics activities.

Payload Summary: Contains processing summary statistics for an individual payload (file) containing one or more initial measurements or device events. Payload Summary activities are related to Payload Statistics activities, and are used to update related payload statistics upon the completion of payload processing.

Upload statistics activities are created during processing of payload files as follows:

- When processing begins for a payload, a Payload Statistics activity is created to record the process.
- If an error occurs during processing, a Payload Error Notification activity is created.
- When payload processing is complete, a Payload Summary activity is created, which in turn, updates the Payload Statistics activity with details concerning the processing of the payload, including (the start and end time of the processing, the total processing time, the number of initial measurements or device events processed, and the number of initial measurement or device event errors (if any).

About Head-End System Processing Statistics

Head-end system processing statistics are summarized processing statistics for payloads received from a given head-end system.

As Oracle Utilities Smart Grid Gateway processes payloads containing initial measurements or device events, statistics for each payload are captured in Payload Statistics activities. Over time, payload statistics for each head-end system are summarized to allow administrators to view statistics summary for the head-end system.

Head-end system processing statistics are stored as aggregated measurements for aggregator measuring components. A separate aggregator measuring component must be set up for each head-end system for which processing statistics will be aggregated.

Consumption Statistics

Please refer to the About Aggregation section for information on consumption statistics.

Time Zone Support

- Daylight Savings Time Support

Copyright © 2026, Oracle and/or its affiliates.

- Multiple Time Zone Support

Daylight Savings Time Support

This section describes how the Oracle Utilities Service and Measurement Data Foundation and its related products support Daylight Saving Time (DST).

All date/times in the system are displayed adjusted for daylight savings time (when in effect). However, not all date/times in the system are stored in daylight savings time:

- Stored in Standard (not adjusted for DST): data that is highly sensitive to DST shifts are stored in standard time without any shifts, this means they have a consistent 24 hour day each day all year and avoid issues that arise from a skipped hour when transitioning to DST and a duplicate hour when transitioning out of DST. For example: initial measurement data, final measurements, device events, TOU map data.
- These date/times are adjusted for daylight savings time prior to being displayed to a user.
- Stored in Legal (adjusted for DST): data that is not as sensitive to DST time shifts are stored in legal time. For example, device configurations, service points, installation events, usage subscriptions, usage transactions.

Adjusting Date/times Upon Receipt

The two largest sources of imported data to the system can be sent in a mixture of date/time formats some in legal time some in standard time:

- Initial Measurement Data
- Device Events

Since both sets of data are sent by head end systems and each head end system handles date/times differently, potentially even differing by device, the interface must be extremely flexible in how it handles date/times. In order to ensure data is accurately stored and processed the system must know how a given meter sends date/time information. This is defined on the device through the Incoming Data Shift field:

- Always in Standard Time: No special handling is required.
- Always in Legal Time: All date/times for the initial measurement data or device event will be converted from legal time into standard time.
- In circumstances where a date/time is received in legal time and it falls on the duplicate hour that occurs when DST ends special logic will be executed to identify whether that hour is the first (still in DST) or second (no longer in DST) of the duplicate hours. If for some reason it cannot be identified which hour it is the transaction will go into error.

Daylight Savings Time Interval Conversion Examples

The following examples show how data received legal time will be shifted into standard time for an interval meter that is read on an hourly basis.

Daylight Savings not in Effect

Date/Time Received in Legal	Date/Time Stored in Standard
01/14/2010 12:00AM	01/14/2010 12:00AM
01/14/2010 1:00AM	01/14/2010 1:00AM
01/14/2010 2:00AM	01/14/2010 2:00AM

Copyright © 2026, Oracle and/or its affiliates.

01/14/2010 3:00AM	01/14/2010 3:00AM
01/14/2010 4:00AM	01/14/2010 4:00AM
01/14/2010 5:00AM	01/14/2010 5:00AM

Daylight Savings Starts (Spring Forward) - No 2AM interval

Date/Time Received in Legal	Date/Time Stored in Standard
03/14/2010 12:00AM	03/14/2010 12:00AM
03/14/2010 1:00AM	03/14/2010 1:00AM
03/14/2010 3:00AM	**03/14/2010 2:00AM**
03/14/2010 4:00AM	03/14/2010 3:00AM
03/14/2010 5:00AM	03/14/2010 4:00AM
03/14/2010 6:00AM	03/14/2010 5:00AM

Daylight Savings in Effect

Date/Time Received in Legal	Date/Time Stored in Standard
06/14/2010 12:00AM	06/13/2010 11:00PM
06/14/2010 1:00AM	06/14/2010 12:00AM
06/14/2010 2:00AM	06/14/2010 1:00AM
06/14/2010 3:00AM	06/14/2010 2:00AM
06/14/2010 4:00AM	06/14/2010 3:00AM
06/14/2010 5:00AM	06/14/2010 4:00AM

Daylight Savings Ends (Fallback) - Duplicate 1AM

Date/Time Received in Legal	Date/Time Stored in Standard
11/7/2010 12:00AM	11/6/2010 11:00PM
11/7/2010 1:00AM	**11/7/2010 12:00AM**
11/7/2010 1:00AM	**11/7/2010 100AM**
11/7/2010 2:00AM	11/7/2010 2:00AM
11/7/2010 3:00AM	11/7/2010 3:00AM
11/7/2010 4:00AM	11/7/2010 4:00AM

Daylight Savings Impact on Periodic Estimation

In periodic estimation both the interval and scalar versions can be impacted by daylight savings time:

- Interval periodic estimation using the "Predictable Cut-off" method.
- All scalar periodic estimation

Refer to About Periodic Estimation for more information about the impact of Daylight Savings Time on periodic estimation.

Multiple Time Zone Support

Copyright © 2026, Oracle and/or its affiliates.

Some utilities have operations in more than a single time zone. When operating in multiple time zones, Oracle Utilities Meter Data Management and Smart Grid Gateway provide the following high level functionality:

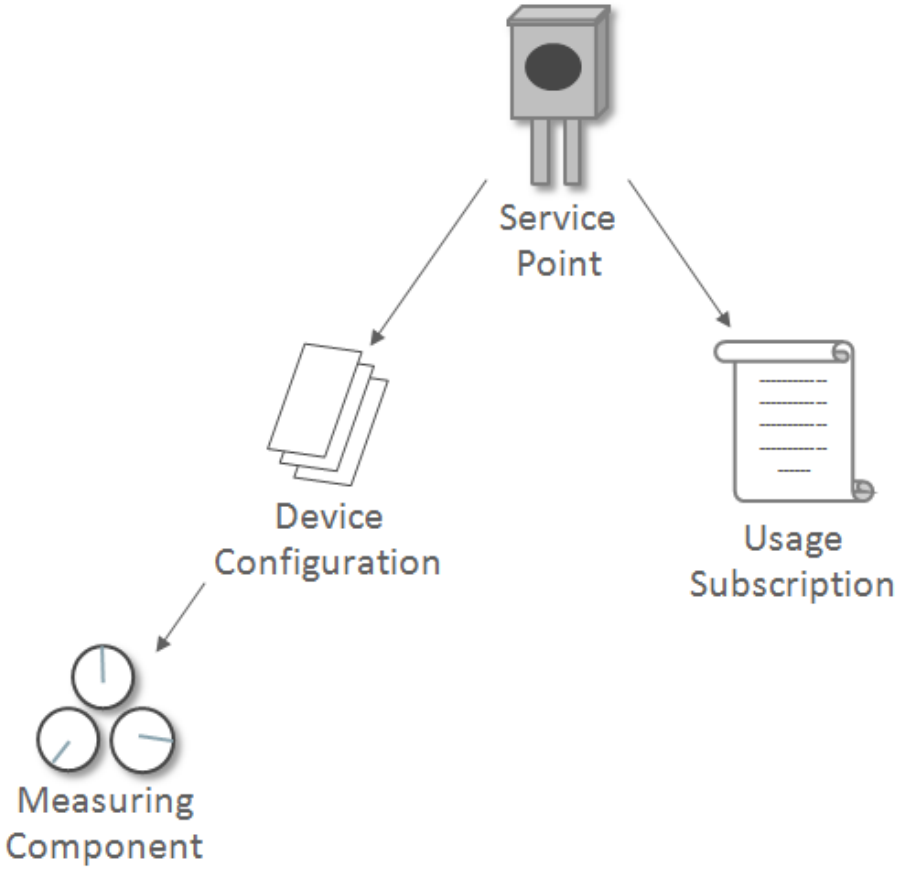
- The ability to receive data in any time zone and convert it to the common time zone used by Oracle Utilities Meter Data Management (as defined by the base time zone)
- The ability to display functional date/times in the time zone of a given device, service point, usage subscription
- The ability to define what time zone a measuring component, device configuration, service point, or usage subscription resides in
- The ability to aggregate data across time zones into a single time zone or without respect to a time zone (see Aggregations on page E-17 for more information).
- The ability to export data to an external system with the appropriate time zone information to enable the external system to consume data from different service points in different time zones

By default, the system assumes only a single time zone is supported. To enable support for multiple time zones it requires that adding the appropriate entry to the general system configuration feature configuration.

Refer to Configuring Feature Configurations for additional on the feature configuration options available.

Date/Time Storage and Display

All date/times in the system are stored in the base time zone. Date/times are stored in either standard time or legal time and this determination is made based on the type of data (e.g. measurements are in standard but installation event date/times are in legal).



All date/times are displayed in legal time. Those date/times that are key functional date/times related to a device, service point, or usage subscription will be displayed in the legal time of the time zone the device resides in.

Refer to the Glossary of Terms for a more detailed definition of Standard and Legal time.

Time Zone Hierarchy and Maintenance

A time zone can be defined at many points within the device to usage subscription hierarchy. This enables the time zone to be accurately portrayed based on the installation status of that device (e.g. not installed, installed but not billed, billed). At each stage of the hierarchy the time zones must match.

Copyright © 2026, Oracle and/or its affiliates.

Once the hierarchy has been established no one portion of that hierarchy can be changed to a time zone that differs from the other levels of the hierarchy. In order to change the time zone for an established device to usage subscription hierarchy the change must be done to the service point. Once the service point time zone has been changed the system will cascade that change to all other levels of the hierarchy.

If a device has been installed at a service point in order for it to be moved to a different service point in a different time zone. It will require that a new device configuration be created for time zone of the new service point since a device configuration cannot be associated to two different service points each with a different time zone from the device configuration.

Note: If the time zone for a device that has existing measurements has been changed there will be no automatic adjustments made to the underlying measurement data. If the measurement data must be changed it will require manual intervention.

Note: Although measuring component has time zone it is not populated on physical devices that are installed at service points. This time zone is used for standalone measuring components.

Impacts on Aggregations

In aggregation there are two use cases for how data should be aggregated for service points that exist in differing time zones:

- **Absolute Time**: If a time zone is provided on the measuring component or measuring component type, then the aggregation horizon date/times will be used across service points of differing time zones. For example the 4/1/2010 12AM interval in US/Pacific would be combined with the 4/1/2010 3AM interval in US/Eastern. Since all date/times are stored in the base time zone there is no need to do time zone conversions.

Copyright © 2026, Oracle and/or its affiliates.

- **Local Time**: If no time zone is specified, consumption is aggregated by converting the aggregation horizon to the appropriate time zone for each service point. For example the 4/1/2010 12AM interval in US/Pacific would be combined with the 4/1/2010 12AM interval in US/Eastern.

Aggregation Measuring Components in general do not have any time zone related dependencies with other master configuration objects. However, when an aggregator is listed as a direct channel measuring component on a usage subscription it share the same time zone as the Usage Subscription.

Impacts on TOU Map Generation

The date and times defined on a Time of Use Mapping Templates (TOU) do not have a time zone associated to them and will be interpreted based on the time zone of the TOU map type of the specific TOU Map being processed. This allows for a single definition of a TOU schedule that can be applied across many different time zones.

During the generation of the TOU map data for a given TOU map template the date/times will be converted from the time zone of the TOU map to the time zone defined in the base time zone defined on the installation options - framework. For example, if 1/1/2010 5:00PM was considered to be "On Peak" and the system time zone was UTC -08:00 and the TOU map time zone was UTC -05:00 then the TOU map data entry would be written as 1/1/2010 2:00PM.

Impacts on Factors

Factor effective dates do not have a time zone associated to them and are assumed to be in the local time zone of the data being validated. For example a factor effective 4/1/2010 12:00AM would be considered to be effective 4/1/2010 12:00AM UTC -08:00 and 4/1/2010 12:00AM UTC -05:00 based on the time zones of the respective meters. This allows a single factor to apply to many time zones and behave uniformly.

Impacts on Holidays

Holiday effective dates do not have a time zone associated to them and are assumed to be in the local time zone of the data being validated. For example a holiday on 12/25/2010 would be considered to be effective beginning 12/25/2010 12:00AM UTC -08:00 and 12/25/2010 12:00AM UTC -05:00 based on the time zones of the respective meters.

Impacts on Periodic Estimation

Refer to About Periodic Estimation for more information about the impact of Daylight Savings Time on periodic estimation.

Impacts on Initial Measurement Creation Online

When creating initial measurements online from the 360 Degree View portals, initial measurements are created as appropriate for measuring components with time zones other than the base time zone.

For example, if you copy measurements from a measuring component in one time zone to a measuring component in a different time zone, the measurements are being moved in absolute time (i.e. the 3:00 PM in UTC -08:00 would be changed 6:00PM in UTC -05:00).

Impacts on Items

The consumption for "badged" and "unbadged" items is driven by configuration on the device type service quantity and the multi-item section of the service point:

- **Device Type Service Quantity**: the effective date of the service quantity does not have a time zone and is assumed to be in the local time zone of the service point it is associated

Copyright © 2026, Oracle and/or its affiliates.

to (whether through a install event for "badged" items or by being directly configured on the service point). For example an effective date time of 1/1/2010 5:00PM would be considered to be effective beginning 1/1/2010 5:00PM UTC -08:00 and 1/1/2010 5:00PM UTC -05:00 based on the time zones of the respective meters

- **Service Point Multi-Item**: the start date time and end date time of the multi-item list are stored in legal time of the base time zone and displayed in the legal time of the service point's time zone.

Service Issue Monitors

- About Service Issue Monitors
- About Service Investigative Orders

About Service Issue Monitors

Service Issue Monitors are service tasks that analyze service points to determine if service is needed. If service is determined to be needed, the Service Issue Monitor creates a Service Investigative Order.

Device events, VEE exceptions, failed smart meter commands, and other events can trigger the creation of a service issue monitor (the type of service issue monitor created is based on the Service Issue Monitor Type specified on the device event type, exception type, or activity type). Once created, service issue monitors analyze the service point where the device associated with the device event, VEE exception, or failed command, based on evaluation criteria specified on the service issue monitor's type. If the criteria are met (in other words, if a specified number of command failures, device events, or VEE exceptions are found for the service point), the service issue monitor creates a service investigative order.

Service Issue Monitor Creation

This section provides an overview of the process that takes place when service issue monitors are created.

> **Note**
>
> The process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

1. One (or more) of the following takes place:
   - A device event or reader remark is received, whose type specifies a Service Issues Monitor Type
   - A VEE exception whose type specifies a Service Issues Monitor Type is generated during VEE processing
   - A usage transaction exception generated during usage calculation
   - A smart meter command fails whose type specifies a Service Issues Monitor Type
   - A business flag is received whose type specifies a Service Issue Monitor Type

Copyright © 2026, Oracle and/or its affiliates.

2. The object received in item (1) creates a service issue monitor based on the referenced Service Issue Monitor Type
3. The service issue monitors analyzes the service point based on the Discard Rules and Evaluation Criteria defined on the service issue monitor's type to determine if a service investigative order should be created or if the service issue monitor should be discarded.

   The "Discard Rules" on the service issue monitor's type are evaluated to determine if the new service issue monitor should be discarded (new service issue monitors are always discarded when created if an existing service investigative order initiated by a service issue monitor of the same type exists for the service point.)

   If the service issue monitor type was configured to require approval, the service issue monitor generates a To Do to notify the appropriate individuals that approval is necessary.

   If the service issue monitor is approved or if no approval was necessary the service investigative order will be continue.
4. The service issue monitor then executes the evaluation criteria defined on the service issue monitor's type. If those criteria are met the Service Investigative Order activity is created. If the criteria are not met the service issue monitor is discarded.
5. If the service issue monitor has completion criteria defined the service issue monitor will wait for the service investigative order to complete. Once complete the the service issue monitor will execute the completion criteria to evaluate if the service investigative order achieved the desired results.

   If either there were no completion criteria or they were satisfied the service issue monitor will complete.

   If the completion criteria were not satisfied the service issue monitor enter an inconclusive investigation state from which manual intervention will be required.

About Service Investigative Orders

Service investigative orders are activities created by a service issue monitor when a specified set of events have occurred at a service point. The type of activity created by the service issue monitor is defined on the service issue monitor's type.

Service issue monitors are often configured to create field activities that are in turn sent to an external field work system.

Market Transaction Management Addendum

This chapter is an addendum to the Market Transaction Management chapter. It describes functionality that is specific to Oracle Utilities Customer to Meter.

- Maintaining Market Usages, Market Charges and Market Payments

Maintaining Market Usages, Market Charges and Market Payments

The following sections describe the pages available to view and work on market usage, market charge and market payment.

- Maintaining Market Usages

Market Transaction Management - US Distribution

Market Transaction Management - US Distribution refers to functionality distributors can use to exchange standardized electronic business transactions in deregulated US distribution markets. The functionality supports the processing of Electronic Data Interchange (EDI) transactions that enable the distributor to communicate operational, customer, billing, enrollment, and service-related information with market participants in a consistent and reliable way.

This functionality (also referred to as "market transaction messaging") provides a common baseline architecture and transaction-processing framework that can be extended to support the specific rules, transaction sets, and validation requirements of individual deregulated distribution markets. The functionality provided is a framework on which specific market implementations can be based. The business objects and algorithms represent a generic "root" and "lowest common denominator" implementation, meaning they serve as the basis upon which a market-specific versions of those objects and algorithms can be created. For example, market-specific versions of the business objects and algorithms used for a PJM

Copyright © 2026, Oracle and/or its affiliates.

implementation of a market invoice (810) transaction would differ from those used for an ERCOT implementation, even though they would be based on the same root objects.

> **Note**
>
> The US Distribution market transaction messaging functionality is intended for use specifically by **distributors** working in a deregulated market within the United States.
>
> This documentation assumes readers have a basic understanding the market transaction messaging business process, including understanding Electronic Data Interchange (EDI) transactions, different types of market transactions, and the different types of market participants in a deregulated market.
>
> It is CRITICAL that you have a firm understanding of how your market operates before you begin planning your implementation. This includes, but is not limited to, details concerning the types of market participants involved, the billing relationship between the distributor and other market participants, and the types and formats of the market messages the distributor will send to and/or receive from other market participants.
>
> Objects provided with MTM are prefixed with "U2". The business objects provided are intended to serve as parent business objects for market-specific versions. None of the business objects provided can be instantiated.
>
> Note that the information provided in this is not sufficient for configuring any specific market. Use of this functionality requires implementers and users have an understanding of their own market.

- Overview
- The Importance of Understanding Your Market
- Customer Lifecycle Example
- Market Transaction Management and Customer Cloud Service
- Implementing an MTM US Distribution Transaction

Overview

In deregulated utility markets, distributors exchange large volumes of business transactions with retail energy providers, market operators, and other participants to support customer choice and delivery operations.

Market transaction management helps the distributor:

- Exchange standardized EDI market transactions
- Automate communication with external market participants
- Support customer enrollment, switching, and service processing
- Manage service requests and account updates
- Process billing and usage information
- Comply with regional market rules and transaction standards
- Reduce manual processing and operational errors

Copyright © 2026, Oracle and/or its affiliates.

The framework provided offers reusable core functionality while allowing market-specific customization and configuration.

Supported transaction types can vary by market implementation, but commonly include:

- Customer enrollments and drops
- Service starts, stops, and transfers
- Meter usage and consumption data
- Billing and payment information
- Customer account updates
- Service order requests
- Move-in and move-out requests
- Transaction acknowledgments and responses

Market-Specific Implementations

Although deregulated markets share many common business processes, each market operates under its own regulatory requirements, transaction standards, and implementation guidelines.

Market transaction messaging provides a common foundational framework that supports:

- Reusable transaction-processing functionality
- Shared integration patterns
- Standardized monitoring and error handling
- Configurable validation and business rules

This approach enables distributors to implement market-specific requirements while maintaining consistency across multiple deregulated markets.

Glossary

The table below lists a number of terms used in market transaction messaging.

Term	Definition
Supplier	The utility responsible for supplying power to the grid Also referred to as: • Electric Generation Suppliers (EGS)
Distributor	The utility responsible for distribution of power within the market. Also referred to as: • Electric Distribution Companies (EDCs) • Local Distribution Company (LDC) • Transmission and Distribution Service Provider (TDSP)

Copyright © 2026, Oracle and/or its affiliates.

Term	Definition
Retailer	The company with which customers enroll to purchase electricity Also referred to as: • Competitive Retailer (CR) • Energy Service Company • Energy Service Provider (ESP) • Retail Electric Provider (REP)
Market Operator	The organization in charge or managing and operating the market. Also referred to as: • Independent System Operator (ISO) • Regional Transmission Organization (RTO)
Service Provider	A generic term for an entity within a market.
Market Participant	A company participating in the electricity market.
Transaction	A message sent between market participants to perform business processes, such as customer enrollment or switching, sending usage, sending charges, sending payments, etc. See Supported Transactions for information about the specific types of transactions provided with MTM USD.

Market Transaction Management Data and Objects

This section provides a high-level overview of the data and objects used by the Market Transaction Management US Distribution functionality.

Markets

The Market object is used to define a deregulated market which is a geographical area operating with a set of rules to manage premises and/or customers for a service type. Separate market instances are created for each geographic area and service type.

Market Participants

Market Participants are participants in a deregulated environment. Relationships between market participants are defined in a particular market record.

Inbound Market Messages

Inbound Market Messages capture instances of market messages received from an external source.

Outbound Market Messages

Outbound Market Messages capture instances of market messages sent from the system to an external source.

Market Message Type

Market Message Type are used to define the different types of market messages, both inbound and outbound, and to define the appropriate market message business object to use when creating objects of this type.

Market Processes

Market Processes capture instances of market processes that may be created to carry out business logic related to a specific inbound or an outbound market message.

Copyright © 2026, Oracle and/or its affiliates.

Market Process Types

Market Process Type are used to define configuration related to processes that may be initiated to support steps that should be execute to support an inbound or an outbound market message. It defines the market process business object to use when creating market processes of this type. It may also define one or more market process event business objects to initiate events that are generated to support steps within the market process.

Market Process Events

Market Process Events are used to orchestrate individual events that may occur to support steps in a given market process, such as creating specific records to define a customer (account, premise, service point, service agreement, and so on).

Market Usage

Market Usage records are used to store usage based on market codes and values. This is typically for current data, as it's received into the system. Historical Market Usage records are created only on request as needed.

Market Charges

Market Charges are used to store charges based on market codes and values. These are typically the charges that appear on a customer bill. When a bill is canceled, the charges are pulled from here.

Market Payments

Market Payments are used to store and capture individual payments received/sent in an "820 Payment Order/Remittance Advice" transaction,

Market Configuration

Market Configurations are used to capture configuration needed to support specific types of market transactions. Each type of configuration use a specific business object that defines the information captured. Each type of configuration may define up to five key fields that may be used to uniquely identify an individual configuration instance.

Registration Points

A registration point is the single point at which a premise is registered in the system. Registration points operate at different levels in different markets. Some are based on the premise, some on the combination of premise and person, some on the meter ID, and so on.

Supported Transactions

MTM USD supports the following types of market transactions.

Copyright © 2026, Oracle and/or its affiliates.

EDI Transaction Number	Name	Description
EDI 814	General Request/Response	Used to manage customer enrollment, account maintenance, drops, move-ins, and supplier switches. Supported request types include: • Historical Usage Request • Enrollment Request • Change Request • Drop Request • Service Order Request • Move Out Request • Price Code Request
EDI 824	Application/Advice	Used to transmit notifications or rejections regarding the status of a previously sent transaction (such as accepting or rejecting an 814 enrollment).
EDI 867	Product Transfer Account Adjustment / Usage	Used to transfer historical customer load data (when requested by a supplier) and routine, actual or estimated monthly metered consumption to the Energy Service Provider (ESP).
EDI 810	Invoice	Used to transmit bill amounts, monthly usage, and charge components. Depending on the market, it is sent from the utility to the supplier or vice versa.
EDI 820	Payment Order/Remittance Advice	Used to transfer payment and allocation details between utilities, retail suppliers, or financial institutions, particularly in dual-billing scenarios or consolidated billing.
EDI 650	Maintenance Service Order	Used to manage, request, and report maintenance-related actions
EDI 248	Account Assignment/Inquiry and Service/Status	Used to assign accounts, update account details, and report on service or collection statuses

The Importance of Understanding Your Market

As noted previously, it is CRITICAL that you have a firm understanding of how your market operates before you begin planning your implementation.

MTM is designed as a configurable framework rather than a market-specific application. Although it provides common processes for enrollment, billing, payments, customer changes, and retailer communications, the business rules governing those processes vary considerably from one market to another.

Copyright © 2026, Oracle and/or its affiliates.

Many implementation decisions—including customer setup, transaction processing, billing behavior, and registration point design—depend on market requirements rather than product configuration alone.

Successful MTM implementations begin with an understanding of the market's business rules. The application provides the framework for implementing those rules but does not prescribe how every market should operate.

Types of Market Participants

Within most markets there are three primary types of participants:

- **Distributor**: This is you, the utility implementing MTM US Distribution. In most markets, the Distributors own the transmission system (including substations, transformers, and wires) as well as the meters installed at customer service points.

  > **Note**
  >
  > When defining Billing Options, "We" and "Us" refers to the Distributor. In the system, the Distributor us defined as a Market Participant service provider.

- **Retailers**: Retailers are organizations that sell electricity to customers. In the system, retailers are defined as Market Participant service providers.

  > **Note**
  >
  > When defining Billing Options, "Them" and "They" refers to Retailers.

- **Customers**: Customers are the residential and commercial/industrial entities that purchase power from a retailer. In the system Customers are represented by a Registration point.

Note that many markets have other market participants, such as Independent System Operators (ISOs) or Regional Transmissions Organizations (RTOs), but the focus of market transaction messaging for US Distribution is between the Distributor and Retailers.

Why Market Knowledge Matters

Unlike many enterprise applications, MTM does not assume a single business model. Different markets define:

- Customer ownership
- Retailer responsibilities
- Distributor responsibilities
- Billing relationships
- Enrollment procedures
- Transaction timing
- Customer switching rules
- Payment settlement
- Registration point identification

These differences influence almost every aspect of an implementation. For example, one market may require the distributor to create customer records during enrollment, while another assumes the customer already exists. Likewise, some markets require retailer settlement

Copyright © 2026, Oracle and/or its affiliates.

based on customer payment, while others require settlement based on bill due dates. Understanding these differences before implementation helps ensure that the application is configured to support the correct business processes.

Markets Differ in More Than Geography

Markets should not be viewed simply as geographic regions. A market defines the business rules under which distributors, retailers, and customers interact. Those rules determine:

- Which organization owns customer information
- Which organization bills the customer
- Which transactions are exchanged
- When transactions are exchanged
- Which participant is considered the system of record for different types of information

Even distributors operating within the same state may implement different business practices to satisfy their market obligations.

Examples of Market Differences

The following examples illustrate how business rules vary from market to market.

Texas

Texas represents a fully deregulated retail market. Characteristics of this market include:

- Retailers own the customer relationship.
- Customers may switch retailers outside normal billing cycles.
- Enrollment often creates the customer within the distributor's system.
- Retailers generally bill customers directly.
- Market processes emphasize frequent enrollment and switching activity.

PJM and Similar East Coast Markets

Many PJM-style markets operate differently.

Characteristics of these markets include:

- Customers typically already exist within the distributor's customer information system.
- Distributor billing is common.
- Retailer relationships are established without creating new customer records.
- Switching frequently occurs at billing-cycle boundaries.

Limited Deregulation Markets

Some markets support only limited customer choice. For example, some markets:

- Restrict the number of customers that may enroll with retailers.
- Allow retailer enrollment only during defined enrollment periods.
- Require customers to return temporarily to distributor service before enrolling with another retailer.

These markets often require different enrollment and customer lifecycle processing than fully deregulated markets.

Copyright © 2026, Oracle and/or its affiliates.

Market Rules Affect the Entire Customer Lifecycle

Market requirements influence every stage of the customer lifecycle. The table below outlines how the market rules affect various processes in the customer lifecycle.

Lifecycle Activity	Market Rules Influence
Enrollment	Customer creation, retailer relationships, effective dates
Billing	Billing responsibility, bill-ready or rate-ready processing
Payments	Retailer settlement and receivables processing
Customer Changes	Which participant owns customer information
Retailer Switching	Transaction timing and conflict resolution
Customer Drop	Manual drop processing and move-out behavior

Because each of these processes depends on market rules, understanding those rules should be an early implementation activity.

Configuration Reflects Market Rules

Most MTM configuration exists to represent market behavior rather than application behavior. Examples include:

- Service Provider Configuration
- Billing Relationships
- Registration Point models
- Customer Registration Process implementations
- Validation rules
- Transaction processing
- Completion processing

Configuration should therefore be driven by documented market requirements rather than assumptions based on previous implementations.

Do Not Assume One Market Represents Another

Because market rules can vary so widely, solutions developed for one market should not automatically be applied to another. For example:

- A Texas implementation may rely heavily on customer creation during enrollment, while another market assumes customers already exist.
- Billing and payment processing may differ depending on whether the distributor or retailer bills the customer.
- Registration points may identify a premise, a service point, or a customer at a premise depending on market requirements.

Although the MTM framework supports all of these approaches, each implementation must determine which model is appropriate for its market.

Implementation Guidance

Before configuring MTM:

Copyright © 2026, Oracle and/or its affiliates.

- Understand the regulatory structure of the market.
- Identify the responsibilities of distributors and retailers.
- Determine who owns customer information.
- Understand the billing model used by the market.
- Identify the registration point model.
- Review enrollment, switching, and drop requirements.
- Understand payment settlement rules.
- Identify any market-specific transaction requirements.

These activities provide the foundation for configuring MTM to support your organization's business processes.

Customer Lifecycle Example

Let's look at a simplified example of the lifecycle of a customer from the perspective of market transaction management. This example involves the following participants:

- The Distributor
- Two Retailers (referred to as Retailer A and Retailer B)
- A Customer (defined in the Distributor's Customer Information System (CIS))

This example is based on a sample market. In this market, the Distributor sends bills to customers on behalf of retailers. In this market, customers pay the distributors, which in turns pays the Retailers via "Purchase of Receivables".

The market used in this example is not based directly on any existing market. It is provided for illustrative purposes only. As noted previously, it is CRITICAL that you have a firm understanding of how your market operates before you begin planning your implementation.

Customer Enrollment

The Customer chooses to enroll with Retailer A.

Retailer A sends a Historical Usage Request transaction (814) to the Distributor.

The Distributor receives the Historical Usage Request transaction, and validates that it has all the information needed to process the request.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer A, and the Distributor sends a Usage transaction (867) to Retailer A.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer A.

Retailer A sends an Enrollment transaction (814) to the Distributor.

The Distributor receives the Enrollment transaction, and validates that it has all the information needed to enroll the customer.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer A, and the customer information system is updated as needed to reflect the customer's enrollment with Retailer A and enable the customer for billing.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer A.

Copyright © 2026, Oracle and/or its affiliates.

Billing

The customer's bill is calculated each billing period based on the customer's billing cycle (typically monthly).

When a bill is completed, the Distributor sends a Usage transaction (867) and an Invoice transaction (810) to Retailer A.

- If either or both are invalid for some reason, Retailer A sends a rejection transaction (824) to the Distributor.

Payments

The billing system sends a AP Request Adjustment to the Financial System, which is routed to the bank.

Once the payment has cleared, the Distributor sends a Payment transaction (820) to Retailer.

The Distributor receives the Payment transaction, and validates that it has all the information needed to process the payment.

- If the transaction passes validation, the Distributor sends an acceptance transaction (824) to Retailer A.
- If the transaction fails the validation, the Distributor sends a rejection transaction (824) to Retailer A.

Switching Retailers

The Customer decides to switch retailers from Retailer A to Retailer B.

Retailer B sends a Historical Usage Request transaction (814) to the Distributor.

The Distributor receives the Historical Usage Request transaction, and validates that it has all the information needed to process the request.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the Distributor sends a Usage transaction (867) to Retailer B.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.

Retailer B sends an Enrollment transaction (814) to the Distributor.

The Distributor receives the Enrollment transaction, and validates that it has all the information needed to enroll the customer.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the customer information system is updated as needed to reflect the customer's enrollment with Retailer B and enable the customer for billing.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.

The Distributor sends a Drop transaction (814) to Retailer A.

The Distributor sends a Confirmation transaction (814) to Retailer B.

Customer Information Changes

The customer's phone number changes.

Retailer B sends a Change Request transaction (814) to the Distributor.

Copyright © 2026, Oracle and/or its affiliates.

The Distributor receives the Change Request transaction, and validates that it has all the information needed to process the request.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the customer information system is updated as applicable.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.

Meter Exchange

The distributor changes the meter at the customer's premise.

Distributor sends a Change Request transaction (814) to Retailer B.

- If the transaction is invalid for some reason, Retailer B sends a rejection transaction (824) to the Distributor.

Customer Drops Retailer

The customer chooses to drop their retailer and purchase direct from the distributor.

Retailer B sends a Drop transaction (814) to the Distributor.

The Distributor receives the Drop transaction, and validates that it has all the information needed to drop the customer.

- If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the customer information system is updated as needed to enable the customer for billing by the distributor.
- If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.

The Distributor sends a Drop transaction (814) to Retailer B.

- Customer Lifecycle Example - Another Look

Customer Lifecycle Example - Another Look

This section expands on the example above, and provides specific references to the system data and objects used for each transaction.

- The Distributor is set up as a Service Provider and Market Participant in Customer Cloud Service
  - Billing Options for the Distributor are defined as "We Bill For Them, Rate Ready"
- Both Retailers are set up as Service Providers and Market Participants in Customer Cloud Service
- The Customer is defined as a Customer/Account/Premise/Service Point/Meter and a Registration Point in Customer Cloud Service

Business Process / Step	MTM USD Data and Objects
Customer Enrollment	A customer enrolls with a retailer.
Retailer A sends a Historical Usage Request transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.

Copyright © 2026, Oracle and/or its affiliates.

Business Process / Step	MTM USD Data and Objects
The Distributor receives the Historical Usage Request transaction, and validates that it has all the information needed to process the request. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer A, and the Distributor sends an Historical Usage transaction (867) to Retailer A. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer A.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Historical Usage Request Root (U2-In814HUReqRoot) parent business object. • Validation is performed based on the validation defined for the 814 Historical Usage Request **Market Message Type**, based on the In 814 Historical Usage Req Admin Root (U2-In814HUReqAdminRoot) parent business object. The Acceptance/Rejection transactions are **Outbound Market Messages**. The business object used for these is based on the Outbound 814 Historical Usage Resp Root (U2-Out814HUResponseRoot) parent business object. The Historical Usage transaction is an **Outbound Market Message**. The business object used for this is based on either the Outbound 867 Historical Usage Intrvl Root (U2-Out867HUIntervalRoot) or the Outbound 867 Historical Usage Scalar Root (U2-Out867HUScalarRoot) parent business object (depending on whether the customer is an interval or scalar customer).
Retailer A sends an Enrollment transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.
The Distributor receives the Enrollment transaction, and validates that it has all the information needed to enroll the customer. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer A, and the customer information system is updated as needed to reflect the customer's enrollment with Retailer A and enables the customer for billing. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer A.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Enrollment Request Root (U2-In814EnrolReqRoot) parent business object. • Validation is performed based on the validation defined for the 814 Enrollment Request **Market Message Type**, based on the Inbound 814 Enrollment Request Admin Root (U2-In814EnrolReqAdminRoot) parent business object. The Acceptance/Rejection transactions are **Outbound Market Messages**. The business object used for these is based on the Outbound 814 Enrollment Response Root (U2-Out814EnrlNtfcnRspRoot) parent business object. Enabling the customer billing is performed by a Market Process that creates the data needed, including creating a Service Agreement and Starting service for the customer. The business object for the Market Process would be based on the Customer Registration Process Root (U2-CRPRoot) example business object.
Billing	The customer is billed for their service.

Copyright © 2026, Oracle and/or its affiliates.

Business Process / Step	MTM USD Data and Objects
The customer's bill is calculated each billing period based on the customer's billing cycle (typically monthly).	This is done via the standard billing functionality provided with Customer Cloud Service.
When a bill is completed, the Distributor sends a Usage transaction (867) and an Invoice transaction (810) to Retailer A. • If either or both are invalid for some reason, Retailer A sends a rejection transaction (824) to the Distributor.	The Add Bill Details to GenProc on Bill Completion (U2BILLGENPRC) Bill Completion algorithm defined on the SA Type creates records in the General Processing table containing bill details. The following batch processes create **Outbound Market Messages**: • Create Outbound 867 Monthly Usage (U2CRE867): The business object for this message is based on the Outbound 867 Monthly Interval Usage Root (U2-Out867MUIntervalRoot) or Outbound 867 Monthly Usage Scalar (U2-Out867MUScalarRoot) parent business objects. • Create Outbound 810 Charges (U2CRE810): The business object for this message is based on the Outbound 810 Invoice Charges Root (U2-Out810InvChargesRoot) parent business object. The specific business objects created by these batch processes are defined in corresponding **Master Configurations**. The messages are created in the "Pending" state. A Monitor batch process moves them into the "Created" state where a series of algorithms populates the messages with appropriate data. The Rejection transaction is an **Outbound Market Message**. The business object for this is based on the Outbound 824 Application Advice Root (U2-Out824AppAdviceRoot) parent business object.
Payment	The customer pays their bill.
The billing system sends a AP Request Adjustment to the Financial System, which is routed to the bank.	This is done via the standard billing functionality provided with Customer Cloud Service.
Once the payment has cleared, the Distributor sends a Payment transaction (820) to Retailer.	The Payment transactions is an **Outbound Market Message**. The business object used for this is based on the Outbound 820 Remittance Advice Root (U2-Out820RemittanceAdviceRoot) parent business object.

Copyright © 2026, Oracle and/or its affiliates.

Business Process / Step	MTM USD Data and Objects
The Distributor receives the Payment transaction, and validates that it has all the information needed to process the payment. • If the transaction passes validation, the Distributor sends an acceptance transaction (824) to Retailer A. • If the transaction fails the validation, the Distributor sends a rejection transaction (824) to Retailer A.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object. As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 820 Remittance Pay Advice Root (U2-IN820RemittanceAdvRoot) parent business object. • Validation is performed based on the validation defined for the 820 Remittance Pay Advice **Market Message Type**, based on the Inbound 820 Remittance Advice Admin Root (U2-IN820RemittanceAdviceAdmin) parent business object. The Acceptance/Rejection transactions are **Outbound Market Messages**. The business objects used for these are based on the Outbound 824 Application Advice Root (U2-Out824AppAdviceRoot) parent business object.
Switching Retailers	The customer decides to switch retailers from Retailer A to Retailer B.
Retailer B sends a Historical Usage Request transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.
The Distributor receives the Historical Usage Request transaction, and validates that it has all the information needed to process the request. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the Distributor sends a Usage transaction (867) to Retailer B. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Historical Usage Request Root (U2-In814HUReqRoot) parent business object. • Validation is performed based on the validation defined for the 814 Historical Usage Request **Market Message Type**, based on the In 814 Historical Usage Req Admin Root (U2-In814HUReqAdminRoot) parent business object. The Acceptance/Rejection transactions are **Outbound Market Messages**. The business object used for these is based on the Outbound 814 Historical Usage Resp Root (U2-Out814HUResponseRoot) parent business object. The Historical Usage transaction is an **Outbound Market Message**. The business object used for this is based on either the Outbound 867 Historical Usage Intrvl Root (U2-Out867HUIntervalRoot) or the Outbound 867 Historical Usage Scalar Root (U2-Out867HUScalarRoot) parent business object (depending on whether the customer is an interval or scalar customer).

Copyright © 2026, Oracle and/or its affiliates.

Business Process / Step	MTM USD Data and Objects
Retailer B sends an Enrollment transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.
The Distributor receives the Enrollment transaction, and validates that it has all the information needed to enroll the customer. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the customer information system is updated as needed to reflect the customer's enrollment with Retailer B and enable the customer for billing. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Enrollment Request Root (U2-In814EnrolReqRoot) parent business object. • Validation is performed based on the validation defined for the 814 Enrollment Request **Market Message Type**, based on the Inbound 814 Enrollment Request Admin Root (U2-In814EnrolReqAdminRoot) parent business object. The Acceptance/Rejection transactions are **Outbound Market Messages**. The business object used for these is based on the Outbound 814 Enrollment Response Root (U2-Out814EnrlNtfcnRspRoot) parent business object. Enabling the customer billing is performed by a Market Process that creates the data needed, including creating a Service Agreement and Starting service for the customer. The business object for the Market Process is based on the Customer Registration Process Root (U2-CRPRoot) parent business object.
The Distributor sends a Drop transaction (814) to Retailer A.	The Drop transaction is an **Outbound Market Message**. The business object used for this is based on the Outbound 814 Drop Req Switch Root (U2-Out814DropReqSwRoot) parent business object.
The Distributor sends a Confirmation transaction (814) to Retailer B.	The Confirmation transaction is an **Outbound Market Message**. The business object used for this is based on the Outbound 814 Enrollment Response Root (U2-Out814EnrlNtfcnRspRoot) parent business object.
Customer Information Changes	The customer's phone number changes.
Retailer B sends a Change Request transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.

Copyright © 2026, Oracle and/or its affiliates.

Business Process / Step	MTM USD Data and Objects
The Distributor receives the Change Request transaction, and validates that it has all the information needed to process the request. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Change Request Root (U2-In814ChangeReqRoot) parent business object. • Validation is performed based on the validation defined for the 814 Change Request **Market Message Type**, based on the Inbound 814 Change Request Admin Root (U2-In814ChangeReqAdminRoot) parent business object. Updating the customer's phone number is performed by a Market Process that updates the data as applicable. The business object for the Market Process is based on the Change Process Root (U2-CPRoot) parent business object.
Meter Exchange	The distributor changes the meter at the customer's premise.
Distributor sends a Change Request transaction (814) to Retailer B. • If the transaction is invalid for some reason, Retailer B sends a rejection transaction (824) to the Distributor.	The Change Request transaction is an **Outbound Market Message**. The business object used for this is based on the Outbound 814 Change Request Root (U2-PLOut814CRRoot) parent business object.
Customer Drops Retailer	The customer chooses to drop their retailer and purchase direct from the distributor.
Retailer B sends a Drop transaction (814) to the Distributor.	The transaction is sent in standard EDI format. A Electronic Service Bus (ESB) or other integration component converts the message into the "MTM XML" format, based on the business object schema of the appropriate business object.
The Distributor receives the Drop transaction, and validates that it has all the information needed to drop the customer. • If the transaction passes validation, the Distributor sends an acceptance transaction (814) to Retailer B, and the customer information system is updated as needed to enable the customer for billing by the distributor. • If the transaction fails the validation, the Distributor sends a rejection transaction (814) to Retailer B.	As the message is received, an **Inbound Market Message** is created. • The business object for this message is based on the Inbound 814 Manual Drop Response Root (U2-In814DropRspRoot) parent business object. • Validation is performed based on the validation defined for the 814 Change Request **Market Message Type**, based on the Inbound 814 Drop Request Admin Root (U2-In814DropReqAdminRoot) parent business object. Updating the customer's billing setup is performed by a Market Process that updates the data as applicable. The business object for the Market Process is based on the Change Process Root (U2-CPRoot) parent business object.
The Distributor sends a Drop transaction (814) to Retailer B.	The Drop transaction is an **Outbound Market Message**. The business object used for this is based on the Outbound 814 Manual Drop Req Root (U2-Out814MDropRequestRoot) parent business object.

Copyright © 2026, Oracle and/or its affiliates.

Market Transaction Management and Customer Cloud Service

This section provides specific details concerning how Market Transaction Management (MTM) processes interact with Customer Cloud Service (CCS).

- Customer Enrollment / Registration / Move Out
- Billing and Usage
- Payments
- Change Requests

Customer Enrollment / Registration / Move Out

MTM and CCS coordinate on customer registrations/enrollments. MTM receives and processes the market enrollment transaction. The Customer Registration Process (CRP) then creates or updates the CCS customer relationship that supports the market model.

The registration process is highly market- and distributor-specific.

MTM manages the market transaction and its market-specific business rules. CCS maintains the customer data that results from the transaction, including:

- The 'V' - Person, Account, Premise, SP and master SA
- SA Relationship
- Sub-SA
- Characteristics

'We Bill For Them' Enrollments / Registrations

In a 'We Bill for Them' model, the distributor generally already maintains the customer relationship in CCS. The 'V' already exists. The CRP makes only the changes needed to support the retailer and market transaction.

For example, the CRP can locate the existing master SA, create the required SA relationship, create a retailer's sub-SA when applicable, and update characteristics. The rest of the 'V' is untouched.

'They Bill For Us' Enrollments / Registrations

In a 'They Bill for Us' model, the distributor does not own the customer. The 'V' is not set up in CCS. CCS is only responsible for sending device/usage details and charges to the retailer that is responsible for billing. CCS will have minimal information such as phone number (for outage notifications), life support / sensitive load indicator on person or premise.

Enrollment / Registration Processing

MTM does most of work in enrollment / registration processing:

1. MTM receives the inbound enrollment, move-in, or switch transaction and applies the configured market rules.
2. MTM identifies the applicable CRP and evaluates existing customer and service agreement information.
3. MTM asks for a meter read.

Copyright © 2026, Oracle and/or its affiliates.

4. MTM invokes the CRP to create the required CCS records, including Person, Account, SA, SA relationship, sub-SA, and characteristics required by the market configuration.

> **Note**
>
> The Person is always created because there is no Person Identifier to match to existing Persons.

MTM completes the 'V'. This can also include Rate Schedule update - for example, the default or the previous customer's rate.

5. MTM uses Completion Events to complete the 'V'. Completion Events provide reusable, configurable points for MTM to coordinate the resulting updates to the 'V'.

> **Note**
>
> The Customer Registration root business objects in MTM USD are intended as examples only. Implementations should create their specific business objects based on their requirements and business rules.

Stops / Move Outs

When a customer relationship ends, MTM evaluates the stop or move-out transaction and invokes the configured completion event. MTM sets the SA's End Date. There may be other information to update - e.g., switch off life support, copy characteristics (based on configuration). CCS stops the SA.

In a 'We Bill for Them' scenario, MTM also flags the bill as final for market processing.

Transfers

MTM US Distribution can support the transfer of a customer from one premise to another with the retailer. However, the solution is implementation-specific, due to varying rules.

Billing and Usage

CCS calculates and completes bills. MTM uses configured billing events and bill calculation data to create the required market usage and market charge transactions.

The billing relationship determines when CCS notifies MTM that bill data is ready for market processing. The notification is configured as an algorithm on the Service Agreement Type. When the configured billing event occurs, CCS creates a General Process that MTM uses to build the applicable market transaction.

The required billing event (trigger) depends on the billing relationship:

Billing Relationship	CCS object that triggers MTM	Purpose
We Bill for Them - Bill-Ready	Frozen Bill Segment	Sends bill-ready charge information when the bill segment is frozen.
We Bill for Them - Rate Ready	Completed Bill	Sends the completed bill after the distributor has rated the charges.
They Bill for Us	Completed Bill	Sends the completed billing information for market processing.

Copyright © 2026, Oracle and/or its affiliates.

The General Process algorithm on the Service Agreement Type is configured for the applicable trigger:

- In a 'We Bill for Them - Bill Ready' scenario, the FT Freeze algorithm starts the process.
- In a 'We Bill for Them - Rate-Ready' or 'They Bill for Us' scenario, bill completion starts the process.

CCS bill calculation lines can contain charges that must be reported to a service provider in an 810 Invoice Charge transaction. The configured Rate Schedule and its Calculation Rules are used to add the required Bill Segment Calculation Line characteristics.

The calculation line characteristic is the key link between CCS billing and the MTM market message. MTM uses it to identify which charges or bill segments must be included in the outbound transaction. Only the market-required calculation line characteristics are included.

For 'We Bill for Them - Bill Ready' processing, the applicable billable charge template is also used.

Usage

Usage transactions can require market-specific data that is not required to calculate the CCS bill. The usage transaction contains the information required by the monthly billed-usage market transaction.

For standard utility processing, the configured Cyclical Billing Usage Request business object is used where appropriate.

Payments

Market Transaction Management (MTM) works with Customer Cloud Service (CCS) to process outbound and inbound payments.

MTM applies market-specific validation and settlement rules; CCS provides billing, payment staging, adjustment, adjustment approval, and standard payment processing.

Payments are processed depending on the billing relationship:

- **We Bill For Them.** The distributor bills the customer on behalf of a retailer and settles the retailer's share. The payments are outbound.
- **They Bill For Us**. An inbound market payment is matched to CCS bills before standard payment processing distributes it.

Outbound Payments

Outbound payments use the established A/P request process in CCS to interact with the financial system, to pay the retailers.

Outbound payments use one of two timing models:

Copyright © 2026, Oracle and/or its affiliates.

Payment Timing	When payment occurs	Processing
Pay at bill time	At bill creation or when bill is due	Used for purchase-of-receivables arrangements. CCS records the settlement activity, less applicable administration and fees. When the 810 Invoice Charge transaction (inbound or outbound) is created, an Invoice Charge Payment Process is created, to manage the payment. The Invoice Charge Payment Process (ICPP) in MTM creates a payment that moves debt (i.e., amount to be paid to the retailer) from the holding SA to the billing/settlement SA when due. There is a one-to-one relationship between ICPP and Invoice Charge Payment because it's the process that triggers when to pay - i.e., on the bill due date. The retailer receives its share, while administration and delinquency fees are directed to the appropriate general ledger accounts. The Service Provider Payment Process (SPPP) in MTM: • Takes the individual adjustments on the holding SA and puts them through the required approval levels. • Creates an A/P adjustment for the settlement SA and bills it. – This involves a rate-able adjustment that performs the calculations and an offsetting adjustment for the settlement SA. – The reason for billing is to have financial transactions for arrears handling and GL processing.
Pay at payment time	When customer payment is received	Used when receivables are not purchased. The Invoice Charge Payment Process in MTM monitors payments that are applied to the SA or sub-SA and creates Invoice Charge Payments based on those payments. Similar processing via Service Provider Payment Process (mentioned above) applies.

The Invoice Charge Payment Process and Service Provider Payment Process are based on the Market Process object in CCS. MTM US Distribution provides a parent business object (BO) for Invoice Charge Payment Process. Refer to the `U2-ICPPRoot` business object in CCS, for more details. Note that there are no parent BOs for Service Provider Payment Process, as these processes are distributor-based.

Inbound Payments

Each retailer typically sends one 820 payment transaction daily.

An Inbound 820 Payment transaction is processed as follows:

1. MTM receives market payment data through the Market Payment maintenance object. The Market Payment Detail records contain the individual payments.
2. MTM performs record-level validation - for example, matching payment to a bill (810 invoice charge).
3. The Market Payment Detail record has the information to indicate whether it is a payment or an overpayment:
    a. For a payment. A payment upload staging record is created. The Bill ID is included in the staging record, for CCS payment upload (PUPL batch process) to match the payment to that particular bill.
    b. For an overpayment, the detail records include one record for the payment amount and another record for an adjustment (for the overpaid amount). MTM will create an

Copyright © 2026, Oracle and/or its affiliates.

adjustment for the overpaid amount. This is not refunded, but rather recorded as credit that a subsequent 820 would typically offset. The Overpayment and Suspense SAs on Market Provider Configuration manage overpayments.

4. PUPL runs as usual. No further matching/validation needed.

Change Requests

CCS is the system of record for the business data that changes. MTM detects, validates, and translates those changes into market transactions, or applies validated inbound market changes through the appropriate CCS processes.

Change requests follow one of these paths:

- **Outbound changes.** MTM monitors data changes in CCS. MTM compares the states before and after the change and, when applicable, creates an outbound market message.
- **Inbound changes.** MTM receives a market change request, validates it against market rules, and creates a change process that updates the appropriate CCS data.

The market configuration determines which changes are supported, which data is included, and whether or not the change is processed immediately.

Outbound 814 Change Requests

Outbound changes consist of CCS changes that must be reported to a market participant, such as a retailer. Examples include changes to service point, device, billing, rate, and/or customer data, depending on the market implementation.

The maintenance objects are configured with audit algorithms that identify the CCS data to monitor.

The Change Event Master Configuration defines the Market, Service Type, Change Type, affected Entity, Business Object, etc. The Change Type is key because it's information that the market looks for. Market-required characteristics are also configured. For example, a meter multiplier audit can identify a change to a device measurement scale. Device installations, removals, exchanges, and effective-dated meter events can also affect the values that must be reported. Some Change Types have derivation scripts that perform additional processing before the change request transaction is created.

Change Event Process & Market Message

When an audited change occurs, MTM creates a Change Event Process in Pending status and captures an initial snapshot. This gives a user an opportunity to reverse change(s) before the final snapshot is evaluated.

The Change Event Process batch then runs. When the batch process sees that there is no change (e.g., in the case where the user reversed the change), it will remove that change from processing and a transaction is not created. On the other hand, if the change is identified, the Change Event Process is linked to the Registration Point, Person, Account, Premise, Service Agreement and Service Point(s). When the change needs to go to more than one retailer (for example, inbound and incumbent), the Service Provider is left blank.

When the Change Event Process goes to the Completed state and a final snapshot is taken, the Outbound 814 Change Request market message is created in Pending status and is populated based on the settings in the Change Event Master Configuration and in the Market Message Type (for example, Market Participant Reference that indicates distributor, market recipient, and/or retailer). Depending on the change, the Outbound 814 Change Request is populated with any of the following: Meter Details, Unmetered Details, Contact Record, etc..

Copyright © 2026, Oracle and/or its affiliates.

Outbound market messages support throttling, which is used to control message volume and protect downstream integrations from a sudden surge of transactions. When throttling is in place, the Outbound 814 Change Request goes to the Message Hold state. Otherwise. it goes through to the Completed state.

When the Outbound 814 Change Request goes to the Completed state, MTM sends the outbound message to the market participant.

Inbound 814 Change Requests

Inbound changes come from a market participant (such as a retailer) or a market hub that sends a change request to the distributor.

The number of inbound changes that a retailer can do is typically small. Some common types of changes are:

- Billing relationship change - such as changing from 'We Bill For Them - Rate Ready' to 'Dual' billing relationship (or vice versa)
- Rate-related changes - such as a rate schedule or bill factor changes

Market Message & Change Event Process

MTM receives the Inbound 814 Change Request market message in the Pending state. The transaction is validated based on the validation rules configured on the related Market Message Type that defines: validation scripts, required fields, applicable To Do Type and To Do Role, Status to Validate, Next Status, Status/Reject Record, Status Reject Reason, etc.. Market Message Type also includes UI Controls that define what users can edit / view.

If validation is successful, the Inbound 814 Change Request goes to the Process Event state, where the Inbound 814 Change Event Process is created.

The Inbound 814 Change Event Process determines which CCS data is changed and how it is updated. Depending on the configuration, the change could be: immediate/automatic (contact details change), bill-based or registration process-based (for example in a billing relationship change, the needed changes to the master SA, SA Relationship and sub-SAs need to be handled by the registration process). For an immediate change, the Change Event Process takes care of updating the data. The common use case for an immediate change is contact information changes. The Market Process Type controls the data that can be changed, such as person details, rates, bill factors, or billing relationships. The change process updates the data based on the configured Change Types and implementation-specific rules.

The applicable market response is also sent. If validation fails, MTM creates an outbound reject response. Otherwise, an accept inbound market response is sent. Note: An accept response does not necessarily mean that the CCS update completed. In most cases, the data coming in from the market is valid. If, for some reason, CCS cannot apply an update, it's likely due to some internal issue (such as a missing/changed configuration) that needs to be resolved.

Implementing an MTM US Distribution Transaction

This section walks through the process involved in implementing a transaction used with MTM US Distribution.

Typical Implementation Steps

The implementation steps commonly include the following:

1. Setting up and/or verifying prerequisite general configuration

Copyright © 2026, Oracle and/or its affiliates.

2. Configuring the Market Message Type
    a. Creating the Market Message transactional Business Object
    b. Creating the Market Message Type admin Business Object
    c. Creating the Outbound Message Type
    d. Creating the Market Message Type
3. Configuring the Change Event Process
    a. Creating the Parent Process transactional Business Object and Parent Process Admin Business Object
    b. Creating the Market Process Type
    c. Configuring implementation-specific change data
4. Setting up Master Configuration
5. Setting up MO Audit Algorithms

Example: Outbound 814 Change Request

The following illustrates the above-mentioned steps using an Outbound 814 Change Request transaction.

General Configuration

Assuming that CIS Division(s), Service Types, SA Types and SA Relationship Types are already set up, configure the following:

1. External Systems, including one for MTM
2. Markets
3. Provider Configuration Options, which define billing relationships
4. Service Providers for the distributor and one or more retailers
5. Market Provider Configuration Options and Service Provider Market Options
6. SA Type SA Relationship Types. including any default sub-SA Types as applicable

> **Note**
>
> Outbound Message Types are configured as part of the outbound Market Message Type configuration

Configure the Outbound 814 Change Request

Create the Market Message Transaction and Administration Business Objects (BOs)

1. Create a parent transaction BO for the Market Message MO using a parent/lifecycle BO such as `U2-Out814ESIMaintReqRoot`.
2. Add market-specific customization or extensions, such as algorithms that populate custom details or values.
3. Create a parent admin BO for the Market Message Type MO, using a parent/lifecycle BO such as `U2-Out814ESIMaintReqAdminRoot`.

Create the Outbound Message Type

1. Add an Outbound Message Type and link it to the new transaction Business Object.

Copyright © 2026, Oracle and/or its affiliates.

2. Add the Outbound Message Type to the applicable External System.

Create the Market Message Type

1. Using the new admin Business Object, configure the Related Transaction Business Object, Service Type, Market, External System, Outbound Message Type, To Do Types and Roles, Derivation Scripts, and UI Controls.
2. Use the delivered MTM USD To Do Types or custom To Do Types. Configure derivation scripts only when overriding MTM USD behavior. UI controls can set read-only behavior, display suppression, and auditing; by default, fields are editable and auditing is off.

Configure the Change Event Process

Create the Change Event Process and Administration business objects

1. Create a Parent Process Business Object, using a parent/lifecycle BO such as `U2-ChgEvtProcAdvRoot`.
2. Add market-specific customization or extensions, such as algorithms that populate custom details or values.
3. Create a Parent Process Admin Business Object using a parent/lifecycle BO such as `U2-ChgEvtProcAdvAdminRoot`.

Create the Market Process Type

1. Configure a Market Process Type using the new admin Business Object with the related Market Process Business Object, Market, and the appropriate delivered or custom To Do Types and Roles.
2. Configure EDI-specific change types and values, including any market-specific or implementation-specific characteristic values.

Set up Master Configuration

For each Market:

1. Duplicate a Master Configuration Business Object such as U2-814ESIMasterConfig
2. Add a Master Configuration for the new Business Object, and set up the Change Configuration fields.

Configure MO Audit Algorithms

Configure the Maintenance Objects with the audit algorithms required by the implementation.

Overview

Customer Program Management refers to the core functionality for utilities to create, run, and maintain demand response and distributed energy resource programs as part of a larger distributed energy resource management system (DERMS).

Customer Program Management functionality is offered via the following products:

- Oracle Utilities Custom Program Management Cloud Service
- Oracle Utilities Customer Program Management (when implemented on-premises)
- Oracle Utilities Customer Cloud Service

> **Note**
>
> Customer Program Management functionality in Oracle Utilities Customer Cloud Service must be licensed separately.

Demand response programs are programs in which customers agree to let their utility service provider temporarily alter the settings of specific devices in their homes (referred to as controllable devices or controllable assets) in response to periods of high demand. For instance, customers might enroll in a program that allows their utility to temporarily adjust their thermostat during a heat wave, or disable an electric vehicle charger during a period a of peak energy usage in the area. Instances such as these are known as "program events".

Customer Program Management also supports behavior-driven demand management programs, such as Critical Peak Pricing Programs or Peak Time Rebate programs that do not involve controllable devices.

Customer program eligibility criteria can include specific types of controllable devices, current utility rates, past and present program participation, customer opt-out history, heating/cooling technology, and specific customer questions (such as "Does your house have an internet connection?").

Customer enrollment involves identifying a specific customer that is eligible for a particular program. Some programs also involve and one or more controllable devices installed at a specific device location that are applicable to a specific program, but not all programs involve devices. Devices can include those that the customer purchases and installs themselves,

Copyright © 2026, Oracle and/or its affiliates.

those that the utility provides to the customer to install, and those that the utility provides and installs at the customer's location, and can include "smart" thermostats, electric vehicle chargers, storage batteries, and other types of devices. Programs that don't involve devices include home energy assessment programs, critical peak pricing, programs, among others.

As devices are installed and registered during the enrollment process, device information is provided to an advanced distribution management system (ADMS) such as Oracle Utilities Network Management System, a distributed energy resource management system, or a supervisory control and data acquisition (SCADA) system. These systems are sometimes referred to as "control systems" and are used to manage communication with and control of individual controllable devices during program events.

Device control scores - numerical ratings that help utilities determine if a device should participate in a program event - are calculated on a daily basis and sent to the distributed energy resource management system. When a utility determines that it should run a program event, control system operators use control score information (in addition to other data) to identify a set of devices that should participate in the program event, and the control system sends details of the event to Customer Program Management. Program event details include the date and time of the event, as well as a list of devices that will participate in the event, and if appropriate, specific dates and times during which each device will participate in the program event. This information is used to create "event participation" records for each device.

After the event has completed, the control system sends a list of devices that participated in the event, and the outcome of each device's participation. Outcomes can include successful participation in the event, cancelation of the event for the device, an "in-flight" override in which the customer overrides the control of the device at its location, or an error. The results of the program event are used to update the event participation records for each device, which are subsequently used in future control score calculations.

Calculation of device control scores is performed through configuration of program rules and score calculation rules that use pre-configured values and customer-defined formulas. Program rule parameters can include the number of times within a specific period (such as a week or month) that an individual device can participate in an event, the frequency of these cyclical periods, the minimum number of days that must transpire between events, and more. Control scores are intended to capture the contract rules the device operates under, both from an operational perspective as well as a financial perspective.

Customer measurement data can used to calculate a customer's "baseline" usage used when calculating reductions in customer usage related to demand response programs.

As device-related events are completed, program event settlement transactions are created that represent credits that will be applied to a customer's bill based on participation in an individual event. Program event settlement transactions can be created either from data received from an external analytics application or via a batch process. When created via batch processing, data regarding reductions in consumption or demand for the event is calculated via Program Settlement Calculation Rules which perform a comparison of actual consumption or demand to a "baseline" that represents an estimate of the customer's consumption or demand for the event period had they not participated in the event. When created from an external analytics application, the application sends files containing details regarding consumption or demand reduction achieved for the duration of an event for each customer. These reductions are multiplied by a price to determine the total credit to be applied to the customer's bill for the event.

Program event settlement transactions aren't applied directly to a customer's bill. Instead, they are collected in customer settlement transactions that summarize all of the events in which the customer participated during a given time period. In other words, customer settlement transactions represent the total of all of the customer's program event settlement transactions for a given time period. Customer settlement transactions are created upon requests from a

Copyright © 2026, Oracle and/or its affiliates.

customer information system. These requests are typically sent on an annual basis (such as at the beginning or end of the year), but customer settlement transactions are also created in the other specific situations such as when a customer moves out or stops their service (in which case the customer settlement is applied to the customer's final bill), when a customer is re-billed (in which case the customer settlement is applied to the customer's new bill), or when a customer unenrolls for a program (in which case the customer settlement is applied to the customer's next bill). Once calculated. customer settlement transactions can be downloaded and sent to the customer information system for use in billing.

Oracle Utilities Customer Program Management Cloud Service also includes other asset management functionality, including inventory, purchasing, financials, work orders and more.

About Customer Program Management

This section describes customer program management objects and data used with Customer Program Management.

- About Controllable Assets and Devices
- About Device Locations
- About Facilities
- About Metered Service
- About Metered Service Points
- About Network Locations
- Programs
- Event Impact Measurement and Verification
- About Customer Program Service Tasks
- About Enrollment and Unenrollment
- About Service Calls

About Controllable Assets and Devices

Controllable assets and devices are the individual devices installed at a device location that can participate in demand response programs and program events. Devices can include those that the customer purchases and installs themselves, those that the utility provides to the customer to install, and those that the utility provides and installs at the customer's location, and include devices and assets such as thermostats, batteries, photo-voltaic solar panels, and other devices.

Controllable assets are represented by two records in the system: a controllable asset, and a controllable device. When a new controllable asset is created, a corresponding controllable device record is created automatically.

Controllable assets are defined by the following:

- **Asset Type**: The asset type record on which the asset is based. Asset types define certain parameters and attributes of a class of assets.
- **Status**: The current status of the asset. Only assets in the "Active" state can participate in program events.

Copyright © 2026, Oracle and/or its affiliates.

- **Identifiers**: The Badge Number, Serial Number, Network Identifier, and Network Address used to identify the asset in the system and in external systems.
- **Specification**: The specification for the asset. See Controllable Asset Specifications below for more information.
- **Asset Disposition Detail**: The current disposition of the asset (such as "In Receipt", "In Store", "Installed", "Retired", and so on), including the asset's location and the date and time the asset was moved to that location.
- **Access Control**: Details about the organizations which have access to data related to the asset.
- **Control Score**: Details about the asset's control score, calculated via program calculation rules, including:
  - **Score**: The most recent control score calculated for the controllable asset or device.
  - **Score Date/Time**: The date and time at which the control score was calculated.
  - **Asset Availability**: A flag that specifies ("Yes" or "No") whether or not the asset is available for events based on the last score calculation.

Controllable devices are defined by the following:

- **Device Type**: The device type record on which the device is based. Device types define certain parameters and attributes of a class of devices.
- **Status**: The current status of the device. Only devices in the "Active" state can participate in program events. A device's status always matches the status of its corresponding asset.
- **Identifiers**: The Badge Number, Serial Number, Network Identifier, and Network Address used to identify the device in the system and in external systems.
- **Manufacturer** and **Model**: The manufacturer and model of the device.
- **Head-End System**: The head end system associated with the controllable device
- **Head-End Registration Status**: The registration status of the controllable device on the head end system. This is updated via data synchronization as appropriate based on data in a related Distributed Energy Resources Management System
- **DER Aggregator Service Provider**: The aggregator with which the device is registered

System Data

Controllable assets are based on the following system data:

Data Type	Description
Maintenance Object	Asset (W1-ASSET)
Business Object(s)	Controllable Asset (X1-ControllableAsset)

Controllable devices are based on the following system data:

Data Type	Description
Maintenance Object	Device (D1-DEVICE)
Business Object(s)	Item (D1-Item)

Controllable Asset Specifications

Controllable asset specifications describe design details and functional performance criteria for a set of controllable assets. This can include manufacturer, model, and other information

Copyright © 2026, Oracle and/or its affiliates.

specified for the assets. Specifications may also contain written procedures, careful handling instructions for hazardous or delicate materials, or any other set of attributes needed to provide information about a set of assets. Controllable asset specifications should be created using the Controllable Asset Specification (X1-ControllableAssetSpec) business object.

See About Specifications for more information about specifications.

System Data

Controllable asset specifications are based on the following system data:

Data Type	Description
Maintenance Object	Specification (W1-SPEC)
Business Object(s)	Controllable Asset Specification (X1-ControllableAssetSpec)

Distributed Energy Resource (DER) Device Attributes

Registration of DER devices includes populating various attributes of the device and related specifications. These DER attributes are captured as characteristics whose Characteristic Types are defined for the "Asset Attribute" and "Specification Attribute" characteristics entities.

See Distributed Energy Resource (DER) Device Attributes in for more information about configuring these attributes and attribute types.

About Device Locations

Device locations represent locations where controllable devices are installed and used. A device location can have multiple controllable devices installed at a time.

Device locations are often created as a result of the customer enrollment process, but can be created on an ad-hoc basis as needed.

Device locations are defined by the following:

- **Device Location Type**: The device location type record on which the device location is based. Device location types define certain parameters and attributes of a class of device locations.
- **Distribution Network Facility**: The network node closest to the device location. In terms of electric networks, facilities typically represent transformers.
- **Division**: The operating company or operating division within a large conglomerate of utilities associated with the device location.
- **Status**: The current status of the device location.
- **Address and Location Information**: The address (including city, state, postal code, and country) and geographic location of the device location.
- **Controllable Devices**: A list of one ore more controllable devices installed at the device location, including the date and time the device was installed or removed (as applicable), and whether or not the device is active. When a controllable device has been removed, this list also indicates a crew (used to identity the Out of Service Location where the the asset is moved to upon removal).
- **Life Support / Sensitive Load Information**: Information regarding life support equipment installed at the device location, or if the load supplied to the device location is considered sensitive.

Copyright © 2026, Oracle and/or its affiliates.

- **Field Information**: Information related to field work performed at the device location, including any applicable warnings or instructions.

System Data

Device locations are based on the following system data:

Data Type	Description
Maintenance Object	Service Point - MDM (D1-SP)
Business Object(s)	Device Location (X1-DeviceLocation)

About Facilities

Facilities represent the network node level closest to the device location. In terms of electric networks, facilities typically represent transformers, but can also be feeders and substations.

Facilities are defined by the following:

- **Facility Type**: The type of facility (derived from the business object). Facilities used with Customer Program Management are typically transformers, but can also be feeders and substations.
- **Service Type**: The type of service provided by the facility. This is most often "Electric".
- **Status**: The current status of the facility.
- **External ID**: An ID used to identify the facility in external systems.
- **Time Zone**: The time zone in which the facility resides.

System Data

Facilities are based on the following system data:

Data Type	Description
Maintenance Object	Facility (D1-FACILITY)
Business Object(s)	Feeder (D1-Feeder) Substation (D1-Substation) Transformer (D1-Transformer)

Defining Facility Types

Different types of facilities can be defined using the Facility Type (D1-FacilityTypeLookup) extendable lookup. This lookup can be used to define the Network Node Type for each type of facility (such as transformer, feeder, or substation), as well as whether or not facilities of a given type are eligible to be connected to metered service points (via the **SP Connection Eligibility** flag).

About Metered Service

Metered service records represent a customer's service agreements and usage subscriptions in Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter),

Metered service records are created via a data synchronization process between Customer Program Management Cloud Service and Customer Cloud Service.

Copyright © 2026, Oracle and/or its affiliates.

Metered Service records are used as Master Subscriptions when creating Program Subscriptions.

Metered service records are defined by the following:

- **Metered Service Type**: The metered service type record on which the metered service is based. Metered service types define certain parameters and attributes of a class of metered services.
- **Status**: The current status of the metered service record.
- **Start and End Date/Time**: The date and time on which the metered service record started, and ended (if applicable).
- **External ID**: An ID used to identify the metered service record in an external system.
- **External Account ID**: An ID used to identify the account associated with the metered service record in an external system.
- **Main Customer**: The program contact associated with the metered service record.
- **Time Zone**: The time zone associated with the metered service record.
- **Bill Cycle**: The bill cycle associated with the metered service record, used when calculating program incentives and fees via batch processing. If defined here, the Bill Cycle is defined by default on all program subscriptions for the metered service.
- **Rate History**: A list of one or more effective-dated Oracle Utilities Customer Care and Billing or Oracle Utilities Customer to Meter (or Customer Cloud Service) rates for the metered service record. These are used to determine a customer's eligibility to participate in a program. Rates can be defined using the Customer Rate Schedule extendable lookup.
- **Metered Service Points**: A list of one or more metered service points associated with the metered service record, including the start and stop dates and times for each.
- **Program Subscriptions**: One or more program subscriptions that have the metered service defined as their Settlement Group.
- **Attribute Values**: Attribute values whose characteristic type are defined as valid characteristic types on the metered service type.
- **Settlement Group Program Subscriptions**: Program subscriptions that have the metered service defined as their Settlement Group.

System Data

Metered service records are based on the following system data:

Data Type	Description
Maintenance Object	Usage Subscription (D1-US)
Business Object(s)	Metered Service (X1-MeteredService)

About Metered Service Points

Metered service points represent service points in Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter).

Metered service points are created via a data synchronization process between Customer Program Management Cloud Service and Customer Cloud Service.

Metered service points are defined by the following:

Copyright © 2026, Oracle and/or its affiliates.

- **Metered Service Point Type**: The metered service point type record on which the metered service point is based. Service points types define certain parameters and attributes of a class of metered service points.
- **Division**: The operating company or operating division within a large conglomerate of utilities associated with the metered service point.
- **Weather Station**: The weather station associated with the metered service point. Weather stations are mapped to metered service points based on geographical location. When a metered service point is added or updated, an algorithm maps the metered service point to the nearest weather station using the **Location Information** (specifically the geographic latitude and longitude). If longitude and latitude are not available, mapping is done based on the metered service point's postal code and assigns the weather station defined for the Postal Code Default that includes the service point's postal code.
- **Status**: The current status of the metered service point.
- **External Service Point ID**: An ID used to identify the metered service point in an external system.
- **External Premise ID**: An ID used to identify the premise associated with the metered service point in an external system.
- **Main Contact**: The program contact associated with the metered service point.
- **Address and Location Information**: The address (including city, state, postal code, and country) and geographic location of the metered service point.
- **Field Information**: Information related to field work performed at the metered service point, including any applicable warnings or instructions
- **Distribution Network Facility**: The network node closest to the metered service point. In terms of electric networks, facilities typically represent transformers.
- **Access Group**: The access group used to control which groups of users have access to the metered service point (if applicable). See Defining Access Groups in the *Administrative User Guide* for more information.

System Data

Metered service points are based on the following system data:

Data Type	Description
Maintenance Object	Service Point - MDM (D1-SP)
Business Object(s)	Metered Service Point (X1-MeteredServicePoint)

About Network Locations

Network locations define the location of a facility within a larger network.

Network locations hold the network nodes that provide service to a facility. In the case of electric networks, network locations define the feeder and substation associated with a transformer (facility). Because these network nodes can change over time, a facility can have many network locations (this is an effective-dated relationship). For example, for electric service, whenever the substation or feeder that provides power to a given transformer is changed, a new record that references the latest substation and feeder is typically created.

Network Locations are defined by the following:

- **Facility ID**: The facility associated with the network location.

Copyright © 2026, Oracle and/or its affiliates.

- **Start** and **End Date/Time**: The date and time range during which the facility was connected to the feeder and/or substation.
- **Feeder**: An ID for the feeder related to the facility.
- **Substation**: An ID for the substation related to the facility.
- **External ID**: An ID used to identify the network location in external systems.

System Data

Network locations are based on the following system data:

Data Type	Description
Maintenance Object	Network Location (D1-NWLOC)

Programs

This section describes components and data related to demand response programs in Customer Program Management.

Information about programs is maintained in Customer Program Management, but other systems are responsible for initiating and creating program events.

- About Programs
- About Program Contacts
- About Contact Communications
- About Program Subscriptions
- About Program Control Scores
- About Program Events
- About Event Participation

About Programs

Programs represent specific demand response programs in which customers agree to let their utility service provider temporarily take control of specific devices in their homes (referred to as controllable devices or controllable assets) in response to periods of high demand. For instance, customers might enroll in a program that allows their utility to temporarily adjust their thermostat during a heat wave, or disable an electric vehicle charger during a period a of peak energy usage in the area. Instances such as these are known as "program events".

Programs are defined by the following:

Copyright © 2026, Oracle and/or its affiliates.

- **Program Type**: The program type associated with the program. Program types define certain parameters and attributes of a class of programs.
- **Status**: The current status of the program. Only programs in the "Active" state are eligible for customer enrollment and events.
- **Eligibility**: A program initiative associated with the program, used to determine eligibility for customers to enroll in the program.
- **Approval Profile**: The process used for approval of the program (see Approvals and Approval Profiles below for more information).
- **Suspend**: A flag that indicates if the program is currently suspended (the default is No).
- **Start Date**: The date on which the program is active and available.
- **End Date**: The date after which the program is no longer active.
- **Division**: The operating company or operating division within a large conglomerate of utilities associated with the program.
- **Program External ID**: The ID for the program used by external systems.
- **Allow Customer Unavailability**:: A flag that indicates (Yes or No) if customers are allowed to make themselves unavailable for a period of time for program events for the program. Customer unavailability for a period of time is captured using Customer Unavailability device events.
- **Program Quantities**: One or more quantities associated with the program such as the default reduction capacity for demand response programs.
  - **Start Date/Time**: The start date and time for the time period during which the quantity applies
  - **End Date/Time**: The end date and time for the time period during which the quantity applies
  - **Program Quantity Type**: The type of quantity (based on the **Program Quantity Types** defined on the program type)
  - **Program Quantity**: The quantity, based on the UOM, TOU, and SQI defined for the program quantity type

In addition, programs can also have the following related objects and data:

- **Specifications**: One or more specifications for devices eligible for the program, used to determine eligibility for customers to enroll in the program (the customer must have devices based on the listed specifications to join the program).
  - Programs based on a program type whose **Program Category** is "DER Registration" must have a specification and attributes defined (see Maintaining Specifications for more information). When registering and enrolling a DER device, the device's specification attributes must match the specification's attributes in order for the DER device to be registered and enrolled.
- **Rates**: One or more rates used to determine eligibility for customers to enroll in the program (the customer must be on one of the listed rates to join the program)
- **Rules**: One or more program rules associated with the program. If a program has more than one program rule, the rule with the latest effective date/time is used. See Understanding Program Rules in the *Administrative User Guide* for more information about program rules.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> : If a Device Score rule is added to program, or an existing Device Score Program Rule associated with a program is edited, a synchronization request and outbound message are created to update external DERMS systems such an Oracle Utilities Grid Edge DERMS.

- **Qualifications**: One or more qualification questions used to determine eligibility for customers to enroll in the program. The **Response Required** flag can be used to indiciate that an answer must be provided for the question. See Understanding Customer Questions in the *Administrative User Guide* for more information about questions.
- **Informational**: One or more informational questions used to capture additional information about customers when enrolling in the program. The **Response Required** flag can be used to indiciate that an answer must be provided for the question. See Understanding Customer Questions in the *Administrative User Guide* for more information about questions.
- **Events**: A list of program events associated with the program. See About Program Events for more information about program events.
- **Program Settlement Calculation Groups** (on the **Calculation Groups** tab): One or more program settlement calculation groups that contain settlement calculation rules used to calculate program settlements for devices associated with the program. When more than one group is defined on the program, the appropriate calculation group is executed based on the **Event Settlement Method**. If more than one group is defined for the same Event Settlement Method, a program settlement transaction is created for each group. If a **Calculation Group Determination** is defined on the program's type, that algorithm may override which calculation group is used. Program Settlement Calculation Groups are defined by the following:
  - **Eent Settlement Method**: A flag that indicates when program settlement events are calculated after participating in an event. Options include:
    - **After Event Participation**: Calculations are performed as each program settlement event is created. This option is used with settlement calculations based on non-peak or consumption measurements (referred to as "kWh Avoided").
    - **End of Season**: Calculations are performed at the end of a specified time period (a year, a season, and so on). This option is used with settlement calculations based on peak or demand measurements ("kW Drop").
  - **Transaction Type**: The type of transaction . Options for this are defined as Characteristic Values for the Settlement Transaction Type (X1-STTRT) Characteristic Type.
  - **Calculation Group**: The program settlement calculation group that contains settlement calculation rules used to calculate program settlements for the selected **Event Settlement Method** and **Transaction Type**.
  - **Effective Date/Time**: The date and time at which the calculation group is in effect.
  - **Expiration Date/Time**: The date and time at which the calculation group expires and is no longer in effect.

System Data

Programs are based on the following system data:

Copyright © 2026, Oracle and/or its affiliates.

Data Type	Description
Maintenance Object	Dynamic Option (D1-DOP)
Business Object(s)	Program (X1-Program) Program Characteristics (X1-ProgramCharacteristics)

Calculate Control Score via Program Transaction Algorithm

The Calculate Control Score via Program Transaction (X1-CLCNTPRTR) algorithm, defined on the "Program (BO) - Control Score Calculation" System Event creates program transactions that are used to calculate control scores for controllable devices associated with a program. This algorithm also defines the following variables that can be used in Program Calculation Rules:

- **Control Score Variable Name**: Defines the variable used to represent control scores. When Program Calculation Rules return a value for this variable (defined as the Result Variable on the rule), the score is saved to the controllable asset (along with the date and time at which the score was calculated). The default value for this variable is "SC".
- **Availability Mark**: Defines the variable used to represent the availability of the device's participation in program events. If Program Calculation Rules return a value of 0 for this variable, the Asset Availability flag in the controllable asset is set to "No". If Program Calculation Rules return a non-zero value for this variable or the rule doesn't return a value for this variable, the Asset Availability flag in the controllable asset is set to "Yes". The default value for this variable is "AV".

Approvals and Approval Profiles

Programs and program types can specify an Approval Profile used to define a process for approval of programs. Programs with an Approval Profile enter the "Approval in Progress" state after being created, and must be approved before moving into the "Active" state. An Enter algorithm on the "Approval in Progress" state creates an approval request based on the specified approval profile.

See About Approvals for more information about creating and maintaining approvals and approval profiles.

Program Incentives and Fees

Beyond incentives based on reductions in consumption (kWh Avoided) demand (kW Drop) via program settlements, programs can be configured to include other customer incentives, such as sign-up incentives for enrollments, referral rebates, and incentives for remaining enrolled during the peak season. Customers may also receive penalties or fees in some circumstance, for instance if they terminate their enrollments before the contracted period, or when the utility incurs charges related to device repairs, device upgrades, premium device fees. The incentive and fees are sent to the customer information system to be passed on to the customer.

Program incentives and fees are configured as Program Rules that define how and when calculations are performed, with corresponding Program Settlement Calculation Rules that define the specific calculations performed for each type of incentive or fee.

Customer Unavailability Events

Customer unavailability events define periods of time during which customers make themselves (and controllable devices at the customer's device location) as unavailable for program events for a particular program. For example, if a customer will be out of town for a period of time, they may choose to make themselves unavailable to participate in program

Copyright © 2026, Oracle and/or its affiliates.

events during that time. Customer unavailability periods for the same device cannot overlap. Customer unavailability events are based on device events.

Customer unavailability events are defined by the following:

- **Customer Unavailability Type**: The customer unavailability device event type. See Understanding Device Event Types for more information about creating device event types.
- **Status**: The current status of the event. Possible statuses include "Active", "Inactive", and "Cancel".
- **Device**: The controllable device marked as unavailable.
- **Device Location**: The device location for the controllable device marked as unavailable.
- **Unavailability Start Date/Time**: The start date and time of the unavailability period for the customer and controllable device
- **Unavailability End Date/Time**: The end date and time of the unavailability period for the customer and controllable device
- **Reason**: The reason the customer is unavailable, from the Device Event Reason (D1-DeviceEventReasonLookup) extendable lookup

System Data

Customer Unavailability events are based on the following system data:

Data Type	Description
Maintenance Object	Device Event (D1-DVCEVENT)
Business Object(s)	Customer Unavailability (X1-CustomerUnavailability)

About Program Contacts

Program contacts represent customers enrolled in programs, and are associated with programs via program subscriptions.

Program contacts are defined by the following:

- **Contact Type**: The program contact type associated with the contact . Contact types define certain parameters and attributes of a class of contacts.
- **Name**: The contact's name.
- **Contact Information**: Contact information for the contact, including phone number and/or email address (used with customer contacts),
- **Contact External ID**: An ID used to identify the contact in external systems (used with customer contacts).
- **Life Support / Sensitive Load Information**: Indicates if the contact is considered to be on life support (used with customer contacts).
- **Asset System Contact ID**: An ID used to identify the contact in external asset systems (used with customer contacts).
- **Address**: The address for a point of contact.
- **Phones**: One or more phone numbers for a point of contact.
- **Emails**: One or more email addresses for a point of contact.

System Data

Program contacts are based on the following system data:

Data Type	Description
Maintenance Object	Contact (D1-CONTACT)
Business Object(s)	Business (D1-Business) Person (D1-Person) Point of Contact (D1-PointOfContact)

About Contact Communications

Contact communications are interactions with the customer, most often notes captured during an enrollment or unenrollment process.

Contact communications are defined by the following:

- **Create Date/Time**: The date and time the communication was created
- **Contact ID**: The contact associated with the communication
- **Communication Channel**: The channel used for the communication, such as email or phone. Values for this are defined in the Customer Communication Channel (X1-CustCommChnLookup) extendable lookup.
- **Contact Communication Class**: The class of the communication, such as enrollment, unenrollment, trouble report, and so on. Each class can have one more associated communication categories. Values for this are defined in the Customer Communication Class (X1-CustCommClassLookup) extendable lookup.
- **Contact Communication Category**: The category of the communication, such as written or verbal. Values for this are defined in the Customer Communication Category (X1-CustCommCatLookup) extendable lookup.
- **Metered Service**: The metered service associated with the communication (from the enrollment or unenrollment service task)
- **Metered Service Point ID**: The metered service point associated with the communication (from the enrollment or unenrollment service task)
- **Program ID**: The program associated with the communication (from the enrollment or unenrollment service task)
- **Service Task ID**: The service task associated with the communication (from the enrollment or unenrollment service task)
- **WO Activity**: The work order activity associated with the communication (from the enrollment or unenrollment service task)
- **Field Activity ID**: The field activity associated with the communication (from the enrollment or unenrollment service task)
- **Notes**: Notes associated with the communication (from the enrollment or unenrollment service task)

System Data

Contact communications are based on the following system data:

Copyright © 2026, Oracle and/or its affiliates.

Data Type	Description
Maintenance Object	Contact Communication (D1-CONTCOMM)
Business Object(s)	Customer Program Communications (X1-CustomerComm)

About Program Subscriptions

Program subscriptions represent a customer's enrollment in a program, and link a customer with a program and (in most cases) a device location. Customers can have separate program subscriptions for different device locations and programs.

Metered service records serve as a parent to individual program subscriptions for each of a customer's programs and/or device location. If multiple program subscriptions are associated to the same device location, one can be defined as a "parent" program subscription. Program subscriptions are most often created as a result of the customer enrollment process, but can be created on an ad-hoc basis if needed.

Program subscriptions are defined by the following:

- **Program Subscription Type**: The program subscription type associated with the program. Program subscription types define certain parameters and attributes of a class of program subscriptions.
- **Metered Service**: The metered service record that serves as a "parent" for the program subscription.
- **Parent Program Subscription**: (Optional) A program subscription that serves as a "parent" for the program subscription.
- **Settlement Group**: A metered service for the Main Customer associated with the program subscription, used to group program subscriptions for customer settlement transactions.
- **External Account ID**: An ID used to identify the program subscription in external systems.
- **Main Customer**: The program contact for the customer associated with the program subscription.
- **Status**: The current status of the program subscription.
- **Start** and **End Date/Time**: The date and time on which the program subscription record started, and ended (if applicable).
- **Time Zone**: The time zone associated with the program subscription.
- **Device Location**: The device location associated with the program subscription. This defines the devices for which the customer is enrolled in the program.
- **Program**: The program in which the customer is enrolled.
- **Program Enrollment Source**: The source of the customer's enrollment in the program. Options incude:
  - **Bring Your Own**: The enrollment was created as a result of the customer installing their own controllable device.
  - **Contact Center**: The enrollment was created by the customer contacting the utility's contact center. This includes enrollments created via the Customer Enrollment Process Flow.
  - **Self Service**: The enrollment was created via an online customer self service portal.

Copyright © 2026, Oracle and/or its affiliates.

- **Bill Cycle**: The bill cycle associated with the program subscription, used when calculating program incentives and fees via batch processing. If defined for the parent metered service, the Bill Cycle is defined by default on all program subscriptions for the metered service.
- **Transaction Calculation Groups**: One or more effective dated program calculation groups that contain program calculation rules used to calculate scores for devices associated with the program subscription. If more than one group is defined on the program subscription, the group with the latest effective date/time is used.
- **Fallback Transaction Calculation Groups**: A list of one or more effective dated program calculation groups used if a program calculation group is not defined on the program subscription (from the program subscription type).

System Data

Program subscriptions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Subscription (D1-US)
Business Object(s)	Program Subscription (X1-ProgramSubscription)

Creating Program Event Settlement Transactions

Program event settlement transactions can be created via the "Initiate program event settlement for completed program events" (X1-INIPES) monitor algorithm defined on the program subscription business object. This algorithm is triggered by the Program Subscription BO Periodic Monitor Process (X1-PSPMB) batch process (see below).

This algorithm scans program events and event participation records related to the program subscription looking for program events that have been in the "Complete" status for a number days (defined as a parameter on the algorithm) with related event participation records that are in either the "Successful participation" or "In-flight override" states. The algorithm creates program event settlement transactions for each program event/event participation found.

Program event settlement transactions are created in the "Pending" state, and are processed by the Process Program Settlement (X1-PREVS) batch process which transitions the transaction to a specific state depending on the type of program event settlement transaction. See About Program Event Settlement Transactions for more information.

Batch Processing

Program subscription processing is supported by the following monitor batch processes:

- Program Subscription BO Periodic Monitor Process (X1-PSPMB): Used to trigger monitor algorithms on the program subscription.

Use the **Batch Control** portal to learn more about the parameters used by these batch processes.

About Program Control Scores

Program control scores are created via a regularly scheduled process that performs control score calculations for each device associated with a program subscription, based on the transaction calculation groups defined for the program subscription. A separate program control scores is created for each device associated with the program subscription.

Copyright © 2026, Oracle and/or its affiliates.

Program control scores are created by the Calculate Asset Score (X1-CALAS) batch process , which should be run on a daily basis to monitor controllable assets that are currently installed on a device location and enrolled in a device control program. This batch process invokes the Calculate Control Score (X1-CLCNTSCR) algorithm (a Monitor algorithm on the "Installed" state of the Controllable Asset (X1-ControllableAsset) business object). This in turn invokes the Calculate Control Score via Program Transaction (X1-CLCNTPRTR) algorithm defined on the "Program (BO) - Control Score Calculation" System Event on the Program, which creates the program control score. When the program control score enters the "Calculate" state, the Identify Program Calculation Group and Apply its Rules (X1-CALCPT) algorithm executes the Program Calculation Group defined on the Program Subscription (if the Program Subscription has multiple calculation groups, the group with the latest effective date/time is used).

Program transactions contain the following data:

- **Program Subscription**: The program subscription for which the program control score was run.
- **Calculation Group**: The transaction calculation group containing the transaction calculation rules executed as part of the program control score.
- **Transaction Date/Time**: The date and time when the program transaction was run.
- **Device**: The device for which the program control score was run.
- **Status**: The status of the program control score. Statuses include Pending, Error, Discarded, and Complete.
- **Calculation Results**: The results of the calculations performed by the transaction calculation rules. This includes the program control score's start and end dates and times, the Program Calculation Rules and variables used to calculate the results, and the individual quantities and formulas for each variable used in the calculation.
- **Issues**: One or more messages related to the program control score.

System Data

Program control scores are based on the following system data:

Data Type	Description
Maintenance Object	Usage Transaction (D1-USAGETRAN)
Business Object(s)	Program Control Score (X1-ProgramTransaction)

About Program Events

Program events represent instances when a utility takes control of a set of controllable assets in response to demand. For example, during a heat wave, a utility may wish to adjust the thermostats (controllable assets) during peak usage times to help alleviate demand.

Program events are performed by an advanced distribution management system (ADMS) or a supervisory control and data acquisition (SCADA) system. When an event is to occur, the ADMS or SCADA system information about the program (including date/time information), and a "Scheduled" event record is created. The same system then creates event participation records for each device to be included in the event. Once the event has been processed, the external system updates the event to the "Complete" status, and then sends list of impacted devices and the status of each. These details are captured in program event participation records.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Program Events and Program Event Stages**
> Program Events in Customer Program Management *program event stages* of program events defined and managed in external systems such as ADMS or SCADA. A program event in ADMS or SCADA can comprise multiple program event stages. For example, a program event in an ADMA or SCADA might be 8 hours in total duration, comprising 4 program event stages of 2 hours each. Each of these 2-hour program event stages would be represented in CPMS/CPM as a program event. Program events in external systems are designated by the **External Event ID** field on each program event.

Program events are defined by the following:

- **Program**: The program associated with the event.
- **Status**: The current status of the event (Pending, Complete, or Canceled).
- **Program Category**: The category of the event, such as Device Test, Economic, Reliability, and so on.
- **Start** and **End Date/Time**: The date and time when the event started and ended.
- **External ID**: An ID used to identify the program event stage in an external DERM system.
- **External Event ID**: An ID used to identify the program event in an external DERM system.

System Data

Program events are based on the following system data:

Data Type	Description
Maintenance Object	Dynamic Option Event (D1-DOPEVT)
Business Object(s)	Program Event (X1-ProgramEvent)

About Event Participation

Event participation records capture the participation of a controllable device in a program event. When a program event is to occur, the ADMS or SCADA system sends a list of devices and date/time information to "reserve" the devices for the event, and event participation records are created. Once the event is complete, the external system sends a list of impacted devices and the status of each. These details are captured in event participation records.

Event participations are defined by the following:

- **Status**: The current status of the event participation record.
- **Participation Start** and **End Date/Time**: The start and end date and time of the event.
- **Reservation Start** and **End Date/Time**: The start and end date and time of the device's participation in the event, Some devices may participate in only a portion of an event. If not applicable, this field is blank.
- **Device ID**: The information string for the controllable device which participated in the event.
- **Program Subscription**: The program subscription associated with the device and program associated with the event.

Copyright © 2026, Oracle and/or its affiliates.

- **Program**: The program for which the event took place.
- **Program Event**: The event associated with the event participation record.
- **Reservation**: A flag that indicates if the event participation record represents a device reservation. This flag is typically set to "Yes" when the system receives a list of devices for a planned event.
- **Outcome**: The outcome of the device's participation in the event. Possibly outcomes include "Successful participation", "Non-responsive device", "In-flight override", "Error", and "Canceled".
- **Preemptive Opt-Out** : A flag which indicates if the device preemptively opted out of the event. This flag is most often set to "Yes" when a device is removed from an event after an event participation record has been created.
- **External ID**: An ID used to identify the event participation record in external systems.

System Data

Event participation records are based on the following system data:

Data Type	Description
Maintenance Object	Event Participation (D1-EVENTPART)
Business Object(s)	Event Participation (X1-EventParticipation)

Successful Event Participations

The number of successful event participations for a device is used when calculating control scores for the device (via Program Transactions). A device's event participation is considered successful in the following circumstances:

- The Event Participation has an **Outcome** of "Successful Participation".
- The Event Participation has an **Outcome** of "Canceled". This happens when a device has been reserved but the event stopped halfway through due to reasons such as, target load control reached. It is considered as a success in customer perspective, since it is the utility that stopped the event which resulted to a cancelled outcome.
- The Event Participation has a blank **Outcome** and the device was not preemptively opted out of the event (**Preemptive Opt-Out** is "No" or blank). Posting of an event's outcome may be delayed, and until then the event participation of a reserved device is considered as a success as long as the customer did not opt out before the event transpires.

About Program Event Settlement Transactions

Program event settlement transactions represent credits that will be applied to a customer's bill based on participation in an individual event. Note that program event settlement transactions aren't applied directly to a customer's bill. A customer's program event settlement transactions are totalized into Customer Settlement Transactions (see About Customer Settlements Transactions) which are applied to the customer's bill.

Program event settlement transactions are calculated in different ways depending on the type of event and the program on which they're based. Typically programs are based on either consumption saved or demand reduction events.

- Program event settlement transactions for consumption-based program events can be calculated as they created. The consumption saved per hour (represented as hourly interval values, typically in kWh) are multiplied by hourly prices for the same date and time

Copyright © 2026, Oracle and/or its affiliates.

and the results are totaled to create an settlement amount that will be applied to the customer's bill. Program settlement transactions for consumption-based programs are referred to "kWh Avoided" program settlement transactions.

- Program event settlement transactions for demand-based program events can be calculated as they created or are calculated based on a calculated demand value for a specified period of time, such as a year, a season, and so on (these are referred to as "end of season"). For these demand-based events, program event settlement transactions capture individual demand reduction interval value as well as a the "Maximum Drop" for an event (the largest demand reduction value for the event) and are saved in a "Calculation Deferred" state until a Customer Settlement Transaction is created for the period. Program event settlement transactions for demand-based programs are referred to "kW Drop" program settlement transactions.
- When a Customer Settlement transaction is created for "end of season" demand-based programs, a new program event settlement transaction is created for the entire time period which calculates the average of a set of the "Maximum Drop" values from the "Calculation Deferred" transactions created previously. These program settlement transactions are referred to as "Combined kW Drop" program settlement transactions.

The **Program Settlement Method** attribute on the Program indicates when settlement is calculated for participating in an event. Options include:

- **After Event Participation**: Calculations are performed as each program event settlement is created. This option is most often used with settlement calculations based on non-peak or consumption measurements ("kWh Avoided"), but can be used with settlement calculations based on peak or demand measurements ("kW Drop").
- **End of Season**: Calculations are performed at the end of a specified time period (a year, a season, and so on). This option is used with settlement calculations based on peak or demand measurements ("kW Drop").

Program event settlement transactions can be created either from data received from an external analytics application or via a monitor batch process run for program subscriptions (see Creating Program Event Settlement Transactions in About Program Subscriptions).

- When created from data received from an external analytics application, the external analtyics applicationsends files containing details regarding consumption or demand reduction achieved for the duration of an event for each customer. A batch process imports these files and creates business flags that capture the data for each metered service point. These business flags in turn create program event settlement transactions containing data regarding reductions in consumption or demand for the event.
- When created via batch processing, data regarding reductions in consumption or demand for the event is calculated via Program Settlement Calculation Rules which perform a comparison of actual consumption or demand to a "baseline" that represents an estimate of the customer's consumption or demand for the event period had they not participated in the event. See **Baseline Calculations** for more information about this calculation.

There are three types of program settlement transactions:

- "kWh avoided" program event settlement transactions are created based on reductions in consumptions achieved for the duration of an event for each customer. See Processing KWH Avoided Files for more information about how "kWh Avoided" program event settlement transactions are created from business flags received from an external analytics application.
- "kW Drop" program event settlement transactions are created based on reductions in demand achieved for the duration of an event for each customer. See Processing KW Drop Files for more information about how "kW Drop" program event settlement transactions are created from business flags received from an external analytics application.

Copyright © 2026, Oracle and/or its affiliates.

- "Combined kW Drop" program event settlement transactions are created by customer settlement transactions and contain demand reduction values derived from individual "kW Drop" program event settlement transactions in the "Calculation Deferred" state that fall within the date range of the customer settlement transaction.

Program event settlement transactions are created in the "Pending" state, and are processed by the Process Program Settlement (X1-PREVS) batch process which transitions the transaction to a specific state depending on the type of program settlement transaction:

- Pending "kWh Avoided" program event settlement transactions (for programs with a **Program Settlement Method** of "After Event Participation") are transitioned to the "Calculate" state where Consumption-based Program Settlement Calculation Rules defined for the program related to the program settlement transactions (See Understanding Program Settlement Calculation Rules for more information) are executed. The amount of a "kWh Avoided" program settlement transaction is calculated by applying the Program Settlement Calculation Rules defined on the metered service's program to the "kWh avoided" values from the program settlement transaction. These rules apply interval prices to the "kWh avoided" interval values and total the results for the event. Once the program settlement transaction calculations are complete, it is transitioned to the "Calculated" state.
- Pending "kW Drop" program event settlement transactions (for programs with a **Program Settlement Method** of "End of Season") are transitioned to the "Calculation Deferred" state. These are later used by customer settlement transactions and "Combined kW Drop" program settlement transactions.
- Pending "Combined kW Drop" program event settlement transactions are transitioned to the "Calculate" state where demand-based Program Settlement Calculation Rules defined for the program related to the program event settlement transactions (See Understanding Program Settlement Calculation Rules for more information) are executed. The amount of a "Combined kW Drop" program event settlement transaction is calculated by applying the Program Settlement Calculation Rules defined on the metered service's program to the "kW Drop" values derived from the program event settlement transactions in the "Calculation Deferred" state to calculate the overall reduction in demand and apply a price to calculate the settlement amount for the event. Once the program event settlement transaction calculations are complete, it is transitioned to the "Calculated" state.

Program event settlement transactions contain the following data:

- **Program Subscription**: The program subscription associated with the event for which the program settlement transaction was created
- **Start Date/Time**: The start date and time of the event
- **End Date/Time**: The end date and time of the event
- **Parent Customer Settlement Transaction**: The customer settlement transaction that is considered the "parent" of the program event settlement transaction. (Note: Only populated after after customer settlement transaction request is received).
- **Used on Bill**: A flag that indicates (Yes or No) if the program event settlement transaction has been included in a customer settlement transaction.
- **Status**: The current status of the program event settlement transaction.
- **Calculation Details**:
  - **Program Event**: The program event for which the program event settlement transaction was created.
  - **Price**: The price used with "kW Drop" program event settlement transactions

Copyright © 2026, Oracle and/or its affiliates.

- **Program Settlement Calculation Group**: The program settlement calculation group containing the program settlement calculation rules executed as part of the program event settlement transaction.
- **Line Description**: A single line description of the program event settlement transaction, which can be used when displaying the transaction on bills or reports.
- **UOM/TOU/SQI**: The unit of measure, time of use period, and service quantity identifier combination used to define the interval usage values used in the program event settlement calculation. These are derived from the UOM/TOU/SQI defined on the business flag type of the business flag that created the program event settlement transaction.
- **Interval Size**: The size of the interval usage values, represented as hours:minutes:seconds (HH:MI:SS). This is derived from the Interval Size defined on the business flag type of the business flag that created the program event settlement transaction. This should match the interval size used for interval price sets.
- **Maximum Drop**: The largest demand reduction interval value for the event
- **Minimum Drop**: The smallest demand reduction interval value for the event
- **Average Drop**: The average demand reduction interval value for the event
- **Settlement Quantity**: The total quantity used for the program event settlement.
  * For "kWh Avoided" program settlements, this is the "kwh avoided" consumption saved for the event period, calculated by adding together the individual "kWh avoided" values for the event period
  * For "Combined kW Drop" program settlements, this is the average of the "Maximum Drop" values selected by the Program Settlement Rule - Demand Based program settlement calculation rule.
- **Actual Consumption**: The actual consumption for the customer for the event period (applicable only for "kWh Avoided" program event settlement transactions)
- **Program Settlement Amount**: The program event settlement transaction's monetary amount, calculated by multiplying interval values by prices that apply to the event.
  * In the case of "kWh Avoided" program settlements, the interval values are individual "kWh avoided" interval values (from the "kWh avoided" business flags received from an external analytics application)
  * In the case of "kW Drop" program settlements, the interval values are those derived from individual "kW Drop" program settlements (based on the Program Settlement Calculation Rule configuration).
- **Intervals**: Details of the interval values and prices used in the program settlement transaction calculation, including:
  * **Service Quantity Data Date/Time**: The date and time of the interval value (per the UOM/TOU/SQI and price (if applicable)
  * **Quantity**: The interval value (per the UOM/TOU/SQI) for the interval date and time
  * **Service Quantity Interval Condition**: The condition code of the interval value (per the UOM/TOU/SQI) for the interval date and time
  * **Price**: The interval price for the interval date and time (applicable only for "kWh Avoided" program settlement transactions)
  * **Program Settlement Amount**: The monetary amount for the date and time, calculated by multiplying the "kWh avoided" interval value times the interval price at the interval date and time (applicable only for "kWh Avoided" program event settlement transactions)

Copyright © 2026, Oracle and/or its affiliates.

- **Issues**: One or more messages related to the program event settlement transaction.

Example - KW Avoided

An event scheduled for 12:00 PM to 6:00 PM on February 11, 2023 results in the following "kWh avoided" values for a particular customer:

Date/Time	kWh Avoided
02-11-2023 12:00:00PM PST	5.00
02-11-2023 01:00:00PM PST	3.00
02-11-2023 02:00:00PM PST	2.00
02-11-2023 03:00:00PM PST	2.00
02-11-2023 04:00:00PM PST	3.00
02-11-2023 05:00:00PM PST	8.00
02-11-2023 06:00:00PM PST	6.00

This represents a total "Consumption Saved" of 29.00.

Later, the system receives the following price data for this event period:

Date/Time	Price
02-11-2023 12:00:00PM PST	0.45
02-11-2023 01:00:00PM PST	0.45
02-11-2023 02:00:00PM PST	0.35
02-11-2023 03:00:00PM PST	0.25
02-11-2023 04:00:00PM PST	0.35
02-11-2023 05:00:00PM PST	0.45
02-11-2023 06:00:00PM PST	0.45

When a program event settlement transaction is calculated for this event, the details of the program event settlement transaction would be as follows:

- UOM/TOU/SQI: kWh
- Interval Size: 01:00:00
- Consumption Saved: 29.00
- Actual Consumption: 430
- Program Settlement Amount: 12.15
- Intervals:

Service Quantity Data Date/Time	Quantity	Service Quantity Interval Condition	Price	Program Settlement Amount
02-11-2023 12:00:00PM PST	5.00	999999	0.45	2.25
02-11-2023 01:00:00PM PST	3.00	999999	0.45	1.35
02-11-2023 02:00:00PM PST	2.00	999999	0.35	0.70

Copyright © 2026, Oracle and/or its affiliates.

Service Quantity Data Date/Time	Quantity	Service Quantity Interval Condition	Price	Program Settlement Amount
02-11-2023 03:00:00PM PST	2.00	999999	0.25	0.50
02-11-2023 04:00:00PM PST	3.00	999999	0.35	1.05
02-11-2023 05:00:00PM PST	8.00	999999	0.45	3.60
02-11-2023 06:00:00PM PST	6.00	999999	0.45	2.70

System Data

Program event settlement transactions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Transaction (D1-USAGETRAN)
Business Object(s)	Program Event Settlement Transaction (X1-EventSettlementTransaction) Program Event Settlement Transaction (X1-ProgramEventSettlementTr)

Batch Processing

Program event settlement transaction processing is supported by the following monitor batch processes:

- Process Program Settlement (X1-PREVS): Used to transition program event settlement transactions in the "Pending" state to the "Calculate" state.
- Retry Program Settlement (X1-RTEVS): Used to retry program event settlement transactions in the "Issue Detected" state.
- Recalculate Program Settlement (X1-RCEVS): Used to recalculate program event settlement transactions in the "Calculated" state. This is used in the case of a rebill, when updated measurement data is received from the customer information system, or when updated "kWh avoided" data is received from an external analytics application.

Use the **Batch Control** portal to learn more about the parameters used by these batch processes.

Correcting Calculated Program Event Settlement Transactions When Measurement Data Changes

In the event that updated measurement data is received after a program event settlement transaction has been calculated, but before it has been included in a customer settlement transaction, the program event settlement transactions must be recalculated and corrected. For example:

- A customer participates in a program event in May, and a program event settlement transaction is created for the event in "Pending" status.
- Measurement data for the customer for the month of May is received in June, and the program event settlement transaction is calculated and updated to the "Calculated" state.

Copyright © 2026, Oracle and/or its affiliates.

- Before the program event settlement transaction been included in a Customer Settlement. updated measurement data for the customer is received.
- The program event settlement transaction must be recalculated to account for the change in measurement data (which could impact the baseline calculation results used in the transaction).

When updated measurement data is received and processed (via Direct Measurement Processing) the Create UT Correction for Baseline Derived SQs (X1-CRUTCORRB) Post-VEE algorithm on the IMD Type creates a Usage Transaction Correction activity (details regarding parameters for this algorithm can be found in the **Detailed Description** of the X1-CRUTCORRB Algorithm Type). When this activity is processed, the Recalculate Program Event Transaction Due to Measurement Change (X1-RECLPETMC) algorithm recalculates the program event settlement transaction and marks the transaction with a reason code of "Measurement Change".

Additionally, program event settlement transactions can be recalculated and corrected using the following options:

- Using the Recalculate Program Settlement (X1-RCEVS) batch process (see Batch Processing). When using this option, the Recalculation Reason parameter must be set to "X1MC" (Measurement Change).
- Using the "Re-Calculate" button in the **Record Actions** section of the program event settlement transaction. When using this option, you must select the "Measurement Change" reason for the recalculation.

About Program Incentives and Fees

Program incentives and fees are program settlement transactions used to calculate incentives and fees for program subscriptions, based on rules configured on the program subscription's program. Incentives include sign-up incentives for enrollments, referral rebates, and incentives for remaining enrolled during the peak season. Penalties or fees are applied in certain circumstance, for instance if they terminate their enrollments before the contracted period, or when the utility incurs charges related to device repairs, device upgrades, premium device fees.

Incentives and fees transactions are created either ad-hoc from the **Program Subscription** portal, or via a regularly scheduled batch process. In both cases, the process performs calculations for program subscriptions based on the program rule(s) configured on the program subscription's program. The Calculate Incentives and Fees (X1-CALIF) batch process should be run on a regular basis to monitor program subscriptions enrolled on in a device control program with an Incentive and Fees program rule in effect as of the batch run date. The Calculate Incentives and Fees (X1-CALIF) batch process creates transactions for all eligible rule types configured on the program rule.

When run either manually or via batch, the process creates the incentives and fees transaction, and when the program transaction enters the "Calculate" state, the Calculate Incentives and Fees (X1-CALCIFT) algorithm executes the Program Settlement Calculation Group defined on the Program Rule.

Program incentive and fee transactions contain the following data:

- **Program Subscription**: The program subscription for which the transaction was run.
- **Start Date/Time and End Date/Time**: The date and time range when the subscription was run.
- **Status**: The status of the program transaction. Statuses include Pending, Error, Discarded, and Complete.

Copyright © 2026, Oracle and/or its affiliates.

- **Program Rule**: The program rule on which the transaction is based.
- **Rule Type Category**: The category for the incentive and fee, from the Incentive and Fee Type Category (X1-IncentiveFeeTypeCatLookup) extendable lookup
- **Calculation Group**: The program settlement calculation group containing the program settlement calculation rules executed as part of the transaction.
- **Interim Calculations**: The interim results of the calculations performed by the program settlement calculation rules, including the variables used in the calculations and the value of each. These are results are based on variables marked as "FPCO" (For Calculation Purposes Only) on the program settlement calculation rules.
- **Calculated Amounts**: The interim results of the calculations performed by the program settlement calculation rules, including the variables used in the calculations and the line description and calculated amount for each.

System Data

Incentives and Fees transactions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Transaction (D1-USAGETRAN)
Business Object(s)	Incentives and Fees Transaction (X1-IncentivesFeesTransaction)

About Customer Settlement Transactions

Customer settlement transactions represent credits that will be applied to customer's bill based on all of the events in which the customer participated during a given time period. In other words, customer settlement transactions represent the total of all of the customer's program settlement calculations for a given time period.

Customer settlement transactions are created upon requests from a customer information system (CIS). Customer settlement transaction requests are sent in a file which is processed by a batch process which creates the individual customer settlement transactions.Customer settlement transaction requests include the customer contact or account or metered service, the program, the start and end date for the requested time period, and the type of request. These requests are typically sent on an annual basis (such as at the beginning or end of the year), but customer settlement transactions are also created in the following specific situations:

- Final Bill: When a customer moves out or stops their service, a customer settlement transaction is created and applied to their final bill.
- Re-Bill: When a customer is re-billed, the customer settlement transaction is recalculated for inclusion on the new bill.
- Customer Unenrollment: When a customer unenrolls from a program, a customer settlement transaction is created and applied to their next bill.

Customer settlement transactions are created in the "Pending" state. Pending customer settlement transactions are processed by the Process Customer Settlement (X1-PRCS) batch process which transitions them the "Calculate" state, in which all of the customer's program settlements for the requested time period are collated and totalized. These are then sent back to the customer information system for application on the customer's bill.

For customer settlement transactions for programs with an **Program Settlement Method** of "End of Season" (typically associated with demand-based programs), the Calculate Customer Settlement (X1-CALCCST) algorithm creates a "Combined kW Drop" program settlement

Copyright © 2026, Oracle and/or its affiliates.

transaction for the customer settlement transaction time period which calculates the average of a set of the "Maximum Drop" values from "Calculation Deferred" program settlement transactions that fall within the customer settlement transaction time period. The customer settlement transaction uses the results of the "Combined kW Drop" program settlement transaction. See About Program Settlement Transactions for more information about "Combined kW Drop" program settlements.

Once customer settlement transaction calculations are complete, they can be sent back to the customer information system for application on the customer's bill. See Downloading Customer Settlement Transactions for more information about how customer settlement transaction information is sent to the customer information system.

By default, the credits from customer settlement transactions are applied to the metered service for which they were calculated. However, in the case of a group of related metered services (such as a set of stores belonging to a common franchise), customer settlement transactions can be applied to a single "parent subscription" via the **Settlement Aggregation Method** (see below). "Parent" subscriptions are defined using the **Settlement Group** attribute on the Program Subscription. A program subscription's **Settlement Group** is a metered service associated with the program subscription's Main Customer, and is used to group program subscriptions for customer settlement transactions (see About Program Subscriptions for more information). "Parent" subscriptions are often used with demand-based programs for commercial customers where credits for overall demand reduction (based on "kW Drop" program settlement transactions) for a group of related accounts (metered services) are applied to the "parent" account.

Customer settlement transactions contain the following data:

- **Metered Service ID**: The metered service (customer) for which the customer settlement transaction was run.
- **Start and End Date**: The start and end date for the customer settlement transaction period.
- **Status**: The current status of the customer settlement transaction.
- **Used on Bill**: A flag that indicates (Yes or No) if the customer settlement transaction has been calculated.
- **Extract**: A flag that indicates (Yes or No) if the customer settlement transaction has been extracted.
- **Customer Settlement Request Type**: The type of customer settlement request. Valid options include Valid options include, End of Season, Final, Rebill, Regular, and Unenrollment.
- **Included Transaction**: The types of transactions included in the customer settlement. This is supplied in the customer settlement request received from the customer information system. Valid options include:
  - **Both**: Include both program event settlement transactions and incentive and fee transactions in the customer settlement transaction.
  - **Event Settlement**: Include only program event settlement transactions in the customer settlement transaction.
  - **Incentive and Fee**: Include only incentive and fee transactions in the customer settlement transaction.
- **Program**: The program associated with the customer settlement.
- **Method**: A flag that indicates the method by which customer settlements are applied to customer accounts. Options include:

Copyright © 2026, Oracle and/or its affiliates.

- **Individual**: Indicates that customer settlements should be applied to the individual customer accounts (represented by metered services).
- **Grouped**: Indicates that customer settlements should be applied to "Settlement Group" customer accounts (metered services specified as a **Settlement Group** on a program subscription).

- **Calculation Details**:
  - **UOM/TOU/SQI**: The unit of measure, time of use period, and service quantity identifier combination used to define the interval usage values used in the program settlement transactions that comprise the customer settlement calculation
  - **Customer Settlement Quantity**: The total quantity on which the customer settlement is base
    - For customer settlements based on "kwh Avoided" program settlements, this is the consumption saved for the customer settlement, calculated by adding together the individual program settlement transaction "Consumption Saved" values
    - For customer settlements based on "kW Drop" program settlements, this is the average of the "Maximum Drop" values from the individual program settlement transactions
  - **Total Actual Consumption**: The total actual consumption for the customer for the customer settlement, calculated by adding together the individual program settlement transaction "Actual Consumption" values (applies only to customer settlements for consumption-based programs)
  - **Customer Settlement Amount**: The monetary amount for the customer settlement.
    - For customer settlements based on "kwh Avoided" program settlements, this is calculated by adding together the individual program settlement transaction "Program Settlement Amount" values.
    - For customer settlements based on "kW Drop" program settlements, this is the amount from the "Combined kW Drop" program settlement transaction.
  - **Issues**: One or more messages related to the customer settlement transaction.
- **Program Settlements**: The program settlement transactions used for the the customer settlement transaction calculations

System Data

Customer settlement transactions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Transaction (D1-USAGETRAN)
Business Object(s)	Customer Settlement Transaction (X1-CustomerSettlementTransaction)

Batch Processing

Customer settlement transaction processing is supported by the following monitor batch processes:

- Process Customer Settlement (X1-PRCS): Used to transition customer settlement transactions in the "Pending" state to the "Calculate" state.
- Retry Customer Settlement (X1-RTCS): Used to retry customer settlement transactions in the "Error" state.

Copyright © 2026, Oracle and/or its affiliates.

Use the **Batch Control** portal to learn more about the parameters used by these batch processes.

About Interval Prices and Price Sets

Interval price sets represent set of interval pricing values used in various types of calculations, including program settlement transactions used with Customer Program Management, settlement calculations used with Market Settlements Management, or pricing calculations used in billing or rating. Interval price values can include market prices or real-time prices. When using multiple sources of interval prices, each source might be represented by a different interval price set.

Interval prices are individual prices based on a defined interval size (for example, hourly prices).

Interval price are defined by the following data:

- **Interval Price Set Type**: The interval price set type on which the interval price set is based. The interval price set type defines a number of attributes of the price set, including the interval size for the price intervals (such as 1 hour, 15 minutes, and so on), and the unit of measure, time of use period, and service quantity identifier used to define the price values.
- **External Identifier**: An identifier for the interval price set used in external systems
- **Time Zone**: The time zone associated with the interval price set
- **Interval Prices**: A set of interval price values belonging to the interval price set, including the following:
  - **Price Date/Time**: The date and time of the interval price
  - **Price**: The price value (based on the unit of measure defined for the interval price set's type)

System Data

Interval Price Sets are based on the following system data:

Data Type	Description
Maintenance Object	Measuring Component (D1-MEASRCOMP)
Business Object(s)	Interval Price Set (D1-IntervalPriceSet)

Interval Prices are based on the following system data:

Data Type	Description
Maintenance Object	Measurement (D1-MSRMT)
Business Object(s)	Interval Prices (D1-IntervalPrices)

Event Impact Measurement and Verification

Event Impact Measurement and Verification (M&V) for Distributed Energy Resource (DER) and Demand Response (DR) programs refers to the overall process of accurately measuring and verifying the actual energy savings or demand reductions achieved by implementing programs of these types, such as rooftop solar panels or battery storage, OR load control devices, like

Copyright © 2026, Oracle and/or its affiliates.

Smart Thermostats or Smart Water Heaters, where customers eventually end up reducing their electricity usage during peak demand periods.

The determination of energy savings achieved for an individual program event using baseline calculation methodologies allows utilities to perform the corresponding financial settlements. Refer to About Program Event Settlement Transactions for more information about how these settlements are calculated.

Event Impact Measurement and Verification (M&V) can be used to determine program-level demand reductions (either achieved or projected to be achieved) and ensure the effectiveness and reliability of these initiatives and can provide transparent data for market participants and regulators. This plays a key role in ongoing assessment and improvement in the program development cycle. At a high-level, this means evaluating the overall effects of a program (load reductions or load increases) related to a particular event or set of events, energy savings (positive or negative) and also cost effectiveness among others. The effects may be determined at the program level or at any level of granularity.

M&V calculations are performed using a type of regression analysis known as "Difference-in-Differences" (or DiD). At a high level the DiD methodology (as defined by Wikipedia), is "a statistical technique used in quantitative research that attempts to mimic an experimental research design using observational study data, by studying the differential effect of a treatment on a 'treatment group' versus a 'control group' in a natural experiment". When applied to demand response events, this analyzes the change in electricity consumption between a group of customers participating in a demand response program (the *treatment group*) compared to a similar group not participating (*control group*), both before and after the demand response event, allowing the outcome to isolate the causal effect of the program on electricity usage by accounting for any pre-existing trends in consumption patterns across the groups. This method using *Treatment* and *Control* groups is effective for impact estimation of relatively similar or uniform groups of customers, such as residential or small commercial customers , where several hundred or several thousand customers might participate in a program. The method is less effective for evaluating smaller numbers of customers or large commercial or industrial customers, because the treatment-control differences will have too much random error to be reliable.

As noted above, M&V calculations are performed for two different types of groups of customers:

- **Treatment Groups:** Groups of customers enrolled in a demand response program, receiving price signals or direct load control during the event. Treatment groups are also referred to as **Device Population Groups**.
- **Control Groups:** Groups of similar customers who are not part of the program and experience normal electricity prices during the event.

Both Device Population (or Treatment) groups and Control groups are defined using Entity Groups. See Understanding Device Population and Control Groups in the *Adminitrative User Guide* for more information.

As part of the DiD regression calculations, average hourly load is calculated for the following two regression periods:

- **Pre-Treatment**: A single period of time, typically 3 hours immediately before and adjacent (without gaps or overlaps) to the **Treatment** period.
- **Treatment**: A period comprising Pre-Event, Event, and Post-Event periods. Pre-Event and Post-Event periods are typically 2-3 hours each, while the Event period itself can up to 8 hours.

More specifically, a load model is constructed for each participant in both the **Device Population** group and the **Control** group using the interval meter reads for the **Pre-Treatment**

Copyright © 2026, Oracle and/or its affiliates.

period and the **Treatment** period. Subsequently a regression analysis is performed across the data to compute a ratio of the estimated **Treatment** period average hourly load of the **Device Population** group assuming no event to the **Control** group **Treatment** period average hourly load, and eventually to the **Device Population** group hourly (kW) Load Impact.

This ratio and other outputs from the regression analysis are captured in M&V Transactions, and additional calculations can be performed using M&V Calculation Rules.

M&V Processing and Dynamic Aggregation

M&V processing leverages functionality Dynamic Aggregation in a number of specific ways.

First, it uses Dimension Scanning to identify changes to Device Population and Control groups, and creates aggregation measuring components for each device population group. This process is run on a regular basis.

Secondly, it uses Find Constituents processing as part of the M&V calculation and regression process to identify the measuring components for both Device Population and Control groups. However, instead of aggregating measurement data for these measuring components, instead it stores the measuring components in a global temporary table called the Entity Group Constituents Temporary Table (D1_GTT11). The algorithms that execute the regression calculations read the measuring components from this table and aggregates the data for the Device Population group and the Control group.

Both of these processes requires configuration of Data Sources, Dynamic Aggregation Measuring Component Types, Aggregation Groups, and Measuring Component Sets.

- About Regression Aggregation Measuring Components
- About M&V Subscriptions
- About M&V Transactions
- About Service Point Event Outcome Snapshots

About Regression Aggregation Measuring Components

Regression aggregation measuring components are Aggregation Measuring Components used to represent Device Population groups. Unlike standard aggregation measuring components, these do NOT store aggregated measurement data. Instead, they are used to orchestrate M&V processing for their associated Device Population groups and their corresponding Control Groups (see Understanding Device Population and Control Groups in the *Administrative Use Guide* for more information about the relationship between Device Population and Control groups).

Regression aggregation measuring components are created via the Dimension Scanning process based on changes to Devce Populaion groups.

Regression aggregation measuring components are defined by the following:

- **Initiating Measuring Component Set**: The measuring component set that triggered creation of the aggregation measuring component via the Dimension Scanning process (see Dimension Scanning for more information).
- **Status**: The current status of the measuring component. Valid values are "Active", "Aggregate", and "Inactive".
- **Service Type**: The type of service (electric, water, and so on) the measuring component supports
- **Time Zone**: The time zone in which the measuring component operates

Copyright © 2026, Oracle and/or its affiliates.

- **Processing Information**: Details of aggregation processing for the aggregation measuring component, including the date and time through which aggregation has been performed.
- **Measuring Component Attributes**: Attributes that describe the dimensions and criteria for the aggregation measuring component (used by the Dimension Scanning process)

System Data

Regression aggregation measuring components are based on the following system data:

Data Type	Description
Maintenance Object	Measuring Component (D1-MEASRCOMP))
Business Object(s)	Regression Aggregator for M&V (X1-RegressionAggregatorMV)

Regression Aggregation Measuring Component Processing

As noted above, regression aggregation measuring components orchestrate M&V processing for their associated Device Population groups and their corresponding Control Groups.

Over time, as program events take place, Event Participation records record which customers participate in which events and the outcome of those events (such as "Successful", "Error", and so on). These are used to create Service Point Event Outcome Staging records.

On a regular basis, the Aggregation by MC Set Monitor (D1-AMCS) batch process triggers processing for aggregation measuring components in the "Active" state. This initiates a series of algorithms which do the following:

- Check for participation in program events
- Build a list of customers from the Device Population group who successfully participated in the event (Find Constituents) in the Entity Group Constituents Temporary Table (D1_GTT11).
- Trim the list of constituents by retrieving related Service Point Event Outcome records and deleting records from the Entity Group Constituents Temporary Table (D1_GTT11) in the event of any of the following:
  - The record indicated an outcome of non-responsive device, or canceled
  - The record has the Multiple Entity Group flag set to "Yes"
  - Any customer where another thermostat for the service point has participated in a different event for the same external event ID.
  - If no Service Point Event Outcome record is found for a customer in the Device Population group
- Perform a "Difference in Differences" regression analysis, aggregating and comparing data from the Device Population group to corresponding data from the Control group, and create a M&V transaction, which uses M&V Calculation Rules to perform calculations based on the regression outcome quantities
- Check for participation in any remaining unprocessed qualifying events
  - If no event occurred, the measuring component remains in the "Active" state
  - If another event is found, the measuring component is set to the "Aggregate" state (and can be transitioned back to the "Active" state via the Transition to Default Next Status (Java) (F1-AT-RQJ) batch process.

Copyright © 2026, Oracle and/or its affiliates.

About M&V Subscriptions

M&V subscriptions represent the enrollment of a group of customers (defined by a "Device Population" entity group) in a program. The same group of customers can have separate subscriptions for different programs.

M&V subscriptions are created whenever a new Device Population group is created or changed. A M&V Subscription's Device Population group defines the group of customers whose data is aggregated and processed when Measurement and Verification Transactions are created.

M&V subscriptions are defined by the following:

- **M&V Subscription Type**: The M&V subscription type associated with the Device Population group and program. M& V subscription types define certain parameters and attributes of a class of M&V subscriptions.
- **Division**: The division in which the customers in the Device Population group reside.
- **Start** and **End Date/Time**: The date and time on which the subscription record started, and ended (if applicable).
- **Entity Group**: The Device Population group
- **Program**: The program in which the Device Population group customers are enrolled.
- **Time Zone**: The time zone associated with the subscription.
- **M&V Calculation Groups**: The calculation groups defined for the subscription and used when creating M&V transactions for the Device Population group, including:
  - **M& V Calculation Group**: The M&V Calculation Group
  - **Effective Date/Time**: The date and time at which the calculation group is in effect.
  - **Expiration Date/Time**: The date and time at which the calculation group expires.

System Data

M&V subscriptions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Subscription (D1-US)
Business Object(s)	M&V Subscription (X1-MsrmtVerifSubscription)

About M&V Transactions

M&V transactions capture the results of the regression analysis and calculations preformed on those results based on data for the Device Population (treatment) group and the Control group. This includes the following coefficients and calculated values:

- Intercept
- Coefficient for Time
- Coefficient for Treatment
- Coefficient for Time * Treatment
- Control group average hourly load over the pre-event reference period (scalar value)

Copyright © 2026, Oracle and/or its affiliates.

- Treatment group average hourly load over the pre-event reference period (scalar value)
- Treatment group hourly average load over the event period (interval values)
- Control group hourly average load over the event period (interval values)

M&V transactions are created by monitor algorithms on aggregator measuring components associated with Device Population groups.

M&V transactions contain the following data:

- **M&V Subscription**: The M&V subscription associated with the event for which the M&V transaction was created
- **Program Event**: The event for which the M&V transaction was created
- **Start Date/Time**: The start date and time of the event
- **End Date/Time**: The end date and time of the event
- **Regression Statistics**: Statistics from the regression calculation, including:
  - **Coefficient of Determination**
  - **Multiple R**
  - **Standard Error**
  - **Number of Observations**
- **Coefficient Statistics**: Statistics for each of the following coefficients: Intercept (b0), Coefficient for Time (b1), Coefficient for Treatment (b2), and Coefficient for Time * Treatment (b3), including:
  - **Standard Error**
  - **Low Confidence Interval**
  - **High Confidence Interval**
- **Issues**: One or more messages related to the transaction.

System Data

M&V transactions are based on the following system data:

Data Type	Description
Maintenance Object	Usage Transaction (D1-USAGETRAN)
Business Object(s)	M&V Transaction (X1-MsrmtVerifTransaction)

Batch Processing

M&V transaction processing is supported by the following monitor batch processes:

- Retry M&V Transaction (X1-RTMVT): This batch process monitors M&V Transactions and advances them to the next state, and will retry M&V Transactions events in error.
- Recalculate M&V Transaction (X1-RCMVT): This batch process monitors M&V Transactions to recalculate and advances them to the next state.

Use the **Batch Control** portal to learn more about the parameters used by these batch processes.

About Service Point Event Outcome Snapshots

Copyright © 2026, Oracle and/or its affiliates.

Service Point Event Outcome Snapshots capture a summary of event data at a service point level for program participants that have multiple controllable devices, such as thermostats, including both residential and commercial customers.

Service Point Event Outcome Snapshots are defined by the following:

- **Metered Service Point**: The metered service point for which the event outcome snapshot was created
- **Treatment Group**: The Device Population group to which the devices that participated in the event belong
- **Program Event**: The program event for which the outcome snapshot was created
- **Program Subscription**: The program subscription associated with the event outcome snapshot
- **Service Point Event Outcome**: The outcome of the service point's participation in the event. Possibly outcomes include "Successful participation", "Non-responsive device", "In-flight override", "Mixed", and "Canceled".
- **Control Group**: The control group to be used for M&V processing for the event
- **Parent**: A flag that indicates (Yes or No) if the program subscription associated with the event outcome snapshot is a parent subscription
- **Device Count**: The number of devices that participated in the event
- **Multiple Entity Group**: A flag that indicates (Yes or No) if the event outcome snapshot is based on multiple entity groups
- **Multiple Program Event**: A flag that indicates (Yes or No) if the event outcome snapshot is based on multiple program events
- **Service Point Event Outcome Quantity**: A list of quantities captured in the event outcome snapshot, including the following for each:
  - **Sequence**: The sequence of the quantity
  - **SQI**: The service quantity identifier for the quantity
  - **Date/Time**: The date and time of the quantity
  - **UOM**: The unit of measure for the quantity
  - **Quantity**: The quantity

System Data

Service Point Event Outcome Snapshots are based on the following system data:

Data Type	Description
Maintenance Object	Service Point Event Outcome (D1-SPEVTOUTC)
Business Object(s)	Service Point Event Outcome (X1-ServicePointEventOutcome)

Batch Processing

Service Point Event Outcome snapshot processing is supported by the following monitor batch processes which create Service Point Event Outcome Snapshots from Event Participation and M&V transaction records:

- Create Service Point Event Outcome Staging (X1-SPEOC): This batch process creates Service Point Event Outcome Staging records from Event Participation records that contain the basic data used for the snapshot

Copyright © 2026, Oracle and/or its affiliates.

- Create SP Event Outcome Quantity Staging (X1-SPEOQ): This batch process creates Service Point Event Outcome Quantity Staging records from M&V Transaction records that contain Service Point Event Outcome Quantities

Use the **Batch Control** portal to learn more about the parameters used by these batch processes.

About Customer Program Service Tasks

Customer program service tasks are used to manage various customer-focused processes such as enrollment, unenrollment, and service calls.. A service task is created for each customer process and orchestrates the various steps and tasks involved in that process.

System Data

Customer program service tasks are based on the following system data:

Data Type	Description
Maintenance Object	Service Task (F1-SVCTASK)
Business Object(s)	Customer Program Enrollment Task (X1-DigitalAssetEnrollTask)
	Customer Program Unenrollment Task (X1-DigitalAssetUnenrollTask)
	Program Service Call (X1-ProgramServiceCall)
	DER Interconnection Request Task (X1-DERInterconnectionTask)
	Customer Program Enroll Additional Device Task (X1-DAAddDeviceToEnrollTask)

About Enrollment and Unenrollment

Enrollment involves identifying a specific customer that is eligible for a particular program, and establishing a relationship between the customer, the program, and if appropriate, a device location where one more controllable devices are (or have been) installed. The primary result of the enrollment process is a program subscription that links a customer with a program and (and in most cases) a device location. The process can also involve one or more actions performed to set up the controllable devices. For example, in the case of devices which the utility provides and installs at the customer's location, the enrollment process creates a work activity used to schedule a crew to install the device. Another common device setup action involves issuing a "device status check" command request in which the control system validates that the device can receive messages from the control system.

Unenrollment involves removing a previously enrolled customer from a program, and deactivating program subscriptions and related controllable devices.

The enrollment and unenrollment processes are managed by the following service task business objects:

- Customer Program Enrollment Task (X1-DigitalAssetEnrollTask)
- Customer Program Unenrollment Task (X1-DigitalAssetUnenrollTask)

To understand the enrollment and unenrollment processes, it’s important understand the lifecycle of these service task business objects. The table below outlines the lifecycle for the above business objects. Specifics for Enrollment and Unenrollment are noted in the descriptions below.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Pending	The initial state for service tasks activities. The service task is transitioned to the next state via a monitor process.
Validate	Enrollment: an Enter algorithm validates the enrollment request, including: • If an existing customer can be retrieved for the customer program enrollment request and the request contains the necessary enrollment details to continue processing. • If the program is accepting enrollments • If the metered service points division is same as the programs division • If asset information is provided when the Installation Method is "Bring Your Own" • If an in store asset exists that is valid for the program when the Installation Method is "Bring Your Own" and Asset Ownership is "Utility Owned" Unenrollment: an Enter algorithm validates that the unenrollment request contains the necessary details to derive the program subscription record to be unenrolled. The service task is transitioned to the next state via a monitor process.
Validation Error	If the service task fails any of the validations in the Pending state, it enters this state. Service tasks in this state can be corrected and retried.
Validated	If the service task passes the validations in the Validate state, it enters this state.
Check Eligibility	Enter algorithms validate the the customer is eligible for the program (based on the Eligibility Criteria defined for the program's Initiative), and that the customer meets the program qualifications (based on the program's qualification questions). Applies to Enrollment service tasks only.
Eligibility Error	If the customer is either not eligible for the program or doesn't meet the program qualifications, the service task fails and enters this state. Service tasks in this state can be corrected and retried. Applies to Enrollment service tasks only.
Re-Evaluate Eligibility	If the service task failed and during the Check Eligbility state, it can enter this state temporarily before returning to the the Check Eligbility state. Applies to Enrollment service tasks only.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Setup Enrollment	An Enter algorithm creates a Program Subscription (in the "Inactive" state) and a Device Location (in the "Active" state). **Note** If the **Location Required Source** field is set to "No" on the program's program type, creation of the device location is skipped. If the Installation Method is "Bring Your Own" and Asset Ownership is "Customer Owned", a controllable device is also created and attached to the device location. Applies to Enrollment service tasks only.
Enrollment Setup Error	If an error occurs in the Setup Enrollment state, it enters this state. Service tasks in this state can be corrected and retried. Applies to Enrollment service tasks only.
Setup Unenrollment	An Enter algorithm deactivates the Program Subscription. Applies to Unenrollment service tasks only.
Unenrollment Setup Error	If an error occurs in the Setup Unenrollment state, it enters this state. Service tasks in this state can be corrected and retried. Applies to Uennrollment service tasks only.
Setup Device	Enrollment: An Enter algorithm determines the device setup actions configured under customer program enrollment service task type and creates the relevant setup actions required to setup the controllable device. Each setup action is captured in the Device Setup section of the service request (as well as in the service task's log). **Note** If the **Location Required Source** field is set to "No" on the program's program type, creation of the device is skipped. Unenrollment: An Enter algorithm determines the device setup actions configured under customer program unenrollment service task type and creates the relevant setup actions required to deactivate the controllable device. Each setup action is captured in the Device Setup section of the service request (as well as in the service task's log). See Device Setup Actions, below for more information.
Device Setup Error	If one or more device setup actions cannot be determined, the request is transitioned to this state. Service tasks in this state can be corrected and retried.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Awaiting Device Setup	The service task remains in this state until all device setup actions are complete. The service task is transitioned to the Device Setup Actions stage via a monitor process until all of the actions configured on the service task type have been completed.
Completed	The service task enter this state when all device setup actions have successfully completed. Enrollment: An Enter algorithm sets the Program Subscription's Status to "Active". Unenrollment: An Enter algorithm populates the "End Date/Time" on the Program Subscription and sets its Status to "Inactive", and any controllable devices on the Program Subscription are deactivated.
Discarded	Service tasks discarded in previous states enter this state.
Canceled	Service tasks canceled in previous states enter this state.

Specifics of the service task, such as the type of program subscription and device location to creates and the types of device setup actions required to complete the enrollment are defined by the service task type associated with the program in which the customer is enrolling (or from which the customer is unenrolling). See Understanding Customer Program Service Task Types in the *Administrative User Guide* for more information.

Device Setup Actions

Enrollment or unenrollment processes can include a number of device setup actions performed to install, investigate, or test controllable devices as part of the enrollment or unenrollment process. Supported device setup actions include:

- **Create Activity**: Creates Service Order Management field activities to perform device installation or investigation.
- **Create To Do**: Creates To Do Entries.
- **Create Work Order**: Create Work and Asset Management work orders to perform device installation or investigation.
- **Initiate Controllable Device Command**: Create and send commands to controllable devices to test if they're capable of communicating with the control system.

See Understanding Customer Program Service Task Types in the *Administrative User Guide* for more information about configuring device setup actions.

Enrollment/Unenrollment Methods

Oracle Utilities Customer Program Management Cloud Service provides two methods of initiating the customer enrollment or unenrollment processes.

The first is through use of the **Process Flow** portal and functionality. The system provides two process flow types to support the enrollment and unenrollment processes:

- Program Enrollment Process (X1-DIGITALASSETENROLLMENT)
- Program Unenrollment Process (X1-DIGITALASSETUNENROLLMENT)

Enrollment/unenrollment service tasks are created by the process flow based on data entered by the user. See Enrolling and Unenrolling Customers using Process Flow for more information about using the **Process Flow** portal for enrollment and unenrollment. See Process Flows in the *Administrative User Guide* for general information the process flow functionality.

Copyright © 2026, Oracle and/or its affiliates.

Customer Program Management also provides an inbound web service to enable submission of enrollment and unenrollment requests from external systems such as a customer information system. The Program Enrollments (X1-ProgramEnrollment) inbound web service provides the following operations:

- Create Program Enrollment (enrollProgram): Used to create an enrollment request to enroll a customer in a program
- Create Program Unenrollment (unenrollProgram): - Used to create an unenrollment request to unenroll (remove) a customer from a program
- Get Program Enrollment (getProgramEnrollment): - Used to retrieve enrollment information
- Get Program Unenrollment (getProgramUnenrollment): - Used to retrieve unenrollment information

About Service Calls

Service calls are created when a customer reports an incident of some kind related to a controllable device installed at their location. Service calls can have different levels of urgency (Emergency or Non-Emergency) and can be used to create a work order to address the incident, or can resolve or escalate a previous service call.

The system provides the following process flow type to support service calls:

- Program Service Call Process (X1-DAPROGRAMSERVICECALL)

Service calls are initiated from the **Current Enrollment** zone in the **Customer Program Summary** portal, and make use of the **Process Flow** portal and functionality. When the user clicks the **Service Call** button on the **Current Enrollment** zone, they are brought to the **Process Flow** portal where they can enter details of the service call. Service call service tasks are created by the process flow based on data entered by the user. See Creating Program Service Calls Using Process Flow for more information about using the **Process Flow** portal for service calls. See Process Flows in the *Administrative User Guide* for general information the process flow functionality.

The service call process is managed by the following service task business object:

- Program Service Call (X1-ProgramServiceCall)

To understand the service call process, it's important understand the lifecycle of this service task business object. The table below outlines the lifecycle for the above business object.

State	Description
Pending	The initial state for service tasks activities. The service task is transitioned to the next state via a monitor process (or as part process flow processing).
Validate	The service task is transitioned to the next state via a monitor process.
Validation Error	If the service task fails any of the validations in the Pending state, it enters this state. Service tasks in this state can be corrected and retried.
Escalated	This state applies only to service calls with an "Escalation" action. An Enter algorithm creates an "Escalated" To Do entry, based on the **Escalation To Do Type** defined on the service task type.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Work in Progress	This state applies only to service calls with a "Create a Work Order" action. An Enter algorithm creates a work order based on the selected template work order. The service task remains in this state until the word order and its related work activities are completed (via a Monitor algorithm).
Completed	The service task enters this state following either the "Escalated" or "Work in Progress" states.
Discarded	Service tasks discarded in previous states enter this state.

Specifics of the service task, such as the type of work order to creates are defined by the service task type associated with the program for which the customer is initiating the service call. See Understanding Customer Program Service Task Types in the *Administrative User Guide* for more information.

Maintaining Controllable Assets and Devices

The **Asset** and **Controllable Asset** portals are used to display and maintain controllable asset and device records.

Refer to About Controllable Assets and Devices for more information.

You can access the portal from **Menu**, select **Asset Management**, then select **Asset**. The **Asset Query** portal and **Asset Search** zone open which you can use to search for the controllable asset/device you wish to view. When you select an asset, the **Controllable Asset** portal opens displaying the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Controllable Asset**: This zone displays basic information about the asset record associated with the controllable asset.
  - Click **Calculate Score** to manually calculate the control score for the asset. The score is calculated based on the Score Calculation Rule configured for the program subscription or program subscription type associated with the program in which the asset is enrolled. See Score Calculation Rule for more information the Score Calculation Rule. If no rule is configured, the **Calculate Score** button does nothing. This option is only available if the asset's **Status** and **Asset Disposition** are "Installed".
- **Attachments**: This zone lists any attachments related to the asset record associated with the controllable asset.
- **Asset Service History**: This zone displays a log of the service history that has been recorded for the life of the asset.
- **Notes**: This zone lists any notes for the asset record associated with the controllable asset.
- **Disposition History**: This zone displays a log of the status and location changes for the life of the asset

The following zones may appear as part of the portal's **Device** tab page:

Copyright © 2026, Oracle and/or its affiliates.

- **Controllable Device**: This zone displays the device record associated with the controllable asset. (Controllable assets/devices have both asset and device records)
- **Device Attachments**: This zone lists any attachments related to the device record associated with the controllable asset.
- **Device Log**: This zone display log information for the device record associated with the controllable asset.
- **Device Entity Groups**: This zone lists the entity groups to assigned to the device. To add an entity group to the device, click **Add Entity Group to Device**. A dialog opens where you can select the entity group.

The following zones may appear as part of the portal's **Log** tab page:

- **Asset Log**: This zone display log information for the asset record associated with the controllable asset.
- **Asset Sync Requests**: This zone lists data synchronization requests associated with the asset record associated with the controllable asset.
- **Asset Shipping Memos**: This zone lists shipping memos associated with the asset record associated with the controllable asset.

Maintaining Device Locations

The **Device Location** portal is used to display and maintain device locations.

Refer to About Device Locations for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Device Location**. You are brought to a query portal with options for searching for a specific record. Once a device location has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Location**: This zone displays location information for this device location record.
- **Customer Unavailability**: This zone lists periods of time during which one more controllable devices are unavailable to participate in program events. Click **Add** to define a new unavailability period for a controllable device at this location. To edit an existing unavailability period for a controllable device at this location, select the period from the list and click **Edit**. To cancel an existing unavailability period for a controllable device at this location, select the period from the list and click **Cancel**.

Maintaining Facilities

The **Facilities** portal is used to display and maintain facility records.

Refer to About Facilities for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Facility**. You are brought to a query portal with options for searching for a specific record. Once a facility has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Facility**: This zone displays general information about the facility.

Copyright © 2026, Oracle and/or its affiliates.

- **Network Locations Related to Facility**: This zone lists the network locations associated with the facility record.
- **Downstream Service Points Related to Facility**: This zone lists the downstream service points associated with the facility record.

Maintaining Metered Service

The **Metered Service** portal is used to display and maintain metered service records.

Refer to About Metered Service for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Metered Service**. You are brought to a query portal with options for searching for a specific record. Once a metered service records has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Metered Service**: This zone displays general information about the metered service records.
- **Program Subscriptions**: This zone displays a list of "child" program subscriptions associated with the metered service record.
- **Attribute Values**: This zone displays a list of attribute values whose characteristic type are defined as valid characteristic types on the Metered Service Type.
- **Settlement Group Program Subscriptions**: This zone lists program subscriptions that have the metered service defined as their Settlement Group.

Maintaining Metered Service Points

The **Metered Service Point** portal is used to display and maintain metered service points.

Refer to About Metered Service Pointsfor more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Metered Service Point**. You are brought to a query portal with options for searching for a specific record. Once a metered service point has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Metered Service Point**: This zone displays basic information for this metered service point.
- **Service Point Attachments**: This zone lists attachments associated with the metered service point.
- **Metered Services**: This zone lists metered services associated with the metered service point.
- **Device Locations**: This zone lists device locations associated with the metered service point.
- **SP Network Locations**: This zone lists all network locations linked to any facility associated with the metered service point.

Copyright © 2026, Oracle and/or its affiliates.

- **SP Business Flags**: This zone lists the 25 most recent business flags associated with the metered service point.

Maintaining Network Locations

The **Network Location** portal is used to display and maintain network locations.

Refer to About Network Locations for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Network Location**. You are brought to a query portal with options for searching for a specific record. Once a network location has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Network Location**: This zone displays general information about the network location, such as Facility ID, Start and End Date/Time, Feeder, and Substation.
- **SP Related to Network Location**: This zone lists the service points associated with the network location record.

Maintaining Programs and Related Records

This section describes how demand response programs and related data are created and maintained in Customer Program Management.

Information about programs is maintained in Customer Program Management, but other systems such as Oracle Utilities Network Management System are responsible for initiating and creating program events.

- Maintaining Programs
- Maintaining Program Contacts
- Maintaining Contact Communications
- Maintaining Program Subscriptions
- Maintaining Program Control Scores
- Maintaining Program Events
- Maintaining Event Participation
- Maintaining Program and Customer Settlement Transactions
- Maintaining Interval Price Sets

Maintaining Programs

The **Program** portal is used to display and maintain programs.

Refer to About Programs for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program**. You are brought to a query portal with options for searching for a specific record. Once a program has been selected, you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

The following zones may appear as part of the portal's **Main** tab page:

- **Program**: This zone displays general information about the program, such as program type, status, and approval profile.
- **Specifications**: This zone lists one or more specifications for devices eligible for the program.
- **Rates**: This zone lists one or more rates used to determine eligibility for customers to enroll in the program (customer must be on one of the listed rates to join the program).
- **Rules**: This zone lists program rules associated with the program.
- **Qualifications**: This zone lists one or more qualification questions used to determine eligibility for customers to enroll in the program.
- **Informational**: This zone lists one or more informational questions used to determine eligibility for customers to enroll in the program.
- **Events**: This zone lists events associated with the program.

The following zones may appear as part of the portal's **Calculation Groups** tab page:

- **Program Settlement Calculation Groups**: This zone lists effective-dated program settlement calculation groups associated with the program.

Approving Program Approval Requests

Programs with an Approval Profile must be approved before they are consider active and eligible for use. Users can use with the **Approval Dashboard** or the **Approval Requests** portal to view and approve program approval requests.

Maintaining Program Contacts

The **Contact** portal is used to display and maintain program contacts.

Refer to About Program Contacts for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program Contact**. You are brought to a query portal with options for searching for a specific record. Once a program contact has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Contact**: This zone displays general information about the contact, such as the contact's name and contact information (phone number, email address, and so on).
- **Contact Communication List**: This zone lists customer communications for the contact.
- **Point of Contact Service Point**: This zone lists metered service points associated with the contact. Used with Customer Program Management.

Maintaining Contact Communications

You use the **Contact Communication** portal to display and maintain contact communications and interactions.

Refer to About Contact Communications for more information.

Copyright © 2026, Oracle and/or its affiliates.

To access the portal select **Menu**, select **Customer Program Management**, then select **Contact Communication**. You are brought to a query portal with options for searching for a specific record. Once a contact communication has been selected, you are brought to the maintenance portal to view and maintain the selected record.

You can also access the portal from the **Contact Communication List** zone on the **Contact** portal. When you select the communication you wish to view you are brought to a maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Contact Communication**: This zone displays the selected communication.

Maintaining Program Subscriptions

The **Program Subscription** portal is used to display and maintain program subscriptions.

Refer to About Program Subscriptions for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program Subscription**. You are brought to a query portal with options for searching for a specific record. Once a program subscription has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Program Subscription**: This zone displays general information about the program subscription, such as the customer, status, and event calculation groups.
  - If the program subscription is for a device control program and has Incentive and Fees Program Rules if effect, you can use the **Calculate** button to initiate calculations of program incentives and fees. A window opens enabling the user to enter a **Cutoff Date** and select one or more eligible **Incentive and Fee Types** (based on the Rule Parameters defined on the Program Rule) to process.
- **Event Participation List**: This zone lists the events in which program subscription was a participant.
  - To opt out of one more more scheduled event, select the events and click **Opt Out**.
- **Program Settlements**: This zone lists program settlements calculated for the program subscription.
- **Incentives and Fees Settlements**: This zone lists incentives and fees calculated for the program subscription.
- **Attribute Values**: This zone lists attribute values whose characteristic type have Program Subscription as characteristic entities and are defined as valid Program Subscription characteristic types on the Program Subscription Type.

Maintaining Program Control Scores

The **Program Control Score** portal is used to display and maintain program control scores.

Refer to About Program Control Scores for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program Control Score**. You are brought to a query portal with options for searching for a specific record. Once a program control score has been selected, you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

The following zones may appear as part of the portal's **Main** tab page:

- **Program Control Score**: This zone displays the selected program control score.

Maintaining Program Events

The **Program Event** portal is used to display and maintain program events.

Refer to About Program Events for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program Event**, or select **Program Event** from the **Program** context menu when viewing either a Program Subscription or Program. When using either approach users are brought to a query portal with options for searching for a specific record. Once a program event has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Program Event**: This zone displays general information about the program event, such as the program, status, program category, the start and end date/time of the event, and an external event identifier (if applicable).

Maintaining Event Participation

The **Event Participation** portal is used to display and maintain event participation records.

Refer to About Event Participation for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Event Participation**. You are brought to a query portal with options for searching for a specific record. Once an event participation has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Event Participation**: This zone displays general information, such as Program Subscription, Dynamic Option ID, Reservation, Outcome, and so on, about the event participation record.

Maintaining Program and Customer Settlement Transactions

The **Program Settlement** portal is used to display and maintain program and customer settlement transactions, , including program incentives and fees.

Refer to About Program Settlement Transactions, About Program Incentives and Fees, and About Customer Settlement Transactions for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Program Settlement**. You are brought to a query portal with options for searching for a specific record. Once a settlement transaction has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Program Event Settlement**: This zone displays the selected settlement transaction.
- **Event Settlements**: This zone displays a list the program event settlements totalized in the selected customer settlement transaction.

Copyright © 2026, Oracle and/or its affiliates.

- **Incentives and Fees Settlements**: This zone displays a list the incentives and fees settlements totalized in the selected customer settlement transaction.
- **Baseline Measurements**: This zone displays a list of baseline measurements used in calculating the program event settlement transaction (if applicable).

Maintaining Interval Price Sets

You use the **Interval Price Set** portal to display and maintain interval price sets and interval prices

Refer to About Interval Price Sets for more information.

You can access the portal from **Menu**, select **Interval Price**, then select **Interval Price Set**. You are brought to a query portal with options for searching for a specific record. Once an interval price set has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Interval Price Set**: This zone displays the selected interval price set.
- **Interval Prices**: This zone displays the individual interval prices for the interval price set.

Maintaining Interval Prices

You use the **Interval Prices** zone to maintain interval prices for an interval price set. You can either manually add or upload prices.

To manually add prices, click **Add** in the upper right corner of the zone. The **Interval Prices Add** dialog opens. The **Interval Price Set ID** is prepopulated based on the interval price set.

- Enter the **Price Date/Time** and **Price** values for each interval price in the **Interval Prices** section.
- Click **Save** to save the interval prices.

To upload prices, click **Upload** in the upper right corner of the zone. The **Interval Prices Upload** dialog opens. The **Interval Price Set ID** and **Target Time Zone** are prepopulated based on the interval price set.

- Select the **Source Time Format** (Local or Standard) for the price data.
  - **Local** : Date/time values adjusted to "Standard" time (reflecting DST if applicable) and both are captured on the Measurement table
  - **Standard**: Date/time values are captured in both Standard and Local time on the Measurement table
- Specify the **Source Time Zone** for the price data. This is the time zone from which the price data originated. This allows for conversion to the time zone defined for the interval price set.
- To upload prices, click **Choose File** to search for and select a comma separated values (CSV) file containing price data and click **Submit**. The **Interval Prices Upload** dialog will display the price data contained in the file. Note that you can edit the price data before saving it.
- Click **Save**to save the interval prices.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You can add prices using both manual entry and upload, but uploading data will overwrite existing prices for the same date/time.

To update one or more prices, select the price(s) to update and click **Edit**. The **Price** dialog opens displaying the selected prices. Edit the prices as needed and click **OK**. Click **Cancel** to close the dialog without making any changes.

To delete one or more prices, select the price(s) to delete and click **Delete**. The **Price** dialog opens asking you to confirm the deletion. Click **OK** to delete the selected prices. Click **Cancel** to close the dialog without deleting the prices.

Interval Prices File Format

The file format used to upload interval prices are comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column must included in the first row of the input file.

Field	Data Type	Sample Content	Description
dt	DATE	2023-02-11-12.00.00	Date and time for the interval price
value	NUMBER	0.35	Interval price amount

Sample File

The following is a sample file for interval prices spanning a six hour event.

```
dt,value 2023-02-11-12.00.00,0.35 2023-02-11-13.00.00,0.35
2023-02-11-14.00.00,0.35 2023-02-11-15.00.00,0.35 2023-02-11-16.00.00,0.35
2023-02-11-17.00.00,0.35
```

Maintaining Event Impact Measurement & Verification Data

This section describes how records and data used with Event Impact Measurement & Verification (M&V) processing are created and maintained.

- Maintaining M&V Subscriptions
- Maintaining M&V Transactions
- Maintaining Service Point Event Outcome Snapshots

Maintaining M&V Subscriptions

You use the **M&V Subscription** portal to display and maintain M&V subscriptions.

Refer to About M&V Subscriptionsfor more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **M&V Subscription**. You are brought to a query portal with options for searching for a specific record. Once an M&V subscription has been selected, you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

The following zones may appear as part of the portal's **Main** tab page:

- **M&V Subscription**: This zone displays general information about the M&V subscription, such as the customer, status, and event calculation groups.

Maintaining M&V Transactions

You use the **M&V Transaction** portal to display and maintain M&V transactions.

Refer to About M&V Transactions for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **M&V Transaction**. You are brought to a query portal with options for searching for a specific record. Once an M&V transaction has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **M&V Transaction**: This zone displays the selected M&V transaction.
- **SQ Details**: This zone displays service quantity details for the M&V transaction.
- **Baseline Measurements**: This zone displays interval data used in calculating the M&V transaction (if applicable).

Maintaining Service Point Event Outcome Snapshots

You use the Service Point Event Outcome portal to display and maintain Service Point Event Outcome snapshots.

Refer to About Service Point Event Outcome Snapshots for more information.

You can access the portal from **Menu**, select **Customer Program Management**, then select **Service Point Event Outcome**. You are brought to a query portal with options for searching for a specific record. Once a record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Event Outcome**: This zone displays general information about the Service Point Event Outcome.

Maintaining Customer Program Service Tasks

The **Service Task** portal is used to display and maintain customer program service tasks.

Refer to About Customer Program Service Tasks for more information.

You can access the portal from **Menu**, then select **Service Task**. You are brought to a query portal with options for searching for a specific record. Once a service task has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Task**: This zone displays general information about the service task.

Copyright © 2026, Oracle and/or its affiliates.

- **DER Attributes**: This lists Distributed Energy Resource (DER) device attributes captured for DER devices related to the service task. Applicable only for enrollment service tasks involving DER devices.

Distributed Energy Resource (DER) Device Service Tasks

The DER Device Management (X1-DERDeviceManagement) inbound web service is used to perform registration and/or enrollment of Distributed Energy Resource (DER) devices. This inbound web service includes the following operations:

- Register DER Device (registerDERDevice): Used by an external application to register and enroll a DER device. This operation creates a DER asset and device, as well as an enrollment service task to enroll the device in a program specified in the inbound web service request, or if a program is not provided based on the specification defined for the asset. The enrollment service task is created in the "Pending" state. The service task should be processed either manually or via the Service Task Monitor (Deferred) (F1-STKDF) batch process.
- DER Interconnection (interconnectDER): Used by an external application to send interconnection attributes of a DER asset from an external system that handles the interconnection process for the utility. The incoming data is validated against existing asset manufacturer and model combinations, leading to the creation of an interconnection service task to allow the initial creation of the DER asset. Enrollment for assets that require interconnection attributes must be performed separately via the Register DER Device operation. The interconnection service task is created in the "Pending" state. The service task should be processed either manually or via the Service Task Monitor (Deferred) (F1-STKDF) batch process.

The **DER Registration Flag** on the controllable asset type specifies whether registration of DER assets require both an interconnection request (using the DER Interconnection operation) and a DER registration request (using the Register DER Device operation), or just a DER registration request.

Enrolling and Unenrolling Customers Using Process Flow

Enrollment and unenrollment processing can be initiated, monitored, and maintained using the **Process Flow** portal and functionality. This allows users to step through a series of panels on which they enter information about the customer, their location, and the controllable device. See **About Enrollment and Unenrollment** for more information.

Enrollment and unenrollment process flows are initiated from the **Eligible Programs** zone of the **Customer View** portal.

When navigating between panels on the **Process Flow** portal, the Next and Previous buttons allow you to move to the next or previous panels in the process respectively. To save your progress and settings before moving on to the next panel, click **Save**. Click **Finish** on the **Summary** panel to mark the process flow as Closed. To cancel the process, click **Cancel Process**. This transitions the service task to the "Canceled" state. See Action Method in the *Administrative User Guide*for more information the process flow functionality.

The following sections describe the content on the different panels used in enrollment and unenrollment process flows.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If the **Location Required Source** field is set to "No" on the program's program type, some enrollment steps are skipped.

Customer

The **Customer** panel is used to specify data about the customer, associated with the enrollment or unenrollment process. This includes the following:

Customer Information: This section displays information about the customer, including:

- **Metered Service**: The customer's metered service record
- **Name**: The customer's name
- **Phone**: The customer's phone number
- **Email**: The customer's email address

Location Information: This section displays information about the customer's location, if applicable, including:

- **Metered Service Point**: The customer's metered service point.

Interaction Details: This section is used to capture details around customer interaction. The information in this section is used to create Customer Communications. See About Customer Communications for more information.

- **Channel**: The channel used for the communication, such as email or phone
- **Class**: The class of the communication, such as enrollment, unenrollment, trouble report, and so on
- **Category**: The category of the communication, such as written or verbal
- **Notes**: Notes associated with the communication

Program Enrollment / Program Unenrollment

The **Program Enrollment** panel is used to determine if the customer is eligible for the program, and includes the following: the program,

Program Information: This section displays information about the program, including:

- **Program**: The program in which the customer will be enrolled (or from which the customer will be unenrolled).
- **Start Date**: The start date of the customer's enrollment in the program (will be used as the program subscription's **Start Date**). Applicable only to enrollment processes.
- **Stop Date**: The stop date of the customer's enrollment in the program (will be used as the program subscription's **End Date**). Applicable only to unenrollment processes.

Qualification Questions: **Enrollment Only**. This section lists the qualification questions associated with the selected program. These are taken from the **Qualifications** configured on the program (see **About Programs**).

Informational Questions: **Enrollment Only**. This section lists the informational questions associated with the selected program. These are taken from the **Informational** questions configured on the program (see **About Programs**).

Copyright © 2026, Oracle and/or its affiliates.

Controllable Devices: **Unenrollment Only**. A list of controllable devices installed at the device location

Interaction Details: This section is used to capture details around customer interaction. See description above.

When the use clicks Next on this panel, the system compares the answers provided in the Qualification sectionanswers the against "correct" answers configured on the program and checks the customer's eligibility for the program based in the program's **Program Initiative** (see **Understanding Program Initiatives**).

This panel is applicable only to enrollment processes.

Related Program Enrollment

The **Related Programs** panel is used to enroll the customer in a related program, and includes the following:

Related Programs: section allows you to select other programs that the customer may be currently enrolled in.

Qualification Questions: This section lists the qualification questions associated with the selected related program, if applicable. These are taken from the **Qualifications** configured on the program (see **About Programs**).

Informational Questions: This section lists the informational questions associated with the selected related program, if applicable. These are taken from the **Informational** questions configured on the program (see **About Programs**).

Interaction Details: This section is used to capture details around customer interaction. See description above.

This panel is applicable only to enrollment processes.

Device Setup

The **Device Setup** panel is used to manage device setup activities (based on the service task's service task type), and can include the following:

Asset Information: This section defines details regarding the asset related to the program enrollment or unenrollment, including:

- **Installation Method**: **Enrollment Only**. The installation method for the controllable devices associated with the enrollment process. Options include:
  - **Re-enroll**: The customer is re-enrolling a utility-owned device
  - **Ship Device**: The utility will ship the device to the customer.
  - **Utility Installation**: The utility will install the device at the customer's device location.
- **Devices to Re-Enroll**: A list of devices to be re-enrolled. At least one of the devices lists must be selected (applicable only if the **Installation Method** is "Re-enroll").
- **Removal Method**: **Unenrollment Only**. The removal method for the controllable devices associated with the unenrollment process. Options include:
  - **Keep**: The customer or utility will keep the device after its removal.
  - **Ship Device**: The customer will ship the device to the utility.
  - **Utility Removal**: The utility will remove the device at the customer's device location.
- **Asset Ownership**: Who owns the asset. Options include:

Copyright © 2026, Oracle and/or its affiliates.

- **Customer Owned**: The customer owns the asset/device.
- **Utility Owned**: The utility owns the asset/device.

Work Order Activities: This section defines details regarding work order activities related to the program enrollment or unenrollment (if applicable). This includes the ability to select an appointment for work activities and field activities. Do the following for each activity type:

- Select a **Crew Shift Type** for the work order activity
- Select a **Crew** for the work order activity (based on the selected crew shift type)
- Enter a date in the **Appointment Date** field to view a list of available appointments for that date . The appointment lists displays available appointments for the activity type, including start and end date and time, and the crew assigned.
- Select the appointment you wish to assign to the activity type. The list of available appointments is based on the **Appointment Date** and the **Appointment Slot Days** parameter defined in the Enrollment/Unenrollment Action Method.

Interaction Details: This section is used to capture details around customer interaction. See description above.

Summary

The **Summary** panel displays a summary of information related to the enrollment or unenrollment process, including:

- **Enrollment Task**: The Service Task used by the process and its current status
- **Customer Information**: Contact and identification for the customer, including the customer's Metered Service record
- **Program Information**: The program the customer will be enrolled in (or unenrolled from) and the start date or stop date (respectively)
- **Location Information**: The device location, including the customer's Metered Service Point
- **Interaction Details**: Customer interaction details from previous panels

Click **Finish** on the **Summary** panel to mark the process flow as Closed. Click **Cancel Process** to cancel the process.

Creating Program Service Calls Using Process Flow

Service call processing can be initiated, monitored, and maintained using the Process Flow portal and functionality. This allows users to step through a series of panels on which they enter information about the customer, their location, and other information. SeeAbout Service Calls for more information.

Service call process flows are initiated from the **Current Enrollment** zone of the **Customer Program Summary** portal.

When navigating between panels on the **Process Flow** portal, the **Next** and **Previous** buttons allow you to move to the next or previous panels in the process respectively. To save your progress and settings before moving on to the next panel, click **Save**. Click **Finish** on the **Summary** panel to mark the process flow as Closed. To cancel the process, click **Cancel Process**. This transitions the service task to the "Canceled" state. See Action Method in the *Administrative User Guide* for more information the process flow functionality,

Copyright © 2026, Oracle and/or its affiliates.

The following sections describe the content on the different panels used in service call process flows.

Customer

The **Customer** panel is used to specify data about the customer associated with the service call. This includes the following:

Customer Information: This section displays information about the customer, including:

- **Metered Service**: The customer's metered service record
- **Contact**: Name and contact information for the customer who initiated the service call

Location Information: This section displays information about the customer's location, including:

- **Metered Service Point**: The customer's metered service point

Interaction Details: This section is used to capture details around customer interaction. The information in this section is used to create Customer Communications. See About Contact Communications for more information.

- **Channel**: The channel used for the communication, such as email or phone
- **Class**: The class of the communication, such as enrollment, unenrollment, trouble report, and so on
- **Category**: The category of the communication, such as written or verbal
- **Notes**: Notes associated with the communication

Program Service Call

The **Program Service Call** panel is used to specify details related to the service call. This includes the following:

Service Call Details: This section is used to select the service task type and other information for the service call, including

- **Related Service Call**: A related program service call. This is used if the current service call is somehow related to a previous service call. This is used often when selecting either "Escalate" or "Resolved" actions (below).
- **Service Call Type**: The service task type to use for the service call.
- **Questionnaire**: A questionnaire applicable to the service call. Available questionnaires are defined on the service task type.

Questions: This section displays questions from the selected questionnaire (if applicable). This section is only displayed if a questionnaire is selected in the **Service Call Details** section.

Action Details: This section is used to specify details regarding the service call, including:

- **Category**: The category of the service call. Options include "Emergency" and "Non-Emergency".
- **Action**: The action to be taken for the service call. Options include:
  - **Create a Work Order**: Creates a work order based on a selected **Template Work Order**. Available template work orders are defined on the service task type.
    - **Template Work Order**: The template work order for work order activities created for this service call.
    - **Crew Shift Type**: The crew shift type for the work order.

Copyright © 2026, Oracle and/or its affiliates.

        - **Crew**: The crew for the work order.
        - **Work Order Activities**: A list of work order activity types based on the selected **Template Work Order**.
        - **Appointment Date**: The date on which field work based on the work activity type is scheduled to be performed. Select an appointment slot from the list of available appointment slots for the selected **Appointment Date**. The list of available appointment slots is based on the selected Template Work Order, Crew Shift Type, and Crew.
    - **Escalate**: Escalates an existing service call. Used with a **Related Service Call**. This creates a To Do Entry based on the the **Escalation To Do Type** defined on the service task type. The To Do Entry can be assigned to one of the To Do Roles defined for the **Escalation To Do Type** from the **Assigned to** drop-down list.
        - **Call Back Required**: Indicates (Yes or No) if the customer must be called back.
        - **Keep Service Call Open**: Indicates (Yes or No) is the service call should be kept open due to the escalation. When set to "Yes", the service task is kept in the "Escalated" state, and can be then selected as a "Related Program Service Call" in a future service call process flow.
        - **Assigned to**: The To Do Role to which To Do entries related to the escalated service call can be assigned.
    - **Resolved**: Resolves an existing service call. Used with a **Related Program Service Call**. Service calls with this action are closed when finished.

Interaction Details: This section is used to capture details around customer interaction. See description above.

Summary

The **Summary** panel displays a summary of information related to the service call, including:

- **Program Service Call**: The Service Task used by the process and its current status.
- **Customer Information**: Contact and identification for the customer, including the customer's Metered Service record .
- **Location Information**: Location information for the service call, including the customer's Metered Service Point.
- **Interaction Details**: Details related to customer interaction. See description above.

Click **Finish** on the **Summary** panel to initiate the action selected on the **Program Service Call** panel. Click **Cancel Process** to cancel the process.

Manually Completing Work Activities Using Process Flow

Work activities in Customer Program Management can be manually completed using the Process Flow portal and functionality. This allows users to step through a series of panels on which they enter completion information about the work activity, including asset installation and removal and service histories (if any) for the asset and activity. This process creates a set of completion events which are used to update the system as needed to reflect the completion of the work activity. See Understanding Completion Events for more information about completion events. When used with work activities associated with enrollment and unenrollment, the enrollment or unenrollment service tasks associated with work activities completed using this process are transitioned to an appropriate status, facilitating progression and completion of enrollment and unenrollment processes.

Copyright © 2026, Oracle and/or its affiliates.

Work activity manual completion process flows are initiated from work activities. Clicking **Initiate Completion** on work activities open the process flow portal. Note that this option is available only if the work activity's activity type has either an 'Update Asset' or a 'Create Any Service History' Completion Event Type (or both) defined, and the activity is in the "In Progress", "In Progress External", "Active", "Sent", or "Finished" state.

When navigating between panels on the Process Flow portal, the **Next** and **Previous** buttons allow you to move to the next or previous panels in the process respectively. To save your progress and settings before moving on to the next panel, click **Save**. Click **Finish** on the **Summary** panel to mark the process flow as Closed. To cancel the process, click **Cancel Process**. This transitions the service task to the "Canceled" state. See Action Method in the *Administrative User Guide* for more information the process flow functionality,

The following sections describe the content on the different panels used in work activity manual completion process flows.

Field Work Details

The **Field Work Details** panel is used to specify completion information related to the asset and location such as installation and removal of assets, as well as recording details for customer-owned assets. This includes the following:

Install Controllable Device: Completion details for an installation of or more controllable devices at the work activity's location.

- To add a controllable device for installation, enter an **Effective Date** for each device's installation and each device's **Serial Number** (and optionally **Manufacturer** and **Model** if the same serial number is used with different Manufacturers and Models). The **Comments** column indicates if the device is present in the system.

Remove Controllable Device: Completion details for an removal of or more controllable devices at the work activity's location.

- To add a controllable device for removal, enter an **Effective Date** for each device's removal and each device's **Serial Number** (and optionally **Manufacturer** and **Model** if the same serial number is used with different Manufacturers and Models). The **Comments** column indicates if the device is present in the system.

Customer Owned Asset: Completion details for recording relevant customer owned assets, such as HVAC components, solar panels, inverters, batteries, or other assets that were discovered by a crew at the work activity's location.

- To add a customer owned asset, enter an **Effective Date**, select the **Manufacturer**, select the model **Model**, and enter the **Serial Number** for each customer-owned asset. The **Comments** column indicates if the asset exists in the system.

A completion event will be created to update the system to reflect installation or removal of the controllable devices specified, and to create new controllable devices based on customer owned assets.

Click **Next** to move to the **Activity Service History** panel.

Activity Service History

The**Activity Service History** panel is used for entering completion information related to service history related to the work activity (if applicable). This includes the following:

Activity Service History: Details for service history information related to the work activity, including the **Service History Type** and corresponding details (such as Effective Date/Time, questions, and so on).

Copyright © 2026, Oracle and/or its affiliates.

- To enter activity service history completion information, select the **Service History Type**, enter the **Effective Date/Time**, and then populate other data fields as appropriate. Required service history types (those that must be completed) are marked with an asterisk (*).

> **Note**
>
> This section is visible only when the work activity has a **Planned Service History** of category "Inspection" and subclass "Questionnaire" and whose activity type has a 'Create Any Service History' **Completion Event Type** defined. Otherwise, this panel displays a "There is no Activity Service History to Complete" message.

For each service history updated on this panel, an appropriate completion event will be created to update the service history in the system.

Click **Next** to move to the **Asset Service History** panel. Note that you must provide details for all required service histories for the activity before moving to the next panel.

Asset Service History

The**Asset Service History**panel is used for entering completion information related to service history. This includes the following:

Asset Service History: Details for service history information related to the asset, including the **Service History Type** and corresponding details (such as Effective Date/Time, questions, and so on).

- To enter asset service history completion information, select the **Asset**, select the **Service History Type**, enter the **Effective Date/Time**, and then populate other data fields as appropriate.

> **Note**
>
> This section is visible only when the assets from the work activity **Asset List** and/or assets defined on the **Field Work Details** panel (in the **Install Controllable Device** and **Remove Controllable Device** sections) have associated service histories. Otherwise, this panel displays a "There is no Asset Service History to Complete" message.

For each service history updated on this panel, an appropriate completion event will be created to update the service history in the system.

Click **Next** to move to the **Summary** panel. Note that you must provide details for all required service histories for the activity before moving to the next panel.

Summary

The **Summary** panel displays completion events related to the work activity, including those defined on the **Field Work Details**, **Activity Service History**, and **Asset Service History** panels.

When initially opened, the Summary panel is empty. Click **Finish** on the **Summary** panel to create completion events based on details defined on the previous panels.

Completion events are created as follows:

Copyright © 2026, Oracle and/or its affiliates.

- A single completion even is created for the assets/devices defined on the **Field Work Details** panel.
- A completion event is created for each service history defined on the **Activity Service History** and **Asset Service History** panels.

These completion events can be viewed on the work activity that created the process flow.

Click **Close Out** on the work activity to execute the completion events and update the system as needed to reflect the completion of the work activity.

Using the Customer Program Summary Portal

The **Customer Program Summary** portal is used to view customer information, such as currently enrolled programs, programs the customer is eligible to enroll in, and program activity, such as specific events in which the customer participated.

To access the **Customer Program Summary** portal, select **Main**, select **Customer Program Management**, and select **Customer Program Summary**. Once you've selected this menu option, you're immediately brought to the initial tab of the portal.

The **Customer Program Summary** portal displays information about the customer on which you are currently working. This is customer currently “in context” or the customer most recently viewed on any of the following portals: **Controllable Asset**, **Device Location**, **Metered Service**, **Metered Service Point**, **Program Subscription**, or **Program Contact**, The **Customer Program Management Full Context Zone** dashboard zone also displays information about the customer currently in context.

The **Customer Program Summary** portal includes the following zones:

- **Current Enrollment**: This zone displays current program enrollment for the customer (for a single location). Each program enrollment is displayed in a separate **Information** box. Click **Unenroll** to unenroll the customer from a program. Click **Service Call** to initiate a service call for a program. Click **Opt Out** to navigate to a list of pending program events for the customer where you can select one or more events from which the customer wishes to opt out. Click **Schedule Unavailability** to navigate to a portal where you can define an unavailability period for a controllable device..
- **Customer Insights**: This zone displays any currently in progress service tasks and work activites related to enrollment or unenrollment. Options on this zone include:
  - **Go To**: Used to navigate to the Process Flow for the enrollment/unenrollment or to the work activity.
  - **Cancel**: Opens the **Cancel "In Progress" Service Task** window that allows the user to cancel the enrollment/unenrollment service task. This also creates a contact communication record as part of this.
  - **Reschedule**: Opens the **Reschedule "In Progress" Service Task** window. Allows the user to specify a new date for the start date of the program subscription. This also creates a contact communication record as part of this.
- **Eligible Programs**: This zone displays programs for which the customer is eligible based on currently installed devices (at a single metered service point). Click **Enroll** to enroll the customer in a program.
- **Customer Program Activity**: This zone displays the customer’s activity in the programs in which they are enrolled. This includes a graphic view of the percentage of successful vs. non-successful event participation (referred to “non-responsive device” or “NRD”), as well

Copyright © 2026, Oracle and/or its affiliates.

as a list of the events in which the customer participated, and other activity such as device installation.

Using the Program Dashboard

This portal is used to display the **Program Dashboard**.

To access this portal select **Main**, select **Dashboards**, and select **Program Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The **Program Subscription Trends** zone displays enrollments, unenrollments by period (week or month) as well as active subscription for that period. The x-axis displays the end date of the monthly or weekly period. The left y-axis shows the number of enrollments and unenrollments. The right y-axis shows the number of active program subscriptions. You can filter the data displayed using the following controls:

- **Time Scale**: Allows specifying the time scale of the graph is weekly or monthly.
- **Period View**: Allows specifying the range of data displayed, such as “Last X Weeks” or “Last Month” and so on.
- **Program Category**: Allows filtering the data based on a selected program category (such as “Device Control”)
- **Program**: Allows filtering the data based on a selected program.
- **Division**: Allows filtering the data based on a selected division.

Click **Configure** to navigate to the Program Dashboard Configuration master configuration. See Configuring the Program Dashboard in the *Administrative User Guide* for information regarding configuration of the dashboard.

Click **Capture** (next to **Snapshot Date/Time** in the lower right corner of the zone) to navigate to the **Statistics Control** portal where you can view a list of snapshots for the statistics control, and create a new snapshot if needed.

Using Unified Search with Customer Program Management

The Unified Search feature allows the use of the toolbar search field to search for business entities as well as to search for menu items. See **Search** for more information about the general use of the unified search field.

In Customer Program Management, the Unified Search field allows searching by a program subscription's contact (Name), address (Address), customer information system account ID (External Account ID), contact information such as a phone number or email address (Contact Information), or a controllable device's serial number (Serial Number).

You can use the following filters to indicate your specific search criteria:

Filter	Filter Rule
Name	Minimum of 5 characters excluding whitespaces
Address	One or more numeric characters followed by space and an alphanumeric character.
External Account ID	Up to 10 characters followed

Copyright © 2026, Oracle and/or its affiliates.

Filter	Filter Rule
Contact Info	Phone Number: Plus character and 1-3 numeric characters (country code, optional) followed by a space, period, dash or open parentheses, 3 numeric characters (area code), followed by a space, period, dash or close parentheses, followed by 3 numeric characters (exchange code), followed by a space, period or dash, followed by 4 numeric characters (subscriber number).] Email Address: Non-whitespace characters followed by an @ sign, non-whitespace characters, a period, non-whitespace characters
Serial Number	Minimum of 5 characters excluding whitespaces.

For example, to search for a program subscription located at 1401 Flower Street, you could enter “1401 Flower”.

To search explicitly using a specific filter, precede the filter value with one of the following predefined hints:

Filter	Hint	Example
Name	n:	n:Smith, J
Address	ad:	ad:1401 Flower
External Account ID	ac:	ac:1234567890
Contact Info	c:	c:555-2287 c:mbrazil@oracle.com
Serial Number	sn:	sn:678912

Examples:

- To search for a metered service point located at 1401 Flower Street, you could enter "ad:1401 Flower" (hint) or “1401 Flower” (no hint)
- To search for a contact named John Smith, you could enter "n:Smith, J" (hint) or “Smith,J” (no hint)
- To search for an external (CIS) account with an ID of ACCT01 you could enter "ac:ACCT01" (hint) or "ACCT01" (no hint)
- To search for a contact whose phone number is 555-2287 , you could enter "c:555-2287" (hint) or “555–2287” (no hint)
- To search for a controllable device whose serial number is 6789, you could enter "sn:6789" (hint) or “6789” (no hint)

Clicking the **Advanced Search** link opens the **Metered Service Query** portal and the **Metered Service Search** zone.

For information about configuring the Unified Search for your implementation, refer to **Understanding Unified Search** in the *Administrative User Guide*.

Search Results

Each result in the search result list may include any of the following:

- Name (highlighted when using the Name filter) or “No Person Information”
- Address (highlighted when using the Address filter) or “No Premise Information”
- External Account ID (highlighted when using the Account ID filter) or “No Account Information”

Copyright © 2026, Oracle and/or its affiliates.

- Contact Info (highlighted when using the Contact Information filter) or “No Contact Information”
- Controllable Device Info (highlighted when using the Serial Number filter)
- Filter Name and Search Criteria (always displayed)

To select an item from the search results, click the result. The **Customer Program Summary** portal opens displaying information for the selected result.

Using Service Order Management for Customer Program-Related Field Activities

This section provides information about using Service Order Management functionality for customer program-related field activities.

At a high-level, this process works like this:

1. A Program Enrollment or Program Unenrollment service task creates a service order field activity, based on configuration of the corresponding service task type.
2. The service order field activity creates an outbound communication to send the required information to the field work system.
3. When the field work is completed, the field work system sends a response and the system creates an inbound communication.
4. The inbound communications create completion events as defined on the field task type configured on the service task type.
5. After receiving the inbound communication, the service order field activity executes completion events, which update device location information as appropriate.

Refer to Service Order Overview and Understanding Service Order Management for more information about the service order management functionality.

> **Note**
>
> Customer Program Management does NOT use Service Order Activities (also referred to Orchestration Activities such as Enable Service, Disable Service and so on). Instead service order field activities are created by customer program service tasks.

See **Defining Customer Program Service Order Management Options** for information about configuring the system to support service order management.

Customer Program Service Order Field Activities

Service order field activities are specific types of tasks performed by field personnel. When used with Customer Program Management, examples include installing/removing controllable devices or performing a home energy assessment. Service order field activities are created when a service task includes required field work (based on the configuration of the service task type).

Refer to About Service Order Field Activities and Maintaining Activities for more information.

In addition to other data, customer program field activities are defined by the following:

- **Program Subscription:** The program subscription for which the activity was created.

Copyright © 2026, Oracle and/or its affiliates.

System Data

Customer program service order field activities are based on the following system data:

Data Type	Description
Maintenance Object	Activity (D1-ACTIVITY)
Business Object(s)	Field Activity (D1-FieldActivity)

Customer Program Outbound Communications

When communicating with field work systems, service order field activities create "two-way" outbound communications to send the required information to the field work system. Outbound communications create outbound messages which are routed to the field work system.

Refer to About Communication Out and Maintaining Communications for more information.

In addition to other data, customer program outbound communications are defined by the following:

- **Notes**: Any notes obtained by the customer service representative during the program enrollment, unenrollment or program service call
- **Transaction Id**: The Service Task ID for the program enrollment, unenrollment or program service call
- **Eligible Related Programs**: A list related programs for which the customer is eligible
  - **Program ID**: The ID of the related program
  - **Information:** A description of the related program
- **Program Location**: The device location associated with the field activity
- **Device Details**: A list of devices installed at the service point
  - **Equipment ID**: An external ID for the device
  - **Serial Number**: The device's serial number
  - **NIC Identifier**: The device's network identification number
  - **Manufacturer**: The device's manufacturer
  - **Model**: The device's model number
  - **Installation Date/Time**: The date and time at which the device was installed
  - **Device Type**: The device's device type
  - **Service History Information**: Valid service history types including the failure and down time information

    Comments: Additional information about the equipment's specific location

System Data

Customer program outbound communications are based on the following system data:

Data Type	Description
Maintenance Object	Communication Out (D1-COMMOUT)
Business Object(s)	Field Activity Outbound Communication (D1-FieldActivityOBComm)

Copyright © 2026, Oracle and/or its affiliates.

Customer Program Inbound Communications

When the field work is completed, the field work system sends a response to the outbound communication and the system creates an inbound communication.

Refer to About Communication In and Maintaining Communications for more information.

In addition to other data, customer program inbound communications are defined by the following:

- **Program Location**: The device location associated with the field activity
- **Device Details**: A list of devices installed at the service point
  - **Equipment ID**: An external ID for the device
  - **Serial Number**: The device's serial number
  - **NIC Identifier**: The device's network identification number
  - **Manufacturer**: The device's manufacturer
  - **Model**: The device's model number
  - **Installation Date/Time**: The date and time at which the device was installed
  - **Device Type**: The device's device type
  - **Action**: The action performed based on the field activity, such as "Attach" or "Detach".
  - **Comments**: Additional information about the equipment's specific location

System Data

Customer program inbound communications are based on the following system data:

Data Type	Description
Maintenance Object	Communication In (D1-COMMIN)
Business Object(s)	Field Activity Inbound Communication (D1-FieldActivityIBComm)

Customer Program Completion Events

Completion events are used to implement the outcome of an activity. They are created by the inbound communication and are executed by the service order field activity.

Refer to About Completion Events for more information.

System Data

Customer program completion events are based on the following system data:

Data Type	Description
Maintenance Object	Completion Event (D1-CEVT)
Business Object(s)	Update Controllable Device Location - FW Completion (X1-UpdateCDL)

Approvals

- About Approvals
- Maintaining Approval Requests
- About Change Requests
- Maintaining Change Requests

About Approvals

Approvals simplify the routing of work orders, purchase requests, timesheets, and other documents that require approval.

Approval requests use approval profiles to define the requirements for the approval:

- Who receives the approval
- Method for notifying the approver
- Which work calendar to use

When the approval request is submitted, the system sends a notification to all approvers defined on the approval profile according to the **To Do Roles** and the **Sequence** defined on the profile. Notifications can be sent using email, To Do List, or both, depending on the system notification settings.

Approvers can use the **Approval Dashboard** to manage the approvals that require their attention.

This section describes how various processes work together to manage approvals throughout the system.

Refer to Maintaining Approval Requests in the **Business User Guide** for information on maintaining approval requests.

Refer to Understanding Approval Processing in the **Administrative User Guide** for more information.

- Approval Profiles
- Approval Routing
- Outstanding Approvals at a Glance
- Approval Dashboard

Approval Profiles

Approval profiles are used to define the approval hierarchy within your organization and controls which approvers are required to approve the record.

Approval Profiles based on **To Do Roles** define:

Copyright © 2026, Oracle and/or its affiliates.

- the approvers level of authority to approve a document
- the types of documents the role can approve
- the working calendar to use when determining approval time lines and when to send To Dos
- dollar amount maximums that the role is authorized to approve

An approval profile can have one or many **To Do Roles** and it is possible for an approver to be assigned to more than one To Do Role in the same approval profile.

Depending on the notification setting designated on the approval profile, the approver can receive an email, an alert, or both in their **To Do List**.

> **Note**
>
> Individual approvers can choose to modify their notification settings for approvals. Navigate to the **User** portal and access the **Characteristic** tab to set the **Approval Profile E-Mail Override** setting to disable email notifications for approval requests. When this is set, the approver does not receive any emails and must rely on the approval dashboard or To Dos.

Approval Routing

The approval request, once submitted, is routed for approval based on the roles of the approvers and their approval decisions. For example:

- **One Standard Role**: If the approval profile consists of one To Do Role with mandatory or standard approval type, the users with that role receive the approval notification and any one of them can approve the request as long as the To Do Role has authority for the needed dollar amount.
- **Multiple Roles/All Standard**: If the approval profile consists of multiple To Do Roles and all are standard, any To Do Role can approve the request as long as they have the authority for the needed dollar limit.
- **Mix of Mandatory and Standard Roles**: If the approval profile consists of multiple To Do Roles with a mix of mandatory and standard, the users with mandatory must approve the request even if the standard approvers have authority based on the dollar limit or other factors. In other words, the mandatory approval role must take an action by agreeing or rejecting the request.
- **Request Time-out**: If approvers do not respond to the request within the time allotted by the time-out threshold, the system sends another notification to the approvers. If action is still not taken, the request moves to the next approval role, as applicable and the next role receives notification.
- **One Approver with Multiple Roles**: If one approver has multiple To Do Role s on one approval profile for the request, the system prompts that person to indicate which role they are approving. For example, approver Jon is in both the supervisor and manager To Do Roles. When an approval request comes in and Jon approves the request, a selection box opens to allow Jon to choose in which **To Do Role** the request is being approved . If Jon selects multiple approval requests to approve at once in the **Approval Dashboard** Jon may receive a warning to specify an **Acting To Do Role** before selecting an action. This means you must pick a role from the **Acting To Do Role** drop down and click **Search** to let the system know which role you are using to approve the requests.

Copyright © 2026, Oracle and/or its affiliates.

- **Insufficient Approval Amount**: If an approval request comes in for a record with a higher dollar amount than anyone on the approval path is authorized to approve, the requestor is notified that no one on the approval profile has sufficient authority. The requestor must choose a different approval profile and resubmit.
- **One Standard Role**: If an approver rejects the approval request, the request terminates and additional approvers on the approval path are not notified. The requestor is notified that the request has been rejected. Any approver in the route can reject and terminate the approval process regardless of their approval authority or limit amount. However, this does not apply for “notification only” approvers.
- **Not Authorized to Approve**: Some roles might be set as “not authorized to approve” but they still appear on the approval path. These approvers receive notification of the request and can approve or reject, but their decision is simply recorded for the next approver on the approval path to be aware of their decision. This setting is only applicable for an approval profile that is for no amount.
  If this type of approver rejects the request, the same processing applies as described for “one standard role”.

Outstanding Approvals at a Glance

The **Approval Dashboard** provides approvers with a quick glance, by document type, of the status of approvals that are currently due or are now past due. Approvers can then take appropriate action to reject or approve the requesting document.

Also, the system includes an **Approval Request Action** dashboard zone in the side dashboard which highlights any new approval requests that require the logged in user’s attention. The user can approve or reject the request directly from this dashboard, if desired.

Approval Dashboard

The approval dashboard provides a summary of approval requests that have been sent to the broad list of approvers with a breakdown of the approval profiles. This overview provides approvers with a simple summary of the records requiring their attention.

The summary list includes the counts of approval requests that have been sent out to any approvers that are not **Notification Only** and shows the current approvers and the mandatory future approvers. The list is broken down by document type and approval profile.

It is possible to filter the list by current or future approvers using the **Queue** field. The filter is used to distinguish current and future approval requests which may require the attention of the approver. For example, if an approver is about to go on vacation, they may want to take action on an approval request early. In this case the list can be filtered by “future” approval requests where this approver is not necessarily next in the approval route. This is a way for the approver to obtain a “preview” of requests that are coming from the route.

Broadcasting an individual line opens a zone where the approver can check off records and choose a button to make their approval decision (approve or reject). The approver can also click the link to open the approval request itself, and to open the individual record.

Note that the dashboard contents are specific to the logged in user, so one person may see a different list than another depending upon their approval authority.

Refer to About Approvals for more information.

Copyright © 2026, Oracle and/or its affiliates.

Work Order Approval Summarization and Work Request Approval Summarization

Work Order Approval Summarization and Work Request Approval Summarization use generative Artificial Intelligence (GenAI) models to compile and provide a summary of the approval. The specific information provided for each is as follows:

- **Work Request Approval Summarization**: A summary of the approval request and work request to help users understand the work to be performed. In addition, related possible-duplicate information and, when available, approval history information is displayed with the summary.
- **Work Order Approval Summarization** A summary of the approval request, work order, and activity information to help users understand the work to be performed. In addition, access to individual activity records requiring approval and, when available, approval history information is displayed with the summary.

Click the icon in **Summarize** column of the **Approval Detail List** zone to view the **Approval Summary**, which provides a summary of the requesting document and approval request, as well as some key observations.

See Enabling the Work Order and Work Request Approval Summarization Features for more information about enabling this feature for work orders and work requests.

> **Note**
>
> - Work Order Approval Summarization and Work Request Approval Summarization are available under Limited and Controlled Availability in approved regions.
> - Work Order Approval Summarization and Work Request Approval Summarization rely on generative AI models that must be deployed as part of your cloud service implementation. Please contact your Oracle Customer Success Manager if you wish to use Work Order Approval Summarization or Work Request Approval Summarization.
> - Work Order Approval Summarization and Work Request Approval summaries are prepared by generative AI. Carefully review and verify them against trusted sources, as they may include out-of-date, inaccurate, or incomplete information.

Maintaining Approval Requests

This portal is used to view and maintain approval requests.

Refer to About Approvals for more information.

You can access the portal from **Menu**, select **Home Page**, then select the **Approvals** tab. Broadcast the **Document Type** and then select the **Approval Request ID** hyperlink from within the **Approval Detail List** zone.

The **Approval Request** zone on the portal's **Main** tab page provides information about the approval request, including approvers, approval amounts, approval profile, etc.

About Change Requests

Change requests simplify the process associated with managing changes respective to assets, asset locations, vendors, vendor locations, stock items, stock item details, and any other records as appropriate.

Copyright © 2026, Oracle and/or its affiliates.

The **Change Request** portal controls the full cycle of the change request, from request creation, review, approval, application, and closure. The portal includes an **Original** zone, which holds all the original data elements, and a **Proposed** zone, which holds all the changed data. The updated data elements are saved as temporary until the change is approved.

When the change request is submitted for approval, the system sends a notification to all approvers defined on the approval profile according to the **To Do Roles** and the **Sequence** defined on the profile. Notifications can be sent using email, To Do List, or both, depending on the system notification settings.

Approvers can use the **Approval Dashboard** to manage the change request approvals that require their attention.

Refer to Maintaining Change Requests in the **Business User Guide** for information on maintaining change requests.

Refer to Understanding Change Request Types in the **Administrative User Guide** for more information.

- Change Request Approval Profiles
- Change Request Approval Routing

Change Request Approval Profiles

Change request approval profiles are used to define the approvers who are required to approve a change request record.

Approval Profiles based on **To Do Roles** define:

- the approvers level of authority to approve a record
- the types of documents the role can approve
- the working calendar to use when determining approval time lines and when to send To Dos

An approval profile can have one or many **To Do Roles** and it is possible for an approver to be assigned to more than one **To Do Role** in the same approval profile. Valid types of approval profiles include the following:

- Non-Amount Based
- No Approval Required

Depending on the notification setting designated on the approval profile, the approver can receive an email, an alert, or both in their **To Do List**.

> **Note**
>
> Individual approvers can choose to modify their notification settings for approvals. Navigate to the **User** portal and access the **Characteristic** tab to set the **Approval Profile E-Mail Override** setting to disable email notifications for approval requests. When this is set, the approver does not receive any emails and must rely on the **Approval Dashboard** or **To Dos**.

Change Request Approval Routing

The change request approval request, once submitted, is routed for approval based on the roles of the approvers and their approval decisions. For example:

Copyright © 2026, Oracle and/or its affiliates.

- If the approval profile consists of one **To Do Role** with mandatory or standard approval type, the users with that role receive the approval notification and any one of them can approve or reject the request.
- If the approval profile consists of multiple **To Do Roles** and all are standard, any valid **To Do Role** can approve or reject the request.

The approver is able to review the proposed changes and approve or reject the change request. Rejected requests can be resubmitted for approval once the issue is resolved. Once approved, a user can click the **Apply Changes** button to apply the change. This action completes the change request and updates the appropriate record.

Maintaining Change Requests

The **Change Request** portal is used to display and maintain a change request record.

Refer to About Change Requests for more information.

You can access the portal from **Menu**, select **Resource Management**, then select **Change Request**.

- If **Add** is selected:
  - Only a “Generic” change request can be created.

> **Note**
>
> Creation of any other type of change request must be on the change request associated record. Once on the associated record, user permissions drive who is able to create the change request. Users having full permissions can select **Edit** to make their changes or select the **Create Change Request** button directly from the **Dashboard**. Users having limited permissions can only create a change request by selecting the **Create Change Request** button directly from the **Dashboard**. Once the change request is created, users having full permissions can view the change request by going directly to the associated record and clicking the change request hyperlink from the zone on the **Dashboard**.

- If **Search** is selected:
  - User is brought to a query portal with options for searching for a specific change request. Once a change request has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Change Request**: This zone displays information about the change request, including the description of the change and any warning information.
- **Original**: This zone displays the original details of the request.
- **Proposed**: This zone initially displays original data. Selection of an **Edit** hyperlink enables the user to update the data to proposed values. This zone highlights the updated **Field** names and also the **List Headers** on the associated record if the content of the list has changed.
- **Attachments**: This zone enables users to manage all types of attachments for the change request record.

The following zones may appear as part of the portal's **Log** tab page:

Copyright © 2026, Oracle and/or its affiliates.

- **Change Request Log**: This zone displays log details for the change request.
- **Approval Request History**: This zone displays the approval histories for the request.

About Specifications

Specifications describe design details and functional performance criteria for a set of assets. This can include manufacturer, model, and other information specified for the assets.

Specifications may also contain written procedures, careful handling instructions for hazardous or delicate materials, or any other set of attributes needed to provide information about a set of assets.

The base package specifications provide a general starting point for your specification set-up including the following:

- General Maintenance Specification
- Operational Maintenance Specification
- Operational Device Specification
- Fleet Specification
- General Specification
- IT Specification
- Infrastructure Specification

In **Oracle Utilities Operational Device Management**

- Analog Meter Specification
- Communication Component Specification
- Communication Relay Specification
- Firmware Specification
- Smart Meter Specification

Implementers may want to include additional specification details. An example of how this can be accomplished using the fleet or vehicle specification would be to extend the data area *W1-VehicleDetail*. Specification detail values may also be extended by adding values to the following look-up fields:

- **MODEL_YEAR_FLG** - model year
- **VEHICLE_COLOR_FLG** - vehicle color
- **DRIVE_TYPE_FLG** - drive type
- **FUEL_TYPE_FLG** - fuel type

Some of the main uses for specifications are as follows:

- **Configuration Specifications** enable definition of different attributes on each device type.
- **Engineering Specifications** enable creation of Manufacturer, Bill of Material (BOM), and Model details for specific types of assets.
- **Preventive Maintenance Specifications** provide for the building and sharing of maintenance strategies between an asset or group of assets.

Specifications can be linked to stock items. This linking associates the stock items to the tracked assets that are also associated with the specification which allows the stock item to be

Copyright © 2026, Oracle and/or its affiliates.

used to track the asset. Only specifications with asset types configured with an ‘inventory controlled storeroom’ node type can be added.

Please note the following with regard to specifications:

- Specifications often include an attachment which supports the specification definition or provides the actual specification from the manufacturer.
- A specification may also include default *in service* and *out of service* maintenance schedules for assets or components linked to the specification. When the specification is associated with the asset or component, the related maintenance schedule becomes in effect for the asset or component.
- Firmware

Firmware

Firmware is software that is embedded in a piece of hardware and enables the hardware to work as the manufacturer intended. For example, commands to enable relay devices to automatically open and close.

Refer to About ODM Firmware for more information.

Maintaining Specifications

This portal is used to display and maintain specification records.

Refer to About Assets for more information.

You can access the portal from **Menu**, select **Asset Management**, then select **Specification**. You are brought to a query portal with options for searching for a specific specification. Once the specification has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Specification**: This zone provides details about the specification.
- **Specification Attributes**: This zone displays a list of attributes for this specification. The asset type defines valid attributes for specifications of this type. Press the **Edit** icon to add or change the attribute's value. Press the **Clear** icon to clear its value. Click the **Edit** link in the zone header to edit multiple attributes at one time.
- **Warranty Term**: This zone lists the warranty terms associated with the specification.
- **Specification Assets**: This zone provides information about the asset associated with the specification.
- **Attachments**: This zone enables users to manage all types of attachments for the specification record.

Oracle Utilities Rate Cloud Service

- Overview
- Setting Up Rates with Oracle Utilities Rate Cloud Service

Copyright © 2026, Oracle and/or its affiliates.

- Using Rate Check with Oracle Utilities Rate Cloud Service

Overview

Oracle Utilities Rate Cloud Service provides access to the rate calculation functionality of Oracle Utilities Customer Cloud Service. This includes the ability to configure and test rate calculations via the user interface, as well as the ability to trigger the rate calculation process from an external system.

This section describes the functionality provided with Oracle Utilities Rate Cloud Service.

Note: Oracle Utilities Rate Cloud Service supports rate calculation for traditional scalar or volume-based billing quantities only. It does not include capabilities for generating billing determinants from interval data input.

Setting Up Rates with Oracle Utilities Rate Cloud Service

Oracle Utilities Rate Cloud Service provides access to pages, portals, and zones used to create and maintain rates and rate configuration data, including:

- Bill Factors
- Bill Factor Values
- Calculation Groups
- Calculation Line Category Types
- Calculation Rules
- Rate Schedules

Refer to the Rates chapter of the *Business User Guide* for detailed information about setting up the above types of configuration data. Note: Some fields and options used with the above types of configuration data are not applicable when using Oracle Utilities Rate Cloud Service when compared to using Oracle Utilities Customer Cloud Service.

Using Rate Check with Oracle Utilities Rate Cloud Service

In addition to rate configuration functionality, Oracle Utilities Rate Cloud Service includes access to the Rate Check feature, which allows users to test their rates.

When using Rate Check, service quantities and characteristic types/values must be provided by the user and entered via the user interface. Oracle Utilities Rate Cloud Service does not support the use of the Rate Check feature based on service agreements, bill segments, or service points.

Refer to the Rate Check section in the **Rates** chapter of the *Business User Guide* for more information about using the Rate Check feature.

Oracle Utilities Billing Cloud Service

- Overview

Copyright © 2026, Oracle and/or its affiliates.

- Billing Cloud Service Functional Areas

Overview

Oracle Utilities Billing Cloud Service provides access to the billing functionality of Oracle Utilities Customer to Meter, which is the foundational component of Oracle Utilities Customer Cloud Service. This includes the ability to manage customer information, load validated measurement data, calculate billing determinants, configure and test rate calculations, calculate billing charges, aggregate billing related data.

Oracle Utilities Billing Cloud Service is intended for customers who

- May not require a full customer information system implementation
- Customers whose legacy customer information system does not support specific billing capabilities that they may now require such as net-metered billing, billing for electric vehicle charging events, advanced billing for specific customer segments (commercial or industrial), and so on.

This section describes the functionality provided with Oracle Utilities Billing Cloud Service.

Billing Cloud Service Functional Areas

This page outlines the functional areas available with Oracle Utilities Billing Cloud Service. The menus provided with Oracle Utilities Billing Cloud Service display only those menu items that correspond to capabilities that are available with the cloud service.

> **Note**
>
> Not all fields and field values available in Oracle Utilities Customer to Meter associated with these menu items are used with Oracle Utilities Billing Cloud Service.

The functional areas listed below are organized based on the main **Menu**.

- 360 Search
- Communication
- Control Central
- Customer Information
- Dashboards
- Data Synchronization
- Device
- Device Installation
- Financial
- Financial Query
- Initial Measurement Data
- Initial Measurement Snapshot
- Market Transaction Management

Copyright © 2026, Oracle and/or its affiliates.

- Process Flow
- Rates
- Service Task
- To Do
- Total and Trends
- Umbrella Agreement Management
- Usage
- My Preferences
- Tools
- Integration

Refer to specific chapter and sections in the *Business User Guide* for more information about working with these above listed functional areas.

Settlement

- Understanding Market Settlement
- Viewing and Managing Settlement Processes
- Settlement Calculations
- Settlement Item Market Participants
- Market Allocations

Understanding Market Settlement

Market settlement is the process of reconciling the difference between a supplier's energy purchases and its customer's usage. Suppliers purchase energy via bilateral contracts and day-ahead market transactions. Any differences between these purchases and supplier customer usage must be determined by the market and charged or credited at real time prices. The supplier's customer usage is not directly determined by the market, but by numerous other market participants that track customer supplier enrollments, aggregate customer usage to the supplier, and submit supplier's usage schedule to the market. This process is called load settlement, and is the primary purpose of Oracle Utilities Market Settlements Management.

The market participant responsible for load settlement can differ per market. For example, load settlement for a large portion of the Texas market is performed by an Independent System Operator (ISO) known as the Electric Reliability Council of Texas (ERCOT), whereas in the PJM market (encompassing Pennsylvania, New Jersey, and Maryland) load settlement is the responsibility of the Electric Distribution Company (EDC). While there are significant differences between markets in how load settlement is preformed, the high-level process steps are basically the same.

Load settlement starts with the bottom up aggregation of actual load or estimated load for individual customer accounts or service points. Distribution and transmission losses are added in to calculate an unreconciled load amount. The market determines the total generation

Copyright © 2026, Oracle and/or its affiliates.

supplied to a zone and the difference with the unreconciled load is referred to as Unaccounted for Energy (UFE). The UFE is then allocated to suppliers on a load ratio share basis.

The load settlement process is typically performed multiple times. The “preliminary” load settlement is done soon after the Operational Day and is often based on estimated load. The “final” load settlement is done around 60 days after the Operational Day, so that actual data has been received and customer bills issued.

- About Market Settlement Processing

About Market Settlement Processing

Market settlement is the process of deriving billing determinants to be used in supplier billing based on the results of a data aggregation processes.

The load settlement process also involves calculating imbalances. An imbalance is the difference between two load shapes representing different estimates of the same period, typically a scheduled load shape and an actual load shape. Imbalances are typically used when money has changed hands based on an estimate that has been improved or finalized by the settlement process. Because the second estimate has more accurate data, the allocations performed by the first process have to be modified.

Imbalance shapes can be further divided by applying bands and TOU components. Bands are error tolerances around zero that allow for differential pricing of the imbalance curve by how well or poorly the scheduled estimate matched the actual usage. Time of Use periods are often defined, allowing a higher penalty for faulty forecasting during higher-priced, on-peak periods. Whether an imbalance calculation is performed and how it is performed varies greatly from market to market.

The following sections provide details regarding some of the specific processing used in settlement processing.

- Importing Data
- Forecasting and Estimating Usage
- Aggregating Data
- Unaccounted for Energy (UFE) Calculations
- Allocating Load via Market Products, Awards, and Contracts

Importing Data

In addition to customer-level data such as meter readings or billed service quantities (which are used aggregation), settlement processing also involves other data that must be available to the application. For example:

- UFE calculations use both aggregated data and overall system, or zonal, load data
- Estimations and forecasting often use weather data
- Settlement billing requires pricing data

Data of these types can be imported into the system from external sources via a number of ways:

- For external sources that send data on a regular basis, data can be imported in a manner similar to how measurement data is received head end systems. See Processing Initial

Copyright © 2026, Oracle and/or its affiliates.

Measurement Data in this guide and Data Import - Message Driven Bean Configuration in the *Oracle Utilities Meter Solution Administrative User Guide* for more information.

- For external systems that send data upon request, data can be requested via measuring component data requests. Requests of this type can be either scheduled or performed manually. See Requesting Measurement Data in this guide for more information.
- For external systems that make data available for use but don't support sending the data directly, data can be imported manually in a comma separated values (CSV) format. See Uploading Measurement Data in this guide for more information.

Forecasting and Estimating Usage

Some settlement processes, such as initial settlement, often have to be performed before actual usage has been received or calculated for service points participating in the settlement market. In these cases, usage must be estimated, and in some cases, forecasted before aggregation and other settlement calculations can happen. A forecast is the term used when estimating usage data for future dates based on historical or profile data. Backcasting is the term used for estimating data for dates in the past. These can also be based on historical and/or profile data.

Two specific methods used for forecasting and backcasting include:

- **Profile Estimation**: This method uses profile data that represents typical usage for the service point to estimate usage. In some cases, profile data can also be adjusted based on scalar usage for the same service point.
- **Proxy Day Estimation**: This process compares data between measuring components to identify an historical day that most closely matches the date for which data is needed and uses data from that historical day to estimate usage

Aggregating Data

Aggregation involves summing real or assigned (profiled or deemed) interval data to a user-defined aggregation level for further processing. Aggregation may occur at a variety of levels for a variety of reasons, including reporting requirements and applying losses and other factors at an aggregated level up to the market participation level. Aggregation is typically used to build ground-up estimates of load for energy market participants for forecasting, scheduling, and settlement.

Aggregation is performed using the Dynamic Aggregation feature of the Oracle Utilities Meter Solution.

Aggregation Levels

Because aggregation involves summing up interval data to a specified level for processing, it's important to understand what is meant by the term "aggregation level" Put simply, an aggregation level is any point along the distribution chain to which entities below that point are summed. For instance, if you were going to sum up all the accounts that are related to a specific bus, that bus would be an aggregation level. Similarly, if you were going to aggregate all the energy used by all the accounts for a given Energy Service Provider (ESP), that ESP would be an aggregation level. In general, aggregation is usually performed at a level below you on the distribution chain from generators to end users.

The entities and/or market participants that serve as aggregation levels are specific to the particular area and market in which your utility is operating, but can include the following:

Copyright © 2026, Oracle and/or its affiliates.

Energy Service Providers (ESP)

Energy Service Providers (ESPs) sell power to customers. They may generate it and/or buy it from other sources. ESPs are also referred to as Retail Energy Providers (REPs) or simply suppliers.

Distribution Companies (DisCo)

A distribution company is responsible for the delivery of power to all customers in its service territory (Jurisdiction), regardless of who the customers have selected as their suppliers. The DisCo owns and operates the distribution lines that bring electricity into homes and businesses, and is responsible for metering, billing, and service calls. However, a DisCo may or may not be affiliated with a customer's power supplier. Distribution companies are also referred to as Operating Companies, Utility Distribution Companies (UDCs), or Local Distribution Companies (LDCs).

Schedule/Service Coordinators (SC)

Schedule Coordinators (or Service Coordinators) are responsible for creating schedules of energy usage that represent the estimated usage for a future time period (most often one day) for a given segment of the market. Schedules are most often based on results generated during the load profiling process, but can also be based on historical usage information and other data.

Independent System Operators (ISO)

An Independent System Operator (ISO) is a non-profit corporation that manages the regional power grid to coordinate the generation and transmission of energy. Its goal is to guarantee a safe and reliable power supply, and to ensure that all suppliers get nondiscriminatory access to the transmission system (while the ISO controls the power grid, commercial entities still own it). In the U.S.market, ISOs are regulated by the Federal Energy Regulatory Commission (FERC).

The various aggregation levels used in settlement processing are defined by Aggregation Groups, Measuring Component Sets, and Aggregation Measuring Components.

Aggregation Dimensions

In addition to aggregating data by aggregation levels, it is useful to be able to aggregate by other factors, such as customer class, voltage class, or loss class. These and other factors are referred as dimensions and are referenced on measuring component sets. Some common aggregation dimensions are described below. Note that these are provided as examples of common aggregation dimensions only.

Specific markets may require aggregation dimensions other than those listed here.

Customer Class

A customer class represents a 'type' of customer or account. Three common customer classes include residential, commercial, and industrial, but others are also prevalent. In addition, there may be multiple types of residential, commercial, or industrial classes, representing distinct types of accounts within each of those broad categories. For instance, residential customers might be divided into apartments, condominiums, and houses.

Voltage Class

A voltage class represents a group of customers or accounts based on the type of voltage used by the end users in that group. Voltage classes differ by market and region, but some common voltage classes include Transmission, Primary, and Secondary. Aggregating by voltage class is often performed for reporting purposes, to track usage of a given voltage type within the system.

Copyright © 2026, Oracle and/or its affiliates.

Loss Class

A loss class represents a group of customers or accounts based on the type of loss (transmission loss, distribution loss, etc.) associated with those accounts. Loss is often related to voltage levels, and so correlations between loss classes and voltage classes are common. Aggregation by loss class is used when calculating losses in the overall settlement process, and allows different loss calculation algorithms to be used with different loss classes, as appropriate.

Rate Class

A rate class represents a group of customers or accounts based on pricing. Rate classes can be based on a number of characteristics, including usage, territory, or even voltage type.

These and other dimensions are typically defined as attributes or characteristics of usage subscriptions, service points, devices, or measuring components.

- Applying Losses

Applying Losses

Markets typically operate using generation-level determinants, meaning that the individual metered entity data must be adjusted for system losses in order to compare the market participant load to the system load, market participant schedules, etc. Loss calculations can vary from simple to complex, ranging from an annual percentage by rate class or voltage level, to seasonal or time of use loss factors, to hourly dynamic loss factor calculations based on system conditions. Loss factors can be applied at the metered level or any aggregation level, as needed. In addition, losses can be applied to generators in markets where generation losses are calculated and used.

Applying losses to aggregated data is performed via value derivation algorithms. These are algorithms which apply a configured formula to aggregated measurement values. For instance, to apply a loss factor, an algorithm can retrieve effective-dated factor values for a loss factor and multiply each aggregated measurement value by the appropriate factor value. Value derivation algorithms can retrieve values from all types of factors, including multi-variable factors defined for settlement units. See Aggregation Calculation — Other Calculations for more information about how losses can be applied during data aggregation.

Unaccounted for Energy (UFE) Calculations

Unaccounted for Energy (UFE) is calculated by comparing the known system load to the sum of all market participant estimates from the estimation, aggregation, and loss adjustment processes. Because the market participant estimates will never perfectly match the system load, these estimates are fine-tuned by allocating a portion of the total UFE to each estimate. Allocation methods differ, but in general each market participant is allocated a portion of the system UFE for each hour based on the ratio of that particular estimate's load in that hour to the total of all estimated loads in that hour. This process forces the total of all estimates to match the system load. Some markets use different UFE allocation methods, including differential allocation of UFE to interval metered loads apart from profiled loads, and adjusting the profile methodologies to minimize UFE where possible.

UFE calculations are performed as part of the settlement calculation process, and can be performed using the Measuring Component Set Calculation Rule settlement calculation rule defined in a Bulk Settlement Calculation Group executed via the Measuring Component Set Calculation (D1-MCSCA) batch process.

Copyright © 2026, Oracle and/or its affiliates.

For smaller markets, UFE calculations can be performed using a chained sequence of Array Math and Vector and Service Quantity Math settlement calculation rules. At a basic level, this sequence looks like this:

1. Sum the market participant load from aggregation results (using Array Math)
2. Subtract the market participant load from the system load to derive the total UFE for the calculation period (using Vector and Service Quantity Math)
3. Allocate the total UFE to the various market participants as appropriate (using Array Math)

> **Note**
>
> The results of UFE calculations are also used in other settlement calculations. These three steps represent part of a larger set of calculations.

Allocating Load via Market Products, Awards, and Contracts

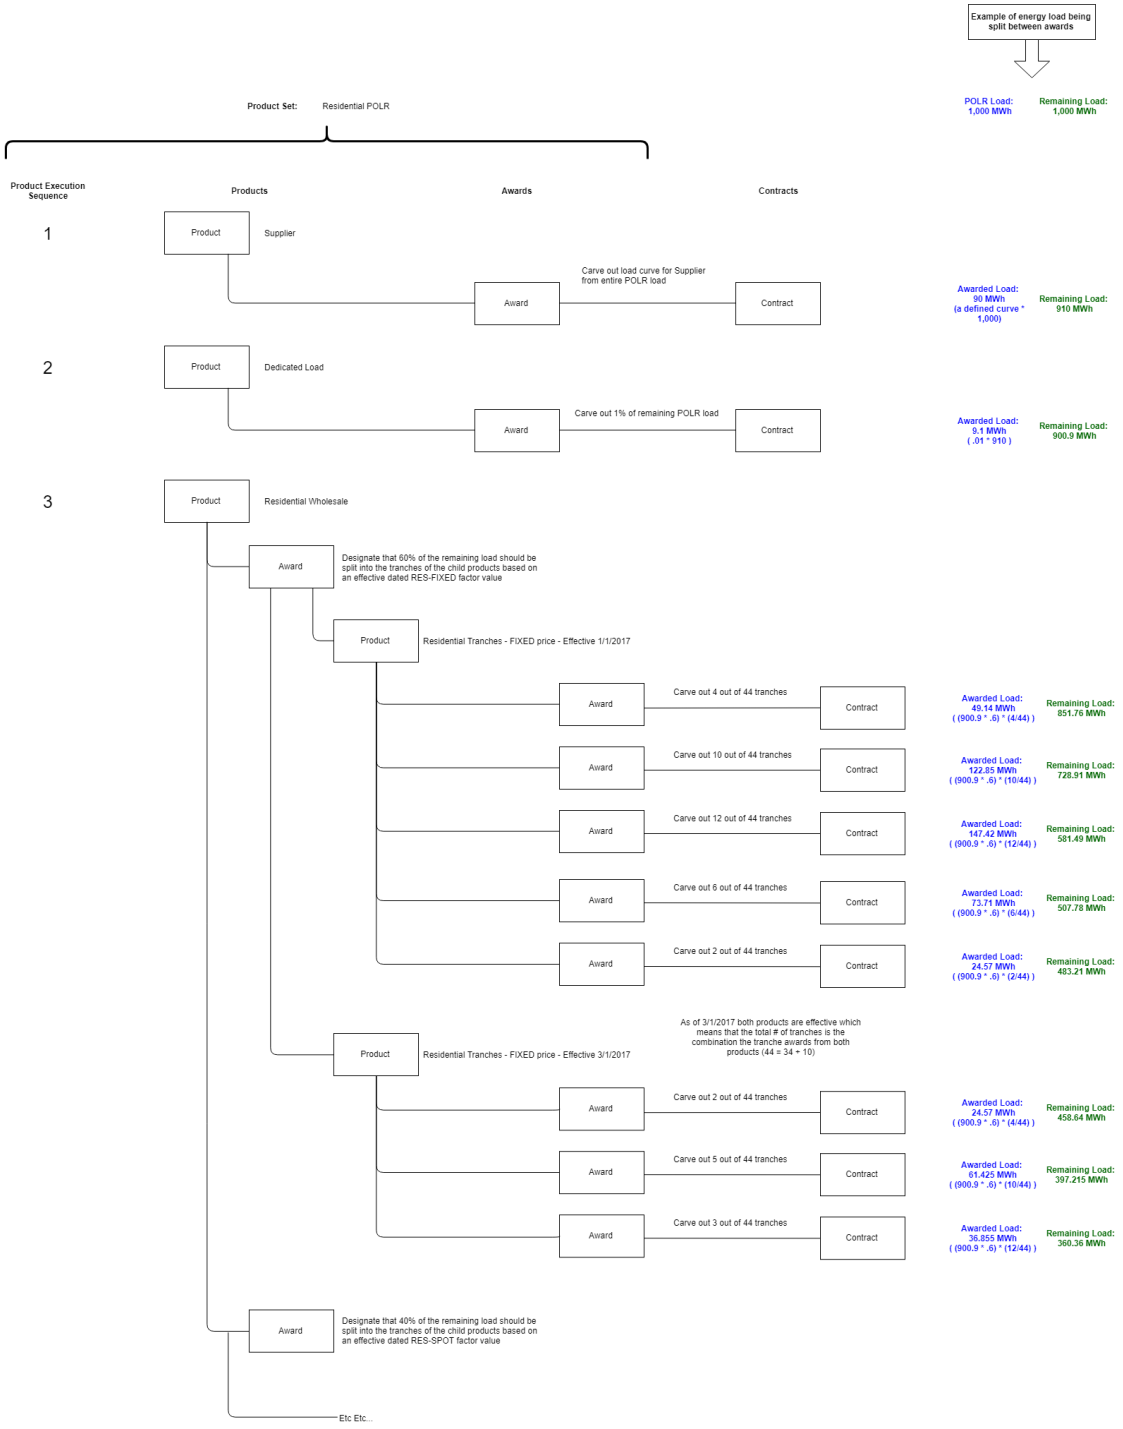
Distribution companies operating in deregulated markets are often designated as the Provider of Last Resort (POLR) for customers that either have not selected a supplier or have been dropped by a supplier. If allowed by legal and market rules, the distribution company can elect to outsource the responsibility of supplying POLR load to qualified wholesalers.

The POLR consumers will still, either directly or indirectly, receive bills for distribution services from and pay the distribution company, but the wholesaler takes responsibility for procuring and serving the POLR load, for which they receive payments from the distribution company.

A simple example of the POLR allocation process might involve the following steps:

1. Subtract all other suppliers from the zonal load to get the remaining POLR load.
2. Allow for the distribution company to separate out any owned generation.
3. Divide POLR load amongst awarded wholesale contracts.

Details of these transactions would be sent to the market operator by contract ID.



These awards of POLR load can be defined in the application by Market Products (which belong to a Market Product Set), Market Awards, and Market Contracts.

To elaborate on the example above, a market product set might the following set of market products:

- A product and award to carve out load from the POLR load for one or more suppliers. This would be a “Fixed Profile” award.
- A product and award to carve out a percentage of the remaining POLR load for owned generation. This would be a “Percentage” award.
- A product and awards that distribute the remaining POLR into various bundles of tranches (chunks of load) to wholesalers. These would be “Tranche” awards.

The following diagram illustrates the way in which this distribution would work.

Copyright © 2026, Oracle and/or its affiliates.

The Market Award Allocation settlement calculation rule is used to perform the allocation of load the designated market products and awards. This rule is part of a larger settlement calculation process, using settlement quantities (the POLR load) calculated by other rules (such as Array Math and Vector and Service Quantity Math). The Market Award Allocation rule allocates those quantities to the products within a specified Market Product Set, and saves the results for export to the appropriate market participants.

Viewing and Managing Settlement Processes

You can use the Process Flows feature of the Oracle Utilities Application Framework to create, view, and manage settlement processes. See Process Flows in the *Oracle Utilities Application Framework Administrative User Guide* for more information.

Settlement Calculations

- About Settlement Calculations
- Settlement Subscriptions
- Settlement Transactions
- Settlement Items
- Settlement Item Quantities
- Settlement Billed Usage

About Settlement Calculations

Oracle Utilities Market Settlements Management can calculate and publish settlement results calculated from aggregated data to market participants on an ongoing basis. Settlement calculations derive a settlement transaction's service quantities using the aggregated measurement associated with one or more market participants.

Before settlement results can be calculated, you must first create a Settlement Subscription. The settlement subscription defines the external system to which the data should be sent as well as the settlement calculation groups that will be used for calculation. The settlement calculation rules defined for the settlement calculation groups are responsible for performing the specific calculations, validations, or estimations for settlement results.

Settlement service quantities are derived from aggregated measurement data the calculation period.

The results of all calculations performed by settlement subscriptions are stored as a Settlement Transaction.

The settlement calculation process has a number of different objects that are detailed below that allow for configurability and flexibility in how the process executes.

Settlement Calculation Groups

Settlement calculation groups are collections of settlement calculation rules that are used to calculate service quantities for market participants. During the settlement transaction process, the system executes the settlement calculation rules defined in the settlement calculation group referenced on the settlement subscription. The rules within a settlement calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

For information on configuration, reference the related section for Configuring Settlement Calculation Groups in the Administrative User Guide.

Settlement Calculation Rules

The specific calculation processing performed on a settlement transaction is defined in individual settlement calculation rules, each performing a specific set of targeted logic. The base product contains many settlement calculation rules you can use in your implementation, but you can also create your own custom settlement calculation rules. Many settlement

Copyright © 2026, Oracle and/or its affiliates.

calculation rules are identical to usage calculation rules used by Oracle Utilities Meter Data Management

For a list of validation settlement calculation rules, reference the About Usage Validations section. For a list of estimation usage calculation rules, reference the About Usage Estimations section. For a list of all other usage calculation rules that handle calculation of bill determinants, reference the Inventory of Other Usage Calculation Rules section.

For information on configuration, reference the related section for Configuring Settlement Calculation Rules in the Administrative User Guide.

Settlement Transaction Exceptions

Each settlement calculation rule defines an exception type and severity that specify how exceptions are tracked by the system. When a settlement transaction fails some part of a settlement calculation rule, an exception of the type specified for the failed settlement calculation rule is created. A single settlement transaction can have multiple exceptions, one (or more) for each rule that failed. This allows users to see all of the problems detected during the settlement calculation process.

There are three levels of severity for settlement transaction exceptions:

- **Information**: Used to highlight minor issues, but not sufficient to cause the settlement transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues**: Used to report a problem that will prevent the settlement transaction from being exported. Multiple "issue exceptions" can be created during settlement transaction processing. If at least one issue exists after all rules have been applied, the settlement transaction is transitioned to a failure state requiring review and approval.
- **Terminate**: Used to report a severe issue that will cause the settlement calculation process to stop and the settlement transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a settlement transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full settlement period should always be set to Terminate as an Exception Severity.

Note that exceptions are not deleted when a settlement transaction is adjusted or corrected. After any issues are corrected or the settlement transaction is overridden (or manually completed), the exceptions persist in a closed state for reporting purposes.

In addition to exceptions, settlement processing can also trigger the creation of To Do Entries related to issues. If Issue or terminate exceptions exist for an initial measurement, a To Do Entry is created when the settlement transaction is transitioned to the Exception state. The To Do Type and default To Do Role of this To Do Entry are defined on the Enter system event for the Exception state of the business object used to define the settlement transaction.

To Do Entries created in this way can be routed to different roles depending on the exception's message category and number (using the To Do Type's Message Overrides tab).

For information on configuration, reference the related section for Configuring Usage Transaction Exception Types in the Administration Guide.

Settlement Calculation Rule Eligibility Criteria

Settlement calculation rule eligibility criteria are user-definable conditions that could cause a given settlement calculation rule to be applied or skipped. This can involve the evaluation of some attribute of the settlement subscription or something else entirely. A settlement calculation rule can have multiple eligibility criteria for determining if the rule should be applied

Copyright © 2026, Oracle and/or its affiliates.

or skipped, based on a user-defined sequence. Eligibility criteria for settlement calculation rules works in the same manner as eligibility criteria for usage calculation rules used by Oracle Utilities Meter Data Management.

For information on configuration, reference the related section for Configuring Usage Calculation Rules in the Administrative User Guide.

Settlement Calculations and Anchor Time

Settlement calculation processing supports calculations based on an "Anchor Time". The Anchor Time is specified on certain measuring component types and defines the start and end time of the business day for purposes of processing settlement transactions. When processing settlement calculations based on dynamic aggregation measuring components whose type specifies an **Anchor Time**, the Start Time and End Time of the calculation period should match the **Anchor Time** on the dynamic aggregation measuring component type.

Note: When processing calculations for measuring components whose type specifies an **Anchor Time**, if the Start Time and End Time of the calculation period do NOT match the **Anchor Time** on the measuring component type, the Start and Stop Time are shifted to align with the closest time to the **Anchor Time** that aligns with the interval size of the measurement data being processed. The Start Time is shifted backwards (to an earlier time) and the End Time is shifted forwards (to a later time). In the case of hourly intervals with Start Times and End Times on the hour, no shift occurs. In the case of daily intervals, the shift is to the nearest Anchor Time. For example, in the Anchor Time is 07:00AM but the Start Time and End Time are both 12:00, the Start Time would be shifted to the previous 07:00AM, and the End Time would be shifted the next 07:00AM.

Settlement Subscriptions

- About Settlement Subscriptions
- Maintaining Settlement Subscriptions

About Settlement Subscriptions

Settlement subscriptions track the ongoing need to calculate a set of data, often aggregated load, for the purpose of settling a market and send the results to a recipient.

Settlement subscriptions must reference the following:

- **Recipient**: The identity of the subscribing system. In other words, you must set up a recipient for any system that subscribes to settlement calculations.
- **Settlement Calculation Groups**: The calculation groups used to perform settlement calculations for settlement transactions based on this settlement subscription. Settlement calculation groups can be configured in a specific sequence of execution. In addition, each group can be configured to require approval before the calculation execution proceeds to the next calculation group.

Settlement subscriptions can also reference the following;

- **Factor Overrides**: One or more factors can be used as override values when performing calculations
- **Measuring Components**: One or more measuring components directly linked to the settlement subscription. These are most often aggregation measuring components, but can also include profile measuring components.

Copyright © 2026, Oracle and/or its affiliates.

- **Measuring Component Sets**: One or more measuring component sets directly linked to the settlement subscription.

Maintaining Settlement Subscriptions

You use the portal **Settlement Subscription** portal to view and maintain settlement subscriptions.

Refer to About Settlement Subscriptions for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Subscription**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Subscription**: This zone displays basic information about the settlement subscription, including factor overrides, settlement calculation groups, measuring components and measuring component sets.
- **Settlement Transaction**: This zone displays a list of settlement transactions for the settlement subscription.

Settlement Transactions

- About Settlement Transactions
- Settlement Transaction Communication
- Maintaining Settlement Transactions

About Settlement Transactions

Settlement transactions are records of calculations for a settlement subscription. All of the service quantities calculated are stored as part of the settlement transaction.

Settlement Calculation Group Determination

The first step in settlement calculation is to determine the settlement calculation group holding the rules set used in calculating or validating the calculations. There are two ways of configuring the settlement calculation group to use in the processing. It may be specified on the settlement subscription during its creation with an effective and expiration date. If there are no settlement calculation groups in effect for the settlement transaction, the **Fallback Settlement Calculation Group** specified in the settlement subscription type will be used.

Calculation Period

Settlement transaction requests must specify the date range for the settlement transaction. This date range is referred to as the calculation period for the settlement transaction.

Date Breaks

Date breaks are used to break up a settlement period into sub-periods based on the dates on which changes took place for market participants. One approach to this situation would be for the system to crate settlement transactions (where each has the desired date range). Another

Copyright © 2026, Oracle and/or its affiliates.

approach is for the system to create single settlement transaction with date breaks that define the date ranges before and after the change.

If a settlement transaction has date break(s), the settlement calculation engine segregates the usage into multiple calculation periods based on the date breaks. If there are no date breaks in the settlement transaction, a single calculation period is created for the entire calculation period.

Service Quantities

Every settlement period created for a settlement transaction contains one or more service quantities. Service quantities are calculated by the settlement calculation group's rules specified for the settlement subscription from which the settlement transaction is created. For example, a settlement transaction might have quantities calculated by a single rule that applies a TOU map to aggregated kWh .

Each service quantity lists details about that quantity, including a UOM (or TOU or SQI as appropriate) and a quantity. In addition, each service quantity also references the source (measuring component) of the quantities (for audit purposes).

Quality Assessment

The Get Interval Data, Get Scalar Details, and Get Time of Use Mapped Usage calculation rules include a "Perform Measurement Quality Assessment" option that indicates (yes or no) if the measurement conditions of the measurements used when calculating usage should be evaluated and included in the resulting settlement transaction and outbound message. When enabled (set to "Yes"), the calculation rule algorithm evaluates the condition codes of the measurements used in the calculation to determine if they fall within a "Regular" range of conditions (this range is defined by the "Bottom Regular Condition Range" and "Top Regular Condition Range" algorithm parameters). The result of this assessment is displayed in the "Data Quality Assessment" column in the Calcuatio0n Periods section which indicates if the service quantity is based on "regular" or "non- regular" data. (If the "Perform Measurement Quality Assessment" option is disabled, the "Data Quality Assessment" column displays "No Assessment Done). In addition, the "Source Measurement Quality List" column contains XML that contains a list of measurements aggregated by condition/quality.

Validations

As settlement transactions are created and move through their various states, several validations are performed to ensure proper processing. These include:

- Validating the business object used to create the settlement transaction
- Validating the start and end dates for the settlement transaction
- Validating the settlement transaction’s service quantities
- Validating the existing settlement transactions for the same calculation period
- Validating whether or not the settlement transaction can be deleted

Creating Settlement Transactions Using Batch Processing

The Create Scheduled Settlement Transaction (D1-CSST) batch process can be used to generate settlement transactions based on a scheduled timetable.

The schedule for creating settlement transactions is defined based a Processing Timetable Type defined on the settlement subscription type. The process uses the details in the Processing Timetable Type (and its **Execution Frequency Class**) to determine the settlement transaction start and end dates. **Execution Frequency Class** options include:

Copyright © 2026, Oracle and/or its affiliates.

- **Daily**: The process runs based on the **Scheduling Information** parameters defined in the Processing Timetable Type .
- **Defined Dates**: The process runs for the most recent period defined in the **Processing Dates** section of the Processing Timetable Type that falls before the Batch Business Date. (but after the **Start Date** on the settlement subscription)

The business object to use for creating settlement transaction(s) is based on what is configured on the settlement subscription type. If there is no processing timetable type specified on a settlement subscription type, it will be skipped.

By default the process creates settlement transactions for all settlement subscription types. The optional "Restrict by Settlement Subscription Type" (restrictBySettlementSubType) parameter can be used to restrict processing to a specific Settlement Subscription Type.

Refer to Processing Timetable Types for more information about processing timetable types.

Settlement Transaction Communication

Upon completion of calculations (or approval of calculations if the approval is required), settlement transaction results can be exported and sent to market participants This is done via an outbound communication created by the Create Settlement Transaction Outbound Communication algorithm. This communication is responsible for deriving and gathering the appropriate data to send to the market participant and creating and sending an outbound message.

There are two many ways in which settlement transactions are sent:

- **Contract**: Sending by contract involves sending the results of a settlement transaction to a recipient (such as an ISO) using an identifier from the market contract.
- **Identifier**: Sending by identifier involves sending the results of a settlement transaction to a recipient using an identifier from the market participant.

Communication Types

The type of outbound communication created is based on the **Outbound Communication Type** defined on the settlement transaction's settlement subscription type. Communication types define the following about settlement transaction outbound communications:

- **Communication Flow**: The direction of communications based on this type (outbound or inbound).
- **Suppress Zeros**: Designates whether or not data should be sent for a service quantity of 0.
- **Message Generation Method**: Specifics if messages be sent as a single message to the market or broken down to one message per Identifier/Contract.
- **External Communication Type**: Defines whether the communication type is "Settlement by Contract" or "Settlement by Identifier".
- **Export Data Identification**: Defines combinations of UOM/TOU/SQI that represent the final outcome of the settlement transaction to be passed to the market
- **Reconciliation**: Defines the appropriate identifier or contract to include in the data sent to the market participant:
  - **Contract Reconciliation**: defines the appropriate identifier for the market contract associated with the service quantity. Used when sending data by contract.

Copyright © 2026, Oracle and/or its affiliates.

- **Identifier Reconciliation**: Defines the characteristic type for the market participant used to retrieve the appropriate identifier. Used when sending data by identifier.

- **Exception Handling**: Defines how exceptions are handled, including To Do Type and Role, Retry Frequency, and the maximum number of times the system will retry to process the communication

Retrieving Service Quantities

Once created, the outbound communication retrieves a list of service quantities for the settlement transaction and inserts the details into the Settlement Transaction Details list. The specifics of how this is done is based on whether the settlement transaction is sent by contract or by identifier.

Send Settlement Transaction By Contract

Sending data by contract uses outbound communications based on the Send Settlement Transaction by Contract business object. The Retrieve Settlement Transaction SQs Contract algorithm retrieves the list of service quantities that match the UOM/TOU/SQI combination defined on the communication type, and for each service quantity found that has a market contract it will retrieve the identifier for that contract and populate the appropriate details into the Settlement Transaction Details list. The algorithm processes the entire service quantity result set even if it cannot find an identifier for a given contract. This way a user can see all identifier resolution errors at once (instead of needing to fix them one by one to see the next error).

Send Settlement Transaction By Identifier

Sending data by identifier uses outbound communications based on the Send Settlement Transaction by Identifier business object. The Retrieve Settlement Transaction SQs for Identifier algorithm extracts the market participant from the attributes associated to the service quantity's measuring component. The measuring components that will be associated to the service quantity in this instance will be aggregation measuring components that hold a list of dimensions that incudes a market participant. The algorithm then retrieves the list of service quantities that match the UOM/TOU/SQI combination defined on the communication type and for each service quantity found that has a measuring component, it retrieves the measuring component's market participant and then retrieve the identifier for that market participant and populate the appropriate details into the Settlement Transaction Details list. The algorithm processes the entire service quantity result set even if it cannot find a market participant or an identifier for a given market participant. This way a user can see all identifier resolution errors at once (instead of needing to fix them one by one to see the next error).

- Sending Settlement Transactions to Market Participants

Sending Settlement Transactions to Market Participants

After the outbound communication has retrieved the appropriate service quantities, the outbound message creates an outbound message to the market participant (defined as the **Recipient** on the settlement transaction's settlement subscription or settlement subscription type).

The Send Settlement Transaction Details algorithm creates one more outbound messages based on the outbound message type defined for the market participant's Settlement Transaction Notification processing method (see below for more details).

- If the **Message Generation Method** on the communication type is set to "One Comprehensive Message" the outbound communication creates a single outbound message that contains all the service quantities retrieved.

Copyright © 2026, Oracle and/or its affiliates.

- If the **Message Generation Method** on the communication type is set to “Multiple Messages Based on Data” the outbound communication creates a separate outbound message for each of the service quantities retrieved.

Configuring Market Participants for Settlement Transaction Communication

To support sending settlement transactions to market participants, the following processing method must be defined for the market participants to which settlement transactions are sent:

Processing Role	Processing Method
Settlement Transaction Notification	How to Send Settlement Subscription Related Information Used to send a settlement transaction outbound message to a market participant. **Default Outbound Message Type**: The default outbound message type to create for outbound message sent to market participants. The base package does not include an outbound message business object for this. This must be created based on the requirements of each implementation and market participant. If appropriate, override outbound message types can be defined for specific settlement subscription types.

In addition, the following objects must be configured to send data requests:

- External System
- Outbound Message Type
- Message Sender

`

Maintaining Settlement Transactions

You use the portal **Settlement Transaction** portal to view and maintain a settlement transactions.

Refer to About Settlement Transactions for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Transaction**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Transaction**: This zone displays basic information about the settlement transaction, including processing information and settlement calculation groups.
- **Outbound Communication**: This zone displays a list of outbound communications sent for the settlement transaction.
- **Calculated Data Overview**: This zone displays an overview of calculated data related to the settlement transaction.
- **Calculated Data Details**: This zone provides ability to query the detailed service quantity interval data for the settlement transaction.

A number of important actions are available for a settlement transaction depending on its status:

Copyright © 2026, Oracle and/or its affiliates.

Action	Allowed Statuses	Details
Approve	Approval In Progress Issue Detected (only when the exceptions are marked to require approval)	Allows a user to bypass any exception or failure message for the settlement transaction and attempt to send it to the requesting system.
Calculate	Approval In Progress Pending	Allows a user to trigger settlement calculations.
Discard	Approval In Progress Export Error Issue Detected	Allows a user to discard the settlement transaction.
Export	Export Error	Allows a user to transition the settlement transaction to the Export status and send the settlement transaction to the recipients.
Export Manually	Export Error	Allows a user to manually export the settlement transaction send it to the recipients.
Override Exception	Issue Detected	Allows a user to override an exception and transition the settlement transaction to the Override Exception state.
Re-Calculate	Issue Detected	Reruns the entire process of calculation along with any validations (all settlement calculation rules) for the settlement transaction.
Supercede	Completed	Allows a user to indicate that the settlement transaction was corrected after being sent. Sets the status of the settlement transaction to Superceded.

Batch Processing

The Create Scheduled Settlement Transaction (D1-CSST) batch process can be used to generate settlement transactions based on a scheduled timetable. Refer to Creating Settlement Transactions Using Batch Processing for more information about this batch process.

Settlement Items

- About Settlement Items
- Maintaining Settlement Items

About Settlement Items

Copyright © 2026, Oracle and/or its affiliates.

Settlement items represent end customer accounts. These are market participants for which settlement calculations are performed, and generally correspond to the market participants which subscribe to settlement calculation results via settlement subscriptions.

Settlement items are defined by the following:

- **Settlement Item Type**: The Settlement Item Type for the settlement item, which defines the business object to use to create the settlement item, the business object to use to capture billed usage for a settlement item (via Settlement Account Billed Usage), and valid service point types.
- **Division**: The division to which the settlement item belongs
- **Access Group**: The access group to which the settlement item belongs (used to limit access to records)
- **Status**: The status of the settlement item
- **Start Date/End Date**: The date range during which the settlement item is active.
- **Main Contact**: The main contact for the settlement item.
- **Time Zone**: The time zone in which the settlement item is active.
- **Measuring Components**: One or more measuring components directly linked to the settlement item. These are most often aggregation measuring components, but can also include profile measuring components.
- **Rate Class**: One or more effective-dated rate classes for the settlement item.

Maintaining Settlement Items

You use the portal **Settlement Item** portal to view and maintain a settlement items.

Refer to About Settlement Items for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item**: This zone displays basic information about the settlement item, including related service points and measuring components.
- **Settlement Item Quantities**: This zone displays a list of settlement item quantities. See About Settlement Item Quantities for more information. To add a new quantity, for the settlement item, click **Add** in the zone title bar.
- **Settlement Item Market Participants**: This zone displays a list of settlement item market participants for the settlement item, via a Settlement Item Market Participant. To add a new market participant for the settlement item, click **Add** in the zone title bar.
- **Characteristics**: This zone displays a list of characteristics related to the settlement item.
- **Identifiers**: This zone displays a list of identifiers used with the settlement item.
- **Interval Measurements**: This zone displays a list of interval measurement data snapshots associated with the settlement item. To add a new interval measurement data snapshot for the settlement item, click **Add** in the zone title bar.
- **Scalar Measurements**: This zone displays a list of scalar measurement data snapshots associated with the settlement item. To add a new scalar measurement data snapshot for the settlement item, click **Add** in the zone title bar.

Copyright © 2026, Oracle and/or its affiliates.

Settlement Item Quantities

- About Settlement Item Quantities
- Maintaining Settlement Item Quantities

About Settlement Item Quantities

Settlement item quantities are quantities that are stored at the settlement item level. These quantities are calculated at irregular frequencies (such as annually or quarterly) and thus do not make sense as a measured quantity on a device and measuring component. For example, in some deregulated markets the Peak Load Contribution could be stored here and effective dated over time to represent the changing contribution of a given settlement item to the market wide coincidence peaks.

Settlement item quantities are defined by the following:

- **Settlement Item**: The settlement item for which the quantities were calculated
- **Settlement Item Quantity Type**: The Settlement Item Quantity Type used for the record
- **Start Date** / **End Date**: The date range for the calculated quantity
- **Settlement Item Quantities**: Calculated quantities based on **Settlement Item Quantity Identifiers** configured on the Settlement Item Quantity Type (see Understanding Settlement Item Quantity Types for more information)

> **Note**
>
> There cannot be more than one Settlement Item Quantity for the same Settlement Item and Settlement Item Quantity Type, for the same time period (defined by the Start Date and End Date parameters).

Maintaining Settlement Item Quantities

You use the **Settlement Item Quantity** portal to view and maintain settlement item quantities.

Refer to About Settlement Item Quantities for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item Quantity**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Quantity**: This zone displays the basic attributes of the settlement item quantity

Settlement Billed Usage

- About Settlement Billed Usage

Copyright © 2026, Oracle and/or its affiliates.

- Maintaining Settlement Billed Usage

About Settlement Billed Usage

Settlement billed usage represents billed usage for a settlement item. Settlement billed usage is calculated via settlement calculations performed for the settlement subscription associated with the settlement item. Settlement billed usage typically corresponds to settlement transactions.

Settlement billed usage records are defined by the following:

- **Settlement Item**: The settlement item for which the billed usage was calculated
- **Start Date/Time**: The date and time of the start of the billing period for the billed usage
- **End Date/Time**: The date and time of the end of the billing period for the billed usage
- **Billed Usage Periods**: one or more billed usage periods for the current settlement billed usage. A billed usage period is a period of time for which usage is calculated, including details calculated for each billed usage period such as UOM/TOU/SQI and quantities

Maintaining Settlement Billed Usage

You use the portal **Settlement Billed Usage** portal to view and maintain settlement billed usage.

Refer to About Settlement Billed Usage for additional functional information.

You can access the portal from the **Main > Settlement > Settlement Billed Usage**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Billed Usage**: This zone displays basic information about the settlement billed usage, including billed usage periods.

Settlement Item Market Participants

- About Settlement Item Market Participants
- Maintaining Settlement Item Market Participants

About Settlement Item Market Participants

Settlement item market participants connects a Market, Market Participant and Settlement Item together over a specified date range. Settlement item market participants can be created either via the **Settlement Item Market Participant** portal, or by adding a market participant to a settlement item via the **Settlement Item** portal.

Settlement item market participants are defined by the following:

- **Settlement Item**: The settlement item for which this settlement item market participant was created.

Copyright © 2026, Oracle and/or its affiliates.

- **Market Relationship Type**: The market relationship (Distributor, Supplier, etc.) of the market participant and its role within a market.
- **Start Date/Time**: The start date/time for when the record is applicable.
- **End Date/Time**: The end date/time for when the record is applicable.
- **External ID**: An ID for the market participant used by external systems.
- **Market Participant**: The market participant associated with the **Settlement Item**, including an optional ID used by the market participant to uniquely identify the settlement item.

Maintaining Settlement Item Market Participants

You use the **Settlement Item Market Participant** portal to display and maintain settlement item market participants.

Refer to About Settlement Item Market Participants for additional functional information.

You can access the portal by selecting **Main**, then **Settlement**, then **Settlement Item Market Participant**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Market Participant**: This zone displays the basic attributes of the settlement item market participant.
- **Sub Settlement Items**: This zone lists settlement items for the settlement item market participant.

Market Allocations

- Market Contracts
- Market Awards
- Market Products

Market Contracts

- About Market Contracts
- Maintaining Market Contracts

About Market Contracts

Market contract are agreements with the market operator (such as an Independent System Operator, or ISO) related to how settlement calculation results are sent to the market. Market contracts are related to a specific market, have a seller and buyer, as well as a date range for when they are effective.

Market contracts are defined by the following:

Copyright © 2026, Oracle and/or its affiliates.

- **Market Contract Type**: The Market Contract Type for the contract. This defines the market in which the contract is in effect and the business object used to create the contract.
- **Contract** : A unique code for the contract, often provided by an external system
- **Start Date** / **End Date**: The date range during which the contract is in effect
- **Seller**: The market participant that serves as the Seller for the contract.
- **Buyer**: The market participant that serves as the Buyer for the contract.

Maintaining Market Contracts

You use the **Market Contract** portal to view and maintain market contracts.

Refer to About Market Contracts for additional functional information.

You can access the portal from the **Main > Market > Market Contract**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Contract**: This zone displays basic information about the market contract.
- **Related Market Awards**: This zone displays a list of market awards related to the market contract.

Market Awards

- About Market Awards
- Maintaining Market Awards
- Maintaining Market Allocations

About Market Awards

Market awards are used to allocate load to various market participants.

Market awards are defined by the following:

- **Market Product**: The Market Product associated with the award
- **Award Class**: The type of award. The base package supports three award classes: Tranche Awards, Percentage Awards, and Fixed Profile Awards.
  - **Tranche Awards**: Tranches are used to handle a whole number division of load. For example, an agreement may be reached that the Provider of Last Resort (POLR) load for a zone should be broken into 64 tranches, or exactly 64 chunks of load that can be purchased. In this example, the load could be broken up in the following manner: Contract #1234 buys 12 tranches, Contract #1235 buys 1 tranche, and Contract #1236 buys 51 tranches (each of these three would be a market award) A factor can be used to define different tranche quantities over time for the same market award.
  - **Percentage Awards**: Percentage Awards allocate a percentage of the remaining load. A factor can be used to define a different percentage over time for the same market award.

Copyright © 2026, Oracle and/or its affiliates.

  - **Fixed Profile Awards**: Fixed Profile Awards leverage a profile measuring component to designate an amount that must be allocated from the overall load to this market award. A factor can be used to define different profiles over time for the same market award.
- **Start Date / End Date**: The date range for the market award
- **Award Details**: Details of the award, including the source (Static Value or Factor) and quantity (either a fixed value or factor value)
- **Characteristics**: Characteristics for the award, if appropriate

Maintaining Market Awards

You use the **Market Award** portal to view and maintain market awards based on Market Products with a **Product Class** of “Contract Fulfillment”.

Refer to About Market Awards for additional functional information.

You can access the portal from the **Main > Market > Market Award**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Award**: This zone displays basic information about the market award, including **Award Details**, related market **Contracts**, and **Characteristics**.

Maintaining Market Allocations

You use the **Market Allocation** portal to view and maintain market awards based on Market Products with a **Product Class** of “Parent Allocation”.

Refer to About Market Awards for additional functional information.

You can access the portal by selecting **Main**, then **Market**, then **Market Award**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the **Market Allocation** portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Allocation**: This zone displays basic information about the market award, including **Award Details**, and **Characteristics**.

Market Products

- About Market Products
- Maintaining Market Products

About Market Products

Market products are used to allocate market awards to market participants. Market products are referenced by the Market Award Allocation settlement calculation rule via a parent Market Product Set. Market products of class “Parent Allocation” can have child products. This allows definition of hierarchies of market products and related awards,

Copyright © 2026, Oracle and/or its affiliates.

Market products are defined by the following:

- **Market Product Set**: The Market Product Set to which the Market Product is associated.
- **Market Product Type**: The Market Product Type for the market product. This defines the business object used to create the market product and its market awards. For formula-based products, the market product type also defines the formula used to calculate award allocation.
- **Product Code**: A unique code for the product, often provided by an external system
- **Product Class**: The type of product. The base package supports two product classes: Parent Allocation or Contract Fulfillment:
  - **Parent Allocation**: Indicates that the market product is a parent level product that divides out a certain allocation of the total amount to be then divided further amongst child products.
  - **Contract Fulfillment**: Indicates that the market product ties to an "end result" award that can then be tied to a Market Contract
- **Execution Sequence**: Defines the sequence in which the market product will be executed within its parent Market Product Set
- **Awards**: One or more Market Awards associated with the market product. These define how load and procurement are allocated when the market product is processed by the Market Award Allocation settlement calculation rule.

Maintaining Market Products

You use the **Market Product** portal to view and maintain market products.

Refer to About Market Products for additional functional information.

You can access the portal from the **Main > Market > Market Product**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Product**: This zone displays basic information about the market product.
- **Awards**: This zone displays a list of market awards related to the market product.

Data Access Restrictions

- Using Data Access Restrictions

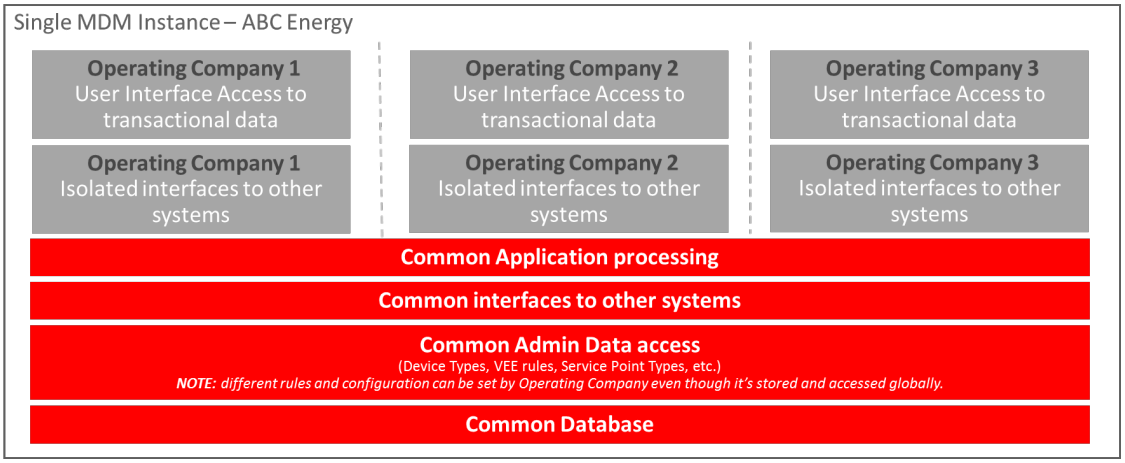
Using Data Access Restrictions

The focus for multi-jurisdiction support in Oracle Utilities Meter Data Management is on restricting access to the user interface. This occurs through defining different Access Groups by operating company which then marks the Service Point with the access capabilities. The Service Point has a field named **Access Group** which allows you to define specific access to the Service Point.

Copyright © 2026, Oracle and/or its affiliates.

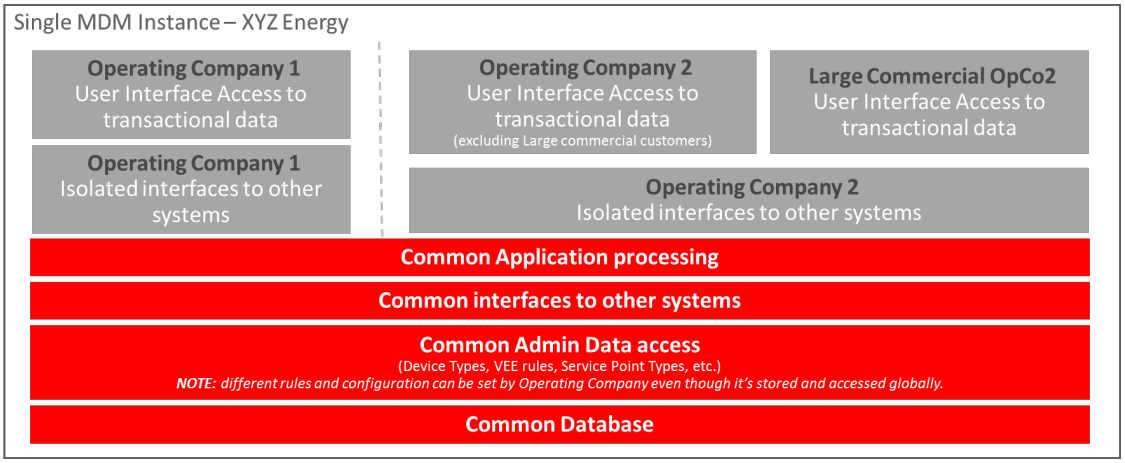
If Access Group is set on the Service Point, then the user interface search screens within Oracle Utilities Meter Data Management will only allow users that are assigned to the proper Access Role to be able to access that Service Point.

For additional information see Defining Access Groups.



Defaulting Access Groups on Service Points

If there is a desire to set a default Access Group by jurisdiction, then this can be accomplished on configuration for Markets. When defining a Market there is an option to add a **Default Access Group**. This value will be used to mark any newly created Service Point with the same Access Group value defined on the related Market.



Example Scenarios

Below are some examples of how Data Access Restrictions can be implemented:

Example 1: Split Access by Market - an example utility "ABC Energy" that has 3 operating companies.

Example 2: Isolating Important Customers - an example utility "XYZ Energy" that has 2 operating companies but would also like to isolate access to Large commercial customers for one of the companies.

To Do Processing

There are numerous events that trigger the creation of email-like messages describing work that requires human attention. For example, if a bill segment has an error, a message is created to highlight such. We refer to each message as a **To Do Entry**. In this section, we describe how to view, manage and work To Do entries.

> **NOT_SUPPORTED**
>
> We recommend familiarizing yourself with the topics described in The Big Picture of To Do Lists to fully appreciate how To Do entries are managed by the system.

- Understanding To Do Processing
- Managing To Do Entries

Understanding To Do Processing

The topics in this section provide background information on To Do processing functionality.

- To Do Role
- To Do Priority
- Work Distribution
- Working On A To Do
- To Do Characteristics
- Related To Do Entries
- Complete A To Do
- Log Entry Events

To Do Role

Each To Do entry is assigned a specific To Do Role. The role defines the users who may work on the entry. The permissible roles that may be assigned to a To Do entry are defined on the entry's To Do type. One or more users within a role may be designated as a supervisor, who is allowed to assign To Do entries to other people. Supervisors are determined through application security access.

Refer to To Do Entries Reference A Role to learn more about role assignment.

After an entry is created, its role may be changed to any role defined as valid for the entry's To Do type. Manual changes of a To Do entry's role are recorded on the To Do entry log.

To Do Priority

A To Do entry is associated with a priority level representing its processing order compared to other entries. Refer to The Priority Of A To Do Entry for more information on how an entry's priority is initially assigned and how it may be automatically updated by the system.

Copyright © 2026, Oracle and/or its affiliates.

A user may manually override a To Do entry's priority at any time. Once overridden, automatic recalculation of the priority is no longer performed so as not to override the value explicitly set by the user. Manual overrides of a To Do entry's priority are recorded on the To Do entry log.

> **Note**
>
> Only users that are currently **Assigned** to a To Do entry or ones that are valid for the role of an **Open** To Do entry may manually change the priority.

Work Distribution

This topic goes overs the various possible actions a user can take to adjust what role or what user is associated with a To Do entry while it is in a non-complete state.

Adjusting the Role

A To Do entry must always reference a role. When a To Do entry are created in the **Open** state and is associated with a role. The following points highlight ways to adjust the role associated with a To Do entry.

- A user viewing a record on the To Do Entry page may use the Forward or Send Back action to change the role.
- A supervisor using the To Do Search page may assign a user not linked to the current role. In this case, the system will update the role to one valid for the assignee.

Assigning a To Do to a User

There are several ways to **Assign** a To Do entry to a user:

- The To Do Management portal provides many filters and viewing options to review To Do entries for a give To Do Type. In addition, it displays a rich amount of detail for the resulting To Do entries, helping users to make decisions. Users may use this page to assign work to themselves and supervisors may use this to assign work to others.
- A user viewing an entry on the To Do Entry page may use the Forward to a User or the Send Back action to assign the entry to a different user.
- **On demand assignment**. The system can be configured to dynamically assign the highest priority work to a user on demand from the Assign me a To Do button on the Current To Do Zone. One of the main benefits of the assignment on demand approach is that work is allocated real-time based on most current information such as skills, priority, user availability, etc. This also means that work remains unassigned until a user is actually going to work on it making it available to any qualified user.

  > **Note**
  >
  > Refer to On Demand Assignment Configuration for information on configuring the system to support this feature.

- Several legacy pages include assignment capability
  - A supervisor can use the Supervisor Functions pages to review, assign and reassign To Dos to users.
  - A user may use the To Do list pages to review and assign To Dos to themselves.

Copyright © 2026, Oracle and/or its affiliates.

- All of the above assignment functions may also be performed using the To Do Search page.

Reopening / Unassigning a To Do

It is possible to transition a To Do entry from **Assigned** back to **Open**.

- A user viewing a record assigned to them on the To Do Entry page may use the Forward to a role action to move the entry back to **Open**.
- The **Unassign** button on the To Do Management portal or the **Reopen** button on the To Do Search page causes the To Do entry to go back to **Open**.

Working On A To Do

The To Do entry you are actively working on is your **In Progress** To Do entry. This To Do entry is visible in the Current To Do zone. Refer to that zone's help topic for all the features enabled on that zone.

> **Important**
>
> The information here assumes that you have configured the system to use the ability to have a substatus of Assigned, which includes the **In Progress** value. If you are not taking advantage of the substatus, then see below for information about how the functionality described here works differently.

If you don't currently have an **In Progress** To Do entry, there are several ways to choose a To Do and indicate that you want to start working on it. Doing so proactively populates the To Do into the Current To Do zone and navigates you to the related object (or if the To Do type is configured to launch a script, the script is launched).

If your organization's practice is to assign work to users up front, then a typical approach is that you would start by reviewing a list of entries assigned to you using one of the base pages and indicate that you want to work on an entry in the list. Or your organization may allow you to review To Do entries that are open and in a role that you are in. In some pages, there is a way for you to enable a list of To Do Entries that you can work through without needing to return to the query page to get the next entry.

The following points highlight the available base pages and their supported functionality.

- To Do Management allows you to use filters to view a list of entries assigned to you or that are open. Click the Work List icon in the Action column to populate the Work List zone in the sidebar with the results of the search. Click the **Work** button to choose the To Do entry you wish to start with. This drills you into the related object and populates the Current To Do zone with this To Do. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you). Use the entries in the Work List zone to subsequently work on other To Do entries.
- If you are viewing a record on To Do Entry that you are allowed to work on, click the **Work** button to indicate that you want to start working on the record. This drills you into the related object and populates the Current To Do zone with this To Do. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you).
- To Do List allows you to start working on a To Do by clicking the entry's message description link. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you). Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list. Note that clicking

Copyright © 2026, Oracle and/or its affiliates.

the next or previous button does not automatically assign the entry to you. Use the **Start Progress** button on the Current To Do zone to change the status. If you don't start progress, it means the To Do in this zone is not your current In Progress to do entry. It remains in this zone until you perform another action to populate a different To Do in this zone. If you open another browser window, the Current To Do zone will not have this same To Do entry populated.

- To Do Search allows you to drill into the details of a To Do by clicking the entry's message description link, but it does not automatically assign it to you or update it to **In Progress**. You can click **Start Progress** on the Current To Do zone once it's populated. Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list. As with the first To Do selected, the subsequent To Do entries will not be assigned to you or progress started automatically.

> **Note**
>
> The To Do Search works differently than other pages in that you can drill in on a To Do entry and push the details into the Current To Do zone even if the To Do entry is assigned to someone else or if you are not allowed to work on that To Do. If you have an **In Progress** To Do entry and use the To Do Search to drill in on a different To Do Entry that doesn't get assigned to you, that To Do is now the one in the Current To Do zone and remains there until you do something else to refresh the data in that zone. If you open another browser window, the Current To Do zone will not have this same To Do entry populated.

Refer to Current To Do for more information about actions available to update To Do entries that you are working on.

Additionally, you may have the option to click on the **Assign me a To Do** button on the Current To Do zone to request your next task. The returned To Do entry automatically becomes the your **In Progress** To Do. This does not enable any work list functionality.

> **Note**
>
> If you do already have an **In Progress** To Do and you perform one of the above actions that results in a different To Do to become **In Progress**, the To Do entry that was already **In Progress** is updated to **On Hold**.

> **Important**
>
> If your implementation is not taking advantage of the substatus as described in The Lifecycle Of A To Do Entry, then the system doesn't have a persistent way of marking which To Do entry is the one you are working on. You may still perform any of the steps described above to make the To Do entry your 'current' To Do. If any of the above steps indicate that the To Do will be assigned to you, that action still occurs, but the To Do entry is not moved to 'in progress'. The To Do entry is only considered the 'current To Do' for your current session. If a different session is opened, you must perform the explicit action again to make the To Do the 'current To Do' for that session.

Copyright © 2026, Oracle and/or its affiliates.

To Do Characteristics

Characteristics are used to associated related information to a To Do entry. Refer to Linking Additional Information to a To Do Entry for more information.

Several pages in the system allow you to view a To Do entry's characteristic values and / or search for To Do entries by their characteristics.

- The To Do Management portal and the To Do Details tab on the To Do Dashboard portal include up to five filters to search for To Do entries by a characteristic value. In addition, the search results display all the current characteristics as name / value pairs.
- The To Do Entry includes a zone to display any existing characteristics. In addition, if a user is allowed to modify a To Do Entry, the edit dialogue allows a user to add or change characteristics. Note that for manual To Do types, the valid characteristic types are driven by the To Do type. For automated To Do types, if valid To Do characteristic types are configured on the To Do type, only those are available. Otherwise, any valid To Do characteristic type may be linked.
- The To Do Search includes a single characteristic type / value filter.

Related To Do Entries

A user working on a To Do may want to know of other To Dos that may be related to the same problem. If they can be worked by the same user they may get resolved faster. It seems almost impossible to programmatically determine whether two To Dos really stem from the same problem. The user should therefore be presented with a list of potentially related To Dos from which they can select the truly relevant ones.

A To Do entry is considered potentially related to a given To Do if they reference a common entity via a characteristic. For example, if a given To Do references a certain account then any To Do referencing that same account is considered related to it.

> **Note**
>
> The common entity is any characteristic value linked to the To Do entry where the characteristic type is a **Foreign Key** and the main table of the foreign key is classified as a **Master** or **Transaction** table.

There are various places where the user is informed as to whether or not the current To Do Entry is related to other To Do Entries.

- To Do entry maintenance displays in insight indicating the number of related To Do Entries for the current To Do. In addition, a Related To Do Entries zone shows information about each related To Do.
- The Current To Do zone includes related To Do information and actions.
- The To Do Management query includes a count of related To Do entries.
- The To Do Search page supports a **Related To Do filter** that lists all related To Do entries for a given entry.

Copyright © 2026, Oracle and/or its affiliates.

Complete A To Do

After you finish working on an entry, you can mark it as **Complete**. At this point, you may want to review potentially related To Do entries and complete those that have been addressed by resolving the problem associated with the current entry.

When you complete a To Do, a log entry is created that indicates when the To Do was completed and by whom.

There are multiple ways in which you can complete a To Do.

- The To Do Management page provides many filters in addition to To Do Type. One or more entries may be completed in this page.
- Use the To Do Entry page to complete a single To Do Entry. The user may also choose to add comments when completing a To Do on this page.
- You may use the Current To Do zone to complete the current entry you are working on and/or all related entries assigned to you.
- The To Do List page allows you to complete one or more selected entries of a specific To Do Type.
- The To Do Search page allows you to search for To Do entries using various search criteria and complete selected ones.

> **Note**
>
> It is possible for the system to automatically mark an entry as **Complete**. Refer to The Lifecycle Of A To Do Entry for more information.

Log Entry Events

Any user may add a **User Details** log entry to any To Do at any time (even after it's completed). Refer to To Do Entry page for more information.

The To Do Management portal also allows users to add a **User Details** log entry to one or more selected entries.

In addition, there are several log entries created automatically by the system. The log includes a status column, which captures the status of the To Do at the time of log. If the To Do entry is **Assigned** and its substatus **In Progress** or **On Hold**, the log captures the substatus value, otherwise it captures the status value.

The following table contains the list of all possible log events.

Event	Log Type	Log Status	Content of Details	Content of Assigned To (on To Do entry and To Do Log)	Log User ID	Contents of Sent By (on To Do entry)
A To Do is created (by the system or by a user)	**Created**	**Open**			ID of user who created the To Do	

Copyright © 2026, Oracle and/or its affiliates.

Event	Log Type	Log Status	Content of Details	Content of Assigned To (on To Do entry and To Do Log)	Log User ID	Contents of Sent By (on To Do entry)
A To Do is created (by the system or by a user) in Assigned status	**Created**	**Assigned**		User ID of user who was assigned this To Do	ID of user who created the To Do	Creating user's ID
A To Do is completed (by the system or by a user)	**Completed**	**Complete**			ID of user who completed the To Do	
A user takes an open To Do	**Assigned**	**Assigned**	Selected by user	Assigned To User ID	Assigned To User ID	ID of user who assigned the To Do
A supervisor assigns a To Do to a user (also happens if they reassign)	**Assigned**	**Assigned**	Assigned to user	Assigned To User ID	ID of user who assigned the To Do	ID of user who assigned the To Do
A user forwards an entry to a user	**Forwarded**	**Assigned**	*Log details entered by user*	Forwarded To User ID	ID of user who forwarded the To Do	ID of user who forwarded the To Do
A user forwards an entry to a role	**Forwarded**	**Open**	Forwarded to role *Role Description (Role ID)* + *Log details entered by user*		ID of user who forwarded the To Do	ID of user who forwarded the To Do
A user sends back a To Do	**Sent back**	**Assigned**	*Log details entered by user*	Sent Back To User ID	ID of user who sent back the To Do	ID of user who sent back the To Do
The status is updated (aside from the cases that have an explicit log type)	**Status Updated**	Current status of To Do		User currently Assigned, if applicable	ID of the user the made the status update	
A user adds a log entry	**User Details**	Current status of To Do	*Log details entered by user*		ID of user who added the entry	
A user manually overrides priority	**Override Priority**	Current status of To Do	Priority changed from *old value* to *new value*	Assigned To User ID	ID of user who made the change	

Copyright © 2026, Oracle and/or its affiliates.

Event	Log Type	Log Status	Content of Details	Content of Assigned To (on To Do entry and To Do Log)	Log User ID	Contents of Sent By (on To Do entry)
Priority is updated by a calculate priority algorithm	**Calculated Priority**	Current status of To Do	Priority changed from *old value* to *new value*		ID of user that added or updated the To Do or the user associated with the Recalculate Priority batch job.	

Managing To Do Entries

This section describes the various pages available to view and work on To Do entries.

- To Do Management
- To Do Dashboard
- To Do Entry
- Billing To Do Dashboard
- Legacy UI Features

To Do Management

The To Do Management portal provides a multi-query zone that includes a search for To Do entries using To Do Type and other To Do information. Users may search for entries using multiple criteria and perform common actions, such as assignment and completion, on selected entries.

It is intended to be used by both supervisors and non-supervisor To Do users. Supervisors are identified by their security access to the portal.

Use **Menu**, and then **To Do**, and then **To Do Management** to navigate to the portal.

To Do Information Search

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

> **Note**
>
> **Results are restricted by role.** For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to To Do Entries Reference A Role for more information about roles.

The following sections describe the features of this zone.

Copyright © 2026, Oracle and/or its affiliates.

Search Filters

The following table describes each of the different filters supported by this zone.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection. If the To Do Role filter is populated, the list is further restricted to valid To Do Types for the To Do Role.
Status	Use this filter to restrict the search to To Do entries with a status of **Open** , **Assigned**, **In Progress** or **On Hold**. If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries.
Days Old	On the **To Do Management** portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old. On the **To Do Dashboard** portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
To Do Role	Use this filter to restrict the search to To Do entries of a specific role. Only To Do Roles where the user is a member will be available for selection. If the To Do Type filter is populated, the list is further restricted to valid To Do Roles for the To Do Type.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Message	Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type.
Characteristic	Use these filters to restrict the search to To Do entries with a specific **Characteristic Type** and value. Up to five characteristic type and value pairs may be entered. If the To Do Type filter is populated and the To Do Type is 'manual', the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown. If an automated To Do Type doesn't define valid characteristics or if no To Do Type filter is populated, all valid characteristic types for the To Do Entry entity are shown. Note that if you have populated characteristic filters and then you change the To Do Type filter, the system retains the characteristic filter as long as the characteristics are applicable to the newly selected To Do Type.

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> For performance reasons, because the filter criteria may be broad, the search zone is configured to only get the first 5000 records that match the criteria and will then sort that number to then display the first 400 sorted by priority and age. The To Do Dashboard portal may be used to get exact counts of records with certain criteria. Use additional criteria to narrow down the search as needed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to What Happens When You Work A To Do Entry for more information.

  > **Important**
  >
  > **Automatic Assignment** When you click the Work button for an open entry, the system changes the status of the entry to **Assigned** / **In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to Working On A To Do for more information.

  > **Note**
  >
  > **Work List**. This column has a Work List icon. Clicking this icon populates the Work List zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do, it will assign it to you if it is **Open** and update it to **In Progress**.

  > **Note**
  >
  > Only 1 **In Progress** To Do entry. If you had a different To Do entry in progress before clicking the Work button, the other To Do entry will be put **On Hold**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry. If the assignment substatus is populated, that value is displayed, otherwise the To Do entry status is displayed.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the To Do Search page with the current entry as the Related To Do Filter value.

Copyright © 2026, Oracle and/or its affiliates.

- **Note** displays a Comment icon if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string. By default this list is collapsed to one line to save vertical space. If additional characteristics exist, you can use the expand arrow to display them.

> **Note**
>
> A feature configuration option is supplied to opt out of the compact view. Under the **To Do Options** feature configuration type, define the **Collapse Characteristics Column** option and set the value to "N".

- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the To Do Entry page to view or maintain the current entry.

Click the **Column Configuration** icon in the zone header to show the Column Configuration Area in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1** to **Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details** log entry to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is assigned to another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is assigned to another user.
- Use the **Complete** button to complete the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

Copyright © 2026, Oracle and/or its affiliates.

To Do Dashboard

This portal provides a high level summary of open and assigned To Do entries by various criteria. It is intended to be used by both supervisors and non-supervisor To Do users. An implementation may introduce additional zones to this portal as needed.

> **Note**
>
> **Results are restricted by role.** For supervisors, the charts consider To Do entries that are in a role of which the supervisor is a member. For non supervisors, the charts consider open To Do entries that are in a role of which the user is a member or entries currently assigned to the user. Refer to To Do Entries Reference A Role for more information about roles.

Use **Menu**, and then **To Do**, and then **To Do Dashboard** to navigate to the portal.

The following zones may appear as part of the portal's **Main** tab page

- **Filters.** This zone displays and manages filters restricting the information being displayed.
- **To Do Entries By Role.** This zone summarizes To Do entries by their currently assigned role.
- **To Do Entries By Status.** This zone summarizes To Do entries by their current status.
- **To Do Entries By Priority.** This zone summarizes To Do entries by their priority.
- **To Do Entries By Age.** This zone summarizes To Do entries by age based on age ranges defined for the current user.
- **To Do Entries By Type.** This zone summarizes To Do entries by their to do type.

Selecting a specific slice of data on any of these zones sets it as a filter and broadcasts its value to the other zones on the portal allowing them to filter their data accordingly.

The following zone appears as part of the portal's **Details** tab page

- **To Do Details** This zone lists To Do entries that match various criteria and allows the user to work and manage the list.

To Do Details

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

> **Note**
>
> **Results are restricted by role.** For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to To Do Entries Reference A Role for more information about roles.

The following sections describe the features of this zone.

Search Filters

Copyright © 2026, Oracle and/or its affiliates.

The following table describes each of the different filters supported by this zone.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection. If the To Do Role filter is populated, the list is further restricted to valid To Do Types for the To Do Role.
Status	Use this filter to restrict the search to To Do entries with a status of **Open** , **Assigned**, **In Progress** or **On Hold**. If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries.
Days Old	On the **To Do Management** portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old. On the **To Do Dashboard** portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
To Do Role	Use this filter to restrict the search to To Do entries of a specific role. Only To Do Roles where the user is a member will be available for selection. If the To Do Type filter is populated, the list is further restricted to valid To Do Roles for the To Do Type.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Message	Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type.
Characteristic	Use these filters to restrict the search to To Do entries with a specific **Characteristic Type** and value. Up to five characteristic type and value pairs may be entered. If the To Do Type filter is populated and the To Do Type is 'manual', the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown. If an automated To Do Type doesn't define valid characteristics or if no To Do Type filter is populated, all valid characteristic types for the To Do Entry entity are shown. Note that if you have populated characteristic filters and then you change the To Do Type filter, the system retains the characteristic filter as long as the characteristics are applicable to the newly selected To Do Type.

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> For performance reasons, because the filter criteria may be broad, the search zone is configured to only get the first 5000 records that match the criteria and will then sort that number to then display the first 400 sorted by priority and age. The To Do Dashboard portal may be used to get exact counts of records with certain criteria. Use additional criteria to narrow down the search as needed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to What Happens When You Work A To Do Entry for more information.

  > **Important**
  >
  > **Automatic Assignment** When you click the Work button for an open entry, the system changes the status of the entry to **Assigned** / **In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to Working On A To Do for more information.

  > **Note**
  >
  > **Work List**. This column has a Work List icon. Clicking this icon populates the Work List zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do, it will assign it to you if it is **Open** and update it to **In Progress**.

  > **Note**
  >
  > Only 1 **In Progress** To Do entry. If you had a different To Do entry in progress before clicking the Work button, the other To Do entry will be put **On Hold**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry. If the assignment substatus is populated, that value is displayed, otherwise the To Do entry status is displayed.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the To Do Search page with the current entry as the Related To Do Filter value.

Copyright © 2026, Oracle and/or its affiliates.

- **Note** displays a Comment icon if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string. By default this list is collapsed to one line to save vertical space. If additional characteristics exist, you can use the expand arrow to display them.

> **Note**
>
> A feature configuration option is supplied to opt out of the compact view. Under the **To Do Options** feature configuration type, define the **Collapse Characteristics Column** option and set the value to "N".

- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the To Do Entry page to view or maintain the current entry.

Click the **Column Configuration** icon in the zone header to show the Column Configuration Area in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1** to **Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details** log entry to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is assigned to another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is assigned to another user.
- Use the **Complete** button to complete the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

Copyright © 2026, Oracle and/or its affiliates.

To Do Entry

Refer to Understanding To Do Processing for detailed explanations about many To Do entry features.

To view a To Do entry, use **Menu**, and then **To Do**, and then **To Do Entry**, and then **Search** . You are brought to a query portal with options for searching for a To Do Entry. Note that some query options limit the results. Refer to the inline help for more information.

> **Note**
>
> **Restricted by role.** Any user may change Comments for any To Do Entry. In addition, any user may add user Log details. However, for all other changes and actions, you may only change To Do entries that are assigned to you or ones that are **Open** and assigned to a role to which you belong. Refer to To Do Entries Reference A Role for more information about roles.

Once a To Do Entry has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The inline help provides information about several fields. The following points highlight information about some of the fields that may be visible.

If the To Do entry has non-complete related entries an insight appears indicating the number of related entries. In addition, details about the related entries are shown in the Related To Do Entries zone.

If the To Do entry was **Created By** a background process, information about that background process appears with a link allowing the user to drill into the batch run, if desired. Refer to To Dos Created for Object-Specific Error Conditions for more information.

If the To Do type is configured to To Do Entries May Be Routed Out Of The System, the **Extract Info** appears. If the extract process is pending, the information indicates that. Otherwise, if it has run, information about the background process appears with a link allowing the user to drill into the batch run, if desired.

The **Characteristics** collection shows existing characteristics. This collection is maintained using the Edit action for users that are allowed to update this To Do entry. Refer to To Do Entry Characteristics for more information.

Actions

Most of the actions are self-explanatory and are related to simply updating the status value. This page has three special actions.

- Using the **Work** button causes several things to occur. You drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. If the To Do entry is Open, it gets assigned to you and the assigned substatus is set to **In Progress**, if your implementation has implemented this functionality. Refer to What Happens When You Work A To Do Entry for more information.
- Use the **Forward** to assign a To Do to another user or role. When a To Do is forwarded, a log entry indicates who forwarded the To Do, to whom it was forwarded, and the specified reason. The dialogue prompts for whether to send to a User or a Role. The search for User

Copyright © 2026, Oracle and/or its affiliates.

includes information about the number of To Do entries already assigned to this user. When choosing a User, confirm the correct Role. The Details provided are captured in the log entry.

- **Send Back** is only applicable if the **Sent By** user is populated. When a To Do is sent back, a log entry is created that indicates when the To Do was sent back and by whom. If the To Do is **Open**, this dialogue allows you to send it back to a different role. If the To Do is assigned to you, the dialogue allows you to re-assign the To Do to the person who assigned it to you. The Details provided are captured in the log entry.

Related To Do Entries

If the To Do has related To Do entries, this zone appears with information about the related entries. Use this zone to perform actions on the current To Do and its related entries.

- Adding a Manual To Do Entry

Adding a Manual To Do Entry

If your system is configured with manual To Do types, you can add a To Do entry online.

Open the **Menu**, and then **To Do**, and then **To Do Entry**, and then **Add.**

You are prompted for a **To Do Type**. Only To Do types that are set up for manual usage appear in the list.

The default **To Do Type Priority** is displayed adjacent. Use **Override Priority** to override the default priority assigned by the system.

Type a **Subject** for your To Do entry. Depending on how the To Do type is set up, the subject may appear as the message in the To Do entry and To Do lists.

Enter a **Comment** to provide a longer description of and more details about the To Do entry.

Send To indicates whether the new To Do will be assigned to a **Role** (the default) or **User**.

The **Role** indicates the role to which this To Do entry will be assigned. Only users of the specified role will be able to view and work on the To Do entry. The role is defaulted from the To Do type. If you want to assign the To Do to a different role, change the specified role. You can only assign the To Do entry to one of the roles specified on the To Do type.

User appears if **Send To** is set to **User**. Use this option if you want to assign the To Do to a specific user. The user must be a member of the selected role.

If the To Do type defines valid characteristic types, the **Characteristics** collection is visible. If any of the characteristic types are flagged as Default on the To Do type, the characteristic type with its default value (if applicable) are displayed.

Billing To Do Dashboard

This portal provides a high-level summary of To Do Entry counts by various criteria. It is intended for supervisor To Do users. An implementation may introduce additional zones to this portal as needed.

The To Do Entry counts are retrieved from statistics snapshots. Refer to the following statistics snapshot business objects in the application, for more information:

- C1-NCToDoPerBillCycleSnapshot - Non-Complete To Dos Per Bill Cycle Snapshot
- C1-ToDoCreatedSnapshot - To Dos Created in the Last n Days Snapshot
- C1-NCToDoPerMessageSnapshot - Non-Complete To Dos Per Message Snapshot

Copyright © 2026, Oracle and/or its affiliates.

For information about capturing statistics, refer to Capturing Statistics

The zones display the counts of To Do Entries of To Do Types with the 'Billing' To Do Type Category (F1-TDCAT) predefined characteristic. The base product provides the C1BILL characteristic value, for this purpose.

Use **Main Menu**, and then **To Do**, and then **Billing To Do Dashboard** to navigate to the portal.

> **Note**
>
> The Billing To Do Dashboard Configuration master configuration can be optionally configured with settings that control how the statistics are shown on this portal - i.e., maximum number of open bill cycles to retrieve, display mode (messages vs. message groups), message groups (list), maximum number of messages to retrieve, maximum number of messages groups to retrieve, To Do trend days and period average. This master configuration is optional. If not configured, the statistics snapshots will run with the assumed defaults. Refer to the master configuration's embedded help, for more information.

The following zones may appear on load this portal:

- **Non-Complete To Dos Per Bill Cycle.** This zone contains a table/grid that summarizes To Do entry counts by **To Do Role** and bill cycle **Window End Date**. It displays the count for each open bill cycle and a single count for To Dos associated with closed bill cycles (i.e., under the **Past Due** column). Use the filters, to further restrict the counts shown.
  - The statistics are restricted by the To Do characteristics: Account (C1-ACCT) and Bill Cycle (C1-BILCY).
  - The maximum number of open bill cycles to retrieve is configurable in the Billing To Do Dashboard master configuration. If not configured, the assumed default is ten (10) open bill cycles.
  - Refer to the Calculate Non-Complete To Dos Per Bill Cycle (C1CALCTDBC) algorithm, for more information.
  - Selecting a count from this zone will navigate to the **Details** tab page, where the To Do Entries for that count are listed, using the **Bill Cycle** query.
- **To Dos Created in the Last N Days.** This zone contains a line chart that summarizes To Do entry counts by Create Date. It displays the daily count of To Dos from the business date (day 1) to a number of days prior, where the number of days is configurable. A Period Average is also configurable. Use the filters, to further restrict the counts shown.
  - The number of days for the daily count is configurable in the To Do Trend Days setting of the Billing To Do Dashboard master configuration. If not configured, the assumed default is thirty (30) days.
  - The Period Average is configured in the Billing To Do Dashboard master configuration. If not configured, the assumed value is 0.
  - Refer to the Calculate To Dos Created in the Last n Days (C1CALCTDCRE) algorithm, for more information.
  - Selecting a count from this zone will navigate to the **Details** tab page, where the To Do Entries for that count are listed, using the **Create Date** query.
- **Non-Complete To Dos Per Message.** This zone contains a row chart that summarizes To Do entry counts by either message category and message number, or by message group (if applicable). Use the filters, to further restrict the counts shown.

Copyright © 2026, Oracle and/or its affiliates.

- The Display Mode in the Billing To Do Dashboard master configuration controls how the statistics are shown on this zone. If the master configuration does not exist, the assumed display mode is by message category and message number.
- The **Message Groups** display mode is useful when the volume of billing-related To Do message numbers is large. One or more message groups can be defined in the master configuration. Each message group defines one or more related message numbers.
- The maximum number of messages to retrieve is configurable. If not configured, the assumed limit is fifty (50) message numbers.
- The maximum number of message groups to retrieve is configurable. If not configured, the assumed limit is twenty-five (25) message groups.
- Refer to the Calculate Non-Complete To Dos Per Message (C1CALCTDMSG) algorithm, for more information.
- Selecting a count from this zone will navigate to the **Details** tab page, where the To Do Entries for that count are listed, using the **Message** query.

Billing To Do Details

The **Details** multi-query zone allows you to view the To Do entry list for a selected statistics count (from the Main tab), and to perform actions on selected records. Each query supports the unique information that each statistics snapshot contains:

- **Search by Bill Cycle.** This query is used when navigating from the **Non-Complete To Dos Per Bill Cycle** zone. It includes filters for: Bill Cycle and Window End Date range.
- **Search by Create Date.** This query is used when navigating from the **To Dos Created in the Last N Days** zone. It includes filters for Create Date range.
- **Search by Message.** This query is used when navigating from the **Non-Complete To Dos Per Message** zone. It includes filters for: Message Category, Message Number and Message Group. The display mode controls the applicable filter's visibility.

The following sections describe the features of this tab page portal.

Search By Bill Cycle - Filters

The following table describes each of the query filters.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection.
To Do Role	This is defaulted to the selected To Do Role (from the Non-Complete To Dos Per Bill Cycle zone). Only To Do Roles where the user is a member of will be available for selection.
Bill Cycle	Use these filters to restrict the search to To Do entries of a specific Bill Cycle.
Window End Date From, Window End Date To	Use this filter to restrict the search to To Do entries of a specific Window End Date range.
CIS Division	Use this filter to restrict the search to To Do entries of a specific CIS Division.
Customer Class	Use this filter to restrict the search to To Do entries of a specific Customer Class.

Copyright © 2026, Oracle and/or its affiliates.

Search Filter	Description
Status	Use this filter to restrict the search to To Do entries with a status of **Open** , **Assigned**, **In Progress** or **On Hold**. If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries.
Days Old	This option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Characteristic	Use these filters to restrict the search to To Do entries with a specific **Characteristic Type** and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown.

Search By Create Date - Filters

The following table describes each of the query filters.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection.
To Do Role	This is defaulted to the selected To Do Role (from the Non-Complete To Dos Per Bill Cycle zone). Only To Do Roles where the user is a member of will be available for selection.
Creation Date From, Creation Date To	Use these filters to restrict the search to To Do entries of a specific Create Date range.
Bill Cycle	Use this filter to restrict the search to To Do entries of a specific Bill Cycle.
CIS Division	Use this filter to restrict the search to To Do entries of a specific CIS Division.
Customer Class	Use this filter to restrict the search to To Do entries of a specific Customer Class.
Status	Use this filter to restrict the search to To Do entries with a status of **Open** , **Assigned**, **In Progress** or **On Hold**. If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries.
Days Old	This option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.

Copyright © 2026, Oracle and/or its affiliates.

Search Filter	Description
Characteristic	Use these filters to restrict the search to To Do entries with a specific **Characteristic Type** and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown.

Search By Message - Filters

The following table describes each of the query filters.

Search Filter	Description
To Do Type	Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection.
To Do Role	Use this filter to restrict the search to To Do entries of a specific To Do Role. Only To Do Roles where the user is a member of will be available for selection.
Message Category, Message Number	Use this filter to restrict the search to To Do entries of a Message Category and Message Number. These filters are available when the **Display Mode** is **Messages** (either specified in Billing To Do Dashboard Configuration master configuration or the assumed default in effect).
Message Group	Use this filter to restrict the search to To Do entries of a specific Message Group. This filter is available when the **Display Mode** is **Message Groups** that is configured in the Billing To Do Dashboard Configuration master configuration.
CIS Division	Use this filter to restrict the search to To Do entries of a specific CIS Division.
Customer Class	Use this filter to restrict the search to To Do entries of a specific Customer Class.
Status	Use this filter to restrict the search to To Do entries with a status of **Open** , **Assigned**, **In Progress** or **On Hold**. If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries.
Days Old	This option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.
Priority	Use this filter to restrict the search to To Do entries with a specific priority.
Key Value	Use this filter to restrict the search to To Do entries with a sort key value containing the entered value.
Assign To User	Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access.
Characteristic	Use these filters to restrict the search to To Do entries with a specific **Characteristic Type** and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do Type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown.

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> For performance reasons, the search zone is configured to restrict the number of rows retrieved by the query. The 'Total Records' number will indicate whether there are more To Do entries that meet the criteria than can be displayed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined as a parameter to the zone. The following columns are displayed initially:

- The **Action** column includes the **Work** button. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to What Happens When You Work A To Do Entry for more information.

  > **Important**
  >
  > **Automatic Assignment** When you click the Work button for an open entry, the system changes the status of the entry to **Assigned** / **In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to Working On A To Do for more information.

  > **Note**
  >
  > **Work List**. This column has a Work List icon. Clicking this icon populates the Work List zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do, it will assign it to you if it is **Open** and update it to **In Progress**.

  > **Note**
  >
  > Only 1 **In Progress** To Do entry. If you had a different To Do entry in progress before clicking the Work button, the other To Do entry will be put **On Hold**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry. If the assignment substatus is populated, that value is displayed, otherwise the To Do entry status is displayed.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the To Do Search page with the current entry as the Related To Do Filter value.

Copyright © 2026, Oracle and/or its affiliates.

- **Note** displays a Comment icon if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string.
- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the To Do Entry page to view or maintain the current entry.

Click the **Column Configuration** icon in the zone header to show the Column Configuration Area in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1** to **Key 5** contain the first five sort key values for the entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details** log entry to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is assigned to another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is assigned to another user.
- Use the **Complete** button to complete the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

Legacy UI Features

The pages described in this section are legacy pages that are retained for backward compatibility. The product plans to deprecate the pages described here in an upcoming release.

- To Do Supervisor Functions
- Using the Service Order Operational Dashboard
- To Do Search

Copyright © 2026, Oracle and/or its affiliates.

To Do Supervisor Functions

This section describes several To Do transactions that aid supervisors in the monitoring and assignment of To Do entries.

- Supervisor To Do Summary
- Supervisor User Summary
- Supervisor To Do Assignment

Supervisor To Do Summary

This Supervisor To Do Summary page summarizes To Do entries by To Do Type. Only entries that are **Open** (i.e., not assigned to a specific user) or **Assigned** are summarized.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Dashboard portal for the page that the product recommends using. Besides providing counts by To Do Type it provides other breakdowns and allows for interaction between graphs.

> **Note**
>
> Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to To Do Entries Reference A Role for more information.

Use **Menu**, and then **To Do**, and then **Supervisor To Do Summary** to open this page.

Description of Page

This page summarizes all To Do entries that are **Open** or **Assigned**.

> **Note**
>
> This page does not further break down the assigned To Do entries by the substatus. Refer to The Lifecycle Of A To Do Entry for more information on the substatus values.

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Assigned** entries. The hyperlink navigates to the Supervisor To Do Assignment transaction, setting it to display all **Open** and **Assigned** entries for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the Supervisor To Do Assignment transaction, setting it to display all **Open** entries for the given To Do Type.

Copyright © 2026, Oracle and/or its affiliates.

- **Assigned** contains the number of To Do entries whose status is **Assigned**. The hyperlink navigates to the Supervisor To Do Assignment transaction, setting it to display all **Assigned** entries for the given To Do Type.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is user-configurable.

Supervisor User Summary

The Supervisor User Summary page summarizes To Do entries by the user who is assigned to work on the entries. Only entries that are **Assigned** are summarized.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Management portal for a page that allows you to view To Do entries currently assigned to users.

> **Note**
>
> Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to To Do Entries Reference A Role for more information.

Use **Menu**, and then **To Do**, and then **Supervisor User Summary** to open this page.

Description of Page

This page contains a grid that displays all assigned To Do entries by User ID and To Do type. It indicates how many To Do entries of the displayed Type are assigned to the user (Assigned this Type) and how many To Do entries in total are assigned to the user (Assigned Total).

> **Note**
>
> This page does not further break down the To Do entries by the substatus. Refer to The Lifecycle Of A To Do Entry for more information on the substatus values.

Clicking the hyperlinks transfer you to the Supervisor To Do Assignment transaction. On this transaction, you can assign / reassign To Do entries to a specific user. The difference is that clicking the To Do Type hyperlink causes only **Open** entries to be displayed on the Assignment transaction. Clicking the count in the Assigned this Type column causes **Assigned** entries assigned to the displayed user to be shown.

Supervisor To Do Assignment

This page lists To Do entries of a given type and allows a supervisor to assign / reassign them to a designated user.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Management portal for the page that the product recommends using. It provides many more filters to narrow down the results. In addition, it provides more data in the results and provides more actions for a supervisor to perform for To Do entries.

Use **Menu**, and then **To Do**, and then **Supervisor To Do Assignment** to open this page.

Description of Page

This page contains **Open** or **Assigned** To Do entries of a given type. These entries can be assigned to a specified user one-by-one or several at a time. The following points describe this functionality:

- You can select a different **To Do Type** by typing in a value or pressing the search button in the upper right corner. An **Info** description of the To Do type appears on the left.
- You can change the list of entries displayed according to their status. Select the **Filter by** status to be All (blank), **Open**, or **Assigned**.
- For **Assigned** entries, you may also **Filter by User** to limit the search to a specific user assigned to the To Do entries.
- If you want to re-sort the entries by a different value, click the search button adjacent to **Extra Information**. Each row's respective sort value is displayed in the **Extra Information** column.

> **Note**
>
> **Extra Information.** Each To Do list's default **Extra Information** is defined on the list's To Do Type. Also note that each To Do list's available **Extra Information** differs.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.
- Use the checkbox if you want to assign specific entries.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Click the Create Date/Time hyperlink to navigate to the To Do page where additional information is visible and where additional actions are possible.
- Click the number of **Related** entries hyperlink to navigate to the To Do Search query to list potentially related entries to the current entry.
- **Worked By** shows the user currently assigned to the To Do entry.
- **To Do Entry Status** is the current status of the To Do entry. If the assigned substatus is populated, that value is shown, otherwise the status value is shown. Refer to The Lifecycle Of A To Do Entry for more information.
- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Note that clicking this action does not push the To Do Entry into the Current To Do zone and does

Copyright © 2026, Oracle and/or its affiliates.

not assign the To Do Entry to you. Refer to Working On A To Do for information about using that functionality.

- You can assign entries to a user:
  - Enter a user ID or search for a user using the **Assign To User** field. You can only select a user that is associated with a role that is associated with this **To Do Type**. Note that the current number of assignments is displayed adjacent.
  - Select one or more entries to assign to this user and click the **Assign** button. The entries' status becomes **Assigned**.

Using the Service Order Operational Dashboard

This portal is used to display the Service Order Operational Dashboard.

You can access the portal from the **Main > Dashboards > Service Order Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The following zones may appear as part of the portal's **Main** tab page:

- **In-Flight Activities By Type**: shows the distribution of in-flight Activities (in progress or in error) by Activity Type.
- **In-Flight Activity Trend**: shows the number of activities that are in-flight on a given day.
- **In-Flight Activities with Issues**: presents a bar chart that indicates the number of activities with issues.
- **In-Flight Activity Status Distribution**: presents a pie chart that displays the distribution of statuses of in-flight activities.
- **Efficiency Trend for In-Flight Activities**: presents a stacked bar chart that displays the distribution of in-flight activity processing efficiency relative to configurable tolerance.
- **Service Order To Do Summary**: this zone uses horizontal bars to highlight the relative number of open To Dos for a set of To Do Types related to Service Order Management.

Refer to About Dashboards for additional functional information. For information on configuration, refer to the related section for Configuring the Service Order Operational Dashboard in the Administrative User's Guide.

Filtering by Division

Data displayed in the zones on this dashboard can be filtered by Division. To enable filtering by Division set the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration to "Yes". If this is set to "No" the zones display data for all divisions.

When filtering is enabled, the **Division** drop-down list allows the user to select the Division for which they wish to view data. Available divisions are based on the divisions assigned to the user in the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal. The division marked "Use As Primary" is the default.

- To Do Summary
- To Do List

To Do Summary

This page summarizes To Do entries that meet the following qualifications:

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Dashboard portal for the page that the product recommends using. Besides providing counts by To Do Type it provides other breakdowns and allows for interaction between graphs.

- The entry is **Open** and you belong to the entry's To Do role. Refer to To Do Entries Reference A Role for more information about roles.
- The entry is **Assigned** and you are the user to which it is assigned.

Use **Menu**, and then **To Do**, and then **To Do Summary** to open this page.

Keyboard Shortcut	Alternate Shortcut
`Alt+X`	`Alt+Shift+X`

> **Note**
>
> Refer to Shortcut Key Summary for information about the alternate shortcut.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of To Do Lists for an overview of To Do functionality.

Description of Page

This page is dedicated to a grid that summarizes the To Do entries on which you can work. The following information is displayed:

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Assigned to You** entries. The hyperlink navigates to the To Do List transaction, setting it to display all **Open** and **Assigned** entries assigned to you for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the To Do List transaction, setting it to display all **Open** entries for the given To Do Type.
- **Assigned to You** contains the number of To Do entries that are assigned to you whose status is **Assigned**. The hyperlink navigates to the To Do List transaction, setting it to display all **Assigned** entries for the given To Do Type.

> **Note**
>
> This page does not further break down the assigned To Do entries by the substatus. Refer to The Lifecycle Of A To Do Entry for more information on the substatus values.

Copyright © 2026, Oracle and/or its affiliates.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is user-configurable.

To Do List

This page lists To Do entries of a given type that are either **Open** (not assigned to a specific user) or are assigned to you.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Management portal for a page that the product recommends using. It provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

> **Note**
>
> **Restricted by role.** Only those entries assigned to a role to which you belong may be seen on this page. Refer to To Do Entries Reference A Role for more information.

> **NOT_SUPPORTED**
>
> We recommend familiarizing yourself with the topics described in The Big Picture of To Do Lists to fully appreciate how To Do entries are managed by the system.

Use **Menu**, and then **To Do**, and then **To Do List** to open this page.

Description of Page

This page contains a grid that summarizes the To Do entries of a given type on which you can work.

The **Info** section contains a concatenation of the **To Do Type**'s description and the user's name.

The area beneath **Info** provides you with options that control which To Do entries appear and the order in which they are displayed. The following points describe the various options:

- Use **Sort By** to define how you want the To Do entries sorted. The following options are available:
  - **Assigned Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.
  - **Assigned Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.

Copyright © 2026, Oracle and/or its affiliates.

  - **Create Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.
  - **Create Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.
  - **Extra Information**. This option sorts the To Do entries by the value of the **Extra Info**.
- Use **Extra Info** to choose data related to the To Do Entry that should be used to sort the To Do entries. This information is displayed in each entry's **Extra Information** column.

> **Note**
>
> **Extra Info.** Each To Do types's available **Extra Info** is defined on the To Do Type Sort Keys. Also note that each To Do type's available **Extra Info** differs based on the configuration of the To Do Type.

- Use **Filter by** to restrict the To Do entries based on their status. The following options are available:
  - **All**. This option shows all entries that are **Open** or **Assigned**.
  - **Assigned**. This option shows all entries that are assigned to you.
  - **Open**. This option shows all entries that are **Open**.

The grid that follows contains the To Do entries that match your criteria. The following information appears:

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** button to remove the selections in the grid.
- Use the checkbox if you want to mark specific entries as **Completed** or **Assigned** using the **Complete** or **Assign** buttons at the bottom.
- A Comment icon appears if there are comments on the To Do item and a Log Entry icon appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do has either comments or a special log entry.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- Click the Create Date/Time hyperlink or either of the special icons to navigate to the To Do entry page.
- Click the number of **Related** entries hyperlink to navigate to the To Do Search query to list potentially related entries to the current entry.
- **Assigned Date/Time** contains the date and time the To Do entry was assigned to a user. This field is only populated on entries that are **Assigned**. If a user assigned the To Do entry, the user ID and name of the user who assigned the To Do entry are displayed beneath the Date/Time.

Copyright © 2026, Oracle and/or its affiliates.

- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to What Happens When You Work A To Do Entry for more information.

> **Important**
>
> **Automatic Assignment** When you drill into an open entry using the message link, the system changes the status of the entry to **Assigned** / **In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to Working On A To Do for more information.

- **To Do Entry Status** is the current status of the To Do entry. If the assigned substatus is populated, that value is shown, otherwise the status value is shown. Refer to The Lifecycle Of A To Do Entry for more information.
- **Extra Information** contains the data for the entry that corresponds to the Extra Info chosen in the sort options above.
- **To Do ID** contains the unique identifier of the To Do entry.
- If you want to mark one or more entries as **Assigned**, check the desired entries and then click the **Assign** button.
- If you want to mark one or more entries as **Completed**, check the desired entries and then click the **Complete** button. Completed entries do not appear on the To Do list (but they are retained on the database for audit purposes).

To Do Search

This page allows you to search for To Do entries using various search criteria, and perform various actions on selected ones. This page includes completed To Do entries in its search results, when applicable with respect to the filter criteria.

Use **Menu**, and then **To Do**, and then **To Do Search** to open this page.

> **Note**
>
> This page will be deprecated in a future release. Refer to the To Do Management portal for a page that the product recommends using. It provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

> **Note**
>
> **No restriction by role.** This page returns all To Do entries that meet the search criteria, regardless of the To Do entry's role. Using the search, a user may drill into the details of a To Do entry even if the To Do is not assigned to the user. Refer to To Do Entries Reference A Role for more information about roles.

The top half of the page is where you enter the criteria used to search for To Do entries.

Copyright © 2026, Oracle and/or its affiliates.

> **⚠ Caution**
>
> Try to be as specific as possible when entering search criteria. Why? Because entering open-ended search criteria may have a severe impact on response times.

The following table describes each of the different search filters.

Search Filter	Description
Related To Do	If you're searching for potentially related entries for a given To Do entry, choose **Specific To Do** for the **Related To Do Filter**. Enter the **To Do ID**. A filter value of **Not Applicable** defaults.
To Do Type	If you're searching for a To Do entry and you know the value of a To Do Type linked to the To Do entry, choose **Specific To Do Type** for the **To Do Type Filter**. Enter the **To Do Type**. A filter value of **All** defaults.
Char Type	If you're searching for a To Do entry and you know the value of a characteristic linked to the To Do entry, choose **Specific Char Type** for the **Char Type Filter**. Enter the **Characteristic Type** and **Characteristic Value**. A filter value of **Not Applicable** defaults. Only characteristic types that include a characteristic entity of **To Do Entry** and that have been marked to allow searching by characteristic value are available.
User	Use this search method if you know the **Created By User**, **Assigned To User** or **Completed By User** for the To Do entry. Enter the appropriate **User Id**. A filter value of **Not Applicable** defaults.
Date Range	Use this field if you're searching for a To Do entry and know the **Date Created** or **Date Completed**. A filter value of **Date Created** defaults. The **Start Date/Time** defaults to the current date, 12:00AM and the **End Date/Time** defaults to the current date, 11:59PM. If you enter a **Date Range Filter** of **All**, the system ignores this search method.
Status	Use this search method to restrict the search to To Do entries with a specific status value. You may search for To Do entries in the status of **Open**, **Assigned** or **Completed**. You may also perform a combination search for To Do entries that have a status value of either **Open** or **Assigned**. A filter value of **All** defaults.

> **ⓘ Note**
>
> **The system allows any combination of values.** The system does not try to validate your search combinations, even if they do not make sense. For example, if you enter a **User Filter** value of **Completed By User** and a **Status Filter** value of **Open**, you will not get an error. In this case, the system will find no records that match your criteria (because To Do entries that are Open do not have a Completed By User).

The system shows the total number of To Do entries that satisfy your search results immediately below the grid.

The first group of To Do entries is displayed in the grid at the bottom of the page.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.

Copyright © 2026, Oracle and/or its affiliates.

- Use the checkbox if you want to perform actions (see below) on specific entries. Only **Open** or **Assigned** entries may be selected.
- A Comment icon appears if there are comments on the To Do item and a Log Entry icon appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do item has either comments or a special log entry. Use either icon to navigate to the To Do entry page.
- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Use the hyperlink to navigate to the To Do entry page.
- Click the number of **Related** entries hyperlink to redisplay this page listing potentially related entries to the current entry.
- **Last Assigned Date/Time** contains the date and time the To Do entry was most recently assigned to a user, if applicable, along with the Assigned To user.
- **Message** contains a description of the To Do entry. If the To Do entry is in the status of **Open** or **Assigned**, the message description allows you to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to What Happens When You Work A To Do Entry for more information.

> **Note**
>
> **Current To Do**. Drilling into the page by clicking the Message hyperlink does not automatically assign **Open** To Do entries to the user (as the To Do List page does when clicking on the Message). But it does treat this as the user's current to do, enabling the functionality in the Current To Do zone. Refer to Working On A To Do for more information.

- **Status** contains the current status of the To Do entry.
- **Completion Date/Time** contains the date and time the To Do entry was completed and the user who completed the entry, if applicable.
- **To Do Type** contains a description of the To Do type for the To Do entry.

Actions

- Use the **Assign** button to assign or reassign the selected entries to a user. Enter a user ID or search for a user using the **Assign To User** field. By default this field is populated with the current user's ID. Note that the user's current number of assignments is displayed adjacent. Upon successful processing, the selected entries are assigned to the specified user and the status of **Open** entries becomes **Assigned**. Additionally, a corresponding log entry is added to each To Do.

> **Note**
>
> You may only assign To Do entries to yourself or to someone else if you are a valid user in the To Do entry's current role.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Only users with **Supervisor Assignment** access rights may reassign entries that are not currently assigned to them.

- Use the **Reopen** button to unassign the selected entries from their users. Upon successful processing, the selected entries become **Open** and a corresponding log entry is added to each To Do.

> **Note**
>
> Only users with **Supervisor Assignment** access rights may unassign entries that are not currently assigned to them and the user must be a valid user in the To Do entry's current role.

- Use the **Complete** button to complete the selected entries.

Reports

- About Reports
- Running Oracle Utilities Meter Data Management Reports

About Reports

Reports include operational reports related to device events, validation exceptions, and other operational data. Reports can also be based on devices, measuring components, Service Points, service providers, and other data.

Oracle Utilities Meter Data Management reports are implemented using Oracle Business Intelligence Publisher (BI Publisher), and are administered via Oracle Business Intelligence Publisher and the Report functionality of the Oracle Utilities Application Framework.

Refer to the Oracle Business Intelligence Publisher documentation for more information about installing Oracle Business Intelligence Publisher and creating and defining reports. For additional details on how reports are defined and administered see Reporting and Monitoring Tools in the Oracle Utilities Application Framework *Administrative User Guide*.

Running Oracle Utilities Meter Data Management Reports

This portal is used to submit a new instance of a Report.

Refer to About Reports for additional functional information.

You can access the portal from the **Main > Tools > Report Submission**.

First, the appropriate Report code must be selected. The Reports provided out-of-the-box are:

- **Device Events Report**: this report generates a pie graph depicting the percentage of Device Events for each Device Event Type for the specific search criteria.

Copyright © 2026, Oracle and/or its affiliates.

- **Device VEE Exceptions Report**: this report generates a pie graph depicting the percentage of VEE Exception for Exception Type and Market for the specific search criteria.

Next, enter the parameter values for the report as appropriate and submit the report.

Copyright © 2026, Oracle and/or its affiliates.

Part III

Application Framework Administrative User Guide

Welcome to the Oracle Utilities Application Framework Administrative User Guide. The topics in this guide describe how to administer the Oracle Utilities Application Framework.

- General Options
- Security & User Options
- User Interface Tools
- Database Options
- Configuration Tools
- To Do Lists
- Background Processes
- Monitoring and Analytics
- External Messages
- Integrations
- Market Transaction Management
- Content Migration Assistant (CMA)
- Facts
- Data Export

General Options

This section describes control tables that are used throughout your product.

- Defining Installation Options
- Support For Different Languages
- Defining Countries
- Defining Currency Codes
- Defining Time Zones
- Defining Geographic Types
- Defining Work Calendar
- Defining Display Profiles
- Defining Phone Types
- Defining Feature Configurations
- Defining Master Configurations

Copyright © 2026, Oracle and/or its affiliates.

- What's New Portal

Defining Installation Options

The topics in this section describe the various installation options that control various aspects of the system.

- Installation Options - Main
- Installation Options - Messages
- Installation Options - Algorithms
- Installation Options - Accessible Modules
- Installation Options - Installed Products

Installation Options - Main

Select **Admin**, and then **General**, and then **Installation Options - Framework** to define system wide installation options.

Description of Page

The **Environment ID** is a unique universal identifier of this instance of the system. When the system is installed, the environment id is populated with a six digit random number. While it is highly unlikely that multiple installs of the system at a given implementation would have the same environment ID, it is the obligation of the implementers to ensure that the environment ID is unique across all installed product environments.

System Owner will be **Customer Modification**.

The **Admin Menu Order** controls how the various control tables are grouped on Admin.

- If you choose **Functional**, each control table appears under a menu item that corresponds with its functional area. Note, the menu that is used when this option is chosen is the one identified with a menu type of **Admin**.
- If you choose **Alphabetical**, each control table appears under a menu item that corresponds with its first letter, using a Roman alphabet. For example, the Language control table will appear under the L menu item entry.

> ⓘ **Note**
>
> The **Alphabetical** option only supports the Roman alphabet. For languages that do not use the Roman alphabet, the recommendation is to configure the system for the **Functional** setting.

> ⚠ **Caution**
>
> In order to improve response times, installation options are cached the first time they are used after a web server is started. If you change the Admin Menu Order and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. Refer to Caching Overview for information on how to clear the system login cache (this is the cache in which installation options are stored).

Copyright © 2026, Oracle and/or its affiliates.

The **Language** should be set to the primary language used by the installation. Note that if multiple languages are supported, each user may define their preferred language.

The **Currency Code** is the default currency code for transactions in the product.

If your product supports effective dated characteristics on any of its objects, define the date to be used as the **Characteristic Default Date** on objects without an implicit start date. The date you enter in this field will default when new characteristics are added to these objects (and the default date can be overridden by the user).

Active Owner displays the owner of newly added system data (system data is data like algorithm types, zones, To Do types, etc.). This will be **Customer Modification** unless you are working within a development region.

Country and **Time Zone** represent the default country and time zone that should be used throughout the application.

> ⚠ **Caution**
>
> In most implementations, the time zone defined here matches the database time zone. However, if there is some reason that the database time zone does not match the installation time zone, an implementation may configure a setting in the properties file to automatically convert data from the database time zone to the time zone defined here when displaying dates. Note that when this property setting is defined, changes to the installation time zone will require the server and the thread pool workers to be restarted in order for the changes to take effect.

Turn on **Seasonal Time Shift** if your company requires seasonal time shift information to be defined. Note that this is currently only applicable to Oracle Customer Care and Billing > Interval Billing functionality.

Installation Options - Messages

Select **Admin**, and then **General**, and then **Installation Options - Framework** and the **Messages** tab to review or enter messages that will appear throughout the application when a given event occurs.

The **Message** collection contains messages that are used in various parts of the system. For each message, define the **Installation Message Type** and **Installation Message Text**. The following table describes the **Message Types** provided by the framework product and how they are used in the system. Your specific product may have introduced addition message types.

Message Type	How The Message Is Used
Company Title for Reports	This message appears as a title line on the sample reports provided with the system. Generally it is your company name. It is only used if you have installed reporting functionality and are using the sample reports (or have designed your reports to use this message).

Copyright © 2026, Oracle and/or its affiliates.

Message Type	How The Message Is Used
Domain Name	The text entered for this message type is meant to identify the environment. If populated, the text is displayed next to the product name in The Application Toolbar. It may be used in other cases where it is useful to indicate the environment for a user. For example, the email sent when a background process finishes includes this information, if populated.

Installation Options - Algorithms

Select **Admin**, and then **General**, and then **Installation Options - Framework** and the **Algorithms** tab to review or enter the algorithms that should be evoked when a given event occurs.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

> ⚠ **Caution**
>
> These algorithms are typically significant processes. The absence of an algorithm might prevent the system from operating correctly.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Validate Email Attachment	Optional	Algorithms of this type are used to validate the attachments for size and total count while sending attachments using the Email service. Refer to Sending Email for more information
Address Geocoding	Optional	Algorithms of this type use Oracle Locator to retrieve latitude and longitude coordinates using address information.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Attachment Malware Scan	Optional	Algorithms of this type are invoked when adding attachment content. The algorithm receives the attachment ID and is expected to use a malware scanning tool to verify the contents of the attachment. Only one algorithm is allowed. Refer to Enabling Malware Scan for more information.
Global Context	Optional	Algorithms of this type are called whenever the value of one of the global context fields is changed. Algorithms of this type are responsible for populating other global context values based on the new value of the field that was changed. Refer to Global Context Overview for more information.
Guaranteed Delivery	Optional	Algorithms of this type may be called by processes that receive incoming messages that should 'guarantee delivery'. Refer to Guaranteed Delivery for more information. The business service `F1-GuaranteedDelivery` may be used to invoke this plug-in spot.
Ldap Import	Optional	Algorithms of this type are called for operations on users, groups, and group memberships after they have been processed.
Ldap Import Preprocess	Optional	Algorithms of this type are called to preprocess data retrieved from LDAP.
Next To Do Assignment	Optional	This type of algorithm is used to find the next To Do entry a user should work on. It is called from the Current To Do zone when the user asks for the next assignment. Refer to On Demand Assignment Configuration for more information about setting up this information.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Reporting Tool	Optional	If your installation has integrated with a third party reporting tool, you may wish to allow your users to submit reports on-line using report submission or to review report history online. This algorithm is used by the two on-line reporting pages to properly invoke the reporting tool from within the system.
SMS Receive	Optional	This type of algorithm is used to provide SMS receive service. Only one algorithm of this type should be plugged in.
SMS Send	Optional	This type of algorithm is used to provide SMS send service. If your installation uses the base algorithm that uses BPEL, you will need to create a feature configuration with the SMS Send Configuration feature type to define your Oracle BPEL server and service call details. If your installation has integrated with a third-party SMS service, you may want to override this algorithm type with your own implementation. Only one algorithm of this type should be plugged in.
To Do Information	Optional	We use the term To Do information to describe the basic information that appears throughout the system to describe a To Do entry. Plug an algorithm into this spot to override the system default "To Do information".
To Do Pre-creation	Optional	These types of algorithms are called when a To Do entry is being added. Refer to Refining a To Do Entry's Details at Creation Time for more information.

Installation Options - Accessible Modules

Select **Admin**, and then **General**, and then **Installation Options - Framework** and the **Accessible Modules** tab to view the list of accessible modules.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

This page displays the full list of the application's function modules. A **Turned Off** indication appears adjacent to a module that is not accessible based on your system's module configuration setup.

> **NOT_SUPPORTED**
>
> Refer to Module Configuration for more information on function modules and how to turn off modules that are not applicable to your organization.

Installation Options - Installed Products

Select **Admin**, and then **General**, and then **Installation Options - Framework** and the **Installed Products** tab to view a read only summary of the products that are installed in the application version that you are logged into.

Description of Page

The **Product Name** indicates the name of the "products" that are installed. The collection should include **Framework**, an entry for your specific product and an entry for **Customer Release**.

Release ID shows the current release of the application that is installed. This field is used by the system to ensure that the software that executes on your application server is consistent with the release level of the database.

The **Release ID Suffix**, **Build Number** and **Patch Number** further describe the details of your specific product release.

> **Note**
>
> If you have developed implementation-specific transactions, you can populate the release ID, release ID suffix, build number and patch number for the **Customer Release** entry to define the latest version of implementation-specific logic that has been applied to this environment. The framework provides a script (`F1CustRelM`) to allow these fields to be updated manually. In addition, the `F1-InstallationOptions` inbound web service provides operations to view and update those fields via a REST call. Alternatively, your implementation team may populate these fields as part of their upgrade scripts.

The **Product Status** is used to indicate if a product installed by default in the version you are logged into is **Active** or **Inactive**.

The **Display** column indicates the product whose name and release information should be displayed in the title bar. Only one product sets this value to **Yes**.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

Product Type indicates if the product is a Parallel Application. A parallel application is one that is independent of, and does not conflict with, other parallel applications. Multiple parallel applications can be installed in the same database and application server.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **About Information**. The information on this tab is used to populate the information displayed in the About window for your product.

Support For Different Languages

- User Language
- Customer Language
- Defining Languages

User Language

The language English (with the locale "en") is provided by the system and all system metadata are delivered with an English description or label. The system provides support for defining other languages and supports multiple languages in a single environment. System users can use the system in their preferred language, as long as a translation into that language has been provided. A user sees the system in the language defined on their user record. If enabled, users can use the Switch Language zone to switch to another supported language real time.

Supporting a New Language

Normally, setting up the system for another language (besides the delivered English language entry) is an implementation issue, not an administrative setup issue. However, there are several online administrative features that are used to set up a new language, and these are described here.

1. **Define a language code and indicate that it is enabled.** For details on this procedure, see Defining Languages.
2. **Install or confirm the existence of a language pack**. For an on-premise installation, if the product supplies a language pack with translations for the system metadata descriptions, follow the instructions for downloading the language pack and installing it into your environment. For a cloud installation, if the product supplies a language pack for a given language, no additional step is needed here. The language pack is already installed.
3. **Copy descriptions of all language-enabled tables from an existing translation (e.g., English).** The copied values act as placeholders while the strings are translated into the new language. It is necessary to do this as a first step in order to create records using the new language code created in the previous step. Language-based descriptions can be copied using a supplied batch process, `F1-LANG`. The batch copies all English labels in the system.

   The batch process will also update the new language rows with the translated metadata descriptions from the language pack, if installed.
4. **Translate additional content.** Translatable descriptions and labels for implementation data may be updated / entered in the application. First the user record must be updated to reference the new language. This may be done in one of the following ways:
   a. Switch to the new language using the Switch Language zone.
   b. If that zone is not available, navigate to the user page, assign the new language code to your User ID, sign out, and sign back in again.

Copyright © 2026, Oracle and/or its affiliates.

Any online functions that you access will use your new language code. You can change the language code for all users who plan to use/modify the new language.

> **Note**
>
> The language pack updates all language entries for base owned system data. If your implementation updates base owned labels and descriptions after applying a language pack, they will be overwritten the next time an updated language pack is applied. Note that most user facing labels and messages support defining an Override Label or Override Description. This information is not updated by the base product and should be utilized if your implementation desires a specific label or description.

Managing Multiple Languages

Once a non-English language has been set up, there are several points to note when adding or updating records that include translatable strings.

- When a new record is added through the user interface or through a REST service call or any other means that goes through the standard maintenance service, the system automatically generates entries for each supported language and copies the text of the entered description to all the generated languages.
- When the translatable string for a record is updated, only the user's language row is updated. The system does not ripple the change to other supported language entries (because it could be overriding a valid translation).
- When your system is upgraded to a new version, the new version typically includes new system data. The upgrade only includes the English language rows. Implementers should run the `F1-LANG` batch program to generate language rows for the your supported languages for this new data. If a new translation pack for your supported language is available at the time of upgrade, then running this process also applies the translated strings. (As mentioned above, for on-premise installations, you need to download and install the language pack before this step). If the language pack is not available at the time of upgrade, then the batch program should be run again when the language pack has been installed.
- New translatable objects may also be included in a patch / hot fix. In this situation, the `F1-LANG` batch program should be run after installing the patch in order to ensure there are language rows for your supported languages. Updated language packs are only provided for full release upgrades and not for hot fixes. So implementations may need to temporarily supply translations for the new strings until you update to the next release with the next updated translation pack.

Customer Language

Your specific product may also support capturing the language of a customer. Such that correspondence sent from the product may be produced in a language set on a customer record. Refer to your specific product documentation for more information about additional language support.

Defining Languages

Your product may support multiple languages. For example, the field labels, input text, and even outputs and reports can be configured to appear in a localized language. A language code for every potential language exists in the system to supply this information in various languages.

Copyright © 2026, Oracle and/or its affiliates.

Select **Admin**, and then **General**, and then **Language** to define a language.

This is a standard All-in-One portal.

When **Language Enable** is checked, the system adds a row for this language whenever a row is added in another language. For example, if you add a new currency code, the system will create language specific record for each language that has been enabled. You would only enable multiple languages if you have users who work in multiple languages. Languages that are configured as enabled, appear in the Switch Language zone.

> **Note**
>
> For on premise applications, the login page displays all the languages that are enabled, allowing the user to toggle the login instructions in that language. The list of enabled languages is captured on the server at startup time. If a new language is enabled, contact your server administrator to refresh the server in order to see the new language displayed in the login page.

The **Locale** is a string containing three portions:

- ISO language code (lower case, required)
- ISO country code (upper case, optional)
- Variant (optional).

Hyphens separate the various portions, and multiple variants are possible.

The locale along with the collator strength control how the contents of grids and search results are sorted by the Java virtual machine (JVM) on your web server: The specific JVM in use by your particular hardware/OS configuration constrains the available **Locales**. Validating the **Locale** against the JVM is outside the scope of this transaction. This means you are responsible for choosing valid **Locales**.

Additionally, external systems that communicate with the product and provide a language use a format that matches the locale. For example in the Accept-Language header for REST web service calls, a requested language is provided.

The following are examples of valid locales:

Locale	Comments
`en-US`	American English
`en-AU`	Australian English
`pt-BR`	Brazilian Portuguese
`fr-FR-EURO`	European French
`ja-JP`	Japanese

The **Collator Strength** parameter is used for the Java collation API . This parameter controls whether, for example, upper and lower-case characters are considered equivalent, or how accented characters are sorted. Valid values for collator strength are **PRIMARY**, **SECONDARY**, **TERTIARY**, and **IDENTICAL**. If you leave this field blank, Java will use its default value for the language. We'd like to stress that the impact of each value depends on the language.

Copyright © 2026, Oracle and/or its affiliates.

Please see https://docs.oracle.com/javase/7/docs/api/java/text/Collator.html for more information about the collator strength for your language.

Display Order indicates if this language is written **Left to Right** or **Right to Left**.

Note that all administrative control tables and system metadata that contain language-specific columns (e.g., a description) reference a language code. In addition, other tables may reference the language as a specific column. For example, on the User record you indicate the preferred language of the user.

Defining Countries

The topics in this section describe how to maintain countries.

- Country - Main
- Country - States

Country - Main

To add or review Country definitions choose **Admin**, and then **General**, and then **Country.**

The **Main** page is used to customize the fields and field descriptions that will be displayed everywhere addresses are used in the system. This ensures that the all addresses conform to the customary address format and conventions of the particular country you have defined.

Description of Page

Enter a unique **Country** and **Description** for the country.

The address fields that appear in the **Main** page are localization options that are used to customize address formats so that they conform to address requirements around the world. By indicating that an address field is **Optional**, you make that field available everywhere addresses for this country are used in the system. You can enter your own descriptions for the labels. These labels will appear wherever addresses are maintained in the system.

> **Note**
>
> Your specific product may also add the ability to mark an address field as **Required**. If that is available, then the product is also supplying appropriate validation in all places where a user defines an address.

> **Note**
>
> For any country where the **State** is enabled, the valid states for the country must be entered on the **Country - State** tab. When entering address constituents on a record that captures this detail, the value for State is verified against the data in the State table. For any country where there is a component of the address that represents a "state" but your implementation does not want to populate the valid states for that country, choose a different field such as County for this constituent (and define an appropriate label). When entering address constituents on a record that captures this detail, no validation is done for the County column.

Copyright © 2026, Oracle and/or its affiliates.

Country - States

To maintain the states located in a country, choose **Admin**, and then **Country**, and then **Search** and navigate to the **State** page.

Description of Page

For any country where you have enabled the State switch, use the **State** collection to define the valid states in the **Country**.

- Enter the standard postal abbreviation for the **State** or province.
- Enter a **Description** for this state or province.

Defining Currency Codes

The currency page allows you to define display options related to currency codes that are used by your system. Use **Admin**, and then **General**, and then **Currency** to define the currency codes in which financial information is denominated.

This is a standard All-in-One portal.

Most attributes are self explanatory.

> **Note**
>
> Please contact your specific product to verify whether it supports a currency with more than 2 **Decimals**.

The **External Reference** may be used to define a currency whose currency code is more than three characters. To support that type of currency, define a currency code that uniquely identifies the currency in the system and use the external reference to define the currency code recognized by external products. Note that your specific integration with an external system where financial information is included may need to be adjusted to use the external reference instead of the system's currency code. Refer to the specific documentation for your integrations to confirm.

Defining Time Zones

The following topics describe how to design and set up time zones.

- Designing Time Zones
- Setting Up Time Zones
- Setting Up Seasonal Time Shift

Designing Time Zones

The Time Zone entity is used to define all the time zones where your customers may operate. Each time zone should define an appropriate Time Zone Name. This is a reference to an external source that defines time zones, their relationship to Greenwich Mean Time, whether the time zone follows any shifting for summer / winter time (daylight savings time) and when this shift occurs.

Copyright © 2026, Oracle and/or its affiliates.

The following sections describe concepts and configuration topics related to managing time zones.

> **Note**
>
> Oracle Utilities Customer Care and Billing - Interval Billing applications customers should consult the topic *Time Issues* (search the Help index for "time issues") for specific information relating to that product's interval billing time related functionality.

The Base Time Zone

When designing your time zones, the first thing to determine is the base time zone. You may choose the time zone where the company's main office resides. Once this is done you can link the time zone code to the installation option as the base time zone. Refer to Installation Options - Main for more information.

> **Note**
>
> An attribute in the system properties file may be configured to indicate that the DB session time zone should be synchronized with the value defined on the Installation Options. Refer to the *Server Administration Guide* for more information.

If your company does business beyond your main office's time zone, define the other time zones where you may have customers or other systems with which you exchange data. At this point, your specific product may include configuration tables to capture default time zones, for example based on a postal code or geographic location.

Standard vs. Legal Time

The term **Legal Time** refers to the actual clock time as may be impacted by daylight saving (also called 'local time'). This time line has a gap hour on entry to the daylight saving period and a duplicate hour on exit from it.

The term **Standard Time** refers to a time line without any daylight saving shifts applied to it. This virtual time line has no gap hour on entry to the daylight saving period nor a duplicate hour on exit, i.e. it is continuous and non-ambiguous. As a general rule, it is recommended that all time sensitive data is stored in the standard time of the base time zone as defined on the installation options. This will prevent any confusion when analyzing data and will ensure that your algorithms do not have to perform any time zone or daylight saving shifting of data that may be stored in different time zones.

Depending on your specific product, entities may have their date/time information stored in either of the following options:

- Standard time of the base time zone.
- Standard time of another time zone related to the entity’s geographical location.
- Legal time of the base time zone.
- Legal time of another time zone related to the entity’s geographical location.

The metadata definition of a table specifies whether any of its date/time fields are stored in standard time or not. While typically all date/time fields of a table that supports standard time would be stored in the same way the system allows each field to specify either of these options.

Copyright © 2026, Oracle and/or its affiliates.

- **Physical Standard Time** indicates that the field is stored in base standard time and is pre-populated by the system. For example, creation time, status update time etc.
- **Logical Standard Time** indicate that the field is stored in base standard time.
- **Referenced Time Zone** indicate that the field is stored in standard time of a time zone related to the entity's geographical location.

Storage vs. Display

Regardless of the time zone option used for storing the data in standard time, all date/time information is entered and displayed on the user interface in the legal time of its respective time zone. If a field is defined to be stored in the standard time of the base or other time zone, the user interface is designed to accept the data in the legal time of the respective time zone and shift it to the standard time of the same time zone before saving the data and performs the reverse shift from standard time back to legal time before displaying the data to the user.

It is important to understand that time zone and daylight saving time conversions to and from standard time are performed behind the scenes as part of the user interface layer. Once data reaches the server it is already in its storage time option. The user should not be aware of these time conversions.

Time shifting between standard and legal times does not happen automatically. When dealing with fields stored in standard time, their data entry and display need to explicitly include time shifting features as part of their user interface and zone configuration.

Date / Time Schema Elements

When defining date / time fields in a business object schema, schema attributes can be used to define whether or not data should be stored in standard or legal time for the base time zone or if it should be stored in the standard time or legal time of another time zone (related to the data).

By default data stored in standard or legal time is displayed in the corresponding time zone's legal time. An additional schema attribute can be used to indicate if the display of the time should be shifted to the legal time of a different time zone. For example, if the data is stored in the base time zone but the data is related to a different time zone, the data will be shown in the time zone appropriate for the data (including the appropriate seasonal adjustment). Refer to Schema Nodes and Attributes- Standard Time Considerations for more information.

Exchanging Date / Time Information With External Systems

Date/time information should be exchanged between systems in standard XSD format as it includes a reference to the time zone of the specified time as an offset from Coordinated Universal Time (UTC). The system automatically converts date/time elements in an inbound message from XSD to internal format and vice versa for an outbound message. The latter is controlled by an explicit date/time format setting on the External System record for the outbound message type.

The offset is determined as followed and it is based on the time zone associated with the element as explicitly defined by the respective inbound or outbound schema:

- Elements defined as stored in the standard time of the base or other time zone would always have the same offset throughout the year as this time line is never shifted for daylight saving. The offset would be the standard offset of that time zone from UTC, i.e. not during daylight saving time.
- Elements stored in the legal time of the base time zone or other time zone would have the standard offset of the their storage time zone when the date/time value is outside the daylight saving period and the shifted offset when it is inside that period of time.

Copyright © 2026, Oracle and/or its affiliates.

User Time Zone

If your company does business in multiple time zones, the user record of each user may reference the time zone of their location. This time zone provides additional information about the location of the user and as such may be used by specific business rules that involve time zone settings.

> **Note**
>
> The time zone defined on the user record is not used to automatically display date/time information in the user's time zone. By default, the system displays date/time fields in the legal time of their respective time zone and not the user's time zone.

Setting Up Time Zones

Refer to Designing Time Zones for background information about defining time zones.

Open this page using **Admin**, and then **General**, and then **Time Zone**, and then **Search** .

This is a standard All-in-One portal.

Refer to the embedded help text for more information on the Time Zone attributes.

Setting Up Seasonal Time Shift

> **Note**
>
> The information in this topic applies only to Oracle Utilities Customer Care and Billing - Interval Billing applications.

Open **Admin**, and then **General**, and then **Seasonal Time Shift**, and then **Search** to define the seasonal time shift schedule.

Description of Page

Enter a unique **Seasonal Time Shift** code and **Description** for the seasonal time shift.

The Collection defines the **Effective Date/Time** (in standard time) that a time zone may shift in and out of standard time. If time is changed from standard time on the effective date/time, enter the **Shift in Minutes** that the time changes from standard time (usually `60`). If the time is changed back to standard time on the effective date/time, enter a **Shift in Minutes** of `0`.

Defining Geographic Types

If your company uses geographic coordinates for dispatching or geographic information system integration, you need to setup a geographic (coordinate) type for each type of geographic coordinate you capture on your premises and/or service points (geographic coordinates can be defined on both premises and service points).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Product specific.** There is no framework functionality that uses this information. Refer to your specific product documentation to verify how this table is used in your specific product. In addition, you can determine if this object is a foreign key on any tables specific to your product. Navigate to the Table page in the application, search for and select the Geographic Type table and use the Relationships tab to view this information.

To define geographic types, open **Admin**, and then **Geographic**, and then **Geographic Type.**

This is a standard All-in-One portal.

The **Validation Format Algorithm**, if specified, is used to validate that the geographic location entered on the premise and/or service point for the geographic type is in the format as defined in the algorithm. If you require validation, you must set up this algorithm in the system.

Defining Work Calendar

This portal is used to view and maintain information about a work calendar. Work calendars are used to ensure system-calculated dates fall on a workday.

You can access the portal from **Admin**, and then **General**, and then **Work Calendar**. You are brought to a query portal with options for searching for a specific calendar. Once a calendar has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Work Calendar.** This zone provides information about the selected calendar.
- **Work Calendar Holidays.** This zone lists the holidays observed by your organization for this calendar. Use the zone actions to add, maintain or duplicate a work holiday entry.

Defining Display Profiles

When you set up your users, you reference a display profile. A user's display profile controls how dates, times, and numbers displayed. Choose **Admin**, and then **General**, and then **Display Profile**, and then **Search** to maintain display profiles.

Description of Page

Enter a unique **Display Profile** and **Description** to identify the profile.

Enter a **Date Format**. This affects how users view dates and how entered dates are parsed. The following table highlights standard supported date mnemonics and what is displayed at runtime.

Mnemonic	Comments
dd	Day of the month.
d	Day of the month, suppressing the leading 0.
MM	Month number.
M	Month number, suppressing the leading 0.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Comments
yyyy	The 4-digit year.
yy	The 2-digit year.
y	Allows entry in either 2 or 4-digit form and is displayed in 2-digit form.

Other characters are displayed as entered. Typically, these other characters should be separators, such as "-", ".", or "/". Separators are optional; a blank space cannot be use.

Examples:

Configuration Format	Sample Output
MM-dd-yyyy	04-09-2001
d/M/yyyy	9/4/2001
yy.MM.dd	01.04.09
MM-dd-y	04-09-01 - In this case you could also enter the date as 04-09-2001

> **Note**
>
> For centuries, the default pivot for 2-digit years is 80. Entry of a 2-digit year greater than or equal to 80 results in the year being interpreted as 19xx. Entry of a 2-digit year less than 80 results in the year being interpreted as 20xx.

In addition, the following date localization functionality is supported. Note that in every case, the date is stored in the database using the Gregorian format. The settings below result in a conversion of the date for the user interface.

- **Hijri Dates**

  Entering **iiii** for the year is interpreted as a year entered and displayed in Hijri format. For example, the Gregorian date 2014–05–30 may be entered / displayed as 1435/07/30 for a user whose display profile date format is iiii/MM/dd. Note that this functionality relies on date mapping to be defined in the Hijri to Gregorian Date Mapping master configuration. entry. Refer to Additional Hijri Date Configuration for more information.

- **Taiwanese Dates**

  Entering **tttt** for the year is interpreted as a year entered and displayed in Taiwanese format where year 1911 is considered year 0000. For example, if the Gregorian date is 01-01-2005, it is displayed as 01-01-0094 for a user whose display profile date format is dd-mm-tttt.

- **Japanese Dates**

  There are two options available for configuring Japanese Era date support. The setting **Gyy** for the year is interpreted as a year entered and displayed using an English character for the era followed by the era number. The letter 'T' is used for dates that fall within the *Taisho* era. The letter 'S' is used for dates that fall within the *Showa* era. The letter 'H' is used for dates that fall within the *Heisei* era. The letter 'R' is used for dates that fall within the *Reiwa* era. For example, for a user whose display profile date format is Gyy/mm/dd the Gregorian date 2008/01/01 is shown as H20/01/01; the Gregorian date 1986/03/15 is

Copyright © 2026, Oracle and/or its affiliates.

shown as S61/03/15. The setting **GGGGyy** is interpreted as a year entered and displayed using Japanese characters for the era followed by the era number.

Japanese date limitations are as follows:

- The years 1912 through the current date are supported.
- Any functionality that displays Month and Year does not support Japanese Era dates. These dates are shown in Gregorian format.
- Graphs that display dates do not support the **GGGGyy** format.

Enter a **Time Format**. The following table highlights standard supported date mnemonics.

Mnemonic	Comments
hh	The hour 1-12.
h	The hour 1-12, suppressing the leading 0.
HH	The hour 0-23.
H	The hour 0-23, suppressing the leading 0.
KK	The hour 0-11.
K	The hour 0-11, suppressing the leading 0.
kk	The hour 1-24.
k	The hour 1-24, suppressing the leading 0.
mm	Minutes.
m	Minutes, suppressing the leading 0.
ss	Seconds.
s	Seconds, suppressing the leading 0.
a	Indicates to include **am** or **pm**. This is only needed for 12 hour formats, not 24 hour formats. (**hh**, h, KK, K). If an **am** or **pm** is not entered, it defaults to **am**.

Examples:

Configuration Format	Sample Output
hh:mma	09:34PM (can be entered as 09:34p)
hh:mm:ss	21:34:00
h:m:s	9:34:0

There are several options for displaying Numbers.

Decimal Symbol defines the separator between the integer and decimal parts of a number. Valid values are "." (a period) or "," (a comma).

Group Symbol defines the means to separate groups of bigger numbers. Valid values are as follows:

- A comma (","). Large numbers group by threes separated by a comma, for example 1,000,000.
- A period ("."). Large numbers group by threes separated by a period, for example 1.000.000.
- **None**. Large numbers do not have any separator, for example 1000000.

Copyright © 2026, Oracle and/or its affiliates.

- **South Asian**. This option uses a comma for its separator but will group large numbers as follows: the first comma is used for the thousands separation and numbers over 9,999 are grouped with 2 units, for example 10,00,000.
- **Space**. Large numbers group by threes separated by a space, for example 1 000 000.

Negative Format defines how negative values are displayed. Valid values are `-9.9`, `(9.9)`, or `9.9-`.

Currency values can have a different **Negative Format** from other numbers. Valid values are `-S9.9`, `(S9.9)`, or `S9.9-`, where the "S" represents the currency symbol.

- Additional Hijri Date Configuration

Additional Hijri Date Configuration

For implementations that wish to support displaying dates according to the Hijri calendar, besides appropriate configuration in the Display Profile, the mapping between the Hijri dates and the Gregorian dates must be entered. This mapping is defined in the **Hijri to Gregorian Date Mapping** master configuration record.

The mapping record contains a collection of entries for each year in the Islamic calendar.

For each year, clicking the Expand Zone icon shows the mapping collection with the first date of each month of the Hijri calendar. The corresponding date in the Gregorian calendar should be entered for each row.

Defining Phone Types

Phone types define the format for entering and displaying phone numbers.

To add or review phone types, choose **Admin**, and then **General**, and then **Phone Type.**

This is a standard All-in-One portal.

The **Phone Number Format Algorithm** for each phone type controls the format for entry and display of phone numbers.

Use **Phone Type Flag** is used to identify phone types that may have specific functionality associated with it. For example if your product had support for sending a facsimile transmittal, identify the phone type that captures a **Fax** number.

Defining Feature Configurations

Some system features are configured by populating options on a feature configuration.

You can access the portal from the **Admin Menu**, and then **General**, and then **Feature Configuration**. You are brought to a query portal with options for searching for a specific feature configuration. Once a feature configuration has been selected you are brought to the maintenance portal to view and maintain the selected record.

Because various options throughout the system may be controlled by settings in feature configuration, this section does not document all the disparate possible options. The administration documentation for each feature describes its options and whether an option supports multiple values. You may also refer to the detailed description of each option type when reviewing a configuration online for more information.

You can create options to control features that you develop for your implementation. To do this:

Copyright © 2026, Oracle and/or its affiliates.

- Review the lookup values for the lookup field EXT_SYS_TYP_FLG. If your new option can be logically categorized within an existing feature type, note the lookup value. If your new option warrants a new feature type, add a lookup value to this lookup field.
- Define the feature's option types. If you have identified an existing feature type to add the options to, find the lookup with the name xxxx_OPT_TYP_FLG where **xxxx** is the lookup value of EXT_SYS_TYP_FLG noted above. If you decided to create a new feature type (by adding a new lookup value to the EXT_SYS_TYP_FLG lookup, you must create a new lookup with the name xxxx_OPT_TYP_FLG where **xxxx** is the new value you defined above.
- Flush all caches.

The following zones may appear as part of the portal's **Main** tab page.

- **Feature Configuration.** This zone provides information about the selected feature configuration.
- **Options.** This zone is used to maintain various options associated with the feature type.
- **External System Messages.** If the feature exists to interface with an external system, you can use this zone to define the mapping between error and warning codes in the external system and our system. The zone is visible for feature types that their definition in the **Feature Type Configuration** Extendable Lookup supports this functionality.

> **Note**
>
> A corresponding message must be defined in the system message tables using a Message Category that is 90000 or greater so as to avoid collisions during upgrades.

Defining Master Configurations

A master configuration is an object that enables an implementation to define configuration for features in the system. It is an alternative to using feature configuration for defining options. A master configuration is defined using a business object. Typically one master configuration exists for a given business object yet some configurations may be designed to support multiple records.

Overview / Initial Setup

The product provides one or more master configuration that may be used for configuration. Some examples of base master configuration business objects are as follows

- **Hijri to Gregorian Date Mapping**. This allows an implementation that uses Hijri dates to define the mapping between those dates and Gregorian dates.
- **ILM Configuration.** For implementations that use Information Lifecycle Management, the ILM configuration record defines some parameters used by the process.
- **Migration Assistant Configuration.** For implementations that use the content migration assistant (CMA), the configuration record defines some parameters used by the process.

For a list of all the master configuration records provided by the product, navigate to the master configuration page in the application. To find help topics related to functionality controlled by the master configuration records, use the keyword ‘master configuration’ in the index.

Implementations may configure the business objects to limit the ones that are visible to users if desired.

Copyright © 2026, Oracle and/or its affiliates.

- If the master configuration does not apply to your implementation, navigate to the business object for this master configuration and update the Instance Control to **Do not allow new instances**. This ensures that the business object will not be visible to any user for the implementation.
- If a given master configuration record is only relevant for certain users in the system, application security may be used to limit the records visible by a given user. By default the base delivered business objects typically reference the Master Configuration MO application service. This may be overridden to link custom application services to the master configuration BOs to provide more granular security. Users will only see the master configurations that they have security for.

Configuration

You can access the portal from the **Admin**, and then **General**, and then **Master Configuration**. You are brought to a query portal with options for searching for a master configuration business object. If a configuration has not yet been set up for the business object use the add icon to define the record. If one or more configuration records exists for the business object you may select the master configuration business object. Once selected you are brought to this portal to view the selected record.

The following zones may appear as part of the portal's **Main** tab page.

- **Master Configuration** This zone provides information about the selected master configuration record. Please see the zone's help text for information about this zone's fields.
- **Related Configurations** This zone lists additional master configuration records for the same business object, representing different parts of the same configuration. You may add additional parts from this zone. The zone is only visible when the business object is designed to support multiple configuration parts and is explicitly marked as such by the **Multiple Configurations** business option.

What's New Portal

> **Important**
>
> This is only available for cloud implementations.

The What's New portal provides a list of maintenance pack fixes that have been applied to your environment along with a summary of the maintenance packs that have been supplied along with their dates. There is also a link for Release Notes. Clicking this link opens the Cloud Application Readiness page. Select the link corresponding to your product and version to see the new features added in your version.

To view the information, open the Help Menu in the toolbar and choose the What's New option.

The following zones appear on the Main page.

- **Maintenance Pack Details**. This zone is populated whenever a maintenance pack or a hot fix is applied to your environment. By default it shows fixes applied in your current maintenance pack and it suppresses copies if your environment already received this fix in a previous release. Use the filters to expand the search to other releases or to include copies. There are also filters to narrow the search based on various criteria. Refer to the zone inline help for more information.

Copyright © 2026, Oracle and/or its affiliates.

- **Installation History Summary**. This zone is visible if you click the 'View Installation Summary' link in the previous zone. It shows a distinct list of installation date and version information.

> **Note**
>
> This zone only has fixes that were applied to your environment after the enhancement to populate this data was fully supported. The system is not populating this zone with fixes applied to your implementation prior to the enhancement.

Security & User Options

The contents of this section describe how to maintain a user's access rights.

- Application Security
- Row Security
- Data Privacy
- Cryptography Keys

Application Security

The system restricts access to various components of the application using application services. The following sections provide more information about this mechanism.

- Understanding Application Security
- Defining Application Services
- Defining Security Types
- Defining User Groups
- Defining Users
- Application Security Query

Understanding Application Security

The contents of this section and supporting topics provide information about application security.

Users

Each user who is granted access to the application is stored in the User object. This object defines the attributes of the user including identifier, name, language, time zone, home page and display profile (which defines the preferred format of dates and amounts). In addition there is configuration related to using the product, including favorite links and scripts, portal preferences and valid To Do roles - controlling what types of To Do entries a user can work on. Additionally, Refer to Users and User Groups for additional information.

Copyright © 2026, Oracle and/or its affiliates.

Application Services

Each object in the system that may be secured is associated with an application service. For example, each page in the system defines its application service allowing you to control what users can view a given page.

An application service defines one or more Acces Modes, which typically correspond to an action associated with the application service. This allows you to control users that can only view a type of record (and grant security to the Inquire access mode) and users that can perform other actions such as add, change and delete. Refer to Secured Objects and Application Servicesto understand what objects are associated with an application service and the typical access modes associated with each type of secured object.
Application Services may also define additional configuration, called security types. Refer to Field Level Security for more information.

User Groups

User Groups are a mechanism for grouping users, usually around job roles. Users are attached to User Groups through a relationship that is effective-dated. This can be useful for the attachment of temporary employees such as contractors or for people who change roles regularly.

Each User Group is authorized to access appropriate Application Services and their access modes. In addition, user groups define access to the application service's security types, if applicable. Refer to Field Level Security for more information.

- Users and User Groups
- Secured Objects and Application Services
- Field Level Security
- Importing Security Configuration from an External Source

Users and User Groups

A user group defines the application services and access modes its users have access to. A user may be associated to more than one user group. The user groups may have overlapping security configurations and the security access for a user is the union of all security granted by all of its user groups.

A major effort for implementations is to decide how to define their user groups. User groups can be created to represent roles or other job-related categorization; or based on organizational factors; or a combination of both. Refer to Secured Objects and Application Services for some guidelines on understanding what application services secure and tools provided to help security administrators identify what application services to grant access to.

The following sections provide additional topics related to users and user groups, including some base functionality related to these objects as well as some best practices.

Base Delivered User / User Groups

The system is delivered with a base User linked to a base User Group, provided to facilitate an initial user accessing the application for an on-premises implementation.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Cloud implementations should refer to the Cloud Services Administrative Guide for information on setting up users.

The system supplied user is **SYSUSER**. This user is delivered so that when an on-premises environment is provisioned, there is at least one user authorized to use the system. It has access to the base delivered user groups. An initial administrator can sign in as this user and proceed to create the actual users that should get access to the environment.

> **Important**
>
> Once appropriate users have been defined, it is recommended to update SYSUSER to set it to disabled. (In cloud implementations, this user is delivered as disabled.)

The product provides several base user groups that serve as a kind of library of services. They are meant for documentation purposes and as a way to easily access the system in a development or testing environment. Some user groups are meant to define a list of services associated with a distinct set of features or functions in the system. The user group `ALL_SERVICES` is a catch-all user group that defines services that are not part of a specific use case. (Note that some services may be defined in ALL_SERVICES as well as another specific user group). You cannot change or remove the information delivered for the base user groups. System administrators should define user groups appropriate for their business requirements.

> **Important**
>
> It is not recommended for any production user to have access to the base delivered user groups that are provided as a library of services. The product often adds or changes records in the base user groups for a new release when there is new or changed functionality. It means that your production users would have a change in what they have access to without the ability to opt in to new features.

Defining a Read-Only User Group

The product does not supply a user group that is 'read only', but it is a common requirement for implementations. This section provides a guideline for creating such a user group.

1. Create the User Group with the desired name and description.
2. Navigate to the Service Manager tab. In the Add Application Service / Access Modes tab, you can use the filter to limit the results to those with Inquire access mode. Click the checkbox in the header to select all rows and click Add. You are prompted for an expiration date. Click Save. (Note that the zone has a limit to 1000 services so you may need to do this more than once to get all services added.)
3. In addition, you should give this user group access to all the access modes for the default application service: `F1-DFLTS` (Default Application Service). This application service is considered one that all users should have for basic access to the system.

Copyright © 2026, Oracle and/or its affiliates.

Template User

The system provides support for defining one or more users as a template user. There are two broad use cases for using a template user.

Inheriting Preferences or Favorites Configuration

Some implementations want all users of a certain team to have the same configuration of portal preferences and / or favorite links. This allows users in that team to have the same information in the same place on their respective displays, facilitating in helping each other with questions.

If your organization wants to implement this practice, define a template user with the desired portal preferences and / or favorite links. You may define different users with different configurations for more granularity.

For each user whose preferences or links should be taken from the template user, go to the User record via **Admin**, and then **Security**, and then **User.** If the portal preferences should be inherited from a template user, define the desired template user as the **Portals Profile User** . If the favorite links should be inherited from a template user, define the desired template user as the **Favorites Profile User**.

If applied, the specified user's portal preferences and / or favorite links will be those defined on the template user and they will be unable to customize those preferences.

Defining a Template User to help in User Creation

The user object in the product captures configuration related to many aspects of using the product. It includes application security configuration, such as its user groups; row level security configuration through its access groups; the To Do roles that define what types of To Do entries a user can work on, along with other configuration. Many users that are in a similar 'role' in the organization would have many of the same settings. As such, it may be useful for implementations to define a template user that represents a 'role' in the organization, with much of the configuration common for users in that role. When creating a new user, you can use the template user as the starting point and then duplicate that record to create the new user. Then you only need to adjust the information that is unique for the newly created user.

Many implementations provision their users first in an external identity management system and use an interface to import the user definition into the product. Refer to Importing Security Configuration from an External Source for more information. For these interfaces, the external system may have the ability to define custom information relevant to the product's user record, but the product also supports referencing a template user so that information from the template user is copied to the new user while creating the record.

How can you refer to a template user when creating a User from and external source?

- When the new user is uploaded to the system, the interface uses the user BO `F1-IDMUser` to create the user. The BO includes a pre-processing algorithm. This algorithm looks for the existence of a template user in the schema of the new user sent as a characteristic of type `F1-TMUSR`. If such a characteristic is found, it uses that template user. If not found, the algorithm supports defining a template user as an algorithm parameter. If a template user is identified, all the information from the template user will be copied onto the new user record except for the information passed in from the external source. The template user is captured on the newly created user via a characteristic for information / audit purposes.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bookmarks** are not included in the data that is copied from a template user.

- Once the new user is created, its configuration can now be adjusted, if applicable. Note that the template user is only a tool used when adding a user. Updates to the template user will not "ripple" to all the other users that were created based on this template.
- Not all external sources may have the ability to define a template user and send it as a characteristic or via another field. For these integrations, using a single template user on the algorithm as a parameter may be used to define basic configuration applicable to a large percentage of new users. (More information on this below). For those integrations that are able to associate a new user with a template user in the external system and provide that template user along with the new user information allows you to associate the new user with a template user that is more aligned with the user's role. Refer to Importing Security Configuration from an External Source for more information on how each integration supports the definition of a template user.

Designing your Template Users for helping Create Users

Before configuring template users, all the administrative control tables that are part of User configuration must be defined, including time zones, display profiles, To Do roles, data access roles and user groups.

If your integration will use a single template user defined as an algorithm parameter, you need to define a template user with the basic information that is applicable to all or at least most users. See below for guidance on referencing this template user as an algorithm parameter.

If the way you create users allows you to associate the user with a more specific template user, the next step is to define the user configuration for your system users. During this exercise, you will find that you have broad categories of users. But you will also see that within a given category of user there may be variations in the user privileges and preferences. For example, perhaps there are supervisors within the Customer Service role that have more security privileges than a typical Customer Service user. In addition, there may be variations based on the attributes of the users themselves. For example, maybe your organization exists in multiple time zones and some of your workers are in one time zone and some are in the other.

At this point your security users that are designing their user provisioning procedures must decide the following:

- What information about a new user will be captured in the identity system (besides the expected information like Name, Email and the User IDs)? For example, for the case of multiple time zones, maybe the best solution is to capture the time zone when defining the user.

  What information is defined on the template user and how many template users should be created to reduce the need for manual steps or additional data captured in the identity management system? In the case of multiple time zones, proliferating the template users to have one set for one time zone and another set for the other time zone may not make sense since this is one field that is different. However it may be reasonable to create additional templates in the case of striations in the levels of privileges for workers of a different category. So rather than template users for Dispatcher, Mobile Worker, System Administrator and Contractor, your organization may have template users for Dispatcher, Mobile Worker, Mobile Worker (Supervisor), System Administrator, Contractor (Short Term) and Contractor (Long Term).

  What information is must be configured on the User record in the application after the user is added? If only a small number of users have a variation from other users, it may be that

Copyright © 2026, Oracle and/or its affiliates.

the easiest way to deal with those variations is to simply update those user records manually. Using the above examples:

- If your organization covers 2 time zones but only a small group of people work in one of the time zones whereas the bulk of the users are in the other time zone, the simplest procedure may be to define the template users for the main time zone and use that for the creation of all users. Then for the small group of users in the separate time zone, navigate to the User page to adjust the time zone after the record is added.
- If only a small number of Mobile Workers are supervisors with separate privileges, rather than defining a special template user for those type of workers, the simpler procedure may be to use the Mobile Worker template and then navigate to the User page to add the additional privileges to the supervisor users after the record is added.

Defining a Template User

Regardless of which use case is applicable for your organization, the procedure for defining a template user is the same.

Navigate using **Admin**, and then **Security**, and then **User.**

- Define a User ID. If you are using a template user to help create users from an external system and the external system is able to capture the template user to send in with the new user information, this is the ID that should be referenced in the external system.
- Be sure to choose a **User Type** of **Template User**.
- Define all the information appropriate based on the use case.
  - For template users used as a Portal Profile user, be sure to define the appropriate portal profile information.
  - For template users used as a Favorites Profile user, be sure to define the appropriate favorite links.
  - For template users acting as a type of 'role' to help with creation of users, define all the information that should be copied onto a new user that references this user as its template user. (Note that **Bookmarks** are not included in the data that is copied from a template user.)

Defining a Default Template User for Integrations

Define the default template user on the algorithm that defaults data from this user as follows:

- Navigate using **Admin**, and then **System**, and then **Algorithm.**
- Search for and select the algorithm `F1-OIMUSR` (Populate User Data from a "Template" User).
- Edit the record. Add a new row in the Algorithm Versions collection. Enter an appropriate date (later than the date of the existing entry, but on or before the current date). Populate the template user you want to use as the default.

Secured Objects and Application Services

The system restricts access to transactions or explicit services using an application service. The following sections provide more information about what objects are secured, how to find out what is secured by each app service as well as additional information related to managing application services.

Copyright © 2026, Oracle and/or its affiliates.

What is Secured by an Application Service

- The following points highlight security related to viewing and modifying individual records in the system:
  - All maintenance objects define an application service that includes the basic actions available, typically **Add**, **Change**, **Delete**, and **Inquire**. The base product supplies an application service for every maintenance object. Some objects that include a fixed lifecycle, may define additional access modes on the maintenance object's application service. The application service for the maintenance object is defined on its related service program.

    > ⚠ **Caution**
    >
    > Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a maintenance object that includes access modes **Freeze**, **Complete** and **Cancel**). If you want to give a user access to any of these special actions, you must also give the user access to the **Change** action.

  - For maintenance objects whose user interface page is not portal-based, the application service also controls whether the menu entry appears. If a user doesn't have access to the maintenance object's application service, the menu item that corresponds with the application service will not be visible.
  - For portal based user interfaces, each main (stand-alone) portal defines an explicit application service with the access mode **Inquire**, allowing the user interface to be secured independently of the underlying object security. If a user doesn't have access to the portal's application service, the menu item that corresponds with the application service will not be visible. The base product supplies an application service for every portal that is accessible from the menu. Note that the application service for the portal is defined on its related service program, which is derived via its navigation option and navigation key.
  - Menu items may define an application service / access mode. Typically the security supplied for portals and maintenance objects provides enough granularity to suppress menu items that a user does not have access to. In addition, by default, the system populates application services / access modes on menu items related to a BPA script. A common use case is the 'Add' menu item for maintaining an object. In this case, typically the application service for the maintenance object is used along with the **Add** access mode. Other types of BPA related menu items may have other appropriate configuration.

    Clients may choose to linking an explicit application service / access mode to further suppress a menu item. For example, imagine your implementation creates a special BPA script to add a To Do Entry and would like users to use the special BPA rather than the base supplied Add dialogue for To Do Entry. The base delivered menu item for adding a To Do Entry uses the To Do Entry maintenance object application service with the Add access. Users need that security setting to be able to add a To Do Entry even from a different dialogue. To suppress the base Add dialogue, override the setting for the base supplied menu item for To Do Entry Add with a special application service and access mode. Then define a menu entry for the new special BPA for adding.
  - Zones define an application service.

Copyright © 2026, Oracle and/or its affiliates.

        * For zones linked to a portal, if a user doesn't have access to the zone's application service, the zone will not be visible on the portal. In most cases the zone is delivered with the same application service as its portal. In special cases, such as the zones on the Sidebar, the product supplies separate application services for each zone allowing implementations to determine at a more granular level which users should have access to which zones.
        * For query zones that are configured on a multi-query zone, if a user doesn't have access to the zone's application service, the zone will not be visible in the dropdown on the multi-query zone. In most cases all zones in a multi-query zone define the same application service as the multi-query zone. The product may supply a special application service for one or more zones in a multi-query zone if the functionality is special to certain markets or jurisdictions and not applicable to all implementations.
        * For zones that are used by business services to perform SQL queries, the product supplies a default application service (`F1-DFLTS`). Security for these zones is not checked by the product as they are used for internal purposes.
    - For portal based pages, individual elements may be shown or hidden based on security using the **oraHasSecurity** function in a UI map's HTML or in UI Hints in a schema. Refer to Check User's Security Access for more information.
    - Business objects define an application service. If the business object defines a lifecycle, the application service must include access modes that correspond to each state. In addition, the standard maintenance object access modes of **Add**, **Change**, **Delete** and **Inquire** are included. The base product business objects are supplied with appropriate application services. In addition, implementations may override the configured application service if desired.

      > ⚠ **Caution**
      >
      > Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a business object that includes lifecycle states **Freeze**, **Complete** and **Cancel**). If you want to give a user access to any of these special actions, you must also give the user access to the **Change** action.

    - Batch controls define an application service which provides the ability to secure submission of individual batch processes. The application service must include an access mode of **Execute**. The base product batch controls are supplied with appropriate application services. These services will typically have an ID that matches the batch control ID.
    - Report Definition records define an application service. The application service must include an access mode of **Submit / View Report**.
- The following objects are securable but are typically executed via internal processes. The security is provided to ensure that any access to the objects from an external source is secured.
    - BPA scripts may define an application service with the access mode **Execute**. The base BPA scripts are typically not configured with any application service. An implementation may define one. Note that as mentioned above, a menu item may also be configured with an application service and access mode. This allows for a BPA that is invoked via a menu entry to be secured in more than one way.

Copyright © 2026, Oracle and/or its affiliates.

- Business Services and Service Scripts define an application service with the access mode **Execute**. This is needed for services that may be executed from an external system, for example via an inbound web service. Base business services and service scripts that are linked to an inbound web service are configured with special application service. All other business services and service scripts are delivered with a default application service (`F1-DFLTS`), which may be overridden by an implementation.
- Scripts may also check security within an Edit Data step type if there is some functionality that should or should not execute based on a user's security access. The Edit Data step would include a call to the business service `F1-CheckApplicationSecurity`
- Service Programs define an application service. As mentioned above, for Portals and Maintenance Objects, their application service is taken from the related service program. In base, specific application services are released for each of these types of service programs. All other service programs are typically delivered with a default application service (`F1-DFLTS`), which may be overridden by an implementation. Note that for service programs linked to a Business Service, the application service on the business service takes precedence when invoking the business service.

Determining What an Application Service Secures

Because the product wants to provide as much granularity as possible so that implementations can have the greatest control over what users can do, there are a large number of application services provided out of the box and it can be daunting to understand who needs to have access to what application services to do their job. The product provides several online tools to help security administrators to understand what application services exist and what they are for.

- On the application service page itself, there is a Secured Objects zone that indicates all the metadata that is related to this application service. There are a small number of application services that are securing functionality that is not discoverable by the Secured Objects zone. For those services, the detailed description of the application service should indicate what it's for.
- A large percentage of security is related to a specific page in the system that is accessible via the menu. Because of the different layers of security, to be able to view a record you may need access to several application services: the one associated with the query portal, the one associated with the maintenance portal, the one associated with the maintenance object of the record and the one associated with the business object governing the record. When viewing a menu, there is an Application Security tab, which allows you to review each menu line and see a list of all the application services a user may need access to for viewing or maintaining data on that related page.
- The Application Security Query portal provides various filters for viewing what objects are being secured by what services. Besides menu items, it shows batch controls, reports, web services and other functionality. In addition, it allows you to view what users and what user groups currently have access to what application services and allows you to compare the security of two users.
- The User Group portal includes several zones that help security administrators to configure security options or review security configuration. The main tab includes a zone to Add Application Services. This zone only shows application services that are not already linked and provides several ways to narrow down the list of application services. The Service Manager tab has a similar zone, but breaks down the information to a combination of application service and access mode. Finally, the Secured Components tab is similar to the Application Security Query. It allows you to query the objects secured by application services in this user group.

Copyright © 2026, Oracle and/or its affiliates.

Application Services Introduced in a Release

When new functionality is provided that includes any object that is associated with an application service, new application services may be introduced. The product release notes indicate the new application services included in the release. In addition, the product includes a special Entity Tag that includes a list of the new application services. The tag's description uses the cloud release reference rather than the on-premise release reference to identify itself.

Field Level Security

Sometimes transaction and action security is not sufficient. There are situations where you may need to restrict access based on the values of data. For example, in Oracle Utilities Customer Care and Billing you might want to prevent certain users from completing a bill for more than $10,000. This is referred to as "field level security".

Field level security can be complex and idiosyncratic. Implementing field level security always requires some programming by your implementation group. This programming involves the introduction of the specific field-level logic into the respective application service(s). The recommendation is to use a business object validation algorithm for checking field level security.

> **Note**
>
> The check for field level security must exist in validation logic to ensure that data is not added or updated if it does not pass the field level security rules.
>
> It is not straight forward to implement user interface changes related to field level security, such as protecting elements under certain conditions. This is because overriding the base product delivered user interface to check for implementation specific conditions is not always supported, depending on how the user interface is built, or requires a full duplication of product artifacts, which is not recommended.

The definition of a user's access rights is performed using the same transactions used to define transaction / action level security. This is achieved as follows:

- Create a security type for each type of field-level security.
- Define the various access levels for each security type. For example, assume you have some users who can complete bills for less than $300, and other users who can complete bills for less than $1,000, and still other users who can complete bills for any value. In this scenario, you'd need 3 access levels on this security type:
  - Level 1 (lowest): May authorize bills <= $300
  - Level 2 (medium): May authorize bills <= $1,000
  - Level 3 (highest): May authorize all bills
- Link this security type to each application service where this type of field level security is implemented. This linkage is performed on the security type transaction.
- Defining each user group's access level for each security type (this is done for each application service on which the security type is applicable).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Highest value grants highest security. The system expects the highest authorization level value to represent highest security level. Moreover, authorization level is an alphanumeric field so care should be taken to ensure that it's set up correctly.

Importing Security Configuration from an External Source

The product provides support for importing security information from an external source. In all cases, the product uses a special user BO `F1-IDMUser` to create the user and the recommendation is to take advantage of the Template Userfunctionality. More information about the out of the box support for using this feature is described in the related links.

- If your organization uses Lightweight Directory Access Protocol (LDAP), you can import your existing LDAP users and groups into the system. Once imported, all user and group functions are available. You can import a user group, or a single user. You can resynchronize your LDAP users and groups at any time.

  > **NOT_SUPPORTED**
  >
  > For more information refer to LDAP Integration.

- The system provides an integration with Oracle Identity Manager. When a user is created in the identity manager product, its information can automatically be interfaced to the product. Once the user is successfully created in the system, all functions are available.

  > **NOT_SUPPORTED**
  >
  > For more information refer to Oracle Identity Manager Integration.

- The system provides a web service with add, update and get operations that follow the System for Cross-domain Identity Management (SCIM) specification for provisioning users.

  > **NOT_SUPPORTED**
  >
  > For more information refer to Provision Users with SCIM Open Standard.

Defining Application Services

Please refer to Understanding Application Security for a description of how application services are used when you grant user groups access rights to transactions and the significance of an application service's access modes.

You can access the portal using **Admin**, and then **Security**, and then **Application Service.** You are brought to a query portal with options for searching for a specific application service. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page

- The **Application Service** zone provides the information about the application service and its access modes.
- The **Secured Objects** zone displays the object (or objects) that are secured by this application service. Refer to Secured Objects and Application Services for details about the types of objects that may be secured.

The **Application Security** tab includes zones to view and manage which user groups have access to the application service and which ones do not have access .The following zone may appear as part of this tab page:

- The **User Groups Linked** zone lists the user groups that currently have a link to the application service. Note that expired links are included when the zone is first displayed. Use the zone filters to exclude expired links and to limit the user groups shown by user ID, user group ID, and user group description.
- The **User Groups not Linked** zone lists the user groups that do not have a link to the application service. Use the zone filters to limit the user groups shown by user ID, user group ID, and user group description.

Defining Security Types

Security types are used to define the types of field level security.

> **Note**
>
> **Programming is required.** You cannot have field level security without introducing programming code. Refer to Field Level Security for more information on how security types are used to define field level security.

- Security Type - Main

Security Type - Main

Select **Admin**, and then **Security**, and then **Security Type** to define your security types.

Description of Page

Enter a unique **Security Type** and **Description**.

Use the **Authorization Level** grid to define the different authorization levels recognized for this security type. Enter an **Authorization Level Number** and its **Description**.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Programming is required.** Note that the values that you enter are not interpreted by the system itself, but by the user exit code used to implement the special security. Check with the developer of the user exit logic for the correct values. Refer to Field Level Security for more information on how security types are used to define field level security.

Use the **Application Services** grid to define the application service(s) to which this security type is applicable. If this application service is already associated with user groups, you must update each user group to define their respective security level. This is performed on the User Group portal.

Defining User Groups

A user group is a group of users who have the same degree of security access. Think of a user group as a "role"; associated with a role are:

- The users who play this role
- The application services to which the role's users have access (along with the actions they can execute for each service and their field level security authorization levels).

Refer to Secured Objects and Application Services and Field Level Security for more information about access modes and security types.

> **Caution**
>
> Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a transaction that supports actions in addition to **Add**, **Change**, and **Inquire** (e.g., **Freeze**, **Complete**, **Cancel**). If you want to give a user access to any of these additional actions, you must also give the user access to the **Inquire** and **Change** actions.

This portal allows a security administrator to view and manage information about a user group.

You can access the portal from the **Admin Menu**, and then **Security**, and then **User Group**. You are brought to a query portal with options for searching for a specific user group. Once a user group has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Caution**
>
> Application services may not be changed or removed from any Base Delivered User / User Groups.

The following zones may appear as part of the portal's **Main** tab page

- **User Group.** This zone provides information about the selected user group.

Copyright © 2026, Oracle and/or its affiliates.

- **Application Services.** This zone lists application services linked to the selected user group. You may use this zone to edit the information for an specific application service or use mass actions to remove selected services or update their effective date.
- **Add Application Services.** You may use this zone to add application services to the selected user group.

The following zones may appear as part of the portal's **Users** tab page

- **Users.** This zone lists users linked to the selected user group. You may use mass actions to remove selected users or update their effective date.
- **Add Users.** You may use this zone to add users to the selected user group.

The following zones may appear as part of the portal's **Service Manager** tab page

- **Application Service / Access Modes.** This zone lists application service and access mode combinations currently linked to the selected user group. You may use mass action to remove a selected set of records.
- **Add Application Service / Access Modes.** You may use this zone to add application service access mode records.
- **Security Type Authorization.** This zone maintains field level security for application services included in the selected user group.

The following zone may appear as part of the portal's **Secured Components** tab page

- **Application Components.** This zone allows you to review various types of application components secured by the selected user group. The query is similar to the Application Security Query restricted to the current user group.

Defining Users

The user maintenance transaction is used to define a user's user groups, data access roles, portal preferences, default values, and To Do roles. To access the user maintenance transaction, select **Admin**, and then **Security**, and then **User**.

The user maintenance transaction is the same transaction invoked when the user launches Preferences from the user menu or shortcut key.

Application Security Query

This portal allows a security administrator to review application security configurations across users, user groups and the various types of application components they secure.

While application security is configured at the granular level of an application service and its access modes, it is more intuitive to review access rights to top level broader components:

- **Menu line.** Several application services may be related to a single menu line and impact the ability to properly leverage various aspects of its functionality:
  - The application service of the transaction page or portal, which also controls the visibility of the menu line or its 'search' part when the line is composed of 'add' and 'search' items.
  - The application services associated with any zones on that portal.
  - The application service of the underlying maintenance object when applicable, which also controls the 'add' item of the menu line.
  - The application services of business objects for the underlying maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

- The application services of portals used to maintain these business objects.
- The application services of related portals.
- The application services of related maintenance objects, their business objects and portals.
- and more

You may review the list of application services associated with a menu line on the **Application Security** tab on the **Menu** portal.

- **Sidebar Zone.** This is a regular or context sensitive zone that the user has access to on the sidebar area.
- **System.** This is a Toolbar or other system wide option a user is allowed to use.
- **Batch Control.** This is a batch process a user is allowed to submit.
- **Report Definition.** This is a report a user is allowed to submit.
- **Web Service.** This is a web service a user is allowed to invoke.
- **Miscellaneous.** This is a special service that a user is allowed to invoke.
- **Internal.** This is an internal item that is secured by default but is assumed to be called in a context that does not require security check.
- **Unclassified.** Some application services may not be related to any type of application component and as such remain unclassified. For example, there are situations where previously released services are enhanced to be associated with dedicated application service in a later release. In this situation the services may retain their original or even custom application service and the new application services may appear as not associated with any component.

Refer to Secured Objects and Application Services for details about the types of objects that may be secured.

Open this page using **Admin**, and then **Security**, and then **Application Security Query**.

Row Security

Some products allow you to limit a user's access to specific rows. For example, in Oracle Utilities Customer Care and Billing, row level security prevents users without appropriate rights from accessing specific accounts.

A combination of framework configuration and configuration in your edge product is required for row level security. The following points describe the configuration:

- For each record that should be secured, associate it with an **Access Group**. Note that if your edge product supports row level security, that product is providing a link between the secure-able record and Access Group. Your access groups may be granular and only referenced by one secured record or they may be more broad and be referenced by multiple secured records that require the same type of security restriction.
- To define which users have access to the secured records, you define a **Data Access Role**. For each data access role, define which Access Groups the role has security clearance for. An access group may be linked to one or more data access roles. In addition, define the **Users** that have access rights to these secured records. When you grant a data access role rights to an access group, you are giving all users in the data access role rights to all secured records in all the referenced access groups. A user may belong to many data access roles.

Copyright © 2026, Oracle and/or its affiliates.

If your edge product supports row level security, it will include logic in the appropriate areas of the system to limit the secured rows that a user may view or maintain based on this configuration. For example, in Oracle Utilities Customer Care and Billing, throughout the system users are only able to view and maintain information about an account and any of its detail if the user is in a Data Access Role for the account's Access Group (or the account is not linked to an Access Group).

> **NOT_SUPPORTED**
>
> Refer to your product's documentation for more information on row level security, if applicable.

- Defining Access Groups
- Defining Data Access Roles

Defining Access Groups

Refer to The Big Picture of Row Security for a description of how access groups are used to restrict access to specific objects.

Access groups control which groups of users (referred to as Data Access Roles) have rights to accounts (or other objects) associated with the access group. You can access the portal using **Admin**, and then **Security**, and then **Access Group**. You are brought to a query portal with options for searching for a specific access group. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Access Mode** zone provides the information about the access group and its data access roles.

- The **Data Access Role** collection defines the data access roles whose users have access to the access group's secured objects. Keep in mind that when you add a **Data Access Role** to an **Access Group**, you are granting all users who belong to this role access to all of the objects linked to the access group.

  > **Note**
  >
  > You can also use Data Access Role - Access Group to maintain a data access role's access groups.

- The **To Do Role Assignment** collection may be used to route To Do Entries of a given To Do Type to a specific To Do Role if the objects related to the To Do Entry are associated with the access group. Refer to Adjusting the To Do Role for more information.

Defining Data Access Roles

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Row Security for a description of how access groups are use to restrict access to specific objects.

The data access role transaction is used to define two things:

Copyright © 2026, Oracle and/or its affiliates.

- The users who belong to the data access role.
- The access groups whose accounts (or other objects) may be accessed by these users.
- Data Access Role - Main
- Data Access Role - Access Group

Data Access Role - Main

Select **Admin**, and then **Security**, and then **Data Access Role** to define the users who belong to a data access role.

Description of Page

Enter a unique **Data Access Role** code and **Description** for the data access role.

The scroll area contains the **Users** who belong to this role. A user's data access roles play a part in determining the accounts (or other objects) whose data they can access.

To add additional users to this data access role, press the add button and specify the following:

- Enter the **User** ID. Keep in mind that when you add a **User** to a **Data Access Role**, you are granting this user access to all of the accounts (or other objects) linked to the data access role's access groups.
- Use **Expiration Date** to define when the user's membership in this data access role expires.

> **Note**
>
> **Also maintained on the user page.** You can also use User - Access Security to maintain a user's membership in data access roles.

Data Access Role - Access Group

Select **Admin**, and then **Security**, and then **Data Access Role** and navigate to the **Access Groups** tab to define the access groups whose accounts (or other objects) may be accessed by the users in this data access role.

Description of Page

Use the **Access Group** collection to define the access groups whose objects can be accessed by this role's users. Keep in mind that when you add an **Access Group** to a **Data Access Role**, you are granting all users who belong to this role access to all of the accounts (or other objects) linked to the access groups.

> **Note**
>
> You can also use Access Group - Main to maintain an access group's data access roles.

Data Privacy

Personally Identifiable Information (PII) is any information that identifies or could be used in combination with other information to identify an individual. Many countries have data privacy

Copyright © 2026, Oracle and/or its affiliates.

laws governing the use of such information. A key aspect of these laws is an organization's obligation to erase personal information when there is no compelling reason to retain it. This obligation can be fulfilled either by deleting data or altering the data in such a way that it is no longer possible to associate the data with the individual.

Organizations are likely to have other legal obligations that impact how long they retain personal data. For example, there could be financial audit requirements that oblige the organization to retain relevant information for a fixed number of years after termination of a contract.

Object Erasure is designed to address right to erasure issues, with a combination of configuration and processes that may be extended to implement the appropriate policies for the PII within your data.

- Encryption and Masking
- The Approach to Implementing Object Erasure
- Data Redaction for Export and Logging
- Defining Redaction Rules
- Obfuscation Configuration

Encryption and Masking

"Encryption" refers to encrypting data stored in the database using an encryption key. There are two different types of encryption described in the sections below. System encryption refers to columns in the system identified by the product to use encryption. Application encryption refers to the ability for an implementation to configure fields and elements that should be encrypted in the database.

"Masking" refers to overwriting all or part of an un-encrypted field value with a masking character. For example, perhaps only the last 4 digits of a tax ID number are visible with the other digits changed to an asterisk. The system provides support for masking fields on the user interface that may be stored as plain text in the database. In addition, there are cases where encrypted fields are shown to the user interface using masked values rather than the encrypted value.

The following sections provide more information about each feature.

- System Encryption
- User Interface Masking
- Application Encryption

System Encryption

The system automatically encrypts certain fields captured in various option tables or context tables. This is mainly used for passwords. For example, passwords captured in Message Sender context or password

In addition, batch control supports configuring a security option for parameters that capture sensitive information, such as a password. Refer to Defining Batch Controls for more information.

It is also possible to enable system encryption using the characteristic type `F1-PWD`. However, the maintenance object must include specific code to enable system encryption for characteristics of this type. In Oracle Utilities Application Framework, the only maintenance

Copyright © 2026, Oracle and/or its affiliates.

object that supports this is extendable lookup. Refer to Extendable Lookup Advanced Topics for more information.

User Interface Masking

The functionality described in this section is used to take data that is stored in plain text in the database and mask the value before it is presented to a user (or an external system). This feature includes the ability to allow some users to view the data unmasked using security configuration. The system allows different masking rules to be applied to different fields. For example, a credit card number can be masked differently than a social security number.

The following topics describe how to mask field values.

Identify the Data to be Masked

Identify the data that is stored as plain text, but should be masked for display to users. For example, imagine that you have identified that Credit Card Numbers and a person's federal ID number (for example, in the United States, the Social Security Number or SSN). Each field identified may be displayed and maintained in different user interfaces throughout the system, but the masking rules for a given field are probably uniform regardless of where the data is displayed.

Primary keys cannot be masked. A field defined as a unique identifier of a row cannot be configured for masking. Masking a field that is part of the primary key causes a problem when attempting to update the record. This restriction also applies to elements that are part of a "list" in an XML column on a maintenance object. One or more elements in the list must be defined as a primary identifier of the list. Be sure that primary key elements in the list are not ones that require masking.

List members that contain different "types". Consider a page with a list that contains a person's identification numbers. You can set up the system so that a person's social security number has different masking rules than their drivers license number. If your implementation has this type of requirement, the list of masked fields should contain an entry for each masking rule.

For each field, if there are some users that may see the data unmasked on one or more of the user interfaces, then security configuration is required. If the value of a field should be masked for all users across all pages in the application, then the security configuration is not needed.

Security Configuration

Define a security type for each field with two authorization levels:

- 1 - Can only see the element masked
- 2 - Can only see the element unmasked

Link all of the security types to an application service of your choosing. We recommend linking every masking-oriented security type to a single application service (e.g., `CM_MASK`) as it makes granting access easier.

For each security type, identify which users can see its data unmasked and which users can only see its data masked. If the masked and unmasked users fit into existing user groups, no additional user groups are necessary. Otherwise, create new user groups for the masked and unmasked users.

After the user groups for each security type are defined, link each user group to the application service defined above. When a user group is linked to the application service, you will define the authorization level for each security type linked to the application service. If a user group's

Copyright © 2026, Oracle and/or its affiliates.

users should see the security type's field values unmasked, set the authorization level to 2; otherwise set it to 1.

> **Note**
>
> Updating masked values. The system supports allowing a user that sees a masked value to update the value. For numbers that are masked, the masked value is typically all 9s. If there is some chance that a user is allowed to update a masked number, the recommendation is that the user is configured with authorization to see the number unmasked. Otherwise, there is a corner case where the user sees the masked number and needs to update the number to a value that exactly matches the masked value. In this case, the update won't go through because the system doesn't recognize it as a change.

> **Note**
>
> Flush the cache. Remember that any time you change access rights you should flush the security cache (by entering flushAll.jsp on the URL of the application) if you want the change to take effect immediately.

Configure a Masking Algorithm

A data masking algorithm (using the algorithm entity value of **Feature Configuration - Data Masking**) must be created for each combination of masking rules and security type. These algorithms determine if a user has the rights to view a given field unmasked, and, if not, how the field should be masked.

The base package provides two algorithm types. Both support configuration to allow a set of users to see the data unmasked. Parameters capture the application service, security type and authorization level defined above used to evaluate this.

- `F1-MASK`: this is for masking alphanumeric data. Its parameters are designed to handle most masking needs. Parameters allow you to configure how much of the data to mask and what masking character to use. Refer to the algorithm type description for more information.
- `F1-MASKNBR`: this is for masking numbers. Refer to the algorithm type description for more information.

Determine How the Fields are Displayed

The masking configuration differs based on how a field is retrieved for access to the user interface. So for the masking of one "logical" field (like a person's SSN), there may be multiple configuration entries required to cover all the access methods. Review each user interface where a given field is displayed and create the following categories:

- The field is an element that is retrieved by invoking a business object, a business service, or a service script
- The field is stored as an ad hoc characteristic
- The field is displayed on a fixed maintenance page (and is therefore retrieved by invoking a page service)
- The field is displayed on a fixed search page (and is therefore retrieved by invoking a search service)

Copyright © 2026, Oracle and/or its affiliates.

Create a Feature Configuration for Each Masked Element

Create a feature configuration with a Feature Type of **Data Masking**. An option entry with option type of **Field Masking** is needed for every combination of field to mask and the method used to display the data. The value will contain mnemonics that reference the appropriate data masking algorithm along with configuration that differs depending on how the field is retrieved for display as described below.

Schema Based Object Field Masking

For data that is accessed via a schema-based object call and displayed in a UI map, the field to be masked must reference a meta-data field name in its schema definition: `field="fld_name", alg="algorithm name"`

If the element references an mdField in the schema, that is the field used to identify the masking rule. If there is no mdField reference but only a mapField reference, that is the field used to identify the masking rule. For example, if you want to mask a credit card number, let's assume that field is defined in the schema is the following:

```
<creditCard mdField="CCNBR" mapField="EXT_ACCT_ID"/>
```

In this case, the option value should be `field="CCNBR", alg="algorithm name"`. An option value of `field="EXT_ACCT_ID", alg="algorithm name"` would not result in masking.

A "where" clause may also be specified. This is useful for data that resides in a list where only data of a certain type needs to be masked: `field="fld_name", alg="algorithm name", where="fld_name='value'"`

For example, person can have a collection of IDs and only IDs of type 'SSN' (social security number) should be masked. If the person data including its collection of person IDs is displayed on a UI map via a business object call, let's assume the collection is defined in the following way:

```
<personIDs type="list" mapChild=CI_PER_ID">
  <isPrimaryId mapField="PRIM_SW"/>
  <idType mapField="ID_TYPE_CD"/>
  <personIdNumber mapField="PER_ID_NBR"/>
</personIds>
```

The option value may look like this: `field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"`

Please note the following important points for schema based masking:

- **Limitation of 'where' field** Although the main use of a 'where' clause for schema oriented elements is to mask certain elements in a list based on a 'type', it is also possible to mask a single field in the schema based on the value of another field. For example, imagine that a customer submits a registration form that defines an ID type and ID value. Although this data is not in a list, the implementation may still want to only mask the ID value if the ID type is "SSN". The framework is only able to mask an element in the schema based on a 'where' clause if the element in the 'where' clause is a "sibling" in the schema.
  - If the element to be masked is in a list, the element in the 'where' clause must be in the same list.

Copyright © 2026, Oracle and/or its affiliates.

- If an element to be masked maps to a real column in a table, the element in the 'where' clause must also map to a real column in the table.
- If an element to be masked maps to and XML column in the table as a single element, the element in the 'where' clause must map to the same XML column as a single element.

- **Multiple feature option entries for the same field.** It's possible that different schemas in the system have a similar type of data that may be masked based on different conditions. For example, imagine that an implementation has different schemas that captured or referenced person identifiers in different ways:
  - One schema captures a single person ID without any corresponding "type" record and it should always be masked using Algorithm CM_SSN_MASK:

    ```
    <personSSN mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
    ```

  - One schema captures a person ID and a corresponding ID Type and it should be masked with Algorithm CM_SSN_MASK if the type is "SSN" and masked with algorithm CM_FEIN_MASK if the type is "FEIN".

    ```
    <personIdType mapXML=BO_DATA_AREA mdField=ID_TYPE_CD/>
    <personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
    ```

  - One schema captures a person ID and a corresponding ID Type and it has the same masking rules as the previous schema, but a different field name is used for the ID Type code. (This scenario could happen if for example a different label is desired for ID Type on the user interface for this schema.)

    ```
    <personIdType mapXML=BO_DATA_AREA mdField=CM_ID_TYPE/>
    <personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
    ```

  For this scenario, the feature options may look like this:

  1. `field="PER_ID_NBR", alg="CM_SSN_MASK"`
  2. `field="PER_ID_NBR", alg="CM_SSN_MASK", where="ID_TYPE_CD='SSN'"`
  3. `field="PER_ID_NBR", alg="CM_FEIN_MASK", where="ID_TYPE_CD='FEIN'"`
  4. `field="PER_ID_NBR", alg="CM_SSN_MASK", where="CM_ID_TYPE='SSN'"`
  5. `field="PER_ID_NBR", alg="CM_FEIN_MASK", where="CM_ID_TYPE='FEIN'"`

  For each schema, the system will first find whether the element applies to any masking option. It will find 5 masking options for the field PER_ID_NBR. Then it will determine if any sibling elements match the 'where' clause.

  - If more than one sibling element matches a 'where' clause, a runtime error is issued. For example if a schema has an element that references "mdField=ID_TYPE_CD" and an element that references "mdField=CM_ID_TYPE", this is an error. Additionally, if multiple elements reference mdField=ID_TYPE_CD", this is an error.
  - If one and only one sibling element matches a 'where' clause, the value of the element is compared to the values defined in the 'where' clause. If it finds a match on the value, the appropriate masking algorithm is applied. If no match is found (for example, the Person ID Type is "LICENSE") the element is displayed as is.

Copyright © 2026, Oracle and/or its affiliates.

- If no sibling element matches a 'where' clause and a feature option exists with no 'where' clause (option 1 above), then the masking algorithm of the option with no 'where' clause is applied.

- **Changing the value in the 'where' clause.** If your implementation has some users that are allowed to change records where some data is masked based on a condition, it is recommended to design the user interface to reset the masked value when the value in the 'where' clause changes. For example, if a user is prevented from viewing a person's social security number, but the user is allowed to make updates to the person's record, changing the value of the Person ID Type should reset the Person ID Number. This would ensure that the user does not 'unmask' the social security number by simply changing the ID Type.

Records Maintained Using Page Maintenance

For data that is accessed via a page maintenance service call, indicate the table name and the field name where the data resides: `table="table_name", field="fld_name", alg="algorithm name"`

For example if the Person record and its collection of identifiers are displayed and maintained using page maintenance, the option value should be `table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name"`

A "where" clause may also be specified: `table="table_name", field="fld_name", where="fld_name='value'", alg="algorithm name"`

This is useful for data that resides in a child table where only data of a certain type needs to be masked. For the person ID example, `table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"`

Characteristic Data

For data that is stored as a characteristic, simply indicate the characteristic type: **CHAR_TYPE_CD='char type', alg="algorithm name"**

This needs to be defined only once regardless of which characteristic entity the char type may reside on. Note that only Ad hoc characteristics are supported.

Masking Fields in Explorer Zones or Info Strings

In explorer zones data is often retrieved using SQL directly from the database. No masking is applied automatically in this case. If there is data in the explorer zone results that should be masked, the masking must be applied by calling a business service.

Similarly, an MO Info algorithm may not use BO interaction to get data. It may access data using SQL for efficiency purposes. No masking in applied when retrieving data via SQL. To apply masking to a string prior to including it in an info string, the masking must be applied by calling a business service.

The system supplies two business services to be called to determine if masking rules apply for a specific field.

- `F1-TableFieldMask`. Mask a Table field. This business service receives a table name, field name and one or more field values. If masking applies it returns the masked value.
- `F1-SchemaFieldMask`. Mask a Schema field. This business service receives a schema name and type, XPath and field value. If masking applies it returns the masked value.

Search Service Results

For data that is displayed on a 'fixed' search page, it is retrieved via a search service call. Indicate the search name and the appropriate field to mask along with the masking algorithm.

Copyright © 2026, Oracle and/or its affiliates.

For example: `search="SearchServiceName", field="PER_ID_NBR", where="ID_TYPE_CD='SSN'", alg="algorithm name"`

To find the name of the search service, launch the search in question, right click in the filter area and choose **Inspect**. Search for "serviceName". The service name is listed there. To find the field name to mask, search for "Widget Info". There should be two results found, one for the filter area and one for the results area. This results area has the text "SEARCH_RESULTS" as prefix for each field. The field names are the ones after the x$. Do not reference the x$ when defining the field name. Note, the "where" statement can only apply to fields that are also part of the search results.

Additional Masking Information

The following points provide additional information to assist in your masking configuration:

- If the demonstration database includes a **Data Masking** feature configuration, review the settings because it will probably contain masking rules that will match your own.
- On data input pages, a user might be able to enter or change masked data, such as a bank account number, but not be able to subsequently see what they added or changed.
- External systems can request information by performing a service call via a web service. Please keep in mind that some web service requests require data to be masked and some do not. For example, a request from an external system to synchronize person information needs the person's social security number unmasked; whereas a request from a web self service application to retrieve the same person information for display purposes needs the person's social security number masked. To implement this type of requirement, different users must be associated with each of the requests and these users must belong to separate user groups with different access rights.
- If a maintenance object (MO) contains a field that holds an XML document and a service call invokes the MO's service program directly, the system will mask individual XML elements in the field if a **Determine BO** algorithm has been plugged into the maintenance object and the element(s) in the respective BO schema have been secured as described above.

Application Encryption

The functionality described in this section allows implementations to configure fields to encrypt when storing it in the database. This functionality is mutually exclusive from the User Interface Masking functionality. This feature also supports encrypting specific elements stored within a CLOB or XML column.

The following points highlight the features of the encryption functionality:

- The encryption key is defined using a key ring. Refer to Field Encryption for information about defining encryption key rings.
- When a field is configured to be encrypted, the encrypted data is stored in a special encryption field that is not the source field (the one exposed to the user on the user interface). The source field captures the data as masked. Because a special field is required to support encryption, the product must provide support for that field to be encrypted.
- For encrypted data that must allow searching, the system supports capturing a hash value in a special field. The product must provide support for this functionality. Besides providing a special field to capture the hash value, base search functionality for that data must also cater for this configuration.

Copyright © 2026, Oracle and/or its affiliates.

- The system supports encrypting data that is captured as an element within an XML field. If the XML field is provided in a schema owned by the product, then the product must provide specific support for the capture of the encrypted data.
- For backward compatibility, the system also supports encryption keys and hash keys defined using a keystore. This is not the recommended method going forward, but further information about defining the keystore in the system can be found in the Installation Guide. Refer to Moving from Keystore to Key Ring for information about adopting the key ring functionality if you are currently using the keystore.

The following sections provide additional information about the support for encryption provided by the framework. Refer to the security chapter of the administration guide for your particular product for more information.

Encrypting and Masking the Data

When a product enables encryption for a given field, a special encryption field should be created to capture the encrypted value. Because encrypting is optional, the source field (the one exposed to the user) should not be this special encrypted field. If encryption is configured, the system will internally populate the encrypted field. The source field will be populated with asterisks by default. That way the masked data is what is shown to the user on the page rather than the encrypted value.

The following points highlight how the system behaves when encryption is configured and when it is not. Assume as an example, the field is a credit card number. The user views and populates a field with the field name CC_NBR. The table also has a second field ENCR_CC_NBR. A user populates the credit card number:

- If encryption is not configured, CC_NBR will be updated with the entered credit card number and ENCR_CC_NBR will be empty. Note that in this case, an implementation may choose to configure user interface masking.
- If encryption is configured, CC_NBR will be updated with '**********' and ENCR_CC_NBR will contain the encrypted value. The asterisks for the standard field will fill the full field size up to 50 characters.

If for some reason the standard masking using all asterisks is not desired, the system supports supplying an explicit masking algorithm using the same Feature Configuration - Data Masking plug-in spot used for User Interface Masking.

> **Warning**
>
> Unlike user interface masking, the masking of encrypted fields is not driven by security. The data stored in the source field for all encrypted data should be masked. Be sure not to configure security authorization logic in algorithms used for this type of masking.

Feature Option Configuration

Create a feature configuration with a Feature Type of **Encryption**. For each source field you are encrypting, enter an option with option type of **Field Encryption**. The value will contain mnemonics that reference the appropriate encryption key ring along with configuration related to the field and its table location. Unlike the user interface data masking, the configuration for data encryption is related to how the data is stored rather than how it is displayed. In addition, each entry may define an explicit masking algorithm to override the default and if supported, may also define a hash field and hash key ring.

Refer to Field Encryption for information about defining encryption key rings.

Copyright © 2026, Oracle and/or its affiliates.

For data that is stored in a specific column on a table, an explicit field to capture the encrypted value must exist. Indicate the table name, source field name and encrypted field name along with the key ring: **table='table_name', field='fld_name', encryptedField='encr_fld_name', keyRing='key ring code'**

A "where" clause may also be specified when data resides in a child table and only data of a certain type needs to be encrypted.

Example, **table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', keyRing='CM-SymmetricKey', where='ID_TYPE_CD='SSN''**

For data that is stored in an XML column in a record, the source field to be encrypted must reference a meta-data field name in its schema definition along with the element that captures the encrypted data and the alias: **field='field_name', encryptedField='encr_field_name', keyRing='key ring code'**

The syntax for adding a reference to a masking algorithm is **maskAlg='algorithm name'** .

The syntax for adding configuration for capturing a hash value for searching purposes is **hashKeyRing='key ring code' hashField='HASH_FLD_NAME'**.

The following is an example of configuration that uses all the possible options (specific masking algorithm, where clause and hash field support):

table='CI_PER_ID', field='PER_ID_NBR', keyRing='CM-SymmetricKey', encryptedField='ENCR_PER_ID_NBR', hashKeyRing='CM-HashKey' hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN', maskAlg='CM-PERIDMASK'
For backward compatiblity, the product supports defining an encryption key using a keystore. For implementations that continue to use this configuration, you reference the alias or hash alias instead of the key ring. The following is an example of the configuration that uses all the possible options, but uses the alias instead of a key ring.

table='CI_PER_ID', field='PER_ID_NBR', alias='aliasKey', encryptedField='ENCR_PER_ID_NBR', hashAlias='hashAliasKey' hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN', maskAlg='CM-PERIDMASK'
In addition, when using an alias, the encrypted field may optionally be "wrapped" with a special marker (e.g., ENC{}) to indicate that the field value is encrypted. This can be specified by the setting wrap="true" or wrap="false". The default is false. This should be set to false unless additional processing in your code is included to handle the special marker.

Refer to Moving from Keystore to Key Ring for information about adopting the key ring functionality if you are currently using the keystore.

Searching by an Encrypted Value

If the product supports a hashed value for an encrypted field for searching purposes, the following points highlight explorer zone configuration for this purpose

- The user filter value should reference the source field and should include an additional `encrypt=` mnemonic. For example

  ```
  type=STRING
  label=PER_ID_NBR
  encrypt=[CI_PER_ID,PER_ID_NBR,ID_TYPE_CD,F1]
  ```

  Refer to User Filters for more information.
- The SQL should include the hashed value in the WHERE clause. Note that because encryption is optional, a product zone that includes searching by a field eligible for

Copyright © 2026, Oracle and/or its affiliates.

encryption will include finding a match for the filter in the source field (as plain text) or in the hashed field. For example:

```
WHERE
   [(F2) (ID.PER_ID_NBR =:F2 OR ID.HASH_PER_ID_NBR = :F2)]
```

Customizing Encryption Algorithm

This feature is only applicable to implementations that use the keystore. This is not the recommended configuration going forward. The text is kept here for information purposes.

Although the encryption algorithm to use with a given key can be gleaned from the key in the keystore, there is sometimes extra information associated with an algorithm that might need to be used to encrypt or decrypt data.

The system provides a feature configuration option for the **Encryption** feature type using the option type **Algorithm Info** that can be used to adjust the behavior of the encryption.

- You can modify the default mode and padding of the encryption algorithm.
- If a key will be used to digitally sign anything, the signing algorithm can also be specified for the key.

For details about the syntax, refer to the feature option type's detailed description.

- Managing Encrypted Data

Managing Encrypted Data

The sections in this topic provide information about encrypting data when first implementing the application along with various use cases that may require re-encrypting data, such as key rotation.

The batch job `F1-FLENC` (Field Encryption for a Maintenance Object) is provided to handle encryption / re-encryption of all data for a given Maintenance Object. Review your encryption configuration and identify all the maitnenance objects that should have data encrypted. Run the batch once for each maintenance object. The below sections highlight various use cases that warrant running this batch for each maintenance object.

Initially Encrypting Data

Once your encryption / hash configuration is complete, any data added or updated from that point on is encrypted / hashed per the configuration. However, for all existing records that have data that should be encrypted / hashed, you need to run the batch job `F1-FLENC` for each maintenance object to go through and encrypt / hash the data in the existing rows.

Mass Key Rotation

If you introduce a new encryption key or hash key, as described in Key Rotation, or you introduced a new key ring as described in Key Ring Rotation, records added or updated from that point on will be re-encrypted / re-hashed with the latest key for the respective key ring. However, to rotate the key for all existing records that are encrypted / hashed with the previous key, you need to run the batch job `F1-FLENC` for each maintenance object to go through and re-encrypt or re-hash the data in the existing rows.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You can independently choose to introduce a new encryption key or a new hash key. The batch program will check each encrypted field or hashed field to confirm that they use the current active key and if not, the data is adjusted.

> **Note**
>
> When rotating a Hash Key, from the time the new key is activated until the time when all records have been successfully updated to use the new hash key, if any end users attempt to search for records via a hashed field, there may be inconsistent results. You should schedule rotation of hash keys to be during a time where end users are not impacted. Ideally you activate the new key and run the key rotation batch control for all maintenance objects during off hours.

Moving from Keystore to Key Ring

Using the key ring for defining your encryption and hash keys allows for key rotation. If your implementation has been using a keystore for field encryption / hashing and would like to use the key ring instead, you can do this as described in the following steps.

- Define a key ring for the Symmetric Key and a key ring for the Hash Key, if applicable.
- Generate and activate a key for each key ring.
- Go to the Feature Option Configuration. For each entry, add references to keyRing / hashKeyRing to define the newly created key rings. Be sure to keep the configuration for the alias mnemonic in place. The system needs this information to know how to unencrypt the existing data if it was encrypted using the keystore. Note that the system doesn't need the hashAlias if you are moving from using the keystore for the hash key to using the key ring. The system simply applies the new hash key.
- Records added or updated from that point on will be re-encrypted / re-hashed using the indicated key ring and its active key. To rotate the key for all existing records that are encrypted / hashed with the keystore alias, you need to run the batch job `F1-FLENC` for each maintenance object to go through and re-encrypt or re-hash the data in the existing rows.
- Once you have confirmed that all the data is using the key ring for encryption and hashing, you can update the feature option configuration to remove the reference to the old alias keys.

The "notes" listed in the Mass Key Rotation section also apply to this use case.

The Approach to Implementing Object Erasure

This section describes the product approach to implementing object erasure for its maintenance objects (MOs).

> **Note**
>
> The approach outlined is intended for managing erasure of master data objects. The assumption is that Information Lifecycle Management will be used for archiving any related transactional data.

Copyright © 2026, Oracle and/or its affiliates.

Various events in the system may signal the need to erase data at some future date. For example, closing an account may indicate the need to erase both the account and person data once there is no longer a need to maintain related financial details. There may also be events that re-establish the business relationship with a person and signal that data marked for erasure should now be retained.

The Object Erasure Schedule is used to capture key details of objects with data that needs to be erased. Records in the schedule are monitored periodically to determine if the date for erasure has been reached and if so, execute the erasure logic. The system will create and maintain records in the schedule when specific events occur for an MO that is marked for erasure.

The system provides the ability to mark an MO as eligible for erasure via a number of MO configuration entries. Included in these is an option that defines the business object for the MO's erasure schedule records. In addition to defining the erasure record elements, this BO defines the monitoring process and the specific erasure logic for the MO.

The following sections provide more information about configuring and managing object erasure.

- Configuring a Maintenance Object for Erasure
- Manage Erasure Schedule Algorithm
- Monitoring the Schedule and Performing Erasure
- Erasing User Information By Obfuscation
- Viewing an Object’s Erasure Status
- Viewing Erasure Configuration
- Archiving the Object Erasure Schedule

Configuring a Maintenance Object for Erasure

There are three types of maintenance object configuration entries that define how to manage erasure:

- An option to define the business object for erasure schedule records.
- An option to define the period between the date on which the need for erasure is detected and the date on which erasure should occur. The common logic provided by the system to add or update erasure records uses this option to determine the erasure date.
- One or more entries in the MO algorithm collection for the algorithms that determine whether a record should be scheduled for erasure, according to the current state of the record, and create or update the erasure schedule entries.

Some MOs that would commonly be regarded as eligible for erasure will be installed with a base Erasure BO already configured. The expectation is that the corresponding Erasure Period option and the algorithm for the Manage Erasure Schedule plug-in spot will be set up by your implementation with the appropriate entries for your organization's business rules.

> **Note**
>
> The presence of an Erasure Period option is the signal to the system that your implementation has enabled an object for erasure.

Copyright © 2026, Oracle and/or its affiliates.

It may not be necessary for all master data objects that contain personally identifiable information to manage their own erasure schedule. For example, the event which triggers erasure for a person record may also trigger the creation of erasure schedule entries for the person's other master data records. In this case, only the person maintenance object will need to be configured with a Manage Erasure algorithm (or algorithms). Refer to your product specific documentation for more information on the recommended approaches for your product's master data objects.

The portal Maintenance Object Configuration includes a zone that shows all the maintenance objects eligible for object erasure. You may use this zone to review or change the configuration for any of the maintenance objects.

Manage Erasure Schedule Algorithm

Algorithms of this type are responsible for determining a record's erasure status and creating or maintaining an entry in the Object Erasure Schedule for the record. They are triggered when certain events occur in the system for maintenance objects that are eligible for erasure. Multiple algorithms can be configured for the plug-in spot.

Depending on the determination made by the algorithm (or algorithms), a number of different actions may need to be taken. For example:

- A new schedule record may need to be added
- An existing schedule record may need to be updated with a new erasure date
- A pending record may need to be discarded if erasure is no longer applicable
- A discarded record may need to be reactivated if erasure now applies again

The base business service `F1-ManageErasureSchedule` performs the common logic to handle the possible actions and is recommended for use by these types of algorithms. The service can also optionally create a log entry for information purposes. Refer to the description of the business service for full details.

In certain circumstances, if one record is scheduled for erasure, other related records may need to be evaluated. The base business service `F1-ManageErasureScheduleDriver` performs the logic to execute an MO's Manage Erasure Schedule algorithms. It can be used to manage any related records from within another algorithm.

This type of algorithm is plugged into the Maintenance Object — Algorithm collection.

Your product may supply algorithms to manage the schedule for base MOs that are regarded as eligible for erasure. If your organization has special business rules that are evaluated to determine the erasure schedule for an MO, a custom algorithm can be created and applied by the implementation team.

Monitoring the Schedule and Performing Erasure

The erasure schedule is managed using the lifecycle of the erasure record's business object. A deferred monitor process is used to periodically check for records that are due for erasure and transition them from the 'pending erasure' state to the 'erased' state. An enter plug in on the 'erased' state is responsible for performing the erasure logic.

The system provides a 'root' business object for the object erasure schedule (`F1-ErasureScheduleRoot`) which defines the lifecycle that erasure schedule business objects should follow. The system also provides a monitor process (`F1-OESMN`) which is configured on the 'pending erasure' state of the 'root' business object. This process is configured to monitor object erasure schedule records whose erasure date is on or before the batch business date.

Copyright © 2026, Oracle and/or its affiliates.

Maintenance objects that are eligible for erasure should be configured with an erasure schedule business object that uses the 'root' business object as its parent. The algorithm that performs the erasure processing applicable to that maintenance object must be plugged in on the 'erased' state of the 'child' business object.

The system provides an erasure schedule business object (`F1-ErasureScheduleCommon`) which is designed to erase an object by deleting the main record and any child records. Your product may supply additional erasure schedule business objects for certain use cases. Refer to your product specific documentation for more information.

Erasing User Information By Obfuscation

Some implementations consider the base User object to have personally identifiable information. Erasing user information by deleting the records is not advisable as it can cause referential integrity problems. The recommended approach is to obfuscate the data instead.

The system provides a user erasure business object (`F1-ErasureScheduleUser`) which is designed to support obfuscating a user's identifiable information by removing it or replacing it with a non-identifiable value if the field is required.

If the User maintenance object is configured to be eligible for erasure in your implementation, the manage erasure schedule algorithm for the record will be invoked whenever the **Enable** flag is changed for a record on the User maintenance page. The system provides a base algorithm (`F1-OBJERSUSR`) specifically for the User MO. This algorithm will add an entry to the object erasure schedule if the user record is disabled or deactivate an existing erasure schedule record if a disabled user record is enabled again.

Viewing an Object's Erasure Status

The system provides a portal for viewing and editing an erasure schedule record. The portal is accessed from the **Object Erasure Schedule** sidebar zone. This is a context sensitive zone which only appears when accessing a record for a maintenance object that is configured to be eligible for erasure. It displays the information for the erasure schedule entry for the record in context, if applicable.

To add the zone to an eligible maintenance object:

- Navigate to Context Sensitive Zone and search for the navigation key for the maintenance object.
- Add the Object Erasure Schedule zone `F1-OBJESRSCD` to that navigation key.

Viewing Erasure Configuration

The erasure configuration may be viewed in the Maintenance Object Configuration portal.

Archiving the Object Erasure Schedule

The system provides the ability to archive older records in the object erasure schedule using Information Lifecycle Management. The object erasure schedule maintenance object is configured with a base ILM eligibility algorithm and an ILM crawler batch control.

The base object erasure schedule BO is configured to set the ILM archive switch when an erasure schedule record enters a final state and to reset it if the record becomes active again.

Refer to The Approach to Implementing Information Lifecycle Management for more information on archiving functionality.

Copyright © 2026, Oracle and/or its affiliates.

Data Redaction for Export and Logging

Personal identifiable information (PII) requires special handling when exported out of the application and written to files, including log files. Information that is encrypted at the database level remain encrypted and therefore protected when exported. With respect to non-encrypted information, the need to obfuscate it for added protection depends on how the exported data is intended to be used. If the exported information is part of an integration flow with an external system then the data should remain unchanged. However, when exporting data from a production environment for testing purposes sensitive information should be anonymized before they can be imported to a lower environment or written to logs for troubleshooting purposes.

The following are key aspects of this functionality:

- Redaction rules define how specific fields should be redacted when needed.
- When redaction rules exist, data redaction is performed by default by specific tools for export and logging. In absence of redaction rules, data is exported in its original form.
- Redaction rules are customer specific and may only be relevant to environments that contain sensitive data. As such, they are not released with the base product. Review your data redaction requirements and configure appropriate rules in relevant environments.
- Certain users may be allowed to export data in a non-redacted form based on application security.

The following sections provide additional information about this topic.

Redaction Rules Are Customer Specific

Redaction rules identify which fields should be redacted and how they should be anonymized. The list of fields to redact and the function to use to manipulate their values are customer specific and therefore are not released with the base product. A sample set of rules are provided as accelerator data for reference only.

It is important that you review your data redaction requirements and configure rules that reflect your business needs.

Redaction By Default

Processes that support data redaction on export and when logging do so by default when redaction rules exists. When rules are not defined, data is exported as is. Note that for this reason it is unnecessary to define such rules in lower environments that do not contain sensitive information.

Specific Export Tools Only

Data redaction is supported by the following tools only:

- **Content Migration Assistant (CMA).** Depending on application security, a user may indicate on a specific data set export request that data should be exported in its original form.
- **General Data Export (GDE) batch processes.** A batch parameter may be used to explicitly request that data is exported in its original form. This option is also protected by application security and enforced at batch submission time.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This type of process establishes a single export stream that may be sent to multiple targets. Review these integrations to ensure they do not have conflicting data redaction requirements and set the batch parameter accordingly.

- **Debug logging**. By default, data is redacted base on redaction rules when writing details to the various logs.
  - In an environment that is not a live production environment, a user with appropriate security may use a feature configuration to turn this off. Find the Feature Configuration record for the **General System Configuration** feature type. (It may need to be defined if it does not exist). Choose the option type **Turn Off Log Redaction** and define a value of **Y**.
  - The system uses a property (isLiveProduction) to check if an environment is a live production environment. In a cloud implementation, the development operations team sets the property when your implementation has indicated that you are live. In an on premises implementation, it is recommended to set this property when you are live. Refer to the system administration guide for more information.

Different Types of Redaction Rules

Sensitive information may reside in various types of storage fields which impact the way they are identified for redaction. You may define rules that target fields on specific tables or provide a more global rules that applies to all references of a specific field.

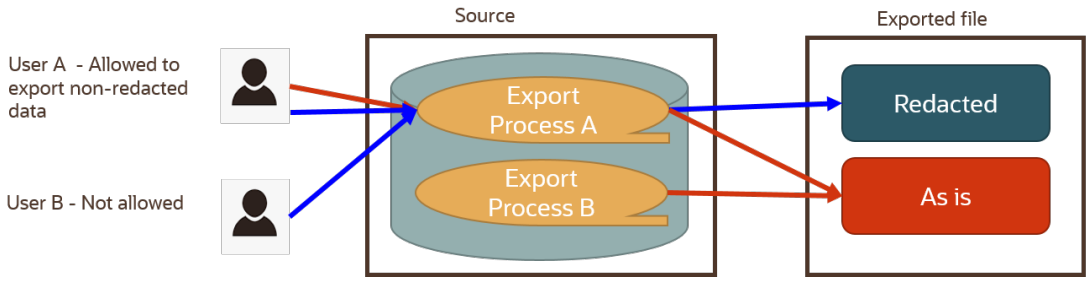
The application supports the following types of redaction rules:

- **Physical Field.** This type of rule applies to a value residing in a field on a specific table. An optional filter expression may be provided when only records of a certain type needs to be redacted.
- **XML Storage.** This type of rule applies a value associated with the specified field name that resides within an XML storage field on a specific table. This option also supports a filter expression.
- **Reference Field.** This type of rule applies to a value residing anywhere and associated with the specified field name. It does not include fields referenced in XML storage fields.

Redaction Function

A redaction function defines the format by which a value is anonymized. The type of function used depends on the field's data type. For example, to anonymize a numeric field the redaction function should only use numeric values etc.

Refer to the **Redaction Function** extendable lookup for a list of available functions. The base product provides a sample of common functions but the list may be extended by your organization as needed.



Fields May Contain Sensitive Information

The field definition record includes an indication as to whether the field may contained sensitive information or not. Note that the indication does not imply that the field is actually used to capture such data but rather that it can potentially be used this way. Use this indication to review fields that may need to be associated with a redaction rule.

Copyright © 2026, Oracle and/or its affiliates.

Exporting Non-Redacted Data Requires Security Rights

By default, the export tools redact data based on existing redaction rules. There are situations where certain users may be allowed to export data in its original form, that is, to request to not apply the redaction rules.

The following points describe the processes for exporting data:

- Some processes always export data as is, in case the target consumer needs the raw data. This is irrespective of the user requesting the export.
- Some processes perform data redaction by default and may offer an option for exporting data as is. The option to export data in its original form is secured by application security.
- In this example, process A supports data redaction by default with an option to export non-redacted data. User A has the right to export the data redacted (default) or explicitly request to export it in its original form. User B does not have the right to do so hence their export content is redacted by default.

The option to export data in its original form is associated with the **Do Not Apply Redaction Rules** access mode associated with the following relevant application services:

- For CMA, the additional access mode is associated with the migration data set export's application service. When granted, the user may select the special non-redacted export option when they create the export data set request.
- For GDE batch processes, the access mode is associated with their application service and is tied to the **Do Not Apply Redaction Rules** batch parameter they support. Only users with the proper application security can submit these batches using the special batch parameter option

Defining Redaction Rules

This portal is used to view and maintain rules that define how specific fields that containing personal information should be redacted when exported out of the application or written to a debug log. For example, an e-mail address may be redacted by replacing some or all characters with '*'.

Refer to Data Redaction for Export and Logging for more information.

You can access the portal from the**Admin Menu**, and then **Security**, and then **Redaction Rule**. You are brought to a query portal with options for searching for a specific redaction rule. Once a redaction rule has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rule.** This zone provides information about the selected rule.

Copyright © 2026, Oracle and/or its affiliates.

Obfuscation Configuration

This portal is used to view and maintain all configuration options related to personal information obfuscation. It includes all masking, encryption and data redaction rules.

You can access the portal from the**Admin Menu**, and then **Security**, and then **Obfuscation Configuration**.

Refer to Encryption and Masking for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rules.** This zone lists all redaction rules. You may add a new rule from this zone.
- **Masking.** This zone lists masking options. You may navigate to the masking related feature configuration to review and edit these options.
- **Encryption.** This zone lists encryption options. You may navigate to the encryption related feature configuration to review and edit these options.
- **Review Fields for Redaction Rules.** This zone lists fields that may contain personal identifiable information and are not associated with a redaction rule. Review these fields and add redaction rules when applicable.

Cryptography Keys

The system provides support for defining various types of cryptography keys to handle different use cases in the system related to encrypting / decrypting data, providing credentials and providing and reading signatures when exchanging data between two parties. This may be used when communicating information with an external system or for internal processing.

The following sections include information about the functionality provided to support this type of security.

- Understanding Key Rings
- Defining Key Rings

Understanding Key Rings

The Key Ring object is provided to define the specific use case and to reference the keys that are used over time for a given business use case. Each key ring references a specific business object, which defines all the rules related to managing the keys. For example:

- If the key ring is used to define a pair of private and public keys, then the business object includes actions for generating a key pair and for viewing the public key.
- If the key ring is used to capture the public key of a third party, then the business object includes actions for capturing the external public key.
- Each key ring defines the rules related to the possible lifecycle of the keys.

The following sections include information about the functionality provided to support different key ring classes for particular use cases.

- Field Encryption
- OAuth Keys
- RSA Signature Keys

Copyright © 2026, Oracle and/or its affiliates.

- File Encryption and Signing Keys

Field Encryption

The system supports encryption of certain sensitive fields in the database. This support includes the ability to capture hash values of encrypted data for searching purposes.

Refer to Application Encryption to understand how to configure which fields you want to encrypt.

The sections in this topic provide more information about the defining the encryption and hash key values and the key rotation support.

Symmetric Key

The product provides an AES Symmetric Key business object. It generates an encryption key using an AES 256 algorithm.

When defining a key ring for this business object, you provide a 3-character "wrap" prefix that is unique across key rings for the 'symmetric key' class. This aids in key rotation, described below.

The business object supports key rotation with respect to the keys. See the section below for more information about key rotation.

Once your symmetric key ring is defined and you have at least one active key, you can configure the fields that you want to encrypt and reference this key ring in the configuration. Refer to Application Encryption for more information.

Hash Key

The product provides an HMAC Hash Key business object. It generates an HMAC key and stores it in PEM format.

When defining a key ring for this business object, you provide a 3-character "wrap" prefix that is unique across key rings for the 'hash key' class. This aids in key rotation, described below.

Once your hash key ring is defined and you have at least one active key, for encrypted fields that support a hash value, you can reference this key ring in the configuration. Refer to Application Encryption for more information.

Key Rotation

Defining your encryption and hash keys using key rings allows for key rotation.

- When the system encrypts the data or creates the hash field, it uses a marker so that the system knows what key ring and key were used to encrypt / hash the data. Data is encrypted / hashed with the current Active key.
- If your organization wants to introduce a new key for either your symmetric key ring or your hash key ring, use the Generate Key button to create a new key. Click the Activate button adjacent to that Key to make it the key to use for all data that gets added or updated going forward. The previous key is marked Inactive.
- All records added or updated going forward use the new key.
- To rotate the keys across all the existing data encrypted / hashed with the previous key, you need to submit a batch. Refer to Mass Key Rotation for more information.

Copyright © 2026, Oracle and/or its affiliates.

Key Ring Rotation

The respective business objects for the symmetric key ring and the hash key ring define the algorithms to use for generating the key. If there comes a point where you want to use a different algorithm for generating the symmetric encryption key or the hash key, a new business object is needed so that the new desired algorithm can be defined. The following points highlight the steps needed to change the key generation algorithm.

- Define the new business object for the use case (symmetric encryption key or hash key). Ensure that the algorithm related to the Generate Key state has the desired key generation logic. This business object should include a field for the 'wrap prefix', similar to the delivered product business objects for the symmetric key ring or hash key ring.
- Define a new key ring for the new business object and be sure to choose a different wrap prefix value. This is needed for key rotation.
- Generate a key for the key ring and activate it.
- Go to the Feature Option Configuration and update the keyRing or hashKeyRing references for all the entries to point to the new key ring.
- All records added or updated going forward use the new key ring and its active key.
- To rotate the keys across all the existing data encrypted / hashed with the previous key ring and its key, you need to submit a batch. Refer to Mass Key Rotation for more information.

OAuth Keys

The system provides support for sending messages secured by OAuth authentication. To deliver the message, the application is required to provide a client ID and secret. The OAuth secret is sensitive data and needs to be stored securely in the application. The Message Sender configuration provides the ability to store the client ID and an encrypted secret directly in the sender context. Alternatively, the sender context can refer to a key ring that stores those details. Using a key ring allows users to apply new secrets over time without having to update the affected message sender configurations.

Refer to Message Sender - Context for more information about configuring a message sender for OAuth security.

The product provides an OAuth Keys business object that supports the following functions:

- Defining the external system related to the key ring
- Adding a client ID and secret key. The secret key is stored in an appropriate "secret store".
- Key rotation. For increased security, a new secret key may be entered periodically. The new key automatically becomes the active key.

RSA Signature Keys

RSA signature key pairs are used in the following cases:

- Certain processes in the system may need to write files to or read files from Oracle Cloud Object Storage. Cloud object storage has its own method for encrypting files, and products using the framework application do not need to define additional configuration for that. However, when communicating with cloud object storage, the application is required to provide a signature key.

  Refer to External File Storage for more information about configuring the system to connect to cloud object storage.

Copyright © 2026, Oracle and/or its affiliates.

- Customers may need the ability to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal. A signature key is required to support secure communication with the endpoint.

  Refer to User Redirection for more information about configuring the system to enable this type of redirection.

- Signature keys are used for outbound messages when using the OAuth JWT assertion grant type. The key is used to sign the assertion.

The product provides an RSA Signature Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party.
- Viewing the public key, allowing a user to copy it to register it with cloud object storage.
- Activating the new key pair (to be done after registering the new public key).
- Inactivating an expired key.
- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.
- Requesting a Certificate Signing Request
- Certificate Signing Request

Certificate Signing Request

If a certificate signing request is required for any use case, the following steps should be followed.

- Navigate to the signature key ring that requires a certificate.
- In the Keys zone, identify the pending or active key that requires a certificate. Click **Generate CSR**.
- You are prompted to provide appropriate distinguished name parameter values and set the duration.

> **Note**
>
> The distinguished name parameters are defined in the `F1-DistinguishedNameParameter` extendable lookup. The visible parameters are those that marked as 'default in grid'. Additional parameter names are available, if needed.

- Optionally check the Self Signed Certificate switch, for example in a development or test environment.
- Click Save

If you didn't check the self signed switch, copy the returned Certificate Signing Request text to a .pem file and use a certificate authority to provide the certificate. Otherwise, use the returned Self Signed Certificate.

Once you have the certificate, provide it to the relevant external party, according to the use case.

Copyright © 2026, Oracle and/or its affiliates.

File Encryption and Signing Keys

For security, files exchanged with third parties may be encrypted, digitally signed or both. This requires the sender and recipient to maintain public/private key pairs and share public keys. The product supports the maintenance and generation of public and private keys in a format suitable for encryption using PGP standards.

The following sections provide additional information about encryption keys.

Encryption Key Pairs

Internal encryption key pairs are used in the following cases:

- Creating a digital signature for an extract file. The signature is encrypted with the private key of the key pair and decrypted by the recipient using the shared public key .
- Decrypting an import file. The expectation is that the sender has encrypted the file data using a temporary key. The temporary key is encrypted using the shared public key and decrypted using the private key.

The product provides an Encryption Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party. Both keys are in formats suitable for PGP encryption.
- Viewing the public key, allowing a user to copy it to register it with third parties.
- Activating the new key pair (to be done after sharing the new public key).
- Inactivating an expired key.
- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.

Public Encryption Keys

External public encryption keys are used in the following cases:

- Verifying the signature of an imported file. The signature is decrypted using the public key provided by the sender.
- Encrypting an extract file. The batch file adapters create a temporary key which is used to encrypt the file data. The temporary key is encrypted using the public key provided by the recipient

The product provides a Public Encryption Key business object that supports the following functions:

- Defining the external system and reference ID related to the key ring.
- Adding a public key to the key ring. The product expects the public key to be in a format suitable for PGP encryption.
- Viewing the public key.
- Inactivating an expired key.
- Key rotation. When new public keys are provided by the external system, the previously active key is set to expiring status. It may be manually inactivated after all messages using that key have been processed.

Copyright © 2026, Oracle and/or its affiliates.

- Deactivating all keys for the key ring.

Defining Key Rings

Refer to Understanding Key Rings for an overview of key ring functionality.

To maintain the key rings applicable to your product or implementation, open **Admin**, and then **Security**, and then **Key Ring.**

This is an All-in-One portal and includes the standard List and display zones for a key ring.

The information captured on the key ring depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Key Zones

The key zones provide information about the keys that are associated with the key ring. The zones displayed and the available actions depend on the type of key. Refer to embedded help for more information.

Key Rotation

For internal keys, it is recommended to practice key rotation and generate new keys periodically. New key pairs are generated in the **Pending** state. The user should register the public key of the new key pair with the associated third party. Once that is done, the new key should be activated.

For external keys, new public keys are added in the **Active** state. The previously active key is set to **Expiring** and may be inactivated when no further processing needs to refer to it.

User Interface Tools

Understanding Portals and Zones

A portal is a page that is comprised of one or more information zones. The base product pages are built using either a fixed page metaphor or using portals and zones.

There are three broad classes of portals:

- **Standalone.** Standalone portals are separate pages where the main tab of the page is built using a portal. These pages are opened using any of the standard methods (e.g., by selecting a menu item, by selecting a favorite link, etc.). Additional tabs for a stand-alone portal may be included using tab page portals.
- **Tab Page.** These types of portals cannot be attached to a menu. They simply define the zones for a tab on a standalone portal.
- **Sidebar.** A sidebar portal is a special portal that dictates what may appear in the Sidebar Area. Its zones contain tools and information that exist on the user's desktop regardless of the transaction. Several sidebar portals and zones are delivered as part of the base-package. Your implementation can add additional zones to these portal.
- **Assistant.** This is a special portal that defines what may appear in the Assistant Area if configured by your specific product.

The contents of this section describe general information about portals and zones.

Portal Page Structure

A portal page has a main tab and may have additional tabs. The page is constructed by first creating a **Standalone** portal, which is also the main portal, followed by creating a **Tab Page** portal for each additional tab and linking it to the main portal. Content is organized on each tab using independent zones.

The entire page is secured by the single application service associated with the main portal.

Portal Roles

An optional attribute called a portal role may be assigned to a portal. The role is typically for information purposes, but in some cases, a role may support additional configuration.

Certain roles may support predefined **UI Template** layouts to choose from.

Portals Are Made Up of Zones

A portal is a page that contains one or more zones, and each zone contains data of some sort. All zones reference a **Zone Type**. The zone type controls the behavior of the zone and the parameters available to configure the zone.

A portal may also use zones to present additional information in a drawer. These zones are not part of the page layout and are only presented upon a user request.

Not All Zones Make Up Portals

Zones may or may not be associated with a portal. The following describes additional uses of zones:

- A data explorer type of zone may implement a search for an entity on an input user interface map. These zones may be referenced on a FK reference record or directly referenced on a UI map.

Copyright © 2026, Oracle and/or its affiliates.

- A data explorer type of zone may implement a Business Service. The latter may be used for an internal process or used to build a user interface dropdown.
- A zone may be defined as a **Context Sensitive Zone** that appears on the Sidebar when a specific page or portal is in context. This type of zone is not linked to the Sidebar portal but associated with the context page or portal's navigation key.
- A 'view detail' zone may be launched into a drawer without being configured as part of the portal it is launched from.

Configuring Zones for a Portal

The portal includes configuration of how the zones should appear on the portal by default. This includes the following options, all of which may be overridden by an implementation.

- The order in which the zone should appear. An implementation may configure an override sequence to change the order zones on a base delivered portal.
- Whether the zone is visible on the portal. Zones delivered in the base product should be configured to be visible. But an implementation may override this if desired.
- Whether the zone should display initially collapsed or not. A zone's data is only retrieved when it is expanded. As such, a zone may be configured to be initially collapsed when the data is not needed very often. A user can expand the zone when the information is required. Implementations may change the collapsed setting of a base product portal / zone. Refer to Zones May Appear Initially Collapsed When a Page Opens for more information.

Flexible Layout Control

By default a zone spans the full width of the portal's display area but can be configured in a number of ways using the layout control features on the portal.

These features allow portal designers to have finer-grained control over how zones are laid out, and enables them to achieve a better user experience and a more optimal layout that reduces unused space.

The following highlight key layout control options:

- In addition to the standard half and full width options, 1/4, 3/4, 1/3 and 2/3 width options are also available.
- Better handling of zones that are dynamically hidden by a visibility script. When a zone becomes invisible its space may be reclaimed by a next zone as long as it is of same width or smaller.
- A zone may define the beginning of a new row. This indication allows for a more fixed layout that is not impacted by hidden zones. The new row indication may establish a layout of one, two or three zones displayed vertically.
- Support the following zone height options:
  - **Content (Unlimited Height)** lets the height be determined by content.
  - **Content (Limited Height)** lets the height be determined by content up to a specified maximum limit. This option may be used to achieve a more consistent portal layout, especially when a zone is rendered on long or small devices.
  - **Fixed Height** sets the zone at a specific height regardless of content.

    This option too may be used to achieve a more consistent portal layout.
  - When a height option is not explicitly selected, zone height is unlimited and determined by content. However, for a data explorer zone, the results grid area itself (not the entire

Copyright © 2026, Oracle and/or its affiliates.

zone) is limited by the zone parameter "height of report" (which has a default value of 50%).

You may also control the visibility of the following page components:

- **Page Title.** Use the **Page Title Visibility** portal option on a standalone portal to indicate that the page title should not be visible for this portal and its related tab portals if any.

> **Note**
>
> The page actions displayed in the same row as the page title are also suppressed. As such, you should only use this option if the actions in that area are not needed, including Bookmark, Clear and Refresh.

- **Tab Menu.** Use the **Tab Menu/Tab Visibility** portal option to suppress one or more tabs on the page based on conditions. It also may be configured to suppress the tab area altogether.
- **Zone Header.** You may use the **Zone Header Visibility** general zone parameter to suppress an explicit map zone's header area to allow for more vertical space when the page only has one zone and the standard actions on the zone header are not relevant.

Portal Specific Page Actions

The system supports defining actions that appear in the Page Actions Toolbar that are specific to a portal. Portal specific actions are first defined using a menu with the menu type of **Page Action Menu**. Each menu line in a page action menu should define one item. The menu line's item may reference a navigation option or a sub-menu (which in turn defines one or more lines with menu items that define navigation options). Use the **Page Action Menu** portal option to associate the menu with the portal. More than one page action menu option may be defined. If the lines on the referenced menus define navigation options, they are shown as distinct buttons. If any line references a sub-menu, then an action menu is shown, using the description on the menu line.

> **Note**
>
> Standard menu security is checked. For any menu item in any of the page action menus defines an application service / access mode, you only see the action if you have security.

Advanced Configuration for Portal Title / Tabs

You may configure your portal to provide additional information to be displayed either in the portal's Page Title Area or in the tab area.

Information String. If the portal is configured to display a single record, you can configure the **Page Info FK Reference** portal option to include the FK reference for the related maintenance object. The system will automatically display the information string for the FK reference when viewing a record on this type of portal.

Advanced Title Configuration. You may provide a service script in the **Enhanced Page Title** portal option to override the page title or to add additional information to be displayed. The service script should include the data area F1PageTitleDetails. Refer to the detailed description of the data area for more information on what the service script can return. This option may only be configured on the standalone ("main") portal, but the information is visible on any of the portal tabs.

Copyright © 2026, Oracle and/or its affiliates.

Scorecard Configuration. For portals that are configured with the role of Dashboard, you may configure a scorecard for each tab in the portal. To do this, you provide a service script in the **Scorecard** portal option. The service script should include the data area F1ScorecardDetails. Refer to the detailed description of the data area for more information on what the service script can return. If the dashboard has multiple tabs, if any of the tabs configure a scorecard service script, all tabs must configure one.

Portal Banners

Important messages related to the context of a page may be displayed in the form of banners presented in the title area. For example, a customer dashboard may show a banner message alerting the agent of an existing outage along with the ability to view outage details in a drawer.

These messages are composed by a script referenced on a **Portal Banners** portal option. Banner messages may be associated with various severity levels and optionally support related actions. The option is defined for the main tab of the portal and applies to the entire page.

The product provides a generic 'Portal Banners by Insight Class' (F1BannesInst) script that composes messages based on insights for an insight class and a given context. Using this script allows banners for a portal to be configurable by the customer.

Portal Templates

When defining a portal with the portal role of **Dashboard**, you may optionally choose a **UI Template**. The UI templates define a predefined layout. You simply need to choose the zones that you wish to include and the template will render the zones based on the template's configuration.

User Preferences

A **Standalone** portal includes configuration to indicate whether or not the portal should appear on a user’s portal preferences. The portal will not appear on the user's portal preferences if the **Show on Portal Preferences** setting is set to No. Note that an implementation may change this value for a product delivered portal. This setting is typically enabled for a portal that provides disparate information where not all zones are applicable to all users or where users may wish to adjust the order of the zones. An example of a portal enabled for portal preferences is the Sidebar portal.

The user can override zone oriented configuration for the portal:

- Which zones appear on that portal
- The order in which the zones appear
- Whether the zones should be initially collapsed when the portal opens.
- The refresh seconds. This is applicable to zones displaying data that changes often.

An implementation can optionally configure the system to define portal preferences on one or more "template" users. When a template user is linked to a "real" user, the real user's preferences are inherited from the "template" user and the "real" user cannot change their preferences. Some implementations opt to work this way to enforce a standard look and feel for users in the same business area.

Refer to User — Portal Preferences for more information about how users configure their zones.

Copyright © 2026, Oracle and/or its affiliates.

View Detail Drawers

A zone may be designed to display related extended information in a drawer. This type of zone is designed and implemented like any other zone. It is recommended to associate it with the 'View Details Drawer' role for reporting purposes.

View detail zones can be configured as follows:

- **Portal panels.** An optional list of 'view detail' zones can be defined as part of a portal's zone configuration. These zones are not rendered as part of the portal's layout. Instead, they represent groups of zones to be presented in a drawer upon user request. A 'view detail' zone is associated with a **Panel Name** which represents a uniquely named drawer content. When the panel name is launched all zones that belong to that panel are presented in the drawer area in sequential order.
- **Not related to a portal.** A zone can be launched directly into a 'view detail' drawer, without being listed on any portal. This technique is used when the zone displays information that is not specific to the current portal. For example, the Knowledge Article drawer may be launched from any portal that supports a default knowledge article.

The product supports small, medium and large drawer sizes. When launched as a panel, the largest drawer size setting of all panel zones is used. When a zone is directly launched, not via an association to a panel, the width of the zone sets the drawer width.

A drawer may be launched from another drawer, forming a nested display of panels.

Support for launching a drawer is available from a display UI map, a data explorer column, and a chart. Refer to Launch a View Details Drawer for more information.

> **Note**
>
> Drawers may not be launched from the Sidebar and Assistant areas.

View Entity Drawer

In some pages, the product supports the ability to review an entity's information in a drawer without navigating to the entity's page.

The default drawer for viewing an entity's information may be dynamically determined using the **View Entity Drawer** maintenance object or business object option. If a business object option exists it overrides the maintenance object option if any. When applicable, you may use these options to override the 'view details' zone used by the product an entity. To do so, implement your custom 'view detail' zone and reference it as an option with a higher sequence number.

This feature is only available in select pages. By default, a link to an entity navigates to its portal, and does not launch the entity's view details drawer. To implement such functionality in a custom user interface, refer to product examples that use the 'Get Drawer Zone for an Entity' (F1GetDrwEnt) script.

Removing Zones From Portal

You cannot remove a base product zone from a base product portal. An implementation may override the **Display** setting to prevent a zone from displaying on the portal. In addition, you cannot remove a zone if a user has enabled it on their portal preferences. To remove a zone from the portal list, first make sure that no user has it enabled in their portal preferences.

Copyright © 2026, Oracle and/or its affiliates.

Granting Access to A Portal

An application service is associated with each portal. A user must be granted access rights to the respective application service in order to see a portal.

When you add a new **Standalone** portal, the system automatically creates its application service behind the scenes and displays it as part of the portal definition. You'll need to use this application service to grant access to the portal. **Tab Page** portals do not have separate security access. If a user has access to the main stand-alone portal, then the user will have security access to all its tabs.

Please note the following in respect of how application security impacts a user's portals:

- A user's Portal Preferences page only shows the portals configured to show on user preferences and where they have security access.
- The system's menus only show portals to which a user has security access.
- Users can set up favorite links to all portals, but they must have security rights to the portal's application service in order to invoke the favorite link.

Granting Access to Zones

An application service is associated with each zone. A user must be granted access rights to the respective application service in order to see a zone on a portal. Refer to The Big Picture Of Application Security for information about granting users access rights to an application service.

Please note the following with respect to zone application security:

- For most base product portals, all the zones for all the portals reference the same application service that is used to grant access to the portal. In other words, if the user has access to the page, then the user has access to all the zones on all portals for the page. There may be exceptions to this rule for certain portals.
- For a base product multi-query zones, typically the individual query zones and the multi-query zone reference the same application service that is used to grant access to the main (standalone) portal for the page. However, there may be individual query zones provided with a unique application service. This may occur when the query option is unusual and not applicable to all users or even to all implementations. If a user does not have security access to an individual query zone, that option will not be available in the dropdown.
- For base product portals that are configured to show on portal preferences, it is common that the portal contains different types of zones that may be applicable to different types of users. Typically these types of portals will deliver a unique application service for each zone so that an implementation may configure which user groups are allowed to view each zone. For these types of portals, please note the following:
  - A user's Portal Preferences page contains a row for a zone regardless of whether the user has access rights to the zone. Because of this, the system displays an indication of the user's access rights to each zone.
  - If a user's access rights to a zone are revoked, the zone will be suppressed when the user navigates to the respective portal.
  - Revoking a user's access rights does not change the user's portal preferences (i.e., a user can indicate they want to see a zone even if they don't have access to the zone - such a zone just won't appear when the respective portal appears).

Copyright © 2026, Oracle and/or its affiliates.

Putting Portals on Menus

When you add a new **Standalone** portal, the system automatically creates its navigation option behind the scenes and displays it as part of the portal definition. You'll need to use this navigation option to add the portal to a menu or to allow any other type of navigation method to the portal.

To add a portal to a menu, you must add a menu item to the desired menu and reference the portal's navigation option on the new menu item. A portal's navigation option can appear on any number of menu items (i.e., you can create several menu items that reference the same portal).

Your users can set up their preferences to include the portal's navigation option on their Favorite Links. This way, they can easily navigate to the portal without going through menus.

Portal Options

Portal options are used to enable various features available for each portal. Several are mentioned in previous sections in this topic. Review the detailed descriptions of each portal option to understand what other features are available.

> **Note**
>
> **You can add new option types.** Your implementation may want to add additional portal option types. To do that, add your new values to the customizable lookup field `PORTAL_OPT_FLG`.

Setting Up Portals and Zones

The topics in this section describe how to set up portals and zones. Please refer to The Big Picture of Portals and Zones for background information.

- Defining Zone Types
- Defining Zones
- Defining Context-Sensitive Zones
- Defining Portals

Defining Zone Types

A Zone Types represents a particular type of zone with a specific behavior. For example, a data explorer zone type is used to select data using a specific SQL statement and display the data based on parameter configuration. The zone type defines the Java Class that controls the behavior of the zone and defines the parameters that the Java Class supports. The base product supports many zone types used to build the portal / zone user interface. Implementations may introduce their own zone types.

> **Note**
>
> It is not very common for an implementation to introduce their own zone types.

Select **Admin**, and then **System**, and then **Zone Type** to maintain zone types.

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Specify an easily recognizable **Zone Type** code and **Description**. Use the **Detailed Description** to describe in detail what the zone type does.

> ⚠ **Caution**
>
> When adding new zone types, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Owner indicates if this zone type is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a zone type. This information is display-only.

Java Class Name is the Java class responsible for building the zone using the parameters defined below.

Two types of parameters are specified when defining a zone type:

- Parameter values that have a **Usage** of **Zone** are defined on the zones and control the functionality of each zone governed by the zone type. A **Usage** value of **Zone - Override Allowed** indicates that an implementation may override the parameter value for a base zone.
- Parameter values that have a **Usage** of **Zone Type** are defined directly on the zone type and control how the zone type operates (e.g., the name of the XSL template, the name of the application service). A **Usage** value of **Zone Type - Override Allowed** indicates that an implementation may override the parameter value for a base zone type.

The following points describe the fields that are defined for each parameter:

- **Sequence** defines the relative position of the parameter.
- **Parameter Name** is the name of the parameter.
- **Description** is a short description that allows you to easily identify the purpose of the parameter.
- **Comments** contain information that you must know about the parameter or its implementation. For parameters with a usage of **Zone** or **Zone - Override Allowed**, this information is visible to the user when viewing or defining this parameter for a zone of this type.
- **Usage** indicates whether the parameter value is defined in a **Zone** of this type or in the **Zone Type**. **Zone - Override Allowed** and **Zone Type - Override Allowed** indicate that override values for the parameters defined in a base zone or base zone type can be entered.
- **Required** is checked to indicate that a zone must define a value for the parameter. It is not checked if a value for the parameter is optional. This field is protected if the **Usage** is **Zone Type** or **Zone Type - Override Allowed**.
- **Parameter Value** is used to define the value of zone type parameters. This field is protected if the **Usage** is **Zone** or **Zone - Override Allowed**.
- **Owner** indicates if this parameter is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a parameter. This information is display-only.

Copyright © 2026, Oracle and/or its affiliates.

Zone Type Parameter Comments

For the product owned zone type parameters, the parameter's detailed description provides the detail needed for properly configuring the parameter. For the Action parameters (IMPLEMENTOR_ACTION_n), the parameter description is abbreviated. Additional detail about configuring this parameter may be found in the Zone Action Parameter detailed information. The same details apply.

Defining Zones

This portal is used to view and maintain the configuration of a zone. Implementations may define custom zones or override the descriptions and some parameter values for base product zones.

You can access the portal from the**Admin Menu**, and then **System**, and then **Zone**. You are brought to a query portal with options for searching for a specific zone. Once a zone record has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Refer to Understanding Portals and Zones for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Zone.** This zone provides general information about the selected zone.
- **Query Options.** This zone maintains the list of query options for a Multi-Query zone. The zone is only visible for Multi-Query zones.
- **Filters.** This zone maintains various zone parameters that handle filtering options for a data explorer zone. The zone is only visible for data explorer zones.
- **General Parameters.** This zone maintains various general purpose zone parameters for a data explorer zone.
- **SQLs.** This zone maintains individual SQLs and their related parameters. The zone is only visible for data explorer zones.
- **SQL Configuration.** This zone maintains all the zone parameters related to a specific data explorer SQL. The zone is only visible when a specific SQL is broadcast from the **SQLs** zone.

The following zones may appear as part of the portal's **References** tab page

- **Zone References.** This zone list various configuration entities referencing the current zone.
- Overriding Parameter Values
- Overriding Zone Parameters

Overriding Parameter Values

Implementation teams may override the value of selected types of base provided zone parameters. The override parameter value field for base owned zone parameters is only enabled when the related zone type parameter usage is **Zone - Override Allowed**.

For multi-query zones, you may use the override parameter value to add custom query options to a base product owned zone.

Overriding Zone Parameters

Implementations may override the value of a base owned zone parameter only if the zone type definition allows such override. The override parameter value is enabled for a specific base owned parameter when the related zone type parameter usage is set to **Zone - Override Allowed**.

You may use the override parameter capability to provide alternative or additional custom query options for a base owned multi-query zone.

Zone Parameter Details

For most zone parameters, the embedded help for the parameter provides the detailed information needed for configuring the parameter values. For some parameters with very detailed descriptions, the embedded help is abbreviated and more detail is provided here.

- Zone Visibility Service Script
- SQL Statement
- Column Parameters
- Zone Action
- User Filters
- Hidden Filters
- Multi-Select Action

Zone Visibility Service Script

All zones support a visibility script that is used to determine if the zone should be displayed to the user or not based on conditions. The script may receive input parameters and is expected to return a Boolean value indicating if the zone should be displayed or not. The embedded help for the **Zone Visibility Service Script** parameter provides details related to the syntax.

The following table highlights some service scripts provided by the product that may be used if applicable to your zone's requirements. This is not an exhaustive list of visibility scripts. There may be others that are specific to a given zone.

Script Code	Description	Comments
`F1-ShldShwZn`	Zone Visibility - Display Zone in Portal	This script simply returns a value of 'true' and is used when the zone should always appear.

Copyright © 2026, Oracle and/or its affiliates.

Script Code	Description	Comments
F1-CondShwZn	Zone Visibility - Display Zone in Portal Conditionally	This is used when the condition for showing the zone is based on the population of a context value. This is commonly used when one zone in the portal should only appear after a broadcast of a record from another zone in the portal. For an example of a zone the uses this visibility script, refer to F1-BSFTYPE .
F1-RwCtShwZn	Zone Visibility - Based on Row Count	This is used when the condition for showing the zone is based on the existence of one or more rows that can be determined using SQL. This script accepts a zone code, user filters 1 through 25 and hidden filters 1 through 10. The script returns an indication of 'true' if at least one row count is returned by the zone. To use this visibility script, a specific data explorer zone must be developed for the specific use case. For an example of a zone the uses this visibility script, refer to F1-MIGRREQEL .

SQL Statement

Data explorer zones are used to select data to display using one or more SQL statements. The SQL parameters are applicable to the following zone types

- Info Data Explorer - Single SQL (F1–DE-SINGLE). The parameter has the description **SQL Statement**.
- Info Data Explorer - Multiple SQLs (F1–DE). The parameters follow the description pattern of **SQL Statement x**.
- Query Data Explorer - Multiple SQLs (F1–DE-QUERY). The parameters follow the description pattern of **SQL Statement x**.

> **Note**
>
> If your implementation has been configured to restrict the functions that may be used when defining an SQL then an error is issued at runtime if there are functions found that are not in the allowlist. The allowlist may be viewed using the **SQL function allowlist** link in the SQLs zone on the zone maintenance page.

> **Note**
>
> Zone SQL should take care not to use the following reserved keywords for the table alias. (For example, the table alias in this SQL is 'XX': SELECT 'X' FROM W1_ACTIVITY_TYPE **XX**.)

Keyword
AT

Copyright © 2026, Oracle and/or its affiliates.

The following table provides a list of SQL substituted keywords that may be used in the SQL Statement parameters in explorer zones. At execution time, the system determines the database and substitutes the keyword with the database specific syntax:

Keyword	Description	Examples
`@toCharacter()`	Converts the input to Character data type.	select **@toCharacter**(batch_cd) as batchCode from ci_batch_ctrl
`@toDate()`	Converts the input to Date data type.	select **@toDate**(last_update_dttm) as lastUpdateDate from ci_batch_ctrl
`@toNumber()`	Converts the input to Number data type.	select **@toNumber**(next_batch_nbr) from ci_batch_ctrl

Copyright © 2026, Oracle and/or its affiliates.

Keyword	Description	Examples
`@currentDate`	Fetches the current date.	select batch_cd, **@currentDate** as today from ci_batch_ctrl

> **⚠ Caution**
>
> The Oracle functions **SYSDATE** and `CURRENT_DATE` should not be used because they do not properly cater for adjusting dates from the database time zone to the installation time zone, if needed.

Copyright © 2026, Oracle and/or its affiliates.

Keyword	Description	Examples
`@currentTimestamp`	Fetches the current date / time. **⚠ Caution** The Oracle functions **SYSTIMESTAMP** and `CURRENT_TIMESTAMP` should not be used because they do not properly cater for adjusting the date / time from the database time zone to the installation time zone, if	select batch_cd from ci_batch_ctrl where last_update_dttm > **@currentTimestamp**

Copyright © 2026, Oracle and/or its affiliates.

Keyword	Description	Examples
	⚠ need ed.	
`@concat`	Combines the result list of two or more columns.	select batch_cd **@concat** next_batch_nbr concatNbr from ci_batch_ctrl
@substr(string, start)	**String** is the input String that you are trying to get a substring of. **Start** is the position of the character for the output results.	select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select **@substr**(batch_cd,3) batchCode from ci_batch_ctrl Result: STCD
@substr(string, start, end)	**String** is the input String that you are trying to get a substring of. **Start** is the position of the character for the output results. **End** is the number of characters required in the output from starting position.	Select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select **@substr**(batch_cd,3,2) batchCode from ci_batch_ctrl Result: ST
`@trim`	Trims the white spaces of the output on both sides.	select **@trim**(batch_cd) as batchCode from ci_batch_ctrl
The following syntax is related to 'fuzzy' searching. It is only applicable if Oracle DB Text is enabled and a context text index has been created. Refer to Advanced Search Options for more information.		
@fuzzy(string, score, numresult, 'weight')	**String** is the input value for the search. **Score** is the degree of 'fuzziness'. Valid values are between 1 - 80. The higher the number the more precise the search. Default is 60. **Numresults** is the number of variations to consider for the string. Valid values are between 1 and 5000. Default is 100. Indicate `'weight'` to signal that the results are returned in order of weight. Leave this setting off to indicate that the results are returned in order of score.	Set score to 70, number results to 6, and specify weight. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6, 'weight')) > 0
`@fuzzy(string)`	This returns a string result from the fuzzy expansion operation where the default value of 60 is assumed for the **score** and the default value of 100 is assumed for the **numresult**.	To use default values: select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1))> 0

Copyright © 2026, Oracle and/or its affiliates.

Keyword	Description	Examples
@fuzzy(string, score)	This returns a string result from the fuzzy expansion operation with the **score** specified and the default value of 100 for the **numresult**.	Set score to 70. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70)) > 0
@fuzzy(string, score, numresult)	This returns a string resulted from the fuzzy expansion operation with the similarity score and the **numresults** specified.	Set score to 70, number results to 6. select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6)) > 0

Column Parameters

Data explorer zones are used to select data to display using one or more SQL statements. For each SQL statement, the zone may configure up to 20 Columns that contain the formatting definition for displaying the output data.

These parameters are applicable to the zone types

- Info Data Explorer - Single SQL (`F1-DE-SINGLE`). The parameters follow the description pattern of **Column x**.
- Info Data Explorer - Multiple SQLs (`F1-DE`). For this zone type, all SQLs are executed and the zone displays a union of all the results. The parameters follow the description pattern of **Column x for SQL y**. There are some mnemonics that do not make sense to differ within rows of the same column. For example, the column label. For these mnemonics, only the value in SQL 1 is considered for that column. The table below indicates which mnemonics follow this rule.
- Query Data Explorer - Multiple SQLs (`F1-DE-QUERY`). For this zone type, only one SQL is executed. The **SQL y Condition** parameter may be used to control this. The system will execute the first SQL whose condition is satisfied (or with no condition populated). The parameters follow the description pattern of **Column x for SQL y**.

The following sections describe the various types of mnemonics.

Source Mnemonics

This table describe the mnemonics that control how the data in a column is derived.

Mnemonic	Description	Valid Values	Comments
`source=`	Defines how the column's value is derived.	`SQLCOL`	Indicates that the source of the column's value comes from a column in the SQL statement. This type of column must also reference the `sqlcol=` mnemonic.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		BO	Indicates that the source of the column's value comes from a business object. This type of column must also reference the `bo=`, `input=` and `output=` mnemonics to define how to interact with the business object.
		BS	Indicates that the source of the column's value comes from a business service. This type of column must also reference the `bs=`, `input=` and `output=` mnemonics to define how to interact with the business service.
		SS	Indicates that the source of the column's value comes from a service script. This type of column must also reference the `ss=`, `input=` and `output=` mnemonics to define how to interact with the service script.
		FORMULA	Indicates that the source of this column's value is calculated using a formula. This type of column must also reference the `formula=` mnemonic.
		SETFUNC	Indicates that the source of this column's value is calculated using a superset of values from the rows in the SQL statement. This type of column must also reference the `setfunc=` mnemonic.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		`ICON`	Indicates that the source of this column's value is a display icon reference (meaning that an icon will be displayed in the column). This type of column must also reference the `icon=` mnemonic to define the icon reference.

Note

When using this source mnemonic, the format

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
			ngmnemonic type = isnotapplicable.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		FKREF	Indicates that the source of this column's value is an FK reference (meaning that the FK reference's context menu and information string will be displayed in the column and will be enabled for navigation). This type of column must also reference the `fkref=` and `input=` mnemonics to define how the FK reference is called.

Note

When using this source mnemonic, the

on Use Cases for the recommended technique.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		SPECIFIED	Indicates that the source of this column's value is specified by concatenating literals and other column values. This type of column must also reference the spec= mnemonic. When constructing an HTML element for a web component or a function, the syntax may be slightly different for a data explorer column. Refer to UI Map Attributes and Functions for the appropriate syntax.
		MSG	Indicates that the source of this column is a message from the message table (along with any substitution variables). This type of column must also reference the msg= mnemonic.
sqlcol=	Defines the column in the SQL statement when source=SQLCOL.	COLUMN_NAME	Enter the name of a column that is retrieved in the SELECT statement. Note that if the select statement uses an alias for a column, then the alias should be referenced here.
		x	Where x is an integer value that references a column by its relative position in the SELECT statement. For example, sqlcol=3 would display the 3rd column in the SELECT statement).

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
bo=	Defines the business object to invoke when source=BO. This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the business object.	'Business Object Code'	
bs=	Defines the business service to invoke when source=BS. This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to/received from the business service.	'Business Service Code'	
ss=	Defines the service script to invoke when source=SS. This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the service script.	'Service Script Code'	

Copyright © 2026, Oracle and/or its affiliates.

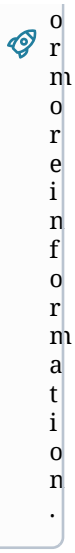
Mnemonic	Description	Valid Values	Comments
`icon=`	Defines the icon to use when `source=ICON`.	Cx	This means the Display Icon code is defined in an earlier column. For example, define `C1` if column 1 defines the icon code value.
		COLUMN_NAME	This means the Display Icon code was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'image'	This means the image file is defined directly. For example '/images/treeRootObject.gif'.
		'Display Icon Code'	This means the Display Icon code is defined directly. For example 'F1EDIT.
`fkref=`	Defines the FK reference used to retrieve the column's information when `source=FKREF`. This mnemonic must be used in conjunction with the `input=` mnemonic to define how information is sent to the FK reference to build the information.	Cx	This means FK reference code is defined in an earlier column. For example, define `C1` if column 1 defines the FK reference value.
		COLUMN_NAME	This means the FK reference was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'FK Reference Code'	This means the FK Reference is defined directly. For example 'F1-ROLE'.
`formula=`	Defines the formula to use when `source=FORMULA`. Examples: • `formula=C1*.90/C2`	The formula can contain numeric constants, operators and column references.	For column references, use the format Cx where x represents the column number.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	• `formula =(C1/ C2)*100`		Refer to Expression Parser for information about the functions supported.
`setfunc=`	Defines the function to apply to the rows of a given column when `source=SETFUNC`.	function(Cx)	Where Cx represents a column whose rows should have the function applied and the function is one of the following: • **MAX**. This derives the maximum value of all rows in the column. • **MIN**. This derives the minimum value of all rows in the column. • **TOT**. This derives the sum (total value) of all rows in the column. • **ACC**. This derives the cumulative total of all rows up to an including the current row.
`input=`	This is used to define one or more input fields and values passed to business objects, business services, service scripts, and FK references. The syntax is as follows: [ELEMENT_NAME=ELEMENT_REF ELEMENT_NAME=ELEMENT_REF ...] In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the	Cx	Where Cx represents the value of a previous column. If the value to pass is in the first column, reference C1.
		COLUMN_NAME	This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'literal value'	This means a literal value within the single quotes should be passed in.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	ELEMENT_NAME, which is the name of the element / field in the target. ELEMENT_REF is the value passed in. The next column indicates the possible values for ELEMENT_REF.	`userTimeZone`	This means the current user's time zone should be passed in. This is typically used with the business service `F1-ShiftDateTime` to convert data in the storage time zone to the user's time zone for display.
		`installationTimeZone`	This means the installation time zone should be passed in. This is typically used with the business service `F1-ShiftDateTime` to convert data in the storage time zone to the installation time zone for display.
		Examples: • `input=[USER_ID=C1]` • `input=[USER_ID=USER_ID]` • `input=[input/targetTimeZone=userTimeZone]`	
`output=`	This is used to define the name of the element retrieved from the business object, business service or service script used to populate this column.	elementName	Example: `output=personInfo`
`pagingkey=`	This mnemonic is only applicable when the **Enable Paging** parameter has been configured. It indicates that this column is one of the keys used by the SQL statement to orchestrate paging through	`Y`	



Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	results. This mnemonic can only be specified when the `source=SQLCOL`.	`N`	This is the default, meaning that you don't need to indicate `pagingkey=N` at all to indicate that the column is not one of the paging keys.

NOT_SUPPORTED

Refer to Paginationconfigurationf

Mnemonic	Description	Valid Values	Comments
			

> **Note**
>
> If multiple columns are configured with the same source BO, BS or SS and the same input data, the system caches the output from the first call and reuses the results for subsequent columns.

Formatting Mnemonics

This table describe the mnemonics that control how a column is formatted.

> **Note**
>
> For the `F1-DE` zone type, zone displays the union of all the different SQLs.

Mnemonic	Description	Valid Values	Comments
`type=`	Defines how the column's value is formatted.	`STRING`	Columns of this type capture a string. This is the default value.
		`DATE`	Columns of this type capture a date and will be displayed using the user's display profile.
		`TIME`	Columns of this type capture a time (in database format) and will be displayed using the user's display profile.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		DATE/TIME **onandForeignKeycolumns**. The source=[source mnemonic] may be use	Columns of this type capture a date and time (in database format) and will be displayed using the user's display profile.
		MONEY	Columns of this type capture a monetary field. This type of column may also reference the cur= mnemonic. If the cur mnemonic is not specified, the currency code on the installation record is used.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		NUMBER dtoindicateacolumnshouldbederivedfromanicon reference or af	Columns of this type capture a numeric field. This type of column may also reference the dec= mnemonic.

		 odefinethelabels.	
`cur=`	Defines the currency code applied when `type=MONEY` if the installation record's currency should not be used.	Cx	This means currency code value is defined in an earlier column. For example, define `C1` if column 1 defines the currency code.
		COLUMN_NAME	This means the currency code was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'Currency Code'	This means the currency code is defined directly. For example 'USD'.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
dec=	Defines the number of decimal places when type=NUMBER. It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.	nR	Where n is the number of decimal places to show. Suffixing the number of decimal places with R means that the system should round up / down. Simply specifying n (without an R) means that decimal places should be truncated. For example, entering dec=4 will display 4 decimal places and truncate the remainder.

Mnemonic	Description	Valid Values	Comments
			on, all 6 decimal places will be used.
`char=`	This mnemonic applies special character(s) to the column's value.	'x[]x'	Where x references the literal value to display and **[ ]** defines the relative position of the characters (before or after the value). You need only include the **[ ]** if you want to position characters in front of the value. For example, `char='%'` will place a percent sign after the value. If you want to position the word 'minutes' before a value, enter **char='minutes [ ]'**. If you want to output a value like **BUDGET $123.12 (YTD)**, enter **char='BUDGET [ ] (YTD)'**.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
`suppress=`	This is used to indicate a column should not be displayed. A column would be suppressed if it's only defined for use by subsequent columns, for example, if there is a formula that derives a column using two other columns. In this scenario, the columns referenced in the formula can be suppressed.	`true`

Click Mnemonics

This table describe the mnemonics that define whether a column value may be clicked and if so, what should happen.

Mnemonic	Description	Valid Values	Comments
`navopt=`	Defines the navigation option that references the target transaction or script when the user clicks a column. Note, this mnemonic should be used in conjunction with the `context=` mnemonic to define what information is sent to the navigation option's target transaction. This mnemonic is ignored if `source=FKREF` because the FK reference code defines the	Cx	This means navigation option code is defined in an earlier column. For example, define `C1` if column 1 defines the navigation option.
		COLUMN_NAME	This means the navigation option was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause. Example: `navopt=MAIN_PORTAL`

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	hyperlink's destination.	'Navigation Option Code'	This means the navigation option code is defined directly. For example `navopt='userMaint'`.
`context=`	This is used to define one or more context fields and values passed to the target navigation option to go along with the `navopt=` mnemonic. The syntax is as follows: [FIELD_NAME =FIELD_REF FIELD_NAME= FIELD_REF ...] In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME, which is the name of the context field in the navigation option. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.	Cx	Where Cx represents the value of a previous column. For example, if the value to pass is in the first column, reference `C1`.
		COLUMN_NAME	This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'literal value'	This means a literal value within the single quotes should be passed in.
`bpa=`	Indicates that a BPA script should be executed with the user clicks the column	Cx	Indicates that the BPA script is defined in a previous column.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	and indicates the BPA to execute. Note, this mnemonic should be used in conjunction with the `tempstorage=` mnemonic to define the temporary storage values that will be initiated when the script is executed. This mnemonic is ignored if `source=FKREF` because the FK reference code defines the hyperlink's destination.	COLUMN_NAME	This means the BPA script to execute was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.
		'BPA Script Code'	This means that the BPA script to execute is defined directly.
`tempstorage=`	This is used to define how temporary storage variables are initiated when the `bpa=` mnemonic is used. The syntax is as follows: [FIELD_NAME =FIELD_REF FIELD_NAME= FIELD_REF ...] In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME,	Cx	Where Cx represents the value of a previous column. For example, if the value to pass is in the first column, reference `C1`.
		COLUMN_NAME	This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.

Mnemonic	Description	Valid Values	Comments
	which is the name of the field in temporary storage. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.	'literal value'	This means a literal value within the single quotes should be passed in.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
`list=`	This is used to enable work list capability for this column. You may optionally populate the `listdesc=` mnemonic to override the text that will be placed in the worklist zone.	`true`	Setting `list=true` will cause the work list icon to appear in the column's header. If a user clicks the column, it will populate all the rows in the output into the work list zone.

`listdesc=`	This is an optional mnemonic when using the `list=` mnemonic. It can be used to override the text that is placed in the work list zone.	Cx	Where Cx represents the value of a previous column. For example, if the text to use is in the first column, reference `C1`.
`listbroadcast=`	Indicates that the broadcast information for the column is also to be made available in the work list zone. This means that the work list can be used to broadcast information to a portal in the same manner as a data explorer.	`true`	Use this setting to turn on the feature.

Common Use Cases

This section provides some common configuration that can be copied and pasted for newly created zones.

Copyright © 2026, Oracle and/or its affiliates.

Use Case	Code Snippet
Displaying the description of a lookup value that has been retrieved in the SQL statement. The business service checks for an override label.	**source=BS** **bs='F1-GetLookupDescription'** **label=FLD_NAME** **input=[fieldName='FLD_NAME' fieldValue=FLD_NAME]** **output=description**
Display a foreign key with its information but suppressing the navigation. (This is useful when you have a foreign key that is additional information in a zone but would cause confusion to enable navigation. To display foreign key reference with its information and enabled for navigation, use the source of FKREF as described above.) The first example assumes that you know the FK Reference. The second example uses a business service that receives the maintenance object as input.	**source=BS** **bs='F1-GetForeignKeyReference'** **input=[input/fkReference=FK_REF_CD input/fkValue1=BUS_OBJ_CD]** **output=output/infoDescription** **label=DESCR** **source=BS** **bs='F1-GetFKReferenceDetails'** **input=[input/maintenanceObject='F1-EXTLKUP' input/pkValue1=BUS_OBJ_CD input/pkValue2=C1]** **output=output/infoDescription** **label=DESCR**
Display a foreign key, including a corresponding navigation link, for generic objects that may or may not have a foreign key reference. If the FK reference exists, its information is shown, otherwise not. Standard foreign key services assume all rows have foreign key details. The service script **F1FKInfoOpt** provides the same foreign key details but does not error when foreign key details do not exist. To build the foreign key description and link, the script needs to be used twice; one column gets the navigation details and another gets the description. The latter references the navigation details column and invokes a BPA script to perform the dynamic navigation.	This column gets the navigation details: **source=SS** **ss='F1FKInfoOpt'** **input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7]** **output=output/navigationOption** **suppress=true** This column constructs the foreign key description and link: **source=SS** **ss='F1FKInfoOpt'** **input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7]** **output=output/infoDescription** **label=F1_APPSEC_COMP_DESCR** **bpa='F1ApsecNav'** **tempstorage=[navopt=C15 pkField1=C10 pkValue1=C6 pkField2=C11 pkValue2=C7]** **list=true**

Zone Action

Most zone types provided by the product allow for one or more Zone Actions to be defined to appear in the zone header. An action can appear as a hyperlink, icon or button. The action can also be provided as an HTML string.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Zone types also include parameters for actions defined at the zone type level using IMPLEMENTOR_ACTION_n (Action n) parameters. These are rarely used by the product zone types. The actions defined here override any actions defined on the zone type (if present). The details below apply to the zone type level actions as well.

A zone action is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
`type=`	This mnemonic defines the appearance of the action in the zone header.	**LINK**	Indicates that the action is shown as a textual hyperlink.
		ICON	Indicates that the action is shown as a graphical icon.
		BUTTON	Indicates that the action is shown as an HTML button.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		ASIS	Indicates that the parameter will provide the HTML to be used for the action.
`action=`	This mnemonic defines the action to take when the link/icon/button is clicked. This is ignored when the type=ASIS.	**NAVIGATION**	Indicates that the action is navigation to a page.
		SCRIPT	Indicates that the action is to run a BPA script.
`navopt=`	Defines the navigation option to use when the `action=NAVIGATION`.	'NAV_OPT_CD'	Enter a reference to a valid navigation option in single quotes.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
bpa=	Defines the script to run when the action=SCRIPT.	'SCRIPT_CD'	Enter a reference to a valid BPA script in single quotes.
icon=	Indicates the icon to use when type=ICON.	DISP_ICON_CD	Enter a reference to a valid display icon.
		'path'	Enter an explicit path to the icon, for example 'images/gotoZone.gif'.
asis=	This is required when the type=ASIS. This provides the ability to precisely define the HTML you wish to have included in the header. All valid HTML is permitted including the use of "ora" css classes and JavaScript functions.	['HTML']	

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
label=	By default, the label or tooltip will come from the navigation option or BPA script description. Use this mnemonic to override that label.	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.
		'text'	Enter the text directly in single quotes.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
`context=`[target1=source1 target2=source2]	This is used to pass context data when navigating to a page or executing a BPA script. The mnemonic supports passing multiple values. In each case the target context field or BPA script variable is defined first followed by an equal sign, followed by source data defined using one of the valid values defined in the next column. One or more values may be defined. Each context value is defined separated by spaces. The whole set of context values should be surrounded by square brackets.	FIELD_NAME	Indicates that the value should be taken from the field with this name from portal context, global context or the page data model. The mnemonic sourceLoc is used for defining the source.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		xpath	Indicates that the value should be taken from a schema field, represented by the Xpath, displayed in this zone. This is valid when the zone is displaying a UI Map.
		'constant'	Indicates that the value defined in single quotes should be passed.
sourceLoc=	This mnemonic defines the source of the FIELD_NAME's value in the context mnemonic. If this mnemonic is left blank, the default behavior is as follows: - The portal context is checked.	G	Indicates that the field's value is retrieved from the global context.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	- If no portal context value is found, the global context is checked. - If neither value is available, the field is ignored.	P	Indicates that the field's value is retrieved from the portal context.
		D	Indicates that the field's value is retrieved from the page data model.
class=	Use this mnemonic to override the look and feel of the link / icon / button using a different CSS style.	'className1' 'className2'	Enter one or more classes in single quotes. Multiple class names may be provided.
style=	Use this mnemonic to override the look and feel of the action element using the indicated css style.	Standard style= format.	All allowed css style definitions may be used.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
vss=	This mnemonic, along with **vinput**= and **voutput**=, may be used to conditionally hide the action. Use this mnemonic to define the service script responsible for determining wherher the action should be visible or not.	'SCRIPT_CD'	Enter a reference to a valid service script in single quotes.
vinput=[target1=source1 target2=source2]	This is used to pass input data to the visibility script. The mnemonic supports passing multiple values. In each case the target field is defined first followed by an equal sign, followed by source data defined using one of the valid values defined in the next column.	FIELD_NAME	Indicates that the value should be taken from the field with this name from portal context.
	One or more input values may be defined. Each value is defined separated by spaces. The whole set of values should be surrounded by square brackets.	'constant'	Indicates that the value defined in single quotes should be passed.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
voutput=	Use this mnemonic to define the XPath name of a Boolean element set by the visibility script indicating whether to show the action or not.	xpath	If the visibility script sets the element to true the action is visible. If it is set to false the action is not visible.

Examples:

- **type=BUTTON action=SCRIPT bpa='F1-SET-USER' context=[USER_ID=USER_ID] label=UPDATE_LBL**
- **type=LINK action=NAVIGATION navopt='gotoUser' context=[USER_ID=path(schema/userdId)]**
- **type=LINK … vss='F1BtrActVis' vinput=[batchControl=BATCH_CD batchNumber=BATCH_NBR batchRerunNumber=BATCH_RERUN_NBR batchRunAction='CLOSE_PARMS'] voutput=showAction**
- **type=ASIS asis=['<A class="oraLink" href="www.google.com">Search']**

> **Note**
>
> If the zone type has actions defined and there is a desire to simply remove the zone type actions, the Zone Action can be set with the following configuration: **type=ASIS asis=[]**

User Filters

Data explorer zones include the ability to define User filters to allow a user to enter data to restrict the zone's rows and / or columns. The filters may be defined individually using User Filter parameters 1–25. Alternatively, a UI map may be defined for capturing filters. In this case, the map's input fields must be associated with the zone's filters by specifying the **xpath=** mnemonic on the respective User Filter parameters.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (F1-DE)

Copyright © 2026, Oracle and/or its affiliates.

- Query Data Explorer - Multiple SQLs (`F1-DE-QUERY`)
- Info Data Explorer - Single SQL (`F1-DE-SINGLE`)

A user filter is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
`name=`	This mnemonic is used if the zone's filter should be pre-populated with a value from global context, portal context or broadcast from another zone.	MD Field Name	
`datasource=`	This mnemonic defines the source of the filter's pre-populated value defined in the name mnemonic. If this mnemonic is left blank, the default behavior is as follows: - If the field has been broadcast from another zone, the broadcast value is used. - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). - If still no value, the global context is checked. - If still no value, no default value is shown.	`G`	Indicates that the zone should look for the filter value in global context.
		`P`	Indicates that the zone should look for the filter value in portal context.
		`D`	Indicates that the zone should look for the filter value in the page data model.
`type=`	Defines the visual metaphor used to capture the filter values.	`DATE`	Filters of this type capture a date.
		`DATE/TIME`	Filters of this type capture a date and time.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		STRING	Filters of this type capture a string
		MONEY	Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic.
		NUMBER	Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic.
		LOOKUP	Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic.
		TABLE	Filters of this type capture an administrative table's value (code and description). This type of filter must also reference the table mnemonic.
		CHARTYPE	Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic.
		ASIS	Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement.
label=	Defines the filter's label that appears in the zone's description bar and in the input area.	MD Field Name	Enter a valid field name whose label should be used for the filter label. This should always be the option used if multiple languages are needed.
		'text'	Defines the text directly.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
cur=	Defines the currency code applied when type=MONEY.	Currency Code	Enter a reference to a valid currency code.
dec=	Defines the number of decimal places when type=NUMBER.	Valid number	It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.
lookup=	Defines the lookup flag whose values appear when type=LOOKUP.	Lookup Field Name	Enter a reference to a valid lookup field name.
table=	Defines the admin table whose values appear when type=TABLE.	Table Name	Enter a reference to a valid control table name.
chartype=	Defines the characteristic type code whose values appear when type=CHARTYPE.	Char Type code	Enter a reference to a valid characteristic type code.
xpath=	This mnemonic is used in conjunction with a Filter Area UI Map. For each filter, you must specify the XPath to the corresponding UI map schema element.	XPath	The type= mnemonic must also be appropriate for the map's input field, otherwise the query's SQL could fail.
likeable=	This mnemonic defines if a likeable search is performed on the entered value when type=STRING.	S	The query will add % to the suffix of the filter value.
		P	The query will add % to the prefix of the filter value.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		PS	The query will add % to the prefix and suffix of the filter value.
divide=	The mnemonic controls if a divider line appears above and/or below the filter. Note, you can specify this parameter twice if you want divider lines placed above and below a filter, e.g., **divide=above divide=below**.	above	This results in a divider line placed above the filter.
		below	This results in a divider line placed below the filter.
searchField=	This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map.	MD Field Name	Enter the field name that exactly matches the searchField name specified in the oraSearchField HTML element in the UI map.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
`oraSearchFilter`	This mnemonic is only applicable when the zone is used as a foreign key search. It indicates that this filter is the one that the user is prompted for in the auto-filtering functionality. No additional values are needed.		

Note

Be sure that a filter that includes this m

Mnemonic	Description	Valid Values	Comments
`encrypt=`	This mnemonic defines if the user filter is encrypted and needs to be searched by hashed value.	[TBL_NAME,FLD_NAME,WHERE_FLD,WHERE_VALUE]	A valid table name and field name are required. The WHERE_FLD and WHERE_VALUE are optional, but if entered, both are required. Use this to only encrypt the field if another field has a certain value. The following is an example. `encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_CD,'SSN']`. The WHERE_VALUE may also reference another filter. The following is an example. `encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_CD,F1]`. The encrypted field should be the source value

			er.

Examples:

- `label=F1_NBR_DAYS type=NUMBER`
- `label=F1_SHOW_ALL_REQ_FLG type=LOOKUP lookup=F1_SHOW_ALL_REQ_FLG`
- Filter value where a Filter UI Map is defined and Description is one of the filters. `type=STRING xpath=description likeable=S`
  - `type=STRING label=DESCR likeable=S divide=below`
  - `label=REQ_TYPE_CD type=TABLE table=F1_REQ_TYPE`

Hidden Filters

Data explorer zones include the ability to define Hidden filters to restrict the rows and / or columns that appear in the zone. The following are the potential sources of a hidden filter's value:

- The global area contains the fields whose values are maintained in global context.
- The portal area contains the fields describing the object currently displayed in a portal.
- Other zones on a portal can broadcast information to the portal area, which can then in turn be used by the zone as a hidden filter.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (`F1-DE`)
- Query Data Explorer - Multiple SQLs (`F1-DE-QUERY`)
- Info Data Explorer - Single SQL (`F1-DE-SINGLE`)

A hidden filter is defined using the following mnemonics:

Mnemonic	Description	Valid Values	Comments
`name=`	This mnemonic defines the name of the field that needs to be broadcast from other zones or populated in the portal context	FIELD_NAME	

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
datasource=	This mnemonic defines the source of the hidden filter's value. If this mnemonic is left blank, the default behavior is as follows: - If the field has been broadcast from another zone, the broadcast value is used. - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). - If still no value, the global context is checked. - If still no value, the zone appears as per the poprule mnemonic.	G	Indicates that the zone should look for the filter value in global context.
		P	Indicates that the zone should look for the filter value in portal context.
		D	Indicates that the zone should look for the filter value in the page data model.
poprule=	This mnemonic controls what happens if the hidden filter is not present.	R	Indicates that a value for the filter is required. The zone will be set to the "empty state" and the "please broadcast" message will appear in the zone. This is the default value.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		0	Indicates that the value is optional. If no value is required, the zone is still built without that value.
type=	Defines the visual metaphor used to capture the filter values.	**DATE**	Filters of this type capture a date.
		DATE/TIME	Filters of this type capture a date and time.
		STRING	Filters of this type capture a string
		MONEY	Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic.
		NUMBER	Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic.
		LOOKUP	Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
		TABLE	Filters of this type capture an administrative table's value (code and description). This type of filter must also reference the table mnemonic.
		CHARTYPE	Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic.
		ASIS	Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement.
`label=`	Defines the filter's label that appears in the zone's description bar.	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.
		'text'	Defines the text directly.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
cur=	Defines the currency code applied when type=MONEY.	CURRENCY_CD	Enter a reference to a valid currency code.
dec=	Defines the number of decimal places when type=NUMBER.	N	It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.
lookup=	Defines the lookup flag whose values appear when type=LOOKUP.	LOOKUP_FIELD_NAME	Enter a reference to a valid lookup field name.
table=	Defines the admin table whose values appear when type=TABLE.	TABLE_NAME	Enter a reference to a valid admin table name.
chartype=	Defines the characteristic type code whose values appear when type=CHARTYPE.	CHAR_TYPE_CD	Enter a reference to a valid characteristic type code.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
searchField=	This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map.	FIELD_NAME	Enter the field name that exactly matches the searchField name specified in the oraSearchField html element in the UI map.

Multi-Select Action

This parameter defines an action to be included in the action area for multi-selection processing. Note that a multi-selection action can only be used if the Multi Select parameter has been set to YES, which causes a checkbox to appear on each row displayed. The action defined here will trigger against all rows selected by the user via the checkbox.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (F1–DE)
- Query Data Explorer - Multiple SQLs (F1–DE-QUERY)
- Info Data Explorer - Single SQL (F1–DE-SINGLE)

A multi select action has the following mnemonics:

Mnemonic	Description	Valid Values	Comments
script=	This mnemonic defines the script to be invoked when the action is clicked. This is required.	SCR_CD	Enter a reference to a valid BPA script or Service Script.
type=	This mnemonic	**BUTTON**	The action is rendered as a button. This is the default.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	defines how the action should be rendered.	**LINK**	The action is rendered as hypertext.
		ICON	The action is rendered as a graphic icon. For this option, the icon mnemonic is required.
`icon=`	This mnemonic defines the icon to display when `type=ICON`.	DISPLAY_ICON_CD	Enter a reference to a valid display icon code.
`refresh=`	This mnemonic indicates how and if a refresh should occur after the script completes.	**NO**	Indicates that no refresh is performed. This is the default.
		ZONE	Indicates that a refresh of the zone is performed.
		PORTAL	Indicates that a refresh of the entire portal is performed.
`label=`	By default, the button label, link text or icon toolti	FIELD_NAME	Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	p will come from the script description. Use this mnemonic to override that label.	'text'	Enter the text directly in single quotes.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
list=	When executing the script, the framework builds an XML list containing information from each row selected. This list must be defined in the script's schema and referenced in this mnemonic.	listElementName	Enter a valid list element name from the script schema.
context=[elementName1=rowData1 elementName2=rowData2]	This mnemonic is used to populate the list with the appr	Cx	Indicates that the element should be populated with a value in the referenced column parameter.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	opriate information from each selected row. The mnemonic supports passing multiple values. In each case the element in the schema list is defined first followed by an equal sign, followed by information about the data used to populate the element defin	Px	Indicates that the element should be populated with a value in the referenced post processing parameter.
		COLUMN_NAME	Indicates that the element should be populated with a value from a column in the SQL statement.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
	ed using one of the valid values defined in the next column. One or more values may be defined. Each context value is defined separated by spaces. The whole set of context values should be surrounded by square brackets. Example of a	'constant'	Indicates that the value defined in single quotes should be passed.

	list and context mnemonics. `list=accountInfo` **context=[accountId=ACCT_ID name=C2 amount=P3 process='O']**		
`class=`	Use this mnemonic to override the look and feel of the action using a different CSS style.	'className1' 'className2'	Enter one or more classes in single quotes to be appended to the standard class(es). Multiple class names may be provided.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description	Valid Values	Comments
style=	Use this mnemonic to override the look and feel of the action element using the indicated css style.	Standard style= format.	All allowed css style definitions may be used.

Data Explorer Graph Configuration

For some data explorer zones, it is more effective to display the results in a graphical form such as a pie or line chart. Visualization option parameters enable the graph configuration to be integrated with the data explorer zone that retrieves the data.

The visualization option parameters support three options:

- **Grid** - displays the data in a standard data explorer grid
- **Chart** - displays the data in the form of a chart
- **Map** - provides the ability to invoke a UI Map to display the data

Up to five visualization option parameters may be specified. One of the options must be the standard grid, allowing for a maximum of four graphical options. The zone will display icons corresponding to the visualization types to allow you to switch between the various views. These icons are presented in the same order are they are defined in the parameter list.

> **Note**
>
> If the only display option is a standard grid, it is not necessary to specify the grid as a visualization parameter.

Visualization option parameters are provided on the Info Data Explorer - Single SQL (`F1-DE-SINGLE`) and Info Data Explorer - Multiple SQLs (`F1-DE`) zone types.

Visualization Option Parameter Configuration

Mnemonics are used to define the attributes for an option type within the parameter value.

Copyright © 2026, Oracle and/or its affiliates.

For a **grid**, the mnemonic is ‘optiontype=GRID’. No other mnemonics are required.

For a **map**, the mnemonics are ‘optiontype=MAP map=MAP_CD schemaPath=xpath’, where ‘MAP_CD’ is the ID of the UI Map and ‘xpath’ is the schema path of the UI Map. In most use cases the schema elements will match the result set from the data explorer, in which case no schemaPath mnemonic is needed. If the UI Map schema has additional elements present, the schemaPath attribute will define the group node that the data explorer information will be copied into.

For a **chart**, the option type mnemonics is ‘optiontype=CHART’. This is followed by the appropriate chart configuration attributes, which are described in the section below.

Chart Configuration

The following attributes are used to configure a graphical representation of a set of data.

The ‘`oraChart:`’ attribute defines the type of graph to display and its general configuration. The set of configuration parameters available for this attribute are as follows:

Parameter	Values	Description

`type:`	`pie`
	`stacked`
	`cluster`
	`line`
	`area`
	`combo`
		Defines the type of chart to display.
		Required

`showLegend:`	`true` `false`	Defines if the chart should have a legend displayed. Optional (default is **true**)

`legendPosition:`	`left`
	`right`
	`bottom`
	`top`
		Defines where the legend should appear.
		Optional (default is **right**)
		Setting position to **left** or **right** will automatically render it vertically.
		Setting position to **top** or **bottom** will automatically render it horizontally.

`legendBorder:`	`true` `false`	Defines if the legend should display with a border around it. Optional (default is **false**)
`depth:`	`true` `false`	A value of **true** indicates a 3 dimensional depth for the chart. Optional (default **false**, which is a 2 dimensional chart)
`animate:`	`true` `false`	A value of **true** indicates that the graph should animate when displayed. Optional (default is **true**). When using large data sets, consider disabling animation.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`dataCursor:`	`on` `off`	A value of **on** enables hovering anywhere in the graph. Optional (default is **off**). It is not applicable to pie charts.
`orientation:`	`horizontal`	Defines the chart orientation. This only applies to bar, line, area, combo charts. E.g., `oraChart="type:cluster; orientation:horizontal"`, defines horizontal cluster chart. Optional (default is vertical).

The **oraChartSeries** attribute defines the source information for the graph. Most charts support 5 of these attributes, with the following mnemonics:

- `oraChartSeries1`
- `oraChartSeries2`
- `oraChartSeries3`
- `oraChartSeries4`
- `oraChartSeries5`

Stacked charts support an unlimited number of series by continuing to add attributes `oraChartSeries6` and above, but beware of performance implications and memory limits when using an excessively high number of series. All attributes are identical in format and accept the same parameters, as described below.

> **Note**
>
> All the charts require `oraChartSeries1`. Stacked, Cluster and Line charts may optionally include the additional series attributes (for multiple bars/lines).

If you define multiple series, then data must be provided for all series defined. The data amounts can be 0 (zero) but they have to be present in order for the chart to display correctly.

The set of configuration parameters available for the **oraChartSeriesN** attribute are:

Parameter	Values	Description
`list:`	XPath value	Defines the XPath to the list in the XML that contains the data to chart. Required only for HTML definitions in UI Maps. Data explorer values are derived from the columns for the zone.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`amount:`	Cn Pn XPath value	Defines the element containing the amount to chart. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Required
`xaxis:`	Cn Pn XPath value	Defines the element containing the x-axis data. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element is specified. Required for Stacked, Cluster, Line, Area and Combo charts.

`xaxisFormat:`	`date`
	`dateTime`
	`time`
	`localDate`
	`string`
		Defines the x-axis data format.
		If it is **date**, **dateTime** or **time** then the value is presented in the format as defined on the user's display profile.
		In case of **localDate** or **string** the data is displayed as is with no special formatting.
		Optional (Default is **date**).

`label:`	Text value	Defines the label for the amount being charted. Either this setting or `labelPath:` must be defined.
`labelPath:`	Cn Pn XPath value	Defines the element that provides the label for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Either this setting or `label:` must be defined.
`currency:`	A valid Currency code	Defines the currency code for the amount being charted. Optional.
`currencyPath:`	Cn Pn XPath value	Defines the element that provides the currency code for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Optional.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`hoverText:`	Text value	Defines the hover text for the chart element. Optional (A default hover text is always available.) Ignored if `hoverTextPath:` is defined. The following substitution variables are available. • `$label` This will be replaced with the label text as determined by the `label:` or `labelPath:` setting. • `$amount` This will be replaced with the amount text as specified by the `amount:` setting. • `$axis` This will be replaced with the x-axis text. • $% This will be replaced by the percentage "slice" of the pie or bar. • `$newline` This will force a line break. If the hover text defined contains any of the above values, they will be replaced by the equivalent text prior to being displayed. Example: `"hoverText:$label$newline$amount"`
`hoverTextPath:`	Cn Pn XPath value	Defines the element that provides the hover text for the chart element. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. The hover text in the element can utilize all the substitution functionality described above in the `hoverText:` description. Optional.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description

`type:`	`bar`
	`line`
	`area`
		This attribute is used for the **combo** chart type only. It defines how each series on the **combo** chart should be presented.
		The following example defines a **combo** chart where one series is rendered as bars and another one as area.
		
		`oraChart="type:combo;" oraChartSeries1="xaxis:C3; label:C2; amount:C1;type:bar" oraChartSeries2="xaxis:C3; label:C2; amount:C1;type:area"`

`navOpt:`	A valid Navigation Option code.	Defines a navigation option to be activated when the chart element is clicked. Optional.
`navOptPath:`	Cn Pn XPath value	Defines the element that provides the navigation option to be activated when the chart element is clicked. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Optional Note that both `navOpt:` and `navOptPath:` may be configured. The `navOptPath:` navigation option is processed first. If a value is found it is used, otherwise the value in the `navOpt:` setting is used. This means that the chart definition can include a default navigation option and a navigation option present in the data will override it.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`key:`	Cn Pn XPath value	Defines the element that contains the key field data to be used in a navigation option. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. This is required if either `navOpt:` or `navOptPath:` is defined. **Note** Only one key field can be configured for a navigation option.
`script:`	A BPA script name	Defines a BPA script to be activated when the chart element is clicked. Optional When a script is executed, all the elements from the chart data will be made available to the script as temporary variables.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`scriptPath:`	Cn Pn XPath value	Defines the element that provides the BPA script to be activated when the chart element is clicked. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Optional Note that both `script:` and `scriptPath:` can be configured. The `scriptPath:` script option is processed first. If a value is found it is used, otherwise the value in the `script:` setting is used. This means the chart definition can include a default script and a script present in the data will override it.

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description
`color:`	HTML Color code / RGB value	Optional (default colors applied) Defines the color for the series. The format is a valid HTML color code, e.g. **green** or **blue**. All valid color names are defined in this link: http://www.w3schools.com/htmL/html_colornames.asp. Alternatively an RGB format may be used. (`00FF00` is green and `0000FF` is blue) **Note** Refer to Color Contrast for information about the use of the HTML color 'red' and its impact on accessibility.
`colorPath:`	Cn Pn XPath value	Defines the element containing a color for the series. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. The valid formats as described in the `color:` setting apply. Optional (default colors applied)

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Values	Description

`pieColors:`	HTML color code / RGB values	Defines the colors for the pie series. Any number of HTML color codes or RGB color values can be specified, separated by spaces. Examples:
		
		`pieColors: green blue`
		
		`pieColors: 00FF00 0000FF`
		
		Optional (default colors are applied if the series exceeds the values specified)

The `oraChartBroadcast=`attribute provides the ability to broadcast a value from a chart to the portal context. An unlimited number of fields can be broadcast, configured as name/value pairs; Broadcast is triggered by clicking on a corresponding section of the chart.

The syntax is as follows where FIELD_NAMEn is the name of the portal context field to be broadcast and Cn (or Pn) is the element that contains the data value to be broadcast.

```
oraChartBroadcast="FIELD_NAME1:C1;FIELD_NAME2:C2;"
```

For HTML definitions in UI Maps, ‘xpathn’ is the element in the list schema that contains the data value to be broadcast.

```
oraChartBroadcast="FIELD_NAME1:xpath1;FIELD_NAME2:xpath2;"
```

The `oraChartViewDetails=`attribute provides the ability to launch a view details drawer for an entry in a chart. The syntax is similar to launching a drawer from a UI map or a data explorer column but without rendering an icon. Refer to Launch a View Details Drawer for more information.

UI map examples:

```
oraChartViewDetails="detailPanelName:VIEWDET; USERID:x[user];"
oraChartViewDetails="detailPanelName:x[panelName]; USERID:x[user];"
```

Data explorer examples:

```
oraChartViewDetails="detailPanelName:VIEWDET; USERID:C1;"
oraChartViewDetails="detailPanelName:C2; USERID:C1;"
```

Zone Configuration Examples

Zone with a simple pie chart

In this example, the zone SQL summarizes To Do entries by Role. The column definitions are:

- C1 - role description

Copyright © 2026, Oracle and/or its affiliates.

- C2 - count of To Do entries by role
- C3 - role ID

Visualization Option 1

This option shows To Do entries by Role as a pie chart. The role ID will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="ROLE_ID:C3"
```

Zone with two chart types

In this example, the zone SQL summarizes To Do entries by Priority and also calculates separate counts by To Do status within priority. The column definitions are:

- C1 - priority description
- C2 - count of To Do entries by priority
- C3 - priority flag value
- C4 - count of Open To Dos by priority
- C5 - count of Assigned To Dos by priority
- C6 - Label for the Open To Dos bar in the cluster chart
- C7 - Label for the Assigned To Dos bar in the cluster chart

Visualization Option 1

This option shows To Do entries by Priority as a pie chart. The priority value will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie; legendBorder:true;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Visualization Option 2

This option shows To Do entries by Priority as a cluster chart with two data series, one for Open To Dos and another for Assigned To Dos . The corresponding priority value will be broadcast to the portal when clicking either the Open or Assigned bar of the cluster chart.

```
optiontype=CHART oraChart="type:cluster;  showLegend:true;"
oraChartSeries1="xaxis:C1; xaxisFormat:string; labelPath:C6;
amount:C4;hoverText:$label$newline$amount;"
oraChartSeries2="xaxis:C1; xaxisFormat:string; labelPath:C7;
amount:C5;hoverText:$label$newline$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Pagination Configuration

Copyright © 2026, Oracle and/or its affiliates.

The various data explorer zones in the product support the ability to configure pagination so that a user can 'page through' a large set of results using "previous" and "next" buttons or links.

There are several zone parameters that are impacted when attempting to configure this functionality. The following steps highlight the configuration.

- The **Enable Pagination** parameter must be configured to define the basic setup for pagination for the zone. This parameter defines whether the "previous" and "next" actions are defined as buttons, links or icons and indicates the location of the actions. It also allows an indication as to whether the additional rows are simply appended, rather than shown in a new "page". Refer to the parameter's embedded help for information about the specific syntax.
- It is recommended that the zone is configured with record count and page information by properly configuring the **Record Count Display** parameter. Refer to the parameter's embedded help for information about the specific syntax.
- Configure the **Number of Rows to Retrieve for SQL**. parameter to define the number of records displayed per page. If this parameter is not specified the value in the **Number of Rows to Display** parameter is used.
- Configure the key that will be used for paging so that the system can keep track of the 'page break'. The data must be sorted by the paging key; as a result, the decision for identifying the paging key must take into account the design for the zone and the data being displayed. In addition, the paging key must be unique to ensure that the page breaks occur correctly. See below for configuration examples.
  - The **SQL Statement** must includes additional clauses **PAGENEXT** and **PAGEPREV** based on the paging key. In addition, as mentioned above, the paging key must be used in the ORDER BY clause.
  - The SQL **Column** parameters must define the paging key mnemonic to be used in conjunction with the SQL statement paging clauses.
  - It is recommended to configure the **SQL Display Column** parameter to show the data in the same order as the ORDER BY clause.

The following zone types support this capability:

- Info Data Explorer - Single SQL (`F1-DE-SINGLE`).
- Info Data Explorer - Multiple SQLs (`F1-DE`). Note that zones of this type support a union of the results of all the SQL statements. As a result, pagination may only be enabled for zones of this type if a single SQL is used. The system is not able to keep track of the pagination across disparate SQL statements.
- Query Data Explorer - Multiple SQLs (`F1-DE-QUERY`).
- Multi Query Data Explorer (`F1-DE-MULQRY`). Zones of this type do not include configuration for SQL statements or column display. However, they do include configuration for the **Enable Pagination**. This parameter must be configured in order for pagination on the individual zones to work.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Zones used for a Business Service.** Note that pagination is ignored when invoking a data explorer zone via a business service. In this scenario, the zone will return the first "chunk" of rows as defined by the Number of Rows parameters.
>
> **Zones with data visualization options.** Pagination is not supported for zones that define visualization options to show data in a graphical form.

Examples

Simple Paging Key

In this example, the Extendable Lookup Value is defined as Column 1 (C1) and is marked as the paging key. This field is unique for the table and works well as a simple paging key.

```
SELECT A.F1_EXT_LOOKUP_VALUE,A.BUS_OBJ_CD
FROM
  F1_EXT_LOOKUP_VAL A,
  F1_EXT_LOOKUP_VAL_L B
WHERE
A.BUS_OBJ_CD = :H1
AND A.BUS_OBJ_CD = B.BUS_OBJ_CD
AND A.F1_EXT_LOOKUP_VALUE = B.F1_EXT_LOOKUP_VALUE
AND B.LANGUAGE_CD = :LANGUAGE
[(F1) AND UPPER(A.F1_EXT_LOOKUP_VALUE) like UPPER(:F1)]
[(F2) AND ((UPPER(B.DESCR_OVRD) like UPPER(:F2))
OR (B.DESCR_OVRD = ' ' AND UPPER(B.DESCR) like UPPER(:F2)))]
[(PAGENEXT) AND A.F1_EXT_LOOKUP_VALUE > :C1]
[(PAGEPREV) AND A.F1_EXT_LOOKUP_VALUE < :C1]
ORDER BY A.F1_EXT_LOOKUP_VALUE
```

Complex Paging Key

Most queries however do not sort by a unique value. In this case, the paging key needs to be set based on the sorting of the query and should include a unique field, such as the primary key, as the last paging key. In this example, the query is showing results sorted by To Do Type, Role and User. All fields, including the To Do Entry ID (the primary key) are marked as paging keys.

```
SELECT TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, ASSIGNED_DTTM, TD_PRIORITY_FLG,
TD_ENTRY_ID
FROM  CI_TD_ENTRY
WHERE
ENTRY_STATUS_FLG IN ('O', 'W')
[(F1) and TD_TYPE_CD = :F1]
[(F2) AND ASSIGNED_TO = :F2]
[(F3) AND ROLE_ID = :F3]
[(PAGENEXT) and ((TD_TYPE_CD>:C1) or (TD_TYPE_CD=:C1 and ROLE_ID>:C2) or
(TD_TYPE_CD=:C1 and ROLE_ID=:C2
and ASSIGNED_TO>:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3
AND TD_ENTRY_ID>:C4))]
[(PAGEPREV) and ((TD_TYPE_CD<:C1) or (TD_TYPE_CD=:C1 and ROLE_ID<:C2) or
(TD_TYPE_CD=:C1 and ROLE_ID=:C2
```

Copyright © 2026, Oracle and/or its affiliates.

```
and ASSIGNED_TO<:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3
AND TD_ENTRY_ID<:C4))]
ORDER BY TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, TD_ENTRY_ID
```

Auto-filtering Configuration

Auto-filtering is the term used to describe functionality available in search fields where a user can type search text without having to open the search. Refer to Input Field with Search for examples of this feature. This section describes how to enable this feature and how to configure a search zone to enable this functionality.

The feature is opt-in. To turn on the feature, navigate to Feature Configuration. Search for an existing feature configuration with the Feature Type `Custom Look and Feel`. If one does not exist, create a feature configuration of this type. Select the `Enable Auto-Filtering` option and set the value to 'Y'.

The feature supports designating a single user filter in the zone as the one to expose to the user for auto-filtering. For example, when searching for a control table record, like To Do Type, the system configures the Description filter as the one that supports auto-filtering. For an object like Person, the person name filter may be the one that is configured for this feature.

To indicate the filter to support auto-filtering, add the mnemonic `oraSearchFilter` to the filter definition. For example, here is the configuration for the description user filter in the To Do Type search zone.

```
type=STRING label=DESCR likeable=S xpath=descr oraSearchFilter
```

In addition, when turning on this feature, the system supports displaying up to 3 columns of content for each record to help the user choose the correct value. The best practice is ensure that at least one of the columns configured to display matches the filter the user is typing. For example, the system has configured that all control table searches show both the code and the description. This configuration goes into the `Initial Display Columns` parameter, or for Query data explorers, if individual SQLs have different display columns, add the configuration to the appropriate `SQL n Display Column` parameter. The syntax is the mnemonic `oraSearchDisplay=` followed by a comma delimited list of up to 3 column references in the order to display. Note that the columns in the search display mnemonic are limited to those referenced in the display parameter. Example:

```
C1 C2 C3 C4 C5 oraSearchDisplay='C2,C1'
```

Use Data Explorer for Derived Data

There are times when a design warrants displaying data in a data explorer zone that is not accessible via SQL. For example, perhaps the data is from another system and it requires a web service call. The JMS Message Browser is another example.

The product provides functionality in the data explorer that allows you to call a script after the user filters are populated but before the SQL is executed. The script can retrieve the data as appropriate, store the data in table format so that the SQL can retrieve the data from the table.

The following points provide more detail:

- Create a service script that retrieves the data as needed. This script should store the retrieved data in a temporary table.

Copyright © 2026, Oracle and/or its affiliates.

  - The product provides a table that may be used. It is called F1_GENERIC_GTT (Generic Global Temporary Table). There is a business service — Create Global Temporary Table Records (`F1-InsertGTTRecords`) that the service script may call to insert the records.
  - Note that if the data is accessed via a web service call, it may be appropriate to execute the web service in a separate session using the business service F1-ExecuteScriptInNewSession to trap errors that may be issued by the web service call and provide a better error.
- In the data explorer zone use this service script in the zone's pre-processing script parameter. If any user or hidden filters should be passed into the script, the parameter supports mnemonics for this purpose. Refer to the parameter's embedded help for the supported syntax.
- The SQL for the data explorer should access the temporary table that was populated by the service script.

Configuring Timeline Zones

This topic highlights information related to configuring a timeline zone. The zone type is `F1-TIMELINE`. A timeline zone contains one or more "lines" where each line shows when significant events have occurred. The output of each line is driven by an algorithm configured on a timeline zone. Each algorithm is responsible for retrieving a single type of data. For example, one algorithm may retrieve bills for an account in a given time period whereas another algorithm may retrieve payments for that account for the same time period.

The algorithms to configure for a timeline zone use the **Zone - Timeline** plug-in spot. Please note the following details about the behavior for algorithms for this plug-in spot.

- The timeline algorithm receives all the global context values currently populated. In addition, it receives a start and end date from the zone, based on the time period chosen by the user, along with the maximum number of events that can be reasonably displayed for the chosen time period. The algorithm should use this information to retrieve data for a given type of transaction related to one or more of the input context values for the provided time period.
- For each event found, the algorithm returns information about the event along with many options that assist the user in getting more detail about each event or acting on an event.
  - Event date
  - Primary key of the record (key / value pairs)
  - FK Reference. With this information, the timeline zone will display the appropriate info string to display in the zone's info area when clicking on the event. In addition, the FK reference identifies the appropriate navigation option to use when a user clicks the info string hypertext to view the record on its maintenance page.
  - Background Color and Text Color to use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
  - Icon use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
  - BPA script to launch when a user clicks on an event. (Optional). The algorithm may return one or more BPA scripts that a user may launch to act on an event. For example, for an event that has a status of **Error**, perhaps a BPA is provided to walk a user through resolving the error.

Copyright © 2026, Oracle and/or its affiliates.

When a script is initiated from a timeline, the system puts the prime key of the event into a field in the page data model. The name of the field is the column name(s) of the event's prime key. For example, when a script associated with a payment event is kicked off, the system populates a field called PAY_ID with the prime-key of the selected payment.

Note that your specific edge application may supply algorithm types for a timeline zone as part of the base product. Although algorithm types may be provided, typically the product does not deliver algorithms because the parameters for the algorithms are driven by a particular implementation's business rules and preferences. As a result, the product will also not deliver pre-configured timeline zones. Please refer to your edge application's documentation for more information about what timeline algorithm types are delivered, if any and recommendations for configuration.

Defining Context-Sensitive Zones

A context-sensitive zone allows you to associate a zone with a specific user-interface transaction. A context-sensitive zone appears at the top of the Sidebar when a user accesses a page for which the zone is specified as the context.

> ⚠ **Caution**
>
> Make sure that the zone is appropriate for the transaction on which you are specifying it.

Select **Admin**, and then **Context Sensitive Zone** to maintain context-sensitive zones.

Description of Page

The **Navigation Key** is a unique identifier of a tab page within the system. **Owner** indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**).

> ⚠ **Caution**
>
> Important! When introducing a new context sensitive zone, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The grid contains the list of context-sensitive zones and the sequence in which they appear in the sidebar for the selected navigation key. The grid contains the following fields:

- **Zone** is the name of the zone to display in the Sidebar.
- **Sequence** is the sequence in which the zone is displayed (if multiple context-sensitive zones are defined).
- **Owner** indicates if this context sensitive zone is owned by the base product or by your implementation (**Customer Modification**).

Where Used

A context-sensitive zone displays at the top of the Sidebar whenever a user accesses the transaction for with the zone is specified.

Copyright © 2026, Oracle and/or its affiliates.

Defining Portals

This portal is used to view and maintain the configuration of portals. An implementation may define their own portals or may override some of the settings for base product provided portals.

You can access the portal from the **Admin Menu**, and then **System**, and then **Portal**. You are brought to a query portal with options for searching for a specific record. Once a portal record has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Refer to Understanding Portals and Zones for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Portal.** This zone provides information about the selected portal definition.
- **Tabs.** This zone lists other tab portals if any are configured for a standalone portal. This zone is only visible when such tabs exist for the current standalone portal.
- **Context Sensitive Zones.** This zone lists context sensitive zones that appear on the sidebar when this portal is displayed . This zone is only visible when such zones exist for the current standalone portal.

The following zones may appear as part of the portal's **Options** tab page

- **Options.** This zone lists various configuration options for the selected portal record.

Some portals may be associated with configurable settings that are maintained on a **Configuration** tab. These settings are defined using a master configuration business object referenced as portal option. The tab is visible when such option exists for the portal.

Defining Menu Options

This portal is used to define / change any menu in the system. You can access the portal from the **Admin Menu**, and then **System**, and then **Menu**. You are brought to a query portal with options for searching for a specific menu. Once a menu has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Caution**
>
> Updating menus requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience with menus.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Security and menus.** Refer to Secured Objects and Application Services for a discussion of how application security can prevent menu items (or an entire menu) from appearing.

> **Note**
>
> **Module configuration and menus.** Your module configuration can prevent menu items (or an entire menu) from appearing.

The following zones may appear as part of the portal's **Main** tab page:

- **Menu.** This zone provides information about the selected menu.
- **Menu Lines.** This zone lists the menu's lines and supports actions to add, edit and delete lines. You may also broadcast a line to review more information about its items configuration.
- **Menu Line Items.** This zone lists item information for a selected menu line.

Application security information for the menu can be reviewed and managed from the **Application Security** tab. The following zones may appear as part of this tab page:

- **Menu Lines.** This zone lists the menu's lines. Broadcast a line to review its application security information.
- **Menu Line Security.** This zone lists application services related to the selected menu line. You may use this zone to review and configure security access for the selected menu line and a specific user group.
- **Menu Line Security Details.** This zone lists the entities secured by a selected application service.

The following zone may appear as part of the portal's **References** tab page:

- **Menu References.** This zone lists entities that reference the selected menu.

The following sections provides more information.

Menu Types

The following types of menus are supported:

- **Main** menu type defines the menu items under the Main Menu entry visible when the menu is initially expanded.
- **Admin** menu type defines the menu items under the Admin Menu entry visible when the menu is intially expanded.
- **Submenu** defines a menu group that appears when the main menu or admin menu is selected. For the Admin menu, this is only visible when it's organized functionally. Refer to Admin Menu for more information about options for organizing the admin menu.
- **Context** refers to a context menu.
- **Page Action Menu** defines buttons that appear in the Page Title Area.
- **User Menu** refers to the menu items that appear on the user menu; for example, User Preferences.

Copyright © 2026, Oracle and/or its affiliates.

Extending Product Owned Menus

An implementation may choose to add custom menu lines along with its menu item (or items) to a base product owned menu.

Overriding Menu Lines Sequence

An implementation may override the sequence of a base product owned menu line. Also note that the sequence is defined on the menu line language table, allowing for different orders to be used for different languages (or to let the menu be sorted alphabetically in one language and in a specified order in a different one).

Menu Information is Cached

Use the **Flush Menu** button to flush the cached menu items so you can see any modified or newly created menus. Refer to Caching Overview for more information.

Defining Navigation Keys

Each location to which a user can navigate (e.g., transactions, tab pages, tab menus, online help links, etc.) is identified by a navigation key. A navigation key is a logical identifier for a URL.

- Navigation Key Types
- Navigation Key vs Navigation Option
- The Flexibility of Navigation Keys
- Linking to External Locations
- Overriding Navigation Keys
- Maintaining Navigation Keys

Navigation Key Types

There are three types of navigation keys:

- **System navigation keys** define locations where the target for the navigation is a transaction or portal within the system. The navigation keys define the program component that identifies the page to navigate to.
- **External navigation keys** define a URL that identifies the target location. External URLs can be specified as relative to the product web server or fully qualified. External navigation keys always launch in a new instance of a browser window. Examples of external navigation keys include URLs to external systems.
- **Help navigation keys** define a online help topic that identifies the specific page within the online help to launch. Help navigation keys may be related to a program component when the help is related to a specific page in system.

Navigation Key vs Navigation Option

The system has two entities that work in conjunction with each other to specify how navigation works:

- Navigation Key defines a unique location to which a user can navigate. For example, each page in the system has a unique navigation key. Navigation keys can also define locations

Copyright © 2026, Oracle and/or its affiliates.

that are "outside" of the system. For example, you can create a navigation key that references an external URL. Think of a navigation key as defining "where to go".

- Navigation Option defines how a page is opened when a user wants to navigate someplace. For example, you might have a navigation key that identifies a specific page. This navigation key can then be referenced on two navigation options; the first navigation option may allow users to navigate to the page with no context included, while the second navigates to the page with context data provided to automatically display information related to that context.
- Please note that a wide variety of options can be defined on a navigation option. In addition to defining if data is passed to the page, it could also define search options. In addition, there are some navigation options that do not reference a navigation key but rather refer to a BPA script that should be launched.

The Flexibility of Navigation Keys

Navigation keys provide a great deal of functionality to your users. Use navigation keys to:

- Allow users to navigate to new pages or search programs
- Allow users to transfer to an external system or web page. After setting up this data, your users may be able to access this external URL from a menu, a context menu, their favorite links, etc. Refer to Linking to External Locations for more information.

Refer to the Tool Suite Guide for more information on developing program components.

> **Note**
>
> **Replacing Base-Package Pages or Searches**. If your new page or search has been designed to replace a module in the base-package, the navigation key must indicate that it is overriding an existing navigation key.

Linking to External Locations

If you want to include links to external systems or locations from within the system, you need to:

- Define a navigation key that specifies the URL of the location. For example, define an external navigation key that as a URL of **http://www.oracle.com/**.
- Define a navigation option that specifies from where in the system a user can go to your external location. For example, define a navigation option with a usage of **Favorites** or with a usage of **Menu**. Your navigation option points to the navigation key you defined above.
- Add your navigation option to the appropriate location within the system. For example, have users add the navigation option to their Favorite Links or add the navigation option as an item on a menu.

Overriding Navigation Keys

Your implementation may choose to design a program component (e.g., a maintenance transaction or search page) to replace a component provided by the system. When doing this, the new navigation key must indicate that it is overriding the system navigation key. As a result, any menu entry or navigation options that reference this overridden navigation key automatically navigates to the custom component.

Copyright © 2026, Oracle and/or its affiliates.

For example, if you have a custom On-line Batch Submission page and would like users to use this page rather than the one provided by the system, setting up an override navigation key ensures that if a user chooses to navigate to the On-line Batch Submission from Menu or a context menu, the user is brought to the custom On-line Batch Submission page.

To create an override navigation key, you need to:

- Define a navigation key using an appropriate naming convention.
- If the Navigation Key Type of the navigation key being overridden is **External**, specify a Navigation Key Type of **Override (Other)** and define the appropriate URL Component.
- If the Navigation Key Type of navigation key being overridden is **System**, specify a Navigation Key Type of **Override (System)** and populate the Program Component ID with your custom program component ID.
- Specify the navigation key that you are overriding in the **Overridden Navigation Key** field.

Refer to the Tool Suite Guide for more information about developing your own program components.

Maintaining Navigation Keys

Select **Admin**, and then **System**, and then **Navigation Key** to maintain navigation keys.

Use the **Navigation Key Query** portal to search for an existing navigation key. Once a navigation key is selected, you are brought to the maintenance portal to view and maintain the selected record.

> ⚠ **Caution**
>
> Important! When introducing a new navigation key, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Description of Page

The **Navigation Key** is a unique name of the navigation key for internal use.

Owner indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**). This information is display-only.

Navigation Key Type includes the following possible values:

- **External** indicates that the location is specified in the **URL Component** field.
- **Help** indicates that the navigation key is used to launch online help where the specific help topic is defined in the **URL Component** field.
- **Override (Other)** indicates that the navigation key overrides another navigation key of type **External** or **Help**. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **Override (System)** indicates that the navigation key overrides a system navigation key. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **System** indicates that the navigation key refers to a transaction in the system identified by its program component.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Navigation Key Types for more information about navigation key types.

NOT_SUPPORTED

Refer to Overriding Navigation Keys for more information about settings required to override a system navigation key.

Program Component ID is the name of the program component identified by the key (for system navigation keys). The program component ID can also be used to specify the transaction with which an online help link is associated.

Overridden Navigation Key is the name of the navigation key that the current navigation key is overriding (if **Override (Other)** or **Override (System)** is selected for the **Navigation Key Type**). Refer to Overriding Navigation Keys for more information.

URL Component is the specific URL or portion of the URL for the navigation key (external and help navigation keys only). The URL can be relative to the product web server or fully qualified.

Open Window Options allows you to specify options (e.g., width and height) for opening a browser window for an external navigation key. (External navigation keys always launch in a new browser window.) You can use any valid features available in the Window.open( ) JavaScript method. The string should be formatted the same way that it would be for the features argument (e.g., `height=600,width=800,resizeable=yes,scrollbars=yes,toolbar=no`). Refer to a JavaScript reference book for a complete list of available features.

Application Service is the application service that is used to secure access to transactions associated with **External** navigation keys. If a user has access to the specified application service, the user can navigate to the URL defined on the navigation key. Refer to The Big Picture of Application Security for more information.

The grid displays menu items that reference the navigation key (actually, it shows menu items that reference navigations options that, in turn, reference the navigation key).

Defining Navigation Options

Every time a user navigates to a transaction, the system retrieves a navigation option to determine which transaction should open. For example:

- A navigation option is associated with every menu item. When a user selects a menu item, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every favorite link. When a user selects a favorite link, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every node in the various trees. When a user clicks a node in a tree, the system retrieves the related navigation option to determine which transaction to open.
- Etc.

Copyright © 2026, Oracle and/or its affiliates.

Many navigation options are shipped with the base product and cannot be modified as these options support core functionality. As part of your implementation, you may add additional navigation options to support your specific business processes.

Navigation options may also be used to launch a BPA script.

The topics in this section describe how to maintain navigation options.

> ⚠ **Caution**
>
> In order to improve response times, navigation options are cached the first time they are used after a web server is started. If you change a navigation option and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. A special button has been provided on the Main tab of the navigation option transaction that performs this function. Please refer to Caching Overview for information on the various caches.

- Navigation Option - Main
- Navigation Option - Tree

Navigation Option - Main

Select **Admin**, and then **System**, and then **Navigation Option** to maintain a navigation option.

Use the **Navigation Option Query** portal to search for an existing navigation option. Once a navigation option is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Navigation Option** code and **Description**.

> ⚠ **Caution**
>
> When introducing a new navigation option, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The **Flush System Login Info** button is used to flush the cached navigation options so you can use any modified navigation options. Refer to Caching Overview for more information.

Owner indicates if this navigation option is owned by the base product or by your implementation (**Customer Modification**). This field is display-only. The system sets the owner to **Customer Modification** when you add a navigation option.

> ⓘ **Note**
>
> You may not change navigation options that are owned by the base product.

Use **Navigation Option Type** to define if the navigation option navigates to a **Transaction**, launches a BPA **Script** or opens an **Attachment**.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The **Attachment** option type is only applicable to navigation options that are used to launch a file attached to a record in the Attachment maintenance object.

For navigation option types of **script**, indicate the **Script** to launch. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to temporary storage variables available to the script. The script engine creates temporary storage variables with names that match the Context Field names.

For navigation option types of **transaction**, define the **Target Transaction** (navigation key) and optionally a specific **Tab Page** (also a navigation key) if a specific tab on the transaction (other than the Main tab) should be opened when navigating to that transaction.

> **Note**
>
> **Finding transaction navigation keys**. When populating the **Target Transaction** and **Tab Page** you are populating an appropriate navigation key. Because the system has a large number of transactions, we recommend using the "%" metaphor when you search for the transaction identifier. For example, if you want to find the currency maintenance transaction, enter "%currency" in the search criteria.

The additional information depends on whether the target transaction is a fixed page or a portal-based page:

- For portal-based pages:
  - **Navigation Mode** is not applicable and should just be set to **Add Mode**.
  - If navigating to a query portal, by default the query portal will open with the default search option defined. If the navigation should open a different search option, define the **Multi-Query Zone** for that query portal and indicate the **Sub-Query Zone** to open by default. Note that for this configuration, it is common to define **Context Fields** to pre-populate search criteria in the target query zone. When using this configuration, be sure that the target query zone's user filters are defined to populate data from context.
- For fixed pages:
  - **Navigation Mode** indicates if the **Target Transaction** should be opened in **Add Mode** or **Change Mode**.
  - **Add Mode** should be used if the option is used to navigate to a transaction ready to add a new object. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to the transaction when it opens.
  - **Change Mode** is only applicable for fixed pages and should be used if the option is used to navigate to a transaction ready to update an object. You have two ways to define the object to be changed:
    - Define the name of the fields that make up the unique identifier of the object in the **Context Fields** (and make sure to turn on **Key Field** for each such field).
    - Define the **Search Transaction** (navigation key) if you want to open a search window to retrieve an object before the target transaction opens. Select the appropriate **Search Type** to define which search method should be used. The options in the drop down correspond with the sections in the search (where **Main** is the first section, **Alternate** is the 2nd section, **Alternate 2** is the 3rd section, etc.).

Copyright © 2026, Oracle and/or its affiliates.

You should execute the search window in order to determine what each section does.

When you select a **Search Type**, define appropriate **Context Fields** so that the system will try to pre-populate the search transaction with these field values when the search first opens. Keep in mind that if a search is populated with field values the search is automatically triggered and, if only one object is found that matches the search criteria, it is selected and the search window closes.

- **Search Group** is only visible if the **Development Tools** module is not turned off. It is used to define the correlation between fields on the search page and the tab page. You can view a tab page's **Search Groups** by viewing the HTML source and scanning for **allFieldPairs**.

The **Go To Tooltip** is used to specify the label associated with the tool tip that appears when hovering over a **Go To** object. Refer to the **Usage** grid below.

The **Usage** grid defines the objects on which this navigation option is used:

- Choose **Favorites** if the navigation option can be used as a favorite link.
- Choose **Menus** if the navigation option can be used as a user's home page or as a menu or context menu item.
- Choose **Script** if the navigation option can be used in a script.
- Choose **Foreign Key** if the navigation option can be used as a foreign key reference.
- Choose **Go To** if the navigation option can be used as a "go to" destination ("go to" destinations are used on Go To buttons, tree nodes, and hyperlinks).
- If your product supports marketing campaigns, you can choose **Campaign** if the navigation option can be used as a "post completion" transaction on a campaign. For more information refer to that product's documentation for campaigns.

The **Context Fields** grid contains the names of the fields whose contents will be passed to the **Target Transaction** or **Script** or used to launch an **Attachment**. The system retrieves the values of these fields from the "current" page and transfers them to the target transaction or to the script's temporary storage. Turn on **Key Field** for each context field that makes up the unique identifier when navigating to a transaction in **Change Mode**.

> **Note**
>
> For an **Attachment**, the grid should contain the Attachment ID.

> **Note**
>
> **Navigating from a Menu**. The standard followed for many base main **menu** navigation options for fixed transactions is that navigation options launched from the Menu dropdown are configured with no context.

Navigation Option - Tree

This page contains a tree that shows how a navigation option is used. Select **Admin**, and then **System**, and then **Navigation Option** and navigate to the **Tree** tab to view this page.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

The tree shows every menu item, favorite link, and tree node that references the navigation option. This information is provided to make you aware of the ramifications of changing a navigation option.

Navigation to External Pages

The URL Navigation (F1-URLNavigation) extendable lookup defines named external pages to which a user may navigate to from the application. For example, a named code for the Service Request page in Oracle Fusion.

The actual URL for the page is specific to your implementation and as such is not delivered on the extendable lookup record. When applicable, update the entry to reference the URL for the corresponding page. The UI location that references the name external page shows the corresponding URL only when a URL is provided.

Understanding System Messages

All error, warning and informational messages that are displayed in the system are maintained on the message table. Every message is identified by a combination of two fields:

- **Message category number.** Think of a message category as a library of messages related to a given functional area. For example, there is a message category for billing messages and another one for payment messages.
- **Message number**. A unique number identifies each message within a category.

Every message has two components: a brief text message and a long description.

The brief message text supports the %n notation within the message text to cause field values to be substituted into a message. For example, the message text "Unable to assign To Do Entry (%1). It is already assigned to another User (%2)" will have the values of 2 fields merged into it before it is displayed to the user (%1 is the To Do Entry ID, %2 is the current assigned user).

> ⓘ **Note**
>
> **You cannot change the text provided with the product.** If the message is "owned" by the product, you cannot change the product's message or detailed description. If you want your users to see a different message or detailed description other than that supplied by the product, enter your desired verbiage in the corresponding override fields (and flush the cache).

- Defining System Messages

Defining System Messages

This portal is used to search for message categories and messages that appear throughout the system. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

You can access the portal from the **Admin Menu**, and then **System**, and then **Message**. You are brought to a query portal with options for searching for a specific message category or a message. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

Refer to Understanding System Messages for more information.

- Defining Message Categories
- Defining Messages

Defining Message Categories

This portal is used to view and maintain a message category and its messages.

> **⚠ Caution**
>
> Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu**, and then **System**, and then **Message**. You are brought to a query portal with options for searching for a specific message category or a specific message. Once a message category has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to Understanding System Messages for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Message Category.** This zone provides information about the selected message category.
- **Messages.** This zone lists and maintains messages for the selected category.

Defining Messages

This portal is used to view and maintain a specific message. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

> **⚠ Caution**
>
> Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu**, and then **System**, and then **Message**. - **Message.** This zone provides information about the selected message.

Understanding Unified Search

Depending on your product, the toolbar search box may support a product specific search for business entities in addition to the standard search for menu items. For example, the search may support a query of business entities by their name, address, contact details etc. The unified search feature is a simplified version of your product's main search, that allows the user to lookup up records using free form search text or hint codes. For more complex queries, the user may navigate to the corresponding advanced search portal.

The configuration of a unified search option includes the following items:

- A **search service script** that implements the data query and defines the supported **filters**. The application service associated with this script is used to secure the unified search option.
- **Search filter rules** and **hints** for the supported filters. These rules are used to parse the text entered by the user to determine whether it qualifies as a valid filter value.
- The **advanced search** portal to use for more complex queries.

The unified search box interacts with a unified search option implementation as follows:

- As the user types free form text in the search box, the application uses the **search filter rules** and **hints** to parse the entered text and translate it to corresponding query filters.
- The **search service script** is then called to query for entities that match these filters and present the results.
- Selecting a result record navigates to the corresponding portal.
- Selecting the **Advanced Search** link in the search box navigates to the general query portal associated with the unified search option.

If a unified search option is not enabled for your product or the user does not have security access to it then the search box may only be used for searching the menu.

The following sections describe various aspects related to the configuration of a unified search option.

The Search Script Controls Everything

A unified search is implemented as a single service script that controls the following:

- **Filters.** The script determines which filters are supported and how they are applied to return results efficiently. Each filter name must be a valid **Field** record.
- **Results.** The script returns a list of business entities that matches the query filters provided by the user, along with the navigation information needed to drill in to a selected record in the list.
- **Application security.** Only users that have access to the script's application service may use the unified search associated with the search script.
- **Override Advance Search.** The script may override the advanced search portal configured for the search option.

When the search box component initializes, the script is called once in **Prepare Search Details** mode to return the list of supported filter names. In this mode the script does not perform any query.

Copyright © 2026, Oracle and/or its affiliates.

As the user types in text in the search box, the search box component analyzes the entered text to derive query filters and calls the search script in **Perform Search** mode to return matching results.

The search box component is designed to support any type of unified search implementation and as such, the interaction between the user interface component and the search script is generic. Filters are defined as name / value pairs and results for each matched entity includes details like primary, secondary and tertiary description lines, along with a line that describes the matching text for entry.

> **Note**
>
> If your organization needs to implement a custom unified search script, it is strongly recommended that you follow the base product's implementation of such scripts as a reference.

Filter Rules and Hints

A unified search is designed to support a predefined set of filters for querying data. For example, searching customers by their address, name, identifiers; or searching locations by address or name etc. Each filter is uniquely identified by a **Field** name as declared by the search service script.

As the user types in free text in the search box, the application applies parsing rules to determine whether the text may be used as the value of one or more filters supported by the unified search. For example, if the user types in the text "ave", parsing rules may determine that it can be used to filter results by a person's name or address but not their email address.

Each parsing rule, defined in the **Search Filter Rule** extendable lookup, associates a filter's field name with a regular expression. Multiple filter rules defined for the same filter name are processed in execution order sequence and it is enough for one rule to return a match for the search text to be used as the value for the specific filter.

Alternatively, the user may use an explicit hint code to identify the filter they would like to use followed by the filter value. For example, an address filter may be associated with the hint "ad:" allowing the user to enter "ad: main" to look up records by address.

Each hint, defined in the **Search Filter Hint** extendable lookup, associates a filter's field name with a hint code. When applicable, a hint may be associated with a value expression rule that is used to qualify the entered value as eligible for use as a filter value. For example, requiring the value to be of a minimum length before a search is performed. If the entered value does not match the hint's value expression the corresponding search is not performed.

Note that filter rules and hints are defined for a specific filter name and not a specific unified search option. The same parsing rules may be shared across searches using the same filter names. For example the parsing rule to identify an "email" filter or the "ad:" hint for an address filter are the same regardless of how these are used by a search query. These rules are automatically associated with any unified search option that uses the same filter names.

> **Note**
>
> You may customize the parsing rules and hints associated with a filter by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

Copyright © 2026, Oracle and/or its affiliates.

Which Unified Search Option is Used?

Each unified search option is defined in the **Unified Search** extendable lookup, referencing the option's search service script and its corresponding advanced search portal. The unified search option is only enabled to users that have access to the search script's application service. When more than one unified search option is configured and enabled for a user, the application chooses the option with the highest sequence as the default option, allowing users to switch to other options they have access to.

Customizing Unified Search

You may customize the parsing rules and hints associated with base product search filters by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

There is no need to duplicate a product hint to override its Value Expression rule. You may do so by populating the Override Value Expression element on the hint definition record.

If you need to support a search for different business entities and filters, you need to implement a custom unified search. The configuration of a unified search option involves the following high level steps:

- Design and implement a search script that supports a predefined set of filters and returns the topmost set of matching results while taking into account performance considerations.
- Design hints and filter rules as needed for each of the supported filters. Review existing hints and filter rules associated with same filter names when applicable.
- Register each hint, if any in the **Search Filter Hint** extendable lookup.
- Register each filter rule, if any in the **Search Filter Rule** extendable lookup.
- Register the search script in the **Unified Search** extendable lookup.

Trees

Many edge products and implementations make extensive use of UI tree structures to display hierarchical relationships between records in the system. The framework provides an objects to define a tree structure and the rules on how to populate the nodes in the tree, and processes to interpret the configuration and dynamically render the tree display.

The topics in this section provide information about what is supplied in the framework. Your product may supply UI components with ready built trees for common use cases. Refer to your product documentation for more information.

Common Attributes of Trees

Your organization may have many portals and zones showing data in a hierarchical tree. Most trees in the system follow a similar pattern:

- Trees have a number of levels. There may be different types of tree nodes present in any given level; for instance a list of algorithm types for a script, followed by a list of script steps. Icons may be displayed to further identify the node’s object type.
- The most common node types reference an entity within the system such as a schema, script, data area and so on. These nodes usually display the information string from the entity's FK reference and provide the ability to navigate to the entity. They may also allow the node context to be broadcast to other zones in the portal.

Copyright © 2026, Oracle and/or its affiliates.

- In addition to the ability to navigate to the associated entity, many node types provide a context menu with further navigation paths.
- Some nodes are simply informational and are used to group a set of child nodes below a type or category. For example, the business object Options tree groups the option value nodes below summary nodes that describe the option type.

Each tree defines the nodes that make up the tree and the parent/child relationship between those nodes. A tree node defines which of the common attributes are applicable to the node and the algorithms responsible for retrieving the node data and, optionally, determining the node information to be displayed.

Populate Node Algorithm

A tree node displays a combination of the attributes listed above, typically for an object in context. For a root node, the object will normally be derived from a global or portal context value, such as the current script. For each lower level node, the context is derived from the context fields of its parent row; for instance, algorithms for a specific algorithm type.

The key responsibility of the populate node algorithm is to receive the tree code, node name and the parent context value (or values), determine if there is data that should be shown for this node, and return the a list of the context fields and values applicable to each row in the node. The following highlights additional optional information that may be returned by the algorithm:

- Entity information. If the node is related to a specific entity, the maintenance object code and primary key values may be returned. These are used for determining default information for the node, including navigation details.
- A display icon value. This is used to override the icon defined on the tree node and/or the default icon for the entity as defined on the maintenance object or business object.
- An information string. This may be used to override the default information string for an entity or to display stand-alone text such as a summary or description of the child nodes to follow.
- Override broadcast details if needed for a specific node. For example, set specific broadcast field names and values when they differ from the related entity's primary keys or indicate that broadcasting is not applicable for a node instance even though broadcasting is enabled by the node's definition.

> **Note**
>
> The populate node algorithm is responsible for returning all the context values required to populate its child nodes. For an informational or summary node, this may require including the node’s parent context fields in its own context. For example, in the script tree, the summary node describing the number of steps is followed by a list of steps for the script. The summary node populate node algorithm needs to include the script code passed in as parent context in its output context list, in order for the steps to be correctly retrieved.

Information Override Algorithm

The information override algorithm has two main purposes:

- Providing alternative information text for a tree node when the information provided isn’t suitable for your implementation.

Copyright © 2026, Oracle and/or its affiliates.

- Retrieving contextual insights related to the tree node entity, to be included in the node's information text. Only badge insight types are currently supported.
- Override broadcast details if needed for a specific node. For example, set specific broadcast field names and values when they differ from the related entity's primary keys or indicate that broadcasting is not applicable for a node instance even though broadcasting is enabled by the node's definition.

The override information algorithm receives the tree code, node name, maintenance object and prime key values for the node. The following highlights the information that may be returned by the algorithm:

- A display icon value.
- An information string. This will be used to override the default information string in the node's formatted string.
- Full node text. This will be used as the full text for the display, overriding the formatting defined on the node.
- A list of badge insight types and their context.

> **Note**
>
> If the information override algorithm returns insight types for the entity, it is also responsible for returning all the context values required for those insight types. Refer to Contextual Insights for more information.

Preparing a Node for Display

The following section highlights key steps in fetching a node's data and formatting it for display.

Determining Node Content

The following steps are performed to retrieve the components making up the tree node display:

- The Populate Node algorithm is called to determine all instance nodes for the tree node along with their related details.
- The Information Override algorithm is called for each node instance to allow for optional override of presentation related details.

The node display contents are determined as follows:

- The icon is determined from the following sources, in order: tree node definition, override information algorithm value, populate node algorithm value, maintenance object / business object default value.
- Broadcast usage is determined by the setting on the tree node definition.
  - This setting can be overriden by either the Populate Node algorithm or the Override Information algoirthm (which takes precedence) to indicate that broadcasting is not applicable for a specific node instance.
  - By default the broadcast fields for a node are the primary key names of its related entity. Broadcast field names can be overriden by either the Populate Node algorithm or an Override Information algorithm where the latter takes precedence.
- The information string is determined from the following sources, in order: override information algorithm value, populate node value, maintenance object / business object information algorithm. If the string is derived from the MO/BO algorithm, the short information text is used when available else the standard information is used.

Copyright © 2026, Oracle and/or its affiliates.

- Context menu usage is determined by the settings on the tree node definition.
- The system supports a different style for header rows, including a larger font. Header style usage is determined by the setting on the tree definition and is only applicable if the node is a root node with only one instance.

Node Text Format

The text for nodes referencing a system entity commonly includes some combination of a label, the entity key and an information string. The node configuration provides a label field and a substitution format string field which may be used to define the node text format. The format string defines which of the components should be included in the text, the order of those components and any surrounding text and HTML markups. For example, a format string of '`%label` - `%key` - `%info`' will result in a node text like the example below:

If the format string is blank, the default text will include '`%info`' only. If an override information algorithm is configured that returns the full node text, the text is presented without further formatting.

Auto Expansion

If the tree node definition indicates that the node should be expanded, the system will automatically fetch and display the data for its child node. This processing continues until there are no further child nodes marked for expansion.

There are cases where a tree node should be conditionally expanded based on business rules. For example, prevent the initial expansion when the number of child nodes exceeds a certain threshold. You may design the "Populate Node" algorithm to indicate whether a tree node should be initially expanded or not. When populated, the indication overrides the setting on the tree node definition.

Base Delivered Trees

Trees are system data and your product may already deliver several trees out of the box. You may choose to customize a base delivered tree in the following ways:

- You may add your own nodes to an existing tree definition.
- You may override the information string for a node by supplying your own **Information Override** algorithm. If a base override algorithm is configured on the node, your custom algorithm should be plugged in at a higher sequence number, to take precedence over the base algorithm.

Rendering a Tree

To render a tree on the UI, you would include the ou-tree web component in a UI map that references the tree definition.

> **Note**
>
> Refer to Include a Web Component for more information.

- Defining Trees

Copyright © 2026, Oracle and/or its affiliates.

Defining Trees

This portal is used to view and maintain information about a tree definition. Trees are commonly used to display hierarchical relationships between objects in the system. Refer to Trees for background information about defining trees.

You can access the portal from **Admin**, and then **System**, and then **Tree**. You are brought to a query portal with options for searching for a specific tree definition. Once a tree has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Tree.** This zone provides information about the selected tree.
- **Tree Nodes.** This zone lists the nodes for this tree in hierarchical order. Use the zone actions to add or maintain a node in the tree.
- **Tree Node.** This zone displays the details for a tree node. It is only visible if a tree node name has been broadcast from the Tree Nodes zone.

Contextual Insights

Contextual Insights provide a powerful way to surface focused intelligence and alerts to users in the context of the core screens for any applications built on Oracle Utilities Application Framework. There are multiple options for the visual patterns when surfacing Contextual Insights and the actions that can be performed by users are easily configurable as well. The subsequent topics provide detail about the Insight Type and Insight Group objects that are used to configure the information that may then be displayed in appropriate screens.

- Insight Types
- Insight Groups

Insight Types

The insight type object contains all the detailed configuration for displaying one or more alerts, or important information for a record in context. The following sections provide more information about all the configuration managed by the insight type.

Insight Algorithm

Each insight type is used to display some information, typically related to an object in context. It is the responsibility of the insight type algorithm to receive the context value (or values), determine if there is information that should be shown for this context, return the text to display.

The following highlights additional optional information that may be returned by the algorithm:

- A secondary message. This is only applicable to some visual structures where more than one line of information may be displayed.
- A severity value. This is used to override the visual display configuration if different emphasis should be used for different severity values. Refer to Override Configuration for more information.
- Entity information. If the insight is related to a specific entity, the maintenance object code and primary key values may be returned. This is useful if the insight type configures a BPA or user action algorithms that may perform logic for this entity.

Copyright © 2026, Oracle and/or its affiliates.

- Navigation and User Action information. This is only applicable to visual structures that support user actions. The algorithm must return the list of all the actions that should be made visible on the insight. If the action includes navigation, the algorithm should return the navigation option and navigation context key and value pairs. Additionally, there is configuration for each action that must be defined. Refer to User Actions for more information.

Each algorithm can return multiple insights, if applicable. For example, if the insight is about To Do entries related to the object being displayed, you could design your insight algorithm to return a single insight summarizing all the To Do related information. Or you could choose to return separate insights based on To Do information so that you provide more granular information and customize actions or navigation based on the different conditions. For example, if there are To Do Entries that the current user may perform actions on and others that current user cannot update, the algorithm could return two separate insights: one with actions and one without.

> **Note**
>
> **Preview mode**. The insight type maintenance page includes an Insight Preview section that shows the output from the insight algorithm when invoked with an insight mode of "Preview". Every algorithm should include logic that returns appropriate text when called in this mode so that something is displayed in that section.

Visual Structures

Each insight type defines a visual structure which dictates what kind of information may be shown. The system has some fixed layout expectations for each visual structure type. The insight type configuration is used to provide the source for the possible layout.

> **Note**
>
> All the insights use color options as part of their configuration. Refer to Color Option for more information.

Badge Insight

The simplest visual structure is the badge. It is used to display a single line of quick text with a solid background (for visibility) that is meant to alert the user to important summary information or attributes.

Inline Insight

The inline insight defines an icon and a single message. This is meant to be more descriptive than a badge. For this type of insight, a default light background is used so the recommendation is to select a color option for both the text and the icon that has only a foreground color defined or has a light background color.

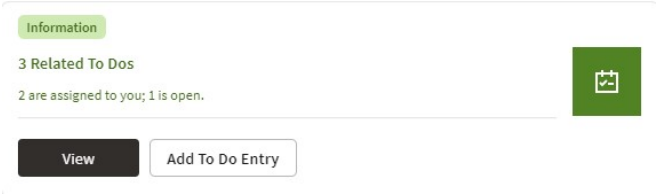
List Insight

The list insight are intended to exist in a list of insights for the object. It defines an icon and can support two lines of text. In addition, this type of insight supports buttons or user actions. Refer to User Actions for more information. Note that for a list insight, if there is one valid action or 2

Copyright © 2026, Oracle and/or its affiliates.

valid actions, the action buttons are shown. If there are three or more valid actions, one action is shown and then an 'Other Actions' button is visible. Clicking this shows the other available actions.

Note that the background color for the insight is used as the color for the full insight snippet. The text and the icon are shown on this background. The icon's background color is ignored.



Card

The card insight is the most information rich, with up to two lines of text, user actions, a large icon to call attention and header text. The header text is chosen from a dropdown list of valid options. The product provides out of the box header text of "Information", "Warning" and "Error". Implementations may add additional values to this using the lookup field HEADER_CAT_FLG.

Please note the following about the treatment of the various components of the card insight:

- The header text is rendered like a badge insight.
- For the message text displayed in the card, the background color is ignored so a color option with no background color or a light background color should be chosen.
- For the icon, the background color is used to create a square area for display and the icon is rendered in the foreground color.

Override Configuration

Each insight supports default visual setting for the various components of the insight. This includes the color option for the applicable components along with icons and header text, where applicable. In each case, override visual settings may be defined for a given severity number.

For example imagine the algorithm for a badge insight that returns a message with the count of related To Do entries uses a different color option if there are more than 10 related records. To do this, the algorithm can return a severity number and then the configuration user can define the override color option for this severity number.

User Actions

The list and card insights support the definition of user actions that may be presented as buttons when displaying the insight. The actions may do one or more of the following:

- Perform algorithm logic. One or more user action algorithms may be associated with an action button. This should be used to perform server logic that does not require any user interaction. For example, you can provide an action to update the status of a record related to the insight. These algorithms are configured on the Insight Type.

Copyright © 2026, Oracle and/or its affiliates.

- Navigate to another page. For this type of action, the insight algorithm must provide the navigation context and the navigation option to launch when clicking the button. It's possible to configure navigation and configure user action algorithms. In that case the algorithms are run first and then the navigation occurs.
- Launch a BPA. This is used if there is user interaction needed to perform additional logic and / or if there is conditional navigation such that the logic is needed before navigating. It's possible to configure a BPA and configure user action algorithms. In that case the algorithms are run first and then the BPA is launched. If the insight algorithm also provides navigation for this action, it is ignored in favor of the BPA. The BPA is configured on the Insight Type.

The list of valid actions to display at run time must be returned by the insight algorithm. This allows for the algorithm to have control over which actions to display, in case there are some actions that are conditional. In addition, each possible button requires configuration related to what text should display and the style of the button.

Button Text

The button text to display is chosen from a button text lookup. The lookup name is `INSIGHT_ACT_FLD_FLG`. Implementations may add additional values to this lookup to include new button text. In addition, if you would like to change button text on any product delivered button, you can override the lookup value description.

Action Class

Each action button defines an action class. Any action configured with the action class value of **Positive** value is shown first and is styled differently for emphasis. Other action class values are for information purposes.

Securing Actions

If the action navigates or launches a BPA, the system automatically checks the underlying security for the target page or the BPA and only shows the action if the user has security rights. Other types of actions, such as ones that should launch an algorithm, do not have security configuration that can be automatically detected by the system. For these types of actions, you can define an explicit application service and access mode on the Buttons collection. It's also possible for the algorithm to check security before returning applicable buttons.

Base Delivered Insight Types

Insight types are system data and your product may already deliver several insight types out of the box. You may choose to include one or more insight types in an Insight Group.

Rendering an Insight

To render an insight for an insight type, you would include the ou-insights web component in a UI map that references this insight type. This is how the Insight Preview section of the insight type maintenance page renders the preview.

> **Note**
>
> Refer to Include a Web Component for more information.

- Defining Insight Types

Copyright © 2026, Oracle and/or its affiliates.

Defining Insight Types

The insight type entity is used to define the configuration of a specific type of alert to display extra information related to one or more records in context. Refer to Insight Types for a detailed description of the supported functionality.

To view or maintain insight types, open **Admin**, and then **General**, and then **Insight Type.**

This is a standard All-in-One portal.

The information captured on the insight type depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Groups

If there are any insight groups that reference this insight type, the **Related Insight Groups** zone displays the linked insight groups.

Insight Groups

An insight group may be used to include several insight types together onto a single map. When defining an insight group, you configure the visual structures that the insight group should include. Only insight types for the configured visual structure are available.

Insight Class

Each insight group must reference a unique insight class. The insight class is defined using a lookup. The lookup field is `INSIGHT_CLASS_FLG`. Your product may already deliver base values for insight class. To display insights in a user interface your UI map would include the ou-insights web component. This component includes syntax to reference an insight class and the logic will find the insight group for that class and render all the insight types linked to that group.

Because the insight class is used as the reference in the web component rather than the insight group, it allows your product to supply base logic to show insight group information in a base delivered user interface. The base logic defines an insight class in base and references it on a base UI map. Your implementation can then define the insight group for this insight class and choose the insight types that should be rendered in that map. Refer to your specific product documentation to find out if there are any base delivered insight classes.

If your implementation identifies a new use case where one ore more insight types should be displayed, once the insight types are configured, do the following:

- Define a new Insight Class lookup value.
- Define an Insight Group that references this insight class and configure the appropriate insight types.
- Include the appropriate web component in the map for your user interface where you wish to display this information.

Multiple Insight Groups for an Insight Class

Typically there should exist a single insight group for an insight class. In cases where the list of insight types for the class needs to vary based on context, a separate insight group needs to be defined for each list.

Copyright © 2026, Oracle and/or its affiliates.

When more than one insight group is associated with an insight class **Action Method** rules may be applied to determine which group to use based on the context provided to insight processing. Refer to Action Method for an overview of action method functionality.

- Defining Insight Groups

Defining Insight Groups

The insight group entity allows implementations to define multiple related insight types that should be displayed together in a given user interface map or zone. Refer to Insight Groups for an overview of insight group configuration and functionality.

To view or maintain insight groups, open **Admin**, and then **General**, and then **Insight Group.**

This is a standard All-in-One portal.

The information captured on the insight group depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Types

The **Related Insight Types** zone displays all the insight types that are currently linked to the group. The Edit link in the zone header allows you to add or remove insight types. Only insight types that reference one of the **Valid Visual Structures** may be selected.

Knowledge Articles

When applicable, a knowledge article icon may be configured to appear in a specific location on a page. Clicking the icon launches a drawer presenting an article on the topic and allows the user to further search and review other articles.

> **Note**
>
> The product supports only knowledge articles defined in Oracle Fusion.

The association between a user interface location and a related knowledge article is registered in the **Knowledge Management Articles** extendable lookup. The user interface location references an extendable lookup knowledge code and the article ID is referenced on the extendable lookup record. The knowledge article icon appears on the page only when the corresponding extendable lookup entry is active and references an article ID.

Some product pages are released with embedded references to knowledge codes. By default, these knowledge codes are not associated with any article. To enable these locations for knowledge functionality update their respective extendable lookup entries with references to your articles.

You may also introduce knowledge functionality to custom pages as follows:

- Add a knowledge code entry to the extendable lookup along with a reference to an article ID.
- Reference the knowledge code on your custom page using the Knowledge Article web component.

Access to knowledge articles requires an integration with Oracle Fusion. Once the integration is established, follow these instructions to complete the configuration:

- Update the context details for the **Get Fusion Article** Message Sender.

Copyright © 2026, Oracle and/or its affiliates.

Table Get Fusion Article - Message Sender (F1-KMGET)

Context Type	Context Value
HTTP Method	GET
HTTP Timeout	60
HTTP Transfer Method	SendReceive
HTTP URL 1	@EXT_PUB@<hostname>:<portnumber>/api/knowledge-management/v2/articles/answers/${pathParms}?${queryParms}
OAuth Grant Type	jwt_user_assertion
OAuth Access Token URL OAuth Client Credentials Key Ring Oauth Signature Key Ring OAuth REST API Scope	Refer to OAuth Configuration for more information.

- Update the context details for the **Search Fusion Articles** Message Sender.

Table Search Fusion Articles - Message Sender (F1-KMSCH)

Context Type	Context Value
HTTP Method	GET
HTTP Timeout	60
HTTP Transfer Method	SendReceive
HTTP URL 1	@EXT_PUB@<hostname>:<portnumber>/api/knowledge-management/v2/search?${queryParms}
OAuth Grant Type	jwt_user_assertion
OAuth Access Token URL OAuth Client Credentials Key Ring Oauth Signature Key Ring OAuth REST API Scope	Refer to OAuth Configuration for more information.

Color Configuration

The topics in this section describe some options for configuring colors to be used in displaying information in the user interface.

- Defining Colors
- Color Options

Defining Colors

The system provides the extendable lookup Color (F1-Color) to define valid colors to be used in the system. The base colors provided are ones related to the standard color palette used in Oracle products.

Copyright © 2026, Oracle and/or its affiliates.

At this time, zones and UI maps that define specific colors do not support any syntax to reference a color extendable lookup. In the meantime, colors applied at the zone or map level can still reference HTML colors or reference hex codes directly.

Color Options

The color option entity is used to define a combination of colors to be used in user interface components. The system provides a standard set of color options used for contextual insights.

To view or maintain color options, open **Admin**, and then **System**, and then **Color Option.**

This is a standard All-in-One portal.

The information captured on the color option depends on the record's business object. Refer to the embedded help text for more information.

Defining Display Icons

Icons are used to assist users in identifying different types of objects or instructions. A limited number of control tables allow administrative users to select an icon when they are configuring the system. Select **Admin**, and then **System**, and then **Display Icon** to maintain the population of icons available for selection. You are brought to a query portal with options for searching for a specific display icon. Once a display icon has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The latest standard is to use Scalable Vector Graphic (SVG) icons. For these types of icons, the Icon Type is **Variable (SVG)**. The product also supports icons in the .gif or .png format. For these types of icons, the Icon Type defines a pixel size.

URL describes where the icon is located (folder) and the icon name (file name).

Note that there is a standard folder structure for delivered assets such as images. The structure is `{DefaultWebApp}/{owner}/assets/images|svgs/`

- {Owner} - this is the owner of the icon. The `/cm` folder is used for custom icons.
- svgs - all images that are of type svg are in this folder.
- images - all files that have a file suffix of jpg, gif, png or other types of image formats are in this folder.

When using the above folder structure, then the URL only needs to contain the icon name (file name). The correct full URL is determined automatically at runtime. Images can optionally be placed in other folders under the DefaultWebApp. However, this is not recommended but if used, the URL must contain the full path to the icon (e.g. /cm/assets/newImages/myIcon.gif)

Custom Look and Feel Options

The default look and feel of the application can be customized via feature configuration. The base product is provided with a **Custom Look And Feel** Feature Configuration type. If you define a feature configuration of this type, you can adjust the look and feel in the following ways.

- You may adjust the look and feel of the application using cascading style sheets. Refer to User Interface Style Customization for more information.
- You may adjust configuration related to the display of the UI Map Help icon.

Copyright © 2026, Oracle and/or its affiliates.

- You may choose to change the UI View Settings for all users in the system. To do this, define an entry for the **UI View** option type and enter the desired value. Note that individual users may override this setting on their user preferences.
- Redwood Enablement
- User Interface Style Customization
- UI Map Help

Redwood Enablement

The Redwood User Experience is opt-in functionality. To enable this in your implementation, navigate to Feature Configuration. Search for an existing feature configuration with the Feature Type `Custom Look and Feel`. If one does not exist, create a feature configuration of this type. Select the `User Interface Style` option and set the value to 'Oracle Redwood'.

User Interface Style Customization

The base product allows for the conditional inclusion of custom style sheets into the system style set. Custom styles may override any style provided by the base product. The style sheet may also include new styles for use in customer zone definitions. Use the **Style Sheet** option on the **Custom Look And Feel** Feature Configuration to define your custom style sheet. The option supports either referencing a *.css file or referencing a Managed Content record (with the content type **CSS Definitions**.)

> **Note**
>
> The Managed Content option is recommended as this makes the Custom CSS available to be easily transferred to other environments if desired using Content Migration Assistant (CMA).

> **Note**
>
> Some styles cannot change if they are part of the HTML code.

> **Caution**
>
> Implementers must ensure that the customized user interface is stable and scalable. Changing font, alignment padding, border size, and other user interface parameters may cause presentation problems, like scrollbars appearing or disappearing, cursors not working as expected, and unanticipated look and feel alterations of some layouts.

The structure of the CSS extension follows the standard CSS file format regardless of using the File option or the Managed Content option. This means that the "<style>" tag is not needed and the file will contain a list of CSS selectors with their declarations (properties and values).

To find the necessary CSS Selector, navigate the application to an appropriate screen, then "right click" on the element you wish to re-style and select **inspect** from the menu (normally at the bottom). This opens a view of the HTML document. From this view you will be able to see any "id" and "class" attributes that are available on the element. These are generally the most suitable attributes for CSS selectors. In order to make the styling more specific, it is also

Copyright © 2026, Oracle and/or its affiliates.

appropriate to scan up the HTML DOM tree to view parent "id" and "class" attributes. Making the CSS selector as precisely targeted as possible will reduce the possibility of custom stylings affecting elements outside your desired area.

All standard CSS is supported. However, when looking at the most up-to-date CSS standards, be aware that not all browsers support all options without some specific browser settings.

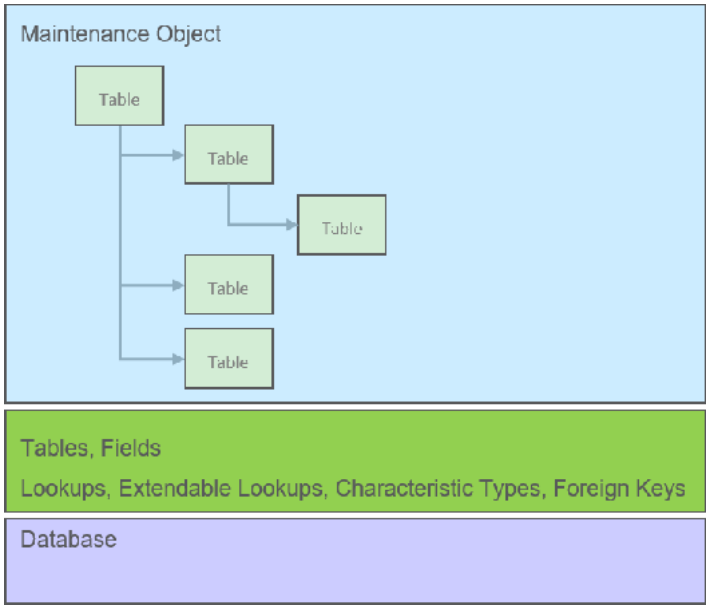
UI Map Help

A tool tip can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map zone or UI Map. Refer to the tips context sensitive zone associated with the UI Map page for more information. The **Custom Look And Feel** Feature Configuration provides options to control the following:

- Whether UI Map Help functionality is turned on or off. By default it is turned on.
- Override the default help image with a custom image
- The location of the help image, either before or after the element.

> **NOT_SUPPORTED**
>
> Refer to the feature configuration for a detailed description of each option.

Database Options



This section describes a variety of database tools that are supplied with the your product.

- Understanding The Data Model
- Defining Tables
- Defining Fields
- Defining Maintenance Objects
- Maintenance Object Configuration
- Defining Lookups
- Defining Extendable Lookups
- Defining Characteristic Types
- Defining Foreign Key References
- Audit Trails
- Bundling
- Revision Control
- Information Lifecycle Management

Understanding The Data Model

The application uses meta-data to describe its data model, from plain description of its tables and fields to more complex hierarchies of maintenance objects.

Copyright © 2026, Oracle and/or its affiliates.

The following points briefly outline key aspects of application's data model as illustrated in this diagram:

- Table and Field records describe all the tables maintained by the application.
- Valid values for certain fields are defined using corresponding Lookup and Extendable Lookup records.
- Characteristic types may be defined to support an extension of a maintenance object via its characteristics table.
- Maintenance Objects define the physical structure of an entity. Business objects further refine maintenance objects to describe business entities. Refer to The Big Picture of Business Objects for more information.
- Foreign Key References define ways for searching and navigating to the maintenance portal of an entity.

The following sections further discusses concepts and guidelines related to the data model.

- Fields
- Tables
- Maintenance Objects
- Defining Valid Values
- Characteristic Types
- Foreign Key References

Fields

A Field definition describes the metadata needed by the application to support the capture and display of a piece of information. Fields may correspond to physical columns on database tables or represent any type of element used for calculation or presentation purposes.

The definition includes the following key details:

- Whether the field refers to a physical column on a database table or used as a work field.
- The type of data the field holds.

Copyright © 2026, Oracle and/or its affiliates.

- The label to use when the field is presented.
- The help text to display when the user clicks on the help icon seeking additional information about this field.
- and more

The following sections further discusses concepts and guidelines related to defining fields.

Physical vs. Work Fields

A Field definition record exists for every physical column on a database table that is used by the application. Refer to Understanding Tables for more information.

A Field that does not represent a physical column on a database table is considered as work field and needs to be marked as such. Work fields are typically used as labels as well as describe internal elements used in business rules.

Data Type Information

The type of data captured by a field is defined using the following attributes:

- **Data Type** indicates the basic type of value the field holds. Valid values are **Character, Character Large Object, Date, DateTime, Number, Time, Varchar2** and **XML Type**.
- **Extended Data Type** is used to further define the type of data for certain data types. Valid values are **Currency Source, Day of Month, Duration, Money, Month of Year, Flag, Switch** and **URI**.
- **Precision** defines the length of the field. In the case of variable length fields, it is the maximum length possible. For number fields that include decimal values, the precision includes the decimal values.
- **Scale** is only applicable for number fields. It indicates the number of decimal places supported by the field.
- **Sign** is only applicable for numbers. It indicates if the data may contain positive or negative numbers.

Data Type Inheritance

A Field can be defined to inherit its data type attributes from the definition of another field. The field to inherit the attributes from is referenced as the **Base Field**. When using a base field reference, the data type attributes are defined once, on the base field, and all the fields inheriting their data type information from it are kept consistent with that definition as it may change over time. Any change of a field's data type attributes is automatically reflected on all the fields that reference it as their base field.

Data type information may either be specified directly on the field itself or by referencing a base field. The system does not support a way to partially override the base field's data type information.

It is recommended to leverage data type inheritance whenever possible, especially when the reason for creating a new field is to provide an alternate label for the original field in a certain context. In that situation the new field should reference the original field as its base field and provide the new labels and help text as needed.

Labels and Help Text

For fields that appear on a user interface, the description acts as a label to be used for presentation purposes. As per the product's multi-language support, a field is associated with a label for each of the languages enabled in the system.

Copyright © 2026, Oracle and/or its affiliates.

A field's help text may be used to provide the user with additional information on how the field is used. When populated for a field that is visible on a user interface that supports display of embedded help, a help icon appears for the field, presenting the help text to the user when clicked.

Overriding Labels and Help Text

The label and help text provided for a product owned field may be overridden by your organization using the corresponding override fields.

The field's label and help text can be overridden for a specific table by populating the corresponding override information as part of the table / field definition. However, this override is not used in portal based user interfaces. It is only applicable if the field is displayed on fixed page user interfaces. For fixed pages, if the override label at the table / field level takes precedence over the override at the field level.

Alternate Labels

There are contexts where a separate label may be needed for the "date" and "time" parts of a date/time field. Such an example is when the field is used by the operational analytics product. For example, for a "Completion Date/Time" field you may provide the context label "Creation Date" for the **Date** context and "Creation Time" for the **Time** context. These context labels are optional.

In the same way, date fields, time fields and date/time fields may be associated with a **Date and Time Base** context label, which is a label without a reference to the word "Date", "Time" or "Date / Time". For example, for a "Completion Date/Time" field, the date and time base label may be "Completion". This label that can be used in combination with date or time attributes such as day, month, year, hours, minutes etc.

Overrides labels are available for these additional context labels.

Tables

A Table definition describes the metadata needed by the application to work with and access a database table or view.

The definition includes the following key details:

- The table's description in the application.
- The list of fields defined on the table and any foreign key constraints they establish with other tables.
- The table's prime key and how it is generated.
- Whether the table holds administrative, master or transactional data.
- Whether the table is released with product owned system data rows or not.
- The table's role in the conversion process.
- How should table content be upgraded.
- and more

The following sections further discusses concepts and guidelines related to defining tables.

System Tables

Tables released with rows that are owned by the base product are referred to as system tables. These tables include the **Owner** (OWNER_FLG) field to capture the owner of each row.

Copyright © 2026, Oracle and/or its affiliates.

Refer to System Data for more information about naming conventions and standards around row record ownership.

The **Upgrade** setting on the table definition record controls what happens to the rows in a table when the system is upgraded to a new release. The most common setting allows customer owned rows to be merged with rows owned by the base product. Other settings may keep the content of the table as is, i.e. rows are not touched by the upgrade, or fully refresh the content of the table with base product rows.

Some fields on certain system owned tables are explicitly marked to allow customization. This means implementation are allowed to change these specific fields for a base owned record. Changes to the field value of one of these types of fields by an implementation are maintained when upgrading to a new version of the product.

Designated Table Roles

Some tables are designed to support the following application roles:

- **Key Tables**
  - A key table holds a copy of a table's prime key only and is only applicable to tables with system generated keys.
  - Tables with a system generated keys reference their Key Table as part of their Table definition record.
  - Records in the key table remain in the system even when the related entity is archived, preventing the same key from being allocated to a new record. Retaining the key allows the system to keep the integrity of any references that may still exist to the archived entity.
- **Language Tables**
  - To support multi-language implementations, all labels and descriptions that are presented to a user are kept in a designated language table where a row exists for each enabled language.
  - The product is released with the English content provided in the various language tables. An additional row is added to these tables for each enabled language along with the translated content for that language. Refer to Support For Different Languages for more information.
  - Tables associated with language sensitive fields reference their corresponding Language Table as part of their Table definition record.
- **Characteristics Tables**
  - Many entities in the system support one or more Characteristics tables, which are used to capture additional fields for the object that are not already supported by the entity's provided attributes.
  - A Characteristics table is designed to capture characteristics applicable to its specific entity only. The entity associated with a Characteristics table is referenced on the Table's definition record.
  - Refer to Setting Up Characteristic Types & Values for more information.
- **Entity Log Tables**
  - Many entities in the system support the ability to capture lifecycle and other important business events on a designated log table.
  - A log table captures the event details in the form of an application message and stores any parameters for the message in a child log parameters table. All log and log

Copyright © 2026, Oracle and/or its affiliates.

parameters tables follow a predefined structure allowing them to be consistently and efficiently implemented.

  - Typically log tables do not participate in the conversion process.

Table Constraints

Foreign key relationships between tables are not enforced at the database level but rather at the application level, providing the application more flexibility around data manipulation and referential integrity.

The following types of constraints may be defined on the Table's definition record:

- **Primary Key** represents the field or set of fields that represent the unique identifier of a record stored in a table.
- **Logical Key** represents an alternate unique identifier of a record based on a different set of fields than the Primary key.
- **Foreign Key** represents a field or set of fields that specifies identifying and non-identifying relationships to other tables in the application. A foreign key constraint references the primary key constraint of another table.
- **Conditional Foreign Key** represents rare relationships between tables where a single field (or set of fields) may reference multiple primary key constraints of other tables within the application as a foreign key.

The system leverages a table's foreign key constraints information to performs referential integrity validation when rows in this table are deleted. These validations can be disabled by checking off the **Enable Referential Integrity** field on the Table definition record.

Table Indexes

The indexes delivered by the base product for a given table are visible in the index metadata. In addition, table index information may be defined as part of the cloud services support for generation of custom tables in certain use cases. Refer to the section Generating Custom Tables below for more information.

Primary Key Type

A table's primary key may be of the following types:

- **User-defined** means the user specifies the key when a record is added. This type of key is typically used for configuration and administrative tables.
- **System-generated** means a program generates a random numeric key for the record when it is added.
  - This type of table is typically associated with a key table. Refer to the **Designated Table Roles** section for more information.
  - System generated keys may be fully random or partially inherited from a parent table's key for performance reasons. Refer to the **System Generated Keys** for more information.
- **Sequential** means a sequence number is incremented whenever a record is added to the table. The next number in the sequence determines the key value.
- **Database Native Sequential Key** means a unique number is assigned using a database sequence object.
- **Other** means some other business rule allocates the table's prime-key or the prime key is made of multiple parts.

Copyright © 2026, Oracle and/or its affiliates.

System Generated Keys

In general, randomly generated numeric system keys are used to attempt to evenly distribute records across a full range of possible IDs. Batch programs that use multiple threads will typically divide the threads using ID ranges and evenly distributed keys will help spread out the work across these threads.

If a table using a system generated key is a child of another table, the child table's key may **inherit** a portion of the random number from its parent table's key. Key inheritance for child records further extends the performance benefit. When considering partitioning, the recommendation for DBAs is to range partition data based on the primary key so that different batch threads operate on different partitions which reduces contention for hot blocks. Ideally the number of batch threads will be an exact multiple of the number of partitions. Batch programs that insert child data (for example batch Billing creation) also benefit from this design especially when the child tables are partitioned in the same way. The parent is often the driver of the batch process. If this is multi-threaded, then each thread is processing a set of parent records in a given ID range and all child records are being inserted into the same ID range.

While most entities with system generated keys either use fully random keys or partially inherited keys from a single parent, entities may be designed to implement more specific key generation rules.

When key inheritance is used, the table definition of the child table defines the following information:

- The number of most significant digits from the parent record's primary key to use as the **prefix** for the child record's key value.
- The **parent key field name** to inherit the key from. This information is provided for display and documentation purposes only and is only provided when the inheritance rule implemented by the entity may be documented this way. Typically the child key value is inherited from a single parent key but in some cases the inheritance rule may be more complex. For example, different types of records in the same child table may inherit their key from different parent key fields. In this case, multiple parent field names may be listed to describe the various inheritance options. When the rule is too complex, this information may not be provided on the table definition record.

Conversion Options

The conversion process manages the process by which master and transaction legacy data, loaded into a staging schema, is validated and assigned new system generated keys before it is copied to the production schema. Refer to Understanding The Conversion Process for more information.

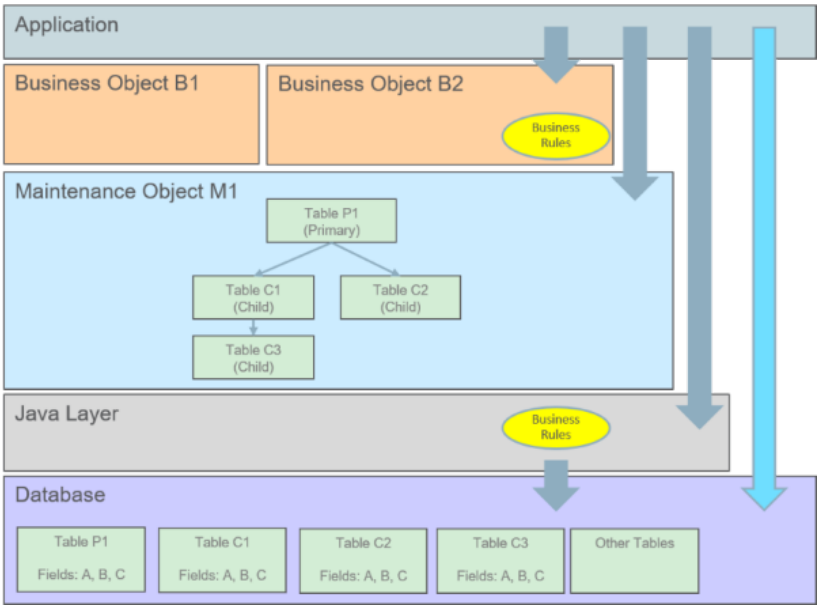
The tool classifies tables into the following roles:

- Administrative tables. These only exist in the production schema. Instead of a table, a view to the production table exists in the staging schema. These views are necessary to enforce foreign key references when data is validated in the staging schema
- Convertible tables that retain their prime keys. Data conversion is supported for these tables and their prime key values remain unchanged.
- Convertible tables that require a new system generated key to be assigned. Data conversion is supported for these tables and their prime key is reassigned by the system during conversion.
- Not convertible tables. Assigning new system generated keys for a record and replacing all foreign key references it might have with the new key is a complicated process that may not be supported for all tables.

Copyright © 2026, Oracle and/or its affiliates.

. The **Data Conversion Role** setting on the table definition record controls if / how the table is used by conversion processing.

Date/Time Configuration



Fields capturing date/time information may be designed to store data in either local legal time or local standard time. Local legal time is captured as entered and displayed as captured in the database. It also assumes the date/time information refers to the time zone defined on the installation options. Refer to Standard vs. Legal for more information.

Generating Custom Tables

For cloud customers and for certain use cases, the product supports defining table metadata for custom tables and generating the related DDLs for that metadata in the database. For these custom tables, there is a Generation Status visible on the Table metadata that identifies where the Table is in the lifecycle for this supported feature. In addition, the index tab on the table portal is used to define custom indexes that are included in the DDL as part of this feature. If you are a cloud customer and would like more information, refer to the Cloud Services Implementation Guide.

Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes a primary table and any additional child tables that together capture the physical data for the entity. The application reads, adds, updates and deletes an entity as a single object by invoking its maintenance object service.

The following points briefly outline key aspects of application’s interaction with maintenance objects as illustrated in this diagram:

- Database tables are maintained solely via the application’s Java layer. Direct updates to a table via its Java class is not common and typically reserved to special processes.
- A maintenance object orchestrates the update to an entity’s primary table and its child tables as a single object.
- A business object defines a logical representation of an entity, including all or a subset of the maintenance object’s tables and fields.

Copyright © 2026, Oracle and/or its affiliates.

- The more common way to maintain an entity is via its maintenance object, either directly or via one of its business objects. Most entities support the use of business objects and as such their maintenance is typically made via their business objects.
- Direct access to database tables is supported for query purposes only.

The following sections further discusses concepts and guidelines related to defining tables.

Maintaining An Entire Object

A maintenance object includes a single primary table and one or more child tables where each child table can further have nested child tables. The table structure of a maintenance object represents the scope of data that should be maintained together as a single object:

- When an object is added, data in added to each corresponding table.
- When an object is updated, data in updated in each corresponding table.
- When an object is read, data in retrieved from all the tables.
- When an object is deleted, data in deleted from all the tables.

Algorithms

Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Options

The maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system.

Maintenance Objects vs. Business Objects

A maintenance object defines the physical structure of an entity as stored in the database. Different business objects may be defined on top of a maintenance object to represent different types of such entity. A business object includes only the relevant information applicable to the specific type of entity as well as enforces business rules applicable only to that type.

When a maintenance object supports business object configuration, the system uses the **Determine Business Object** maintenance object algorithm to determine the identifying business object that controls a given entity's data structure and rules.

Refer to The Big Picture of Business Objects for more information.

Defining Valid Values

The product provides several options for defining valid values for a column on a table:

- Lookup
- Extendable Lookup
- Control Table

The following provides more information about the functionality of each of the options available for defining valid values for a column.

Lookup

The simplest mechanism for defining valid values for a column on a table is via the Lookup table. This is sometimes referred to as a "simple" lookup to distinguish it from an extendable lookup (described below). Using the lookup table, you can define valid values and their

Copyright © 2026, Oracle and/or its affiliates.

descriptions. When choosing a valid value that is defined by a lookup, a dropdown UI metaphor is used.

The following highlights functionality related to lookups:

- Lookups are associated with a Field. The field is defined as a character data type with an extended data type of **Flag**. The field's label serves as the description for the prompt to select the valid value.
- The lookup code is limited to four characters and must be all uppercase. If there is any functionality where a valid value in the application must match valid values in an external system, the lookup table may not be the appropriate choice.
- The lookup table does not support additional attributes to be defined for each value. This option is only appropriate when a simple code and description pair is needed.
- The product may also use Lookups to define valid values for functionality unrelated to a column on a table. For example, an algorithm plug-in spot may define an input parameter that supports one or more valid values. The plug-in spot may define the valid values using a lookup, allowing for a simple way to validate the value supplied when invoking the algorithm and to document the valid values.

> **NOT_SUPPORTED**
>
> For more information, refer to Defining Lookup Options.

Extendable Lookup

The extendable lookup provides a way of defining valid values for a column with additional capabilities that are not supported using the Lookup table. When choosing a valid value that is defined by an extendable lookup, a dropdown UI metaphor is used.

The following highlights functionality related to extendable lookups:

- Each Extendable Lookups is defined using a business object.
- A field should be defined for the extendable lookup code. The field defines the label for the lookup code and defines the size of the lookup code. The size is determined based on the business use case. In addition, there are standard fields included in all extendable lookups, including a description, detailed description and an override description (so that implementations can override the description of base delivered values).
- The extendable lookup may define additional information for each value if warranted by the business requirement. See Additional Attributes for technical information about additional attributes.

> **NOT_SUPPORTED**
>
> For more information, refer to Defining Extendable Lookups.

Control Table

There may be scenarios where a list of valid values warrants a standalone maintenance object, which is considered an administrative or control table object. When choosing a valid value that is defined by a control, either a dropdown UI metaphor or a search metaphor is used, depending on how it has been designed.

The following points highlight some reasons why this option may be chosen:

Copyright © 2026, Oracle and/or its affiliates.

- The records require a lifecycle such that BO status is warranted.
- The additional attributes are sophisticated enough that they warrant their own column definition rather than relying on using CLOB or flattened characteristic. For example, if a list of information needs to be captured with several attributes in the list and the information in the list needs to be searchable.

In this situation, if a product has provided a control table for this type of functionality, it will be documented fully in the appropriate functional area. If an implementation determines that a custom control table is warranted, all the standard functionality for a maintenance object is required: database tables, maintenance object metadata, appropriate Java maintenance classes, portals, zones, etc. Refer to the Software Development Kit for more information. No further information is provided in this section for this option.

Characteristic Types

Many maintenance objects in the system support characteristics tables, which are used to capture additional fields for the object that are not already supported by the object's provided attributes. Each characteristic is associated with a characteristic type, which defines attributes of the field you wish to capture.

While each characteristic is stored in a separate row in the characteristic table, the user interface metaphor used to capture and display them differ based on the type of page that is used to maintain the object.

- For portal based pages, the business object drives the display and maintenance of the object. The display and maintenance of each characteristic is determined by the business object's user interface design. For these types of pages, it is recommended that characteristics are defined as flattened elements allowing the user interface to display the characteristic as if it is another field. Refer to The Flattening Nodes and Attributes for more information about flattening characteristics on a business object schema.
- There are some fixed pages in the system that do not support customization of the user interface. For these objects, the characteristics are displayed / maintained as a generic list.

The topics in this section describe various aspects of a characteristic type definition and usage.

Characteristic Value Types

Every characteristic referenced on an object references a characteristic type. The characteristic type controls the validity of the information entered by a user when they enter the characteristic's values. For example, if you have a characteristic type on user called "skill", the information you setup on this characteristic type controls the valid values that may be specified by a user when defining another user's skill.

When you setup a characteristic type, you must classify it as one of the following categories:

- **Predefined Value.** When you setup a characteristic of this type, you define the individual valid values that may be entered by a user. A good example of such a characteristic type would be one on User to define one or more predefined skills for that user. The valid values for this characteristic type would be defined in a discreet list.
- **Adhoc Value.** Characteristics of this type do not have their valid values defined in a discreet list because the possible values are infinite. Good examples of such a characteristic type would be ones used to define a user's birth date or their mother's maiden name. Optionally, you can plug-in an algorithm on such a characteristic type to validate the value entered by the user. For example, you can plug-in an algorithm on a characteristic type to ensure the value entered is a date.

Copyright © 2026, Oracle and/or its affiliates.

- **Foreign Key Value.** Characteristics of this type have their valid values defined in another table. For example perhaps you want to link a user to a table where User is not already a foreign key. Valid values for this type of characteristic would be defined on the user table. Before you can create a characteristic of this type, information about the table that contains the valid values must be defined on the foreign key reference table.

  > **Note**
  >
  > When you are searching for a foreign key characteristic value, there are some limitations of when a search is available depending on the search metaphore. Refer to Search Options for more information.

- **File Location.** Characteristics of this type contain a URL. The URL can point to a file or any web site. Characteristics of this type might be useful to hold references to documentation / images associated with a given entity. For example, the image of a letter sent to you by one of your customers could be referenced as a file location characteristic on a customer contact entry. When such a characteristic is defined on an entity, a button can be used to open the URL in a separate browser window.

  File location characteristic values must be entered in a "non-relative" format. For example, if you want to define a characteristic value of *www.msn.com*, enter the characteristic value as `http://www.msn.com`. If you omit the `http://` prefix, the system will suffix the characteristic value to the current URL in your browser and attempt to navigate to this location when the launch button is pressed. This may or may not be the desired result.

  > **Note**
  >
  > Due to browser security restrictions, opening URLs using the file protocol ("file://") from pages retrieved using http does not work. If the file protocol is used, the browser either does not return properly or an error is thrown (e.g., "Access Denied", which usually results from cross site scripting features added for security reasons). This issue has no known workaround. To comply with browser security standards, the recommendation is to move the target files to an FTP or HTTP server location to avoid protocols that are subject to browser security restrictions.
  >
  > Also note that the functionality described in the topics for Referencing URIs do not apply to this value given that the browser is responsible for connecting to the URI and does not go via server logic.

  For references to a file, the recommendation is to use the Attachment functionality to link a file to an object rather than a characteristic type of File Location. Refer to Attachment Overview for more information. The documentation related to file location remains for upgrade purposes.

Searching By Characteristic Values

For certain entities in the system that have characteristics, you may search for a record linked to a given characteristic value. The search may be done in one of the following ways:

- Some base searches provide an option to search for an object by entering Characteristic Type and Characteristic Value.
- Your implementation may define a customized search for an entity by a characteristic value for a specific characteristic type using a query data explorer.

Copyright © 2026, Oracle and/or its affiliates.

- Your implementation may require a business service to find a record via a given characteristic value. For example, maybe an upload of user information attempts to find the user via an Employee ID, defined as a characteristic.

Not all entities that support characteristics support searching by characteristics. To confirm if a given characteristic table supports searching, verify that it includes the field SRCH_CHAR_VAL.

> ⚠ **Caution**
>
> For ad hoc characteristics, only the first 50 bytes are searchable. For foreign key characteristics, the search value is populated by concatenating the values of each foreign key column to a maximum of 50 bytes.

For the base searches that provide a generic option to search by characteristic type and value, you can restrict the characteristic types that can be used to search for an entity. For example, imagine you use a characteristic to define a "jurisdiction" associated with a To Do for reporting purposes. If your company operates within a very small number of jurisdictions, you wouldn't want to allow searching for a To Do by jurisdiction, as a large number of To Do entries would be returned.

A flag on the characteristic type allows an administrator to indicate if searching by this characteristic type is **allowed** or **not allowed**.

Data Typing an Ad hoc Characteristic Value

An **Adhoc Value** characteristic type may further restrict the data type of the captured value by referencing a Field. When populated, the system validates that the captured characteristic value complies with the data type definition of the referenced field.

Valid Characteristic Entities

Characteristics are stored in designated tables, each associated with a unique characteristic entity value referenced on the table definition record. A characteristic type record lists all the valid characteristic entities it is allowed to be captured on.

Customizing Base Owned Characteristic Types

Implementations may customize the following aspects of a base owned characteristic type:

- Extend the list of valid values for a base owned **Predefined Value** characteristic type to include additional custom values. Such extension is only supported if the characteristic type is defined with the **Custom** option turned on.
- Provide a custom algorithm to validate an **Adhoc Value** characteristic type.
- Indicate whether characteristics of this type may be used in searches.
- Extend the list of entities associated with the characteristic type.

Foreign Key References

A Foreign Key Reference defines the necessary information needed to reference an entity in a certain table.

You need to set up this control table if you need to validate a foreign key value against a corresponding table. For example, if a schema element is associated with an FK Reference the system validates the element's value against the corresponding table. Refer to Configuration Tools to learn more about schema-based objects. Another example is characteristics whose

Copyright © 2026, Oracle and/or its affiliates.

valid values are defined in another table (i.e., you use "foreign key reference" characteristic types). Refer to Characteristic Types for a description of characteristics of this type.

A FK Reference is used not just for validation purposes. It also used to display the standard information description of the reference entity as well as provide navigation information to its maintenance transaction. Info descriptions appear throughout the UI, for example, whenever an account is displayed on a page, a description of the account appears. The product provides base product FK references for many of its entities as they are used for validation and display of elements in both fixed page user interfaces as well as portal based user interfaces.

An implementation may also see the need to define a foreign key reference. The following points describe what you should know before you can setup a foreign key reference for a table.

- The physical name of the table. Typically this is the primary table of a maintenance object.
- The program used by default to construct the referenced entity's info description.
- The transaction used to maintain the referenced entity. This is where the user navigates to when using the "go to" button or hyperlink associated with the entity.
- The name of the search page or zone used to look for a valid entity.

The topics in this section describe various aspects of a foreign key reference definition and usage.

Information Description Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the standard information associated with a specific referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the Determine BO maintenance object algorithm system event for more information. If a business object has been determined, the system lets the business object's Information plug-in, if any, format the description.
- If a business object has not been determined or the business object has no such plug-in, the system lets the maintenance object's information plug-in, if any, format the description.
- If the maintenance object has no such plug-in, the system uses the info program specified on the FK Reference to format the information.

> **Note**
>
> **Technical note.** The class that returns the information displayed adjacent to the referenced entity is generated specifically for use as an info routine. Please speak to your support group if you need to generate such a class.

> **Note**
>
> **Generic routine.** The system provides a generic information routine that returns the description of control table objects from its associated language table. By "control table" we mean a table with an associated language table that contains a **DESCR** field. Refer to Defining Table Options for more information on tables and fields. The java class is `com.splwg.base.domain.common.foreignKeyReference.DescriptionRetriever`.

Copyright © 2026, Oracle and/or its affiliates.

Navigation Information Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the actual transaction to navigate to for a given referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the Determine BO maintenance object algorithm system event for more information. If a business object has been determined, use the maintenance portal defined as its **Portal Navigation Option** business object option.
- If a business object has not been determined or the business object defines no such option, the system uses the transaction specified on the FK Reference.

Search Options

The product provides two main metaphors for implementing a user interface. For input fields that are foreign keys, search options are dependent on the metaphor used by the page in question.

- A portal based user interface is a more flexible user interface where an implementation has more options for customizing the look and feel. The base product uses UI maps or automatic UI rendering to display input fields. Elements that are foreign keys may display a search icon if the FK reference defines a Search Zone.

  > **Note**
  >
  > **Defining search zones directly.** It's possible for elements on a UI map to define a specific search zone directly in the HTML, rather than using the search zone defined on an FK reference. Refer to the UI map tips for more information on implementing searches using zones.

- A fixed maintenance page user interface is a page supplied by the base product where only minor enhancements, if any, can be introduced by implementations. The foreign key reference may be used in one of two ways.
  - The based product may use an FK reference to define a base element on one of these pages. If a search is available for such elements, the FK reference's Search Navigation Key is used to implement the search.
  - Entities that support characteristics typically include a generic characteristic collection UI metaphor on these types of pages. In this metaphor, a foreign key characteristic displays a search icon if the FK Reference has configured a Search Navigation Key.

> **Note**
>
> Not every FK reference provided with the product is configured with a search option. This may be the case if the base delivered pages use a dropdown for this foreign key rather than a search. In addition, base provided FK references that do provide a search may not be configured with both search options. It means that if linking this type of object as a characteristic, the search may not be available if the appropriate search is not configured.

Copyright © 2026, Oracle and/or its affiliates.

Defining Tables

This portal is used to view and maintain information about an application table.

You can access the portal from the**Admin Menu**, and then **Database**, and then **Table**. You are brought to a query portal with options for searching for a specific table. Once a table has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to Tables for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Table.** This zone provides information about the selected table.
- **Fields.** This zone lists all fields of the selected table and provides various actions to maintain this information.

The following zones may appear as part of the portal's **Relationship** tab page

- **Entity Relationship Diagram.** This zone provides a visual representation of the table's relationship to other tables in the application's data model.

The following zones may appear as part of the portal's **Constraints** tab page

- **Table Constraints.** This zone lists the various key constraints defined for the selected table and provides various actions to maintain this information.
- **Referred By Constraints.** This zone lists all tables referring to the selected table via foreign key constraints.

Refer to Tables for more information.

The following zones may appear as part of the portal's **Indexes** tab page

- **Table Indexes.** This zone lists the indexes defined for the selected table and provides various actions to maintain this information.

Refer to Tables for more information.

Defining Fields

This portal is used to view and maintain information about a field. For product owned fields, you may use this portal to override the label of a field on the various pages in the system.

You can access the portal from the **Admin Menu**, and then **Database**, and then **Field**. You are brought to a query portal with options for searching for a specific field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Refer to Fields for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Field.** This zone provides information about the selected field.

Copyright © 2026, Oracle and/or its affiliates.

- **Tables Using Field.** This zone lists tables referencing the field. It is not visible for work fields.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field. The zone is only visible when the selected field is a lookup field.

The following zone may appear as part of the portal's **References** tab page

- **Field References.** This zone list various configuration entities referencing the current field.

Defining Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes the definition of the tables that together capture the physical data for the entity. In addition, the maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system. Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Most maintenance objects are provided with the base package. An implementation can introduce custom maintenance objects when needed. Most fields may not be changed if owned by the base package.

Many maintenance objects in the system support the use of business objects to further define configuration and business rules for a given record. Refer to Maintenance Objects for more information.

You can access the portal from the **Admin Menu**, and then **Database**, and then **Maintenance Object**. You are brought to a query portal with options for searching for a specific maintenance object. Once a maintenance object has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Maintenance Object.** This zone provides information about the selected maintenance object.
- **Tables Information.** This zone displays information about the tables included in the maintenance object.

The following zone may appear as part of the portal's **Relationship** tab page

- **Entity Relationship Diagram.** This zone describes the relatiomship of this entity to other entities in the data model.

The following zone may appear as part of the portal's **Options** tab page

- **Options.** This zone is used to maintain various configuration options associated with the current maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **You can add new option types.** Your implementation may want to add additional maintenance option types. For example, your implementation may have plug-in driven logic that would benefit from a new type of option. To do that, add your new values to the customizable lookup field `MAINT_OBJ_OPT_FLG`.

The following zone may appear as part of the portal's **Algorithms** tab page

- **Algorithms.** This zone is used to maintain the algorithms associated with the current maintenance object. Refer to the table that follows for a description of all possible system events. If the algorithm is implemented as a script, a link to the **Script** is provided. Refer to Plug-in Scripts for more information.

The following zone may appear as part of the portal's **Business Objects** tab page

- **Business Objects.** This zone displays business objects associated with the current maintenance object.

The following zone may appear as part of the portal's **References** tab page

- **Maintenance Object References.** This zone list various configuration entities referencing the current maintenance object.

Actions

The page supports the following special actions:

- **Create an Algorithm.** Use this action, on the Algorithm tab to create a script based algorithm related to this maintenance object. You are prompted for information regarding the plug-in spot and the system event, the name, description, etc. Once all the information is provided, the system creates an algorithm type, a script, an algorithm and links the algorithm to the maintenance object. You may then navigate to the script to adjust it as needed.
- **Inactivate / Activate Base Algorithms.** You can inactivate algorithms on Maintenance Objects. Your implementation may want to use a maintenance object provided by the base product, but may want to inactivate one or more algorithms provided by the base maintenance object. To do that, use the "Inactivate" action on the appropriate algorithm entry on the Algorithm tab. Use use the "Activate" action to mark an inactive algorithm as active.
  Note that these actions add and remove the "Inactive Algorithm" maintenance option as needed.
- Maintenance Object Algorithms

Maintenance Object Algorithms

The following table describes all the system events supported for maintenance objects.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Audit	Optional	Algorithms of this type are called to notify of any changes to the maintenance object's set of tables. These algorithms are invoked just before the commit at the end of a logical transaction. The system keeps track of what records are added or changed in the course of a transaction and all MO audit algorithms are executed in order of when each record was first added or updated.
Determine BO	Optional	Algorithm of this type is used to determine the Business Object associated with an instance of the maintenance object. It is necessary to plug in such an algorithm on a Maintenance Object to enable the business object rules functionality. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.
ILM Eligibility	Optional	Algorithms of this type are used for maintenance objects that are enabled for object erasure for Information Lifecycle Management. They are used to review records that have reached the maximum retention days and evaluate if they are ready to be archived. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Information	Optional	We use the term "Maintenance Object Information" to describe the basic information that appears throughout the system to describe an instance of the maintenance object. The data that appears in this information description is constructed using this algorithm. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.
Manage Erasure Schedule	Optional	Algorithms of this type are used for maintenance objects that are enabled for object erasure, which is a measure to protect Data Privacy. They are triggered when certain system events occur for those objects. The algorithms are used to determine if the record needs to be scheduled for erasure and, if so, create or maintain an entry for the record in the Object Erasure Schedule.
Revision Control	Optional	An algorithm of this type is used to enforce revision control rules when an object is added, changed, or deleted. The maintenance object service calls the plug-in once before the object is processed and once more after applying all business object rules. This allows revision rules to take place in proper revision timings.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Transition	Optional	The system calls algorithms of this type upon each successful state transition of a business object as well as when it is first created. These are typically used to record the transition on the maintenance object's log. Note that most base maintenance objects are already shipped with an automatic logging of state transitions. In this case you may use these algorithms to override the base logging functionality with your own. Refer to State Transitions are Audited for more information.
Transition Error	Optional	The system calls this type of algorithm when a state transition fails and the business object should be saved in its latest successful state. The algorithm is responsible for logging the transition error somewhere, typically on the maintenance object's log. Notice that in this case, the caller does NOT get an error back but rather the call ends successfully and the exception is recorded somewhere, as per the plug-in logic. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.

Maintenance Object Configuration

The Maintenance Object Configuration portal provides several zones to help implementations manage configuration across several maintenance objects. It is a standard All-in-One portal.

Navigate using**Admin**, and then **Implementation Tools**, and then **Maintenance Object Configuration.**

The following zones appear on the portal.

- **Object Erasure Configuation.** This zone displays a list of maintenance objects that support object erasure. Press the edit icon to open a window in which the configuration values for that maintenance object can be changed.

Copyright © 2026, Oracle and/or its affiliates.

- **Generalized Initial Export Batch Controls.** This zone displays a list of maintenance objects that are eligible for generalize data export, but where appropriate batch controls have not been created. Note that base delivered maintenance objects are delivered with the appropriate batch controls. This zone may not show any data unless you have custom maintenance objects that should be configured for Generalized Data Export.
- **Conversion Batch Controls.** This zone displays a list of maintenance objects whose primary table is eligible for conversion, but where appropriate batch controls have not been created. Note that base delivered maintenance objects are delivered with the appropriate batch controls. This zone may not show any data unless you have custom maintenance objects that should be configured for conversion.

Defining Lookups

Lookup fields may be used to define valid values for a column in a table or for other types of values like parameters to an algorithm. This portal is used to view and maintain information about a lookup field and its values. Note that all lookup information is also maintained as part of the corresponding Field portal.

You can access the portal from the **Admin Menu**, and then **Database**, and then **Lookup**. You are brought to a query portal with options for searching for a specific lookup field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

NOT_SUPPORTED

Refer to Defining Valid Values for some background information.

Note

When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Lookup.** This zone provides information about the selected lookup field.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field.

The base product provides many different lookup fields and their values as part of the product. The following points highlight some functionality related to base-package lookups.

- Fields that are owned by the product will typically provide base lookup values. Implementations are not permitted to remove base delivered lookup values. Implementations may be able to add custom values to base owned lookups. This is controlled with the Custom switch on lookup.
  - When the custom switch is unchecked, it means that there is functionality controlled by the base values and an implementation may not extend or customize this functionality. An example of this type of lookup is the Data Type field on the Field table. The system supports a distinct list of data types and an implementation may not add additional values.
  - When the custom switch is checked, it means that there is base functionality supplied for the base values but that an implementation can extend the functionality by supplying their own values. An example of this type of lookup is the Access Mode on

Copyright © 2026, Oracle and/or its affiliates.

Application Service. The product provides many values for the access mode lookup, representing various actions a user may perform. Implementations may add their own values to this lookup. Documentation should indicate when functionality may be extended and should highlight the lookup value that can be extended.

> ⚠ **Caution**
>
> Important! If you introduce new lookup values, you must prefix the lookup value code with X or Y. If you do not do this, there is a possibility that a future release of the application could introduce a new lookup value with the name you allocated.

- There may be some scenarios where the product supplies a base field and base lookup field with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the lookup values. Typically this type of lookup is for information or categorization purposes. The configuration guide for the functional area associated with the lookup should include a configuration step regarding defining values for this type of lookup.
- The description of base delivered values may be overridden by an implementation.

An implementation may also identify the need for defining a new lookup field with its values.

Defining Extendable Lookups

Extendable lookups are a way of defining valid values that are more sophisticated than simple lookups.

> **NOT_SUPPORTED**
>
> Refer to Defining Valid Values for some background information.

The base product provides extendable lookups as part of the product. The following points highlight some functionality related to base-package extendable lookups.

- The base product may supply base extendable lookup values. Implementations are not permitted to remove base delivered extendable lookup values. It is also possible that implementations may be able to add custom values to base owned lookups. If an implementation is not permitted to add lookup values to the base extendable lookup, the extendable lookup business object will include validation to prevent this. There is no equivalent of the Custom switch that is on the lookup field.
- There may be some scenarios where the product supplies a base extendable lookup with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the extendable lookup values. The configuration guide for the functional area associated with the extendable lookup should include a configuration step regarding defining values for this type of extendable lookup.
- The description of base delivered values may be overridden by an implementation.

Open this page using **Admin**, and then **General**, and then **Extendable Lookup.**

You are brought to the **Extendable Lookup Query** where you need to search for the extendable lookup object (in other words, its business object).

Copyright © 2026, Oracle and/or its affiliates.

Once you have found the appropriate extendable lookup, select the value and you are brought to a standard All-in-One portal that lists the existing lookup values for the extendable lookup. The standard actions for an All-in-One portal are available here.

- Extendable Lookup Advanced Topics

Extendable Lookup Advanced Topics

This section provides some addition technical information about extendable lookup attributes

Defining Additional Attributes

The product provides a few different ways to define additional values for an extendable lookup. Some of the methods are only relevant for base delivered lookup values as they may impact whether or not an implementation can update the values.

The following table highlights the options available and some summary information about what the option provides.

Option	Brief Description	Extendable Lookup Value Searchable by this Attribute?	Base Delivered Value Modifiable?
Element mapped to BO_DATA_AREA	The element is mapped to a CLOB field that allows for base delivered values to be modified.	No	Yes
Element mapped to BASE_BO_DATA_AREA	The element is mapped to a CLOB field that does not allow for base delivered values to be modified.	No	No
Flattened characteristic	The element is defined using the flattened characteristic mechanism.	Yes	No

The following points highlight information from the table above:

- The decision of defining an additional attribute using a CLOB mapping or a flattened characteristic will depend on whether the functionality expects that the lookup value is known when the attribute is needed (in which case a CLOB mapping is appropriate) or if the functionality expects to determine the lookup value based on the attribute (in which case, a flattened characteristic is appropriate).
- When the base product defines an extendable lookup with additional attributes and intends to provide base extendable lookup values, it needs to determine whether or not implementations may update the additional attribute or not.
  - If no and the value is mapped to a CLOB, it will map the value to the BASE_BO_DATA_AREA column. This means that implementations will receive an owner mismatch error when attempting to change the value. In addition, upgrading to a new release will replace the value with the base value.
  - If yes and the value is mapped to a CLOB, it will map the value to the BO_DATA_AREA column. This means that implementations will be able to change the value for a base owned record. In addition, upgrading to a new release will not make any changes to the value.

Copyright © 2026, Oracle and/or its affiliates.

- For values mapped to a characteristic, the product does not support an implementation changing the value of a base delivered record. If the product would like to support an implementation overriding this type of value, the business object will need to be designed with a corresponding "override" element (also a flattened characteristic), similar to how the product supplies an Override Description field to support an implementation overriding the base product delivered description for a base value. This element will not be delivered with any value and will allow an implementation to populate that value.

  > **Note**
  >
  > Note that in this situation, the product functionality that uses this value must cater for the override value.

- All of this detail is only relevant for base provided extendable lookup values. If an implementation adds custom values for a base supplied extendable lookup, all the additional attributes may be populated as appropriate.
- If an implementation defines a custom extendable lookup business object and wants to define an additional attribute using a CLOB, it doesn't matter which CLOB column is used. Both BO_DATA_AREA and BASE_BO_DATA_AREA provide the same functionality for custom business objects.

Capturing a Password

If an extendable lookup includes configuration of a password for some functionality, the system supports automatic encryption of the password value if the schema maps the password to a characteristic using the characteristic type `F1-PWD`.

Defining Characteristic Types

This portal is used to view and maintain characteristic types. An implementation may define their own characteristic types or override some of the settings for base product provided characteristic types.

You can access the portal from the **Admin Menu**, and then **General**, and then **Characteristic Type**. You are brought to a query portal with options for searching for a specific record. Once a characteristic type record has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **Note**
>
> When introducing a new record, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Refer to Characteristic Types for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Characteristic Type.** This zone provides information about the selected characteristic type.
- **Characteristic Values.** This zone is visible for pre-defined characteristic types and shows the existing values (if applicable) with action buttons. It also allows you to add new values.

Copyright © 2026, Oracle and/or its affiliates.

Note that you may only add values to a product owned characteristic type if the Custom switch is checked.

Defining Foreign Key References

The topics in this section describe the transaction that allows you to define foreign key references.

Refer to Foreign Key References for more information.

You can access the portal from the **Admin Menu**, and then **Database**, and then **FK Reference**. You are brought to a query portal with options for searching for a specific foreign key reference. Once a foreign key reference has been selected you are brought to the maintenance portal to view and maintain the selected record.

> ⚠ **Caution**
>
> Important! If you introduce a new foreign key reference, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Foreign Key Reference.** This zone provides information about the selected foreign key reference.
  - Navigation to the referenced entity may be dynamic. The page associated with the specified Navigation Option is used when a dynamic option is not available. Refer to Navigation Information Is Dynamically Derived for more information.
  - The information description of the referenced entity may be composed dynamically depending on the specified Info Program Name. Refer to Information Description Is Dynamically Derived for more information.
  - Certain restrictions apply when displaying the context menu for a referenced entity.

    > ⓘ **Note**
    >
    > Context Menu Name is not applicable to user interface elements displaying a generic collection using a foreign key characteristic type. It is only applicable for pages utilizing the foreign key compound element type for fixed page user interface and for data displayed in a portal based user interface where the foreign key reference is defined as an attribute for an element. Report parameters that reference foreign key characteristics are an example of a user interface where a context menu is not displayed even if the foreign key reference defines one.

  - Certain restrictions apply to search features on fixed page user interfaces.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Search Type and Search Tooltip attributes are only applicable to user interface elements utilizing the foreign key compound element type on fixed page user interfaces. Report parameters that reference foreign key characteristics are an example of a user interface where this information is not used even if the foreign key reference defines them.

The following zones may appear as part of the portal's **References** tab page.

- **Foreign Key References.** This zone list various configuration entities referencing the current foreign key reference.

Actions

The page supports the following special actions:

- **View the source.** If the foreign key information program is shipped with the base package, you can use the adjacent button to display the source code of this program in the Javadocs viewer.

Audit Trails

The topics in this section describe one way of auditing changes in the system. Note that this technique has limitations and may not be the best option for all situations.

- This functionality is configured at the table and field level. Many base maintenance objects use an XML or CLOB field to capture one or more elements using XML format, configured using a BO schema. This auditing technique is not able to capture changes to individual elements. It can only capture overall changes to the single field. The BO Audit plug-in is a better option for auditing changes to individual elements with the CLOB / XML field.
- The base table provided for supporting audits limits the field size of the before and after values to 254 bytes.
- Auditing is captured for each field. In some cases it is prefered to capture a before and after image for several fields at once. For example, if an address is changed, it's more user friendly to capture the before and after for the full address rather than the individual address components. The BO Audit plug-in allows for capturing a single audit record for multiple elements rather than granular changes for each element.

The subsequent topics highlight how to enable auditing for fields, and describe the auditing queries that you can use to view audit records.

- Captured Information
- How Auditing Works
- The Audit Trail File
- How To Enable Auditing
- Audit Queries

Captured Information

When auditing is enabled for a field, the following information is recorded when the field is changed, added and/or deleted (depending on the actions that you are auditing for that field):

- User ID

Copyright © 2026, Oracle and/or its affiliates.

- Date and time
- Table name
- Row's prime key value
- Field name
- Before image (blank when a row is added)
- After image (blank when a row is deleted)
- Row action (add, change, delete)

How Auditing Works

You enable auditing on a table in the table's meta-data by specifying the name of the table in which to insert the audit information (the audit table) and the name of the program responsible for inserting the data (the audit trail insert program). Then you define the fields you want to audit by turning on each field's audit switch in the table's field meta-data. You can audit fields for delete, insert and update actions.

Once auditing is enabled for fields in a table, the respective row maintenance program for the table assembles the list of changed fields and calls the audit trail insert program. If any of the changed fields are marked for audit, the audit program inserts audit rows into the audit table.

> **Note**
>
> **Customizing Audit Information.** You may want to maintain audit information other than what is described in Captured Information or you may want to maintain it in a different format. For example, you may want to maintain audit information for an entire row instead of a field. If so, your implementation team can use the base audit program and base audit tables as examples when creating your own audit trail insert program and audit table structures.

The Audit Trail File

Audit log records are inserted in the audit tables you define. The base product contains a single such table (called `CI_AUDIT`). However, the base audit insert program is designed to allow you to use multiple audit tables.

If you want to segregate audit information into multiple tables, you must create these tables. Use the following guidelines when creating new audit tables (that use the base delivered audit insert program):

- The new audit tables must look identical to the base table (`CI_AUDIT`).
- The new tables must be prefixed with **CM** (e.g., `CM_AUDIT_A`, `CM_AUDIT_B`, etc.). An appropriate java table name must be defined and an *_impl.java program for that java table name must be defined.
- The name of the new table must be referenced on the various tables whose changes should be logged in the new table.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> It's important to note if you use your own tables (as opposed to using the base package table called `CI_AUDIT`), the SQL used to insert and access audit trail records in the base delivered audit program is dynamic. Otherwise, if the base package's table is used, the SQL is static.

How To Enable Auditing

Enabling audits is a two-step process:

- First, you must turn on auditing for a table by specifying an audit table and an audit trail insert program.
- Second, you must specify the fields and actions to be audited for the table.

The following topics describe this process.

- Turn On Auditing For a Table
- Specify The Fields and Actions To Be Audited

Turn On Auditing For a Table

In order to tell the system which fields to audit, you must know the name of the table on which the field is located. You must specify the audit table and the audit trail insert program for a table in the table's meta-data.

> **Note**
>
> Most of the system's table names are fairly intuitive. For example, the user table is called SC_USER, the navigation option table is called CI_NAV_OPT, etc. If you cannot find the table using the search facility on the Table portal, please contact customer support.

To enable auditing for a table:

- Navigate to the Table portal and find the table associated with the field(s) for which you want to capture audit information.
- Specify the name of the **Audit Table**.

> **Note**
>
> **Specifying the Audit Table.** You can use the audit table that comes supplied with the base package (`CI_AUDIT`) to audit multiple tables and fields. All the audit logs are combined in a single table (`CI_AUDIT`). However, you can also have a separate audit table for each audited table. Refer to The Audit Trail File for more information.

- Specify the name of the **Audit Program** . The product provides two programs. `com.splwg.base.domain.common.audit.DefaultTableAuditor` is a standard table audit program. In addition

Copyright © 2026, Oracle and/or its affiliates.

`com.splwg.base.domain.common.audit.ModifiedTableAuditor`is supplied as an alternative. This program does not audit inserts or deletes of empty string data.

> **⚠ Caution**
>
> By default, none of a table's fields are marked for audit. Even though you have enabled auditing for a table, you must still specify the fields and actions on those fields to be audited (see below).

Specify The Fields and Actions To Be Audited

The system only audits actions (insert, update and delete) made to fields that you want audited.

To specify the fields and actions to be audited:

- Navigate to the Table portal for a table on which you have enabled auditing.
- For each field you want to audit, specify the actions you want to audit by turning on the **Audit Delete**, **Audit Insert** and **Audit Update** switches as appropriate.

> **ⓘ Note**
>
> You can also turn on the audit switches using the Field zone at the bottom of the Table portal.

> **⚠ Caution**
>
> Audit Program Caching! The audit program from the table meta-data is read into a program cache on the application server whenever the date changes or when the server starts. If you implement new auditing on a table, your audit trail does not become effective until this program cache is reloaded. In other words, new audits on tables where the audit program was not previously specified do not become effective until the next day (or the next restart of the application server). However, if you change the fields to be audited for a table where the audit program is already in the cache, your changes are effective immediately.

Audit Queries

There are two queries that can be used to access the audit information.

- Audit Query by User
- Audit Query by Table / Field / Key

Audit Query by User

This transaction is used to view changes made by a user that are stored on a given Audit Trail File.

Copyright © 2026, Oracle and/or its affiliates.

> **⚠ Caution**
>
> The system only audits changes that you've told it to audit. Refer to The Big Picture Of Audit Trails for more information.

Navigate to this page by selecting **Admin**, and then **Database**, and then **Audit Query By User**.

Description of Page

To use this transaction:

- Enter the **User ID** of the user whose changes you wish to view.
- Enter the name of the table on which the audit trail information is stored in **Audit Table**. Refer to The Audit Trail File for more information about this field.

> **ⓘ Note**
>
> **Default Note**. If only one audit table is used to store audit trail information, that table is defaulted.

- Specify a date and time range in **Created between** to restrict the records that result from the query.

> **ⓘ Note**
>
> **Default Note**. The current date is defaulted.

- Click the search button to display all changes recorded on a specific audit table associated with a given user.

Information on this query is initially displayed in reverse chronological order.

The following information is displayed in the grid:

- **Row Creation Date** is the date and time that the change was made.
- **Audited Table Name** contains the name of the table whose contents were changed.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents where changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.
- **Field Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Field Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Audit Query by Table / Field / Key

This transaction is used to view audited changes made to a given table.

Copyright © 2026, Oracle and/or its affiliates.

> **⚠ Caution**
>
> The system only audits changes that you've told it to audit. Refer to The Big Picture Of Audit Trails for more information.

This transaction can be used in several different ways:

- You can view all audited changes to a table. To do this, enter the **Audited Table Name** and leave the other input fields blank.
- You can view all audited changes to a given row in a table (e.g., all changes made to a given user). To do this, enter the **Audited Table Name** and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).
- You can view all audited changes to a given field in a table (e.g., all changes made to all customers' rates). To do this, enter the **Audited Table Name** and the **Audited Field Name**.
- You can view all audited changes to a given field on a specific row. To do this, enter the **Audited Table Name**, the **Audited Field Name**, and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).

Navigate to this page by selecting **Admin**, and then **Database**, and then **Audit Query By Table/Field/Key**.

Description of Page

To use this transaction:

- Enter the name of the table whose changes you wish to view in **Audited Table Name**.
- If you wish to restrict the audit trail to changes made to a specific field, enter the **Audited Field Name**.
- If you wish to restrict the audit trail to changes made to a given row, enter the row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**). These fields are dynamic based on the **Audited Table Name**.
- Specify a date and time range in **Created between** to restrict the records that result from the query.

> **ⓘ Note**
>
> The current date is defaulted.

- Click the search button to display all changes made to this data.

Information on this query is initially displayed in reverse chronological order by field.

The following information is displayed in the grid:

- **Create Date/Time** is the date / time that the change was made.
- **User Name** is the name of the person who changed the information.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents where changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.

Copyright © 2026, Oracle and/or its affiliates.

- **Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Bundling

The topics in this section describe the bundling features in the application.

- About Bundling
- Configuring Maintenance Objects for Bundling
- Working with Bundles

About Bundling

Bundling is the process of grouping entities for export or import from one environment to another.

For example, you might export a set of business objects and service scripts from a development environment and import them into a QA environment for testing. The group of entities is referred to as a bundle. You create export bundles in the source environment; you create import bundles in the target environment.

Working with bundles involves the following tasks:

- Configuring entities for bundling if they are not preconfigured
- Creating an export bundle, which contains a list of entities to be exported from the source environment
- Creating an import bundle to import those entities to the target environment
- Applying the import bundle, which adds or updates the bundled entities to the target environment

- Sequencing of Objects in a Bundle
- Recursive Key References
- Owner Flags on Bundled Entities

Sequencing of Objects in a Bundle

Bundle entities are added or updated to the target environment in the sequence defined in the bundle

Typically, the sequence of entities does not matter. However, sequence is important in the following situations:

- Entities that are referenced as foreign keys should be at the top of the sequence, before the entities that reference them. Specify zones last, as they typically contain numerous foreign key references.
- When importing a business object, specify the business object first, then its plug-in scripts, then the algorithms that reference the scripts, and then the algorithm types that reference the algorithms.
- When importing a portal and its zones, specify the portal first and then its zones.

Copyright © 2026, Oracle and/or its affiliates.

- When importing a multi-query zone, specify the referenced zones first and then the multi-query zone.
- Always specify algorithms types before algorithms.

You can specify the sequence when you define the export bundle or when you import the bundle to the target environment.

Recursive Key References

Recursive foreign keys result when one object has a foreign key reference to another object that in turn has a foreign key reference to the first object.

For example, a zone has foreign keys to its portals, which have foreign keys to their zones. If the objects you want to bundle have recursive relationships, you must create a 'bundling add' business object that has only the minimal number of elements needed to add the entity. A bundling add business object for a zone contains only the zone code and description, with no references to its portals. In the same way, a bundling add business object for a portal defines only its code and description.

When you apply the bundle, the system initially adds the maintenance object based on the elements defined in the bundling add business object. Before committing the bundle, the system updates the maintenance object with the complete set of elements based on its physical business object.

Note that use of the bundling add BO also benefits records that have optional foreign keys or foreign keys that are part of a child table. That way the person creating the bundle does not have to worry about the sequence of the records. For example, an FK Reference may optionally reference a zone for searching. If a new FK Reference and its search zone are bundled together to copy to another region, the bundling add BO for FK Reference (which doesn’t include the Zone) ensures that the FK reference could be added before the zone without getting any validation errors.

Owner Flags on Bundled Entities

The owner flag of the entities in an import bundle must match the owner flag of the target environment.

If you need to import objects that your source environment does not own, you must replace the owner flag in the import bundle with the owner flag of the target environment.

Configuring Maintenance Objects for Bundling

Most base package meta-data objects are pre-configured to support bundling. All other objects must be manually configured.

If a base package maintenance object is pre-configured for bundling, the **Eligible For Bundling** option will be set to "Y" on the Options tab for the maintenance object.

To configure other objects for bundling, review the configuration tasks below and complete all those that apply:

Configuration Task	Scope of Task
Make maintenance objects eligible for bundling	All objects to be included in the bundle.
Add a foreign key reference	All objects to be included in the bundle.

Copyright © 2026, Oracle and/or its affiliates.

Configuration Task	Scope of Task
Create a physical business object	All objects to be included in the bundle.
Create a bundling add business object	Only needed if there are objects with recursive or optional foreign key references.
Add the Current Bundle zone	Perform this step for any object where you want the Current Bundle zone to appear on the sidebar when on the maintenance page for this maintenance object. This is not required by the bundling process.
Create a custom Entity Search zone and add it to the Bundle Export portal	Perform this step if you would like the object to be listed in the Entity Search zone in the Bundle Export portal. This is not required by the bundling process.

Making Maintenance Objects Eligible for Bundling

The "Eligible For Bundling" maintenance object option must be set to "Y" for all bundled objects. Go to the Maintenance Object page and search for the maintenance object. On the Options tab, add a new option with the type **Eligible For Bundling**. Set the value to "Y" and click **Save**. This configuration must be in both the source environment and the target environment.

Adding a Foreign Key Reference

Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to FK Reference and set up a foreign key reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.

Creating a Physical Business Object

If the maintenance object does not already have a Physical BO configured, one must be created to support using it in a bundle. Refer to Creating a Physical Business Object for more information.

Creating a Bundling Add Business Object

If the objects to be bundled have recursive foreign key references, optional foreign key references or child tables that include foreign key references, create a bundling add business object to avoid problems with referential integrity.

1. Navigate to Business Object and add a business object for the maintenance object. Do not fill in any of the UI oriented configuration.
2. The business object is created with a schema that looks like the physical structure of the maintenance object.
3. Remove all child tables and all elements that are not required.
4. Save the business object.
5. Navigate to Maintenance Object and search for the maintenance object you want to bundle.
6. On the **Option** tab, add a new option with the type **Bundling Add BO**. The value is the name of the bundling add business object you just created.

Copyright © 2026, Oracle and/or its affiliates.

Adding the Current Bundle Zone

If you want the Current Bundle zone to appear on the sidebar when the a user is on the maintenance page for the maintenance object, you must add the Current Bundle zone as a context-sensitive zone for the maintenance page's navigation key.

1. Navigate to Context Sensitive Zone and search for the navigation key for the maintenance page of this object.
2. Add the Current Bundle zone F1-BNDLCTXT, to that navigation key.

Adding a Customized Entity Search Query Zone to the Bundle Export Portal

If you want the maintenance object to be searchable in the Bundle Export portal in the Entity Search zone, you must first create an entity-specific query zone to search for the maintenance object. Then you must create a customized entity search zone that references this new query zone. Finally, you must add the customized entity search zone to the Bundle Export portal.

Note that not all base product entities that are eligible for bundling have a search configured for this zone. There is a limit to the number of searches that may be listed here. The base product has provided searches for only the most common objects that are bundled.

Create an entity-specific query zone to search for the maintenance object:

1. Navigate to Zone and search for one of the base query zones, such as the Algorithm Search zone F1-BNALGS.
2. Click the **Duplicate** button in the record actions section.
3. Enter a name and description for the new zone.
4. Click **Save**.
5. Customize the details of the parameters for your maintenance object.

Create a customized entity search zone. This step only needs to be done once. If you already have a customized search zone in the Bundle Export portal, skip this step.

1. Navigate to Zone and search for the F1-BNDLENTQ Entity Search zone.
2. Duplicate this zone.
3. Remove any references to base query zones.

Add the new entity-specific query zone to the customized entity search zone:

1. Locate the customized entity search zone for your Bundle Export portal. This is the zone created in the previous step.
2. Add the name of the query zone you created in the first step to the list of Query Zones.

Add the customized entity search zone to the Bundle Export portal. This step needs to be done only once.

1. Navigate to Portal and search for the Bundle Export portal, F1BNDLEM.
2. In the zone list, add the entity search zone you created above. (Add the new zone after the base entity search zone).
3. Save the portal.

Copyright © 2026, Oracle and/or its affiliates.

Working with Bundles

Use the Bundle Export portal to create an export bundle. The export bundle contains a list of entities to be exported from the source environment. When you are ready to import the objects, use the Bundle Import portal to import the objects to the target environment.

- Creating Export Bundles
- Creating and Applying Import Bundles
- Editing Export Bundles
- Editing Import Bundles

Creating Export Bundles

An export bundle contains a list of entities that can be imported into another environment.

To create an export bundle:

1. Log on to the source environment from which objects will be exported.
2. Select **Admin**, and then **Implementation Tools**, and then **Bundle Export**, and then **Add**.
3. Complete the fields in the Main section to define the bundle's basic properties.

> **Note**
>
> You can use the Entities section to add bundle entities now, or save the bundle and then add entities as described in step 5.

4. Click **Save** to exit the Edit dialog. The export bundle status is set to Pending.
5. While an export bundle is in Pending state, use any of the following methods to add entities to the bundle:
   a. Use the **Entity Search** zone on the Bundle Export portal to search for entities and add them to the bundle. If an entity is already in the bundle, you can remove it.
   b. To import entities from a .CSV file, click **Edit** on the Bundle Export portal, and then click **CSV File to Upload.** Specify the file name and location of the .CSV file containing the list of entities. Click **Submit** to upload the file, and then click **Save** to save the changes.
   c. Use the **Current Bundle** zone in the sidebar of the entity you want to add. (All entities that are configured to support bundling display a Current Bundle zone). This zone displays a list of all pending export bundles to which you can add the entity.
   d. When you check an entity into revision control, specify the export bundle on the **Revision Info** dialog.
6. When you have added all entities, click **Bundle** in the Bundle Actions zone on the Bundle Export portal. The export bundle state is set to Bundled and the Bundle Details zone displays the XML representation of every entity in the bundle.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The owner flags of the entities in the bundle must match the owner flag of the bundle itself. If the owner flags do not match, the system displays a warning message. Click **OK** to continue or **Cancel** to abort the bundle. If you click OK, you will need to resolve the owner flag discrepancy before you import the bundle to the target environment.

7. Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file). You can now create an import bundle and apply it to the target environment.

> **Note**
>
> If you need to make additional changes to the bundle, you must change the bundle state by selecting the **Back to Pending** button in the **Bundle Actions** zone.

Creating and Applying Import Bundles

Import bundles define a group of entities to be added or updated in the target environment.

Before you create an import bundle, you must have already created an export bundle, added entities, and set the bundle's state to Bundled.

To create an import bundle and apply it to the target environment:

1. If you have not already copied the XML from the export bundle, do so now:
   a. Select **Admin**, and then **Implementation Tools**, and then **Bundle Export** and search for the bundle.
   b. Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file).
2. Log on to the target environment.
3. Select **Admin**, and then **Implementation Tools**, and then **Bundle Import**, and then **Add**.
4. In the **Bundle Actions** zone, click **Edit XML**.
5. Paste the contents of the clipboard (or text file if you created one) into the **Bundle Detail** zone.
6. Make any necessary changes to the XML and click **Save**. The status of the import bundle is set to Pending.

> **Note**
>
> Use caution when editing the XML to avoid validation errors.

7. To remove entities from the import bundle or change their sequence, click **Edit**. Enter your changes and click **Save** to exit the Edit dialog.
8. When you are ready to apply the bundle, click **Apply**. The import bundle state is set to Applied and the entities are added or updated in the target environment.

Copyright © 2026, Oracle and/or its affiliates.

Editing Export Bundles

You can add or remove entities from an export bundle when it is in Pending state. You can also change the sequence of entities.

To edit to an export bundle that has already been bundled, you must change the bundle state by selecting the **Back to Pending** button on the Bundle Export portal.

To edit a pending export bundle:

1. Open the bundle in edit mode.
2. Click **Edit** on the Export Bundle portal.
3. Make any necessary changes on the edit dialog and then click **Save**.

Editing Import Bundles

You can remove entities from an import when it is in Pending state. You can also change the sequence of entities and edit the generated XML.

To edit a pending import bundle:

1. Open the bundle in edit mode.
2. To edit the XML snapshot, click **Edit XML**. Edit the XML code as needed, then click **Save**.

> **Note**
>
> Use caution when editing the XML to avoid validation errors.

3. To remove entities or change their sequence, click **Edit**. Make any necessary changes and click **Save**.

Revision Control

The topics in this section describe the revision control features in the application.

- About Revision Control
- Working with the Revision Control Zones
- Revision Control Portal

About Revision Control

Revision control is a tool provided for the development phase of a project to allow a user to check out an object that is being worked on. In addition, it captures the version of the maintenance object when users check in an update, maintaining a history of the changes to the object.

If revision control is enabled for an object you must check out the object to change it. While the object is checked out no one else can work on it. You can revert all changes made since checking out an object, reinstate an older version of an object, recover a deleted object, and force a check in of an object if someone else has it checked out. You may also compare two versions of the object to more easily review changes.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Revision control does not keep your work separate from the environment. Because the metadata for maintenance objects is in the central database, any changes you make to an object while it is checked out will be visible to others and may impact their work.

Many of the maintenance objects used as configuration tools are already configured for revision control, but it is turned off by default. For example, business objects, algorithms, data areas, UI maps, and scripts are pre-configured for revision control.

- Turning On Revision Control
- Configuring Maintenance Objects for Revision Control

Turning On Revision Control

Revision control is turned off by default for maintenance objects that are configured for revision control.

To turn on revision control:

1. Add the base package **Checked Out** zone to the Sidebar portal.
   a. Navigate to Portal.
   b. Search for the sidebar portal F1SDBTOOL.
   c. In the zone list for the portal, add the zone F1-USRCHKOUT.
2. Set up application security.

   For users to have access to revision control, they must belong to a user group that has access to the application service F1-OBJREVBOAS.
3. Add the revision control algorithm to the maintenance object that you want to have revision control.

   This step must be repeated for each maintenance object that you want to have revision control.
   a. Go to the Maintenance Object page and search for the maintenance object that you want to have revision control.
   b. On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Configuring Maintenance Objects for Revision Control

Most configuration tool maintenance objects are pre-configured for revision control. You can configure other maintenance objects for revision control, as well.

To configure other objects for revision control:

1. Create a physical business object for the maintenance object, if it doesn't already have one. Refer to Creating a Physical Business Object for more information.
2. Add a foreign key reference to the maintenance object (if it doesn't already have one) so that the standard information string is displayed. Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to FK Reference and set up a foreign key

Copyright © 2026, Oracle and/or its affiliates.

reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.

3. Add the **Revision Control** zone to the maintenance object.
    a. Navigate to Context Sensitive Zone and search for the navigation key for the maintenance object.
    b. Add the Revision Control zone, F1-OBJREVCTL, to that navigation key.
4. Add the revision control algorithm to the maintenance object.
    a. Go to the Maintenance Object page and search for the maintenance object that you want to have revision control.
    b. On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Working with the Revision Control Zones

You use two zones in the sidebar to work with revision controlled objects when revision control is turned on.

The **Revision Control** zone gives you several options for managing the revision of the currently displayed object. This zone also shows when the object was last revised and by whom. This information is linked to the **Revision History** portal which lists all of the versions of the object.

Using the Revision Control zone you can:

- Check out an object in order to change it.
- Check in an object so others will be able to work on it.
- Revert the object back to where it was at the last checkout.
- Force a check in of an object that is checked out by someone else. You need special access rights to force a check in.
- Compare the latest version of the object to the previous checked in version.
- Delete an object.

See the subsequent sections for more information about each action.

The **Checked Out** zone lists all of the objects that you currently have checked out. Clicking on an object listed in this zone will take you to the page for that object. The zone is collapsed if you have no objects checked out.

See Revision Control Portal for more information about Check In, Force Check In, and Check Out one or more records simultaneously.

Checking Out an Object

If an entity's maintenance object is configured for revision control, you must check out the entity in order to change it. Go to the object you want to work on and click **Check Out** in the Revision Control sidebar zone.

The following points highlight behavior related to this functionality:

- When you create a record for a maintenance object that is managed with revision control, the system automatically associates the new record with a revision control in Checked Out status.

Copyright © 2026, Oracle and/or its affiliates.

- When you update an object governed by revision control, if you forget to check it out first, a dialog box informs you that the object is under revision control. You can select **OK** to check out the object and save your changes, or **Cancel** to stop the update.
- If another user has the object checked out, you will not be able to make changes.

> **Note**
>
> The system also supports Mass Check Out from the Revision Control search portal.

Checking In an Object

Once you are finished with changes, you should check in the object. This captures the latest revision and allows others to check it out.

While viewing the object, click **Check In** in the Revision Control sidebar zone. You are prompted for an **External Reference** and **Detailed Description**. It is recommended to put meaningful information in both of these fields to allow for future users that review changes to this object have a good understanding of the reason for the change.

The **Keep Checked Out** option is useful if you are checking in a version of the object that is stable but allows you to keep it checked out for further changes. The latest revision is one available for you to restore to later if you want to back out newer changes.

If you are using Bundling to manage copying objects to another environment, use the Add to Bundle option to automatically include this object in a current open bundle.

> **Note**
>
> The system also supports Mass Check In from the Revision Control search portal.

Reverting Changes

Reverting changes will undo any changes you made since you checked out an object.

While viewing the object, click **Revert** in the Revision Control sidebar zone. Once your change is reverted, the object is available to be checked out by another user.

> **Note**
>
> To restore the version of the object to a different revision than the most recent checked in revision, drill into the object's revision history. Refer to Revision Control Portal for more information.

> **Note**
>
> Any change to the object increments the version number. If you make changes and then revert your changes, internally the system updates the object to match the previously checked in revision. The version number, however, is incremented. It is not restored to the version number of the previous revision.

Copyright © 2026, Oracle and/or its affiliates.

Comparing Versions

When viewing an object that is governed by revision control, a link on the Revision Control sidebar zone allows you to **Compare to Previous Version**. The comparison works as follows:

- When viewing an object that is currently checked out, clicking the link compares the current view of the object in the database with the snapshot view of the object from its most recent checked in revision.
- When viewing an object that is checked in, when clicking the link, the behavior differs based on whether or not the current view of the object matches the most recent revision.
  - If they match, you are shown the comparison between the most recent check in to the check in before that.
  - If they do not match, it means that some process changed the object outside of revisions. In that case, you are shown the difference between the current view of the object and the most recent revision.

> **Note**
>
> The revision history view of an object in the Revision Control Portal allows you to select any two revisions to compare.

Forcing a Check In or Restore

If an object is checked out by another user and that person is not available to check it in or revert it, you may force a check in or force a restore (which is equivalent to a Revert action).

While viewing the object, click **Force Check In** in the Revision Control sidebar zone to keep the latest updates made by the checked out user. Click **Force Restore** in the Revision Control sidebar zone to discard the changes made by the checked out user and revert the object to the previously checked in revision.

> **Note**
>
> A user can only perform the Force Check In or Force Restore actions if they have security for the **Force Check In** and **Restore** access modes, respectively for the Object Revision BO application service (**F1-OBJREVBOAS**).

> **Note**
>
> The system also supports Mass Force Check In from the Revision Control search portal.

Deleting an Object

If revision control is turned on for an object, you must use the **Revision Control** zone to delete it. The object must be checked in before it can be deleted.

While viewing the checked in object, click **Delete** in the Revision Control sidebar zone. You are prompted for an **External Reference** and **Detailed Description**. Provide this information and then click OK. The system creates a revision record before the object is deleted so that the deleted object can be restored.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If the object is maintained on a legacy UI page, you remain on the page with a cleared input form. If the object is maintained on a portal page, after deleting an object, you remain on the maintenance portal page, which should now be blank, which is unusual. Unlike deleting an object using the record actions on the record's maintenance page, deleting from the sidebar zone lacks the metadata to bring the user to a better portal after deletion, such as the related query portal for the deleted object.

Revision Control Portal

The **Revision History** portal lists the revision control history for a given object.

You can navigate to the **Revision History** portal from either a link in the **Revision Control** sidebar zone from that object's maintenance page or by going to **Revision Control** portal through the **Admin Menu** and using the search function to find the object whose history you want to view.

Use the broadcast icon to view the details of a given entry in the revision history.

To view the differences between two revision entries, click any two entries and then use the **Compare** button to see the differences.

You can restore a previous version of the object by clicking **Restore** in the row for the version that you want to restore. You would also use this option if an object was deleted and you want to reinstate it to a specific revision from before it was deleted.

See Working with Revision Control Zones for more information about tasks that can be performed through the Revision Control sidebar zone.

The following sections highlight other actions that are supported using the Revision Control Search portal besides searching for a specific revision. Navigate to this portal via **Admin Menu**, and then **Implementation Tools**, and then **Revision Control.**

Mass Check In

To perform a mass check in of several objects that you have checked out, choose **Check In** from the Search By dropdown on Revision Control Search.

Use the filters to narrow down the list of objects that you have checked out, if desired.

Select the desired entries and click **Check In**.

Mass Force Check In

If there are entities that are currently checked out by other users and they are not able to check them in, you can do a mass Force Check In of those objects. Choose **Force Check In** from the Search By dropdown.

Use the filters, including the Checked Out By User filter, to narrow down the list of objects to force check in on.

Select the desired entries and click **Force Check In**.

Mass Check Out

If you plan to work on updates to several objects, you can opt to proactively check out the objects en masse. Choose **Check Out** from the Search By dropdown.

Copyright © 2026, Oracle and/or its affiliates.

Use the filters to narrow down the list of objects to check out. Note that only objects that are currently checked in are available to check out.

Select the desired entries and click **Check Out**.

Information Lifecycle Management

Information Lifecycle Management (ILM) is designed to address data management issues, with a combination of processes and policies so that the appropriate solution can be applied to each phase of the data's lifecycle.

Data lifecycle typically refers to the fact that the most recent data is active in the system. As time progresses, the same data becomes old and unused. Older data becomes overhead to the application not only in terms of storage, but also in terms of performance. This older data's impact can be reduced by using advanced compression techniques, and can be put into slower and cheaper storage media. Depending on how often it's accessed, it can be removed from the system to make an overall savings of cost and performance. The target tables for ILM are transactional tables that have the potential to grow and become voluminous over time.

- The Approach to Implementing Information Lifecycle Management
- Enabling ILM for Supported Maintenance Objects
- Ongoing ILM Tasks
- Archived Foreign Keys

The Approach to Implementing Information Lifecycle Management

This section describes the product approach to implementing ILM for its maintenance objects (MOs).

> **Note**
>
> The term archiving is used to cover any of the possible steps an implementation may take in their data management strategy, including compression, moving to cheaper storage, and removing the data altogether.

Age is the starting point of the ILM product implementation for some of its high volume data. In general "old" records are considered eligible to be archived. In the product solution, maintenance objects (MOs) that are enabled for ILM have an ILM Date on the primary table and the date is typically set to the record's creation date. (An MO may have special business rules for setting this date, in which case, a different date may be used to set the initial ILM Date). For implementations that want to use ILM to manage the records in the MO, the ILM date is used for defining partitions for the primary table.

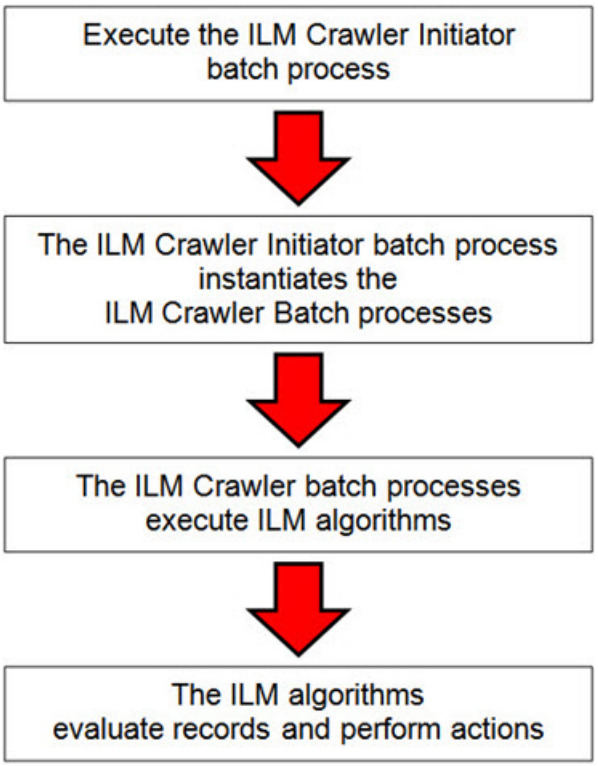
There are cases where a record's age is not the only factor in determining whether or not it is eligible to be archived. There may be some MOs where an old record is still 'in progress' or 'active' and should not be archived. There may be other MOs where certain records should never be archived. To evaluate archive eligibility using information other than the ILM Date, the ILM enabled MOs include an ILM Archive switch that is used to explicitly mark records that have been evaluated and should be archived. This allows DBAs to monitor partitions based on age and the value of this switch to evaluate data that may be ready to be archived.

Evaluating records to determine their archive eligibility should still occur on "old" records. The expectation is that a large percentage of the old records will be eligible for archiving. The small

Copyright © 2026, Oracle and/or its affiliates.

number that may be ineligible could be updated with a more recent ILM date. This may cause the records to move into a different partition and can delay any further evaluation of those records until more time has passed.

For each MO enabled for ILM, the product provides a batch process to review "old" records and an ILM eligibility algorithm that contains business logic to evaluate the record and mark it eligible for archiving or not. The following sections provide more information about the batch process and algorithm functionality.



- Batch Processes
- Eligibility Algorithm

Batch Processes

There are two main types of batch processes that manage data for ILM in the application: ILM Crawler Initiator and individual ILM Crawlers (one for each MO that is configured for ILM).

- **ILM Crawler Initiator**: (`F1-ILMIN`) - The ILM Crawler Initiator is a *driver* batch process that starts the individual ILM Crawler batch control as defined by the MO's options.

  Restartable: In case of server failure, the ILM Crawler Initiator process can be restarted, which will also restart the ILM Crawler processes.
- **ILM Crawler**: Each maintenance object that is configured for ILM defines an ILM Crawler. These are *child* batch processes that can be started either by the ILM Crawler Initiator or by a standalone batch submission.

The ILM Crawler batch process selects records whose retention period has elapsed and invokes the MO's ILM eligibility algorithm to determine if the record is ready to be archived or not. The ILM eligibility algorithm is responsible for setting the record's ILM archive switch to 'Y' and updating the ILM date, if necessary.

Copyright © 2026, Oracle and/or its affiliates.

The retention period defines the period that records are considered active. It spans the system date and cutoff date (calculated as system date - retention days).

The retention days of an MO is derived as follows:

- If the ILM Retention Days MO option is defined, that is used.
- Otherwise, the Default Retention Days from the ILM Master Configuration record is used.

An error is issued if no retention period is found.

The crawler calculates the cutoff date and selects all records whose ILM archive switch is 'N' and whose ILM date is prior to the cutoff date. Each record returned is subject to ILM eligibility.

If the Override Cutoff Date parameter is supplied, it will be used instead of the calculated cutoff date. An error is issued if the override cutoff date is later than the calculated cutoff date. This parameter is useful if an object has many years of historic data eligible for archiving. Setting this parameter allows for widening the retention period and therefore limiting the process to a shorter period for initial processing.

> **Note**
>
> ILM Crawler batch processes are designed not to interfere with current online or batch processing. Because of this, these batch processes can run throughout the day.

> **Note**
>
> Before passing the cut-off date to the algorithm, the ILM crawler ensures that the number of days calculated (System Date – override cut-off date) is more than the retention period specified in the MO option or the Master Configuration. If the number of days calculated **is less than** the retention period specified on the MO option or the Master Configuration, then it throws an error.

Eligibility Algorithm

Algorithms are triggered by the ILM batch crawler for the maintenance object. The key responsibility of the ILM algorithm is to determine whether a record can be marked as ready to be archived or not. If a record is determined to be ready for archive, the algorithm should set the ILM Archive switch to Y. If not, the algorithm leaves the switch set to N and may decide to update the ILM Date to something more recent (like the System Date) to ensure that the record does not get evaluated again until the future.

This algorithm is plugged into the Maintenance Object — Algorithm collection.

Oracle Utilities Application Framework provides the algorithm **ILM Eligibility Based on Status** (`F1-ILMELIG`) to support the ILM batch crawler. Refer to the algorithm type description for details about how this algorithm works. If a maintenance object has special business rules that are evaluated to determine the eligibility for ILM, a custom algorithm can be created and applied by the implementation team.

Enabling ILM for Supported Maintenance Objects

In order to enable ILM for one or more maintenance objects, several steps are needed in both the configuration and in the database. This section describes some configuration enabled by

Copyright © 2026, Oracle and/or its affiliates.

default and some steps that must be taken in order to fully implement ILM. While some configuration is enabled by default, it will not be used unless ILM is fully configured.

Managing a maintenance object's data for ILM involves the following aspects:

- Determining which records are eligible for archiving and marking them as such. Depending on the entity, this step is implemented using one of this methods:
  - **Configurable.** This option relies on a configurable eligibility algorithm that is processed in batch periodically.
  - **Non-configurable batch.** This option uses a specific batch process that embeds non-configurable eligibility rules as part of its logic for performance reasons.
  - **Set at creation time.** Records in very high volume tables that rarely change are marked as eligible for archival at creation time for performance reasons. For example, measurement data, some snapshot tables, etc.
- Partitioning the entity's tables and archiving old partitions as needed.

Each maintenance object that follows the configurable option has the following provided out of the box:

- **Special Table Columns**: Maintenance objects that support ILM include two specific columns: ILM Archive Switch (`ILM_ARCH_SW`) and ILM Date (`ILM_DT`).
- **Crawler Batch Process**: A "crawler" batch process is provided for each maintenance object that supports ILM and it is plugged into the MO as an option. Refer to Batch Processes for more information.
- **ILM Eligibility Algorithm**: Each maintenance object that is configured for ILM defines an eligibility algorithm that executes the logic to set the ILM Archive switch appropriately. This is plugged in to the MO algorithm collection.

If an implementation decides to implement ILM, there are steps that need to be followed, which are highlighted below.

Create the Master Configuration Record

The first step when enabling ILM is to create the **ILM Configuration** master configuration record.

The master configuration for ILM Configuration defines global parameters for all ILM eligible maintenance objects. For example, the Default Retention Period. In addition, your product may implement additional configuration. Refer to the embedded help for specific details about the information supported for your product's ILM configuration.

In addition, the user interface for this master configuration record displays summary information about all the maintenance objects that are configured to use ILM.

Confirm the Maintenance Objects to Enable

In viewing the list of maintenance objects that support ILM in the ILM master configuration page, your implementation may choose to enable ILM for only a subset of the supported maintenance objects. For example, some of the maintenance objects may not be relevant for your implementation. Or perhaps, the functionality provided by the maintenance object is used, but your implementation does not expect a high volume of data.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Customizing the list of maintenance objects managed by ILM is not supported in a cloud installation.

For each maintenance object that your implementation has confirmed for ILM, the following steps should be taken:

- Determine if the maintenance object should have a different number of default retention days than the system wide value defined on the master configuration. If so, use the MO option **ILM Retention Period in Days** to enter an override option for this maintenance object.
- When applicable, review the functionality of the ILM Eligibility algorithm provided by the product for this maintenance object. Each algorithm may support additional configuration based on business needs. If your organization has special business rules that aren't satisfied by the algorithm provided by the product, a custom algorithm may be provided to override the base algorithm.

For each maintenance object that follows the configurable option and that your implementation does not want to enable for ILM, inactivate the eligibility algorithm. This will ensure that the ILM Crawler Initiator background process does not submit the crawler batch job for the maintenance object in question.

- Go to the Maintenance Object - Algorithm tab for each maintenance object and inactivate the **ILM Eligibility** algorithm.

Database Administrator Tasks

In order to implement ILM for each of the maintenance objects determined above, your database administrator must perform several steps in the database for the tables related to each MO. The following points are a summary of those steps. More detail can be found in the Information Lifecycle Management section of your product's *Database Administration Guide*.

- **Initializing ILM Date**: Your existing tables that are enabled for ILM may not have the ILM Date and ILM Archive switch initialized on all existing records. When choosing to enable ILM, a first step is to initialize this data based on recommendations provided in the *Database Administration Guide*.
- **Referential Integrity**: The recommended partitioning strategy for child tables in a maintenance object is referential partitioning. In order to implement this, database referential integrity features must be enabled.
- **Partitioning**: This provides a way in which the data can segregate into multiple table partitions and will help in better management of the lifecycle of the data.

Schedule the ILM Crawler Initiator

The final step of enabling the system for ILM is to schedule the ILM crawler initiator `F1-ILMIN` regularly based on your implementation's need. It is recommended to only schedule this batch process once all the required database activities are complete.

Ongoing ILM Tasks

For an environment where ILM is enabled, besides the periodic execution of the ILM crawler batch processes to review and mark records, your database administrator has ongoing tasks.

Copyright © 2026, Oracle and/or its affiliates.

The DBA reviews and maintains partitions and identifies partitions that may warrant some type of archiving step. The Information Lifecycle Management section of your product's *Database Administration Guide* provides more information for your DBA.

Archived Foreign Keys

If your DBA chooses to archive a partition, there may be records in the system that refer to one of the archived records as a foreign key.

When a user attempts to view a record using a hyperlink or drill down mechanism, if the implementation of the navigation uses FK Reference functionality, the system will first check if the record exists. If not, it will display a message to the user indicating that the record has been archived.

Configuration Tools

This section describes tools to facilitate detailed business configuration. The configuration tools allow you to extend both the front-end user interface as well as create and define specialized back-end services.

- Business Objects
- Data Areas
- Business Services
- User Interface (UI) Options
- Process Flows
- Action Method
- Algorithms
- Script Options

Understanding Business Objects

The topics in this section describe background topics relevant to business objects.

- What Is A Business Object?
- Business Object Inheritance
- Each Business Object Can Have A Different Lifecycle
- BO Algorithm Execution Summary
- Granting Access To Business Objects

What Is A Business Object?

A business object (BO) is a powerful tool used throughout the system. For many maintenance objects, a BO is a key attribute of the record used to define the data it captures, its user interface behavior and its business rules. Some business objects support the definition of a lifecycle, capturing different states that a record may go through, allowing for different business rules to be executed along the way. This type of business object is considered the "identifying" or "governing" business object. We will see later that other types of BOs exist that are different from the "identifying" business object.

The use of business objects allows for extensibility and customization of product delivered maintenance objects. There are many options to adjust the behavior of base delivered business objects. In addition, implementations may introduce their own business objects if the base product delivered objects do not meet their business needs.

> **Note**
>
> Not all maintenance objects in the product support business objects as a "identifying" or "governing" tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

- A Business Object Has a Schema
- A Business Object May Define Business Rules
- A Business Object Defines its User Interface
- A Business Object Defines Options
- Invoking A Business Object
- Determine the Identifying BO
- Base Business Objects

A Business Object Has a Schema

A business object has elements. The elements are a logical view of fields and columns in one of the maintenance object's tables. The structure of a business object is defined using an XML schema. The main purpose of the schema is to identify all the elements from the maintenance object that are included in the business object and map them to the corresponding maintenance object fields. Every element in the BO schema must be stored somewhere in the maintenance object. The BO may not define elements that are derived.

Copyright © 2026, Oracle and/or its affiliates.

When defining elements for the primary table or the language table (for an administrative object) there is no need to define the name of the physical table in the schema. The system infers this information. The following is a snippet of a schema:

```
<schema>
    <migrationPlan mapField="MIGR_PLAN_CD" suppress="true" isPrimeKey="true"/>
    <bo mapField="BUS_OBJ_CD" fkRef="F1-BUSOB"/>
    <customizationOwner mapField="OWNER_FLG" suppress="input"/>
    <version mapField="VERSION" suppress="true"/>
    <description mapField="DESCR"/>
    <longDescription mapField="DESCRLONG"/>
  â€¦
```

Many maintenance objects have child table collections (e.g., a collection of names for a person, or a collection of persons on an account). Depending on the requirements, the business object may define the full collection such that the user will maintain the information in a grid. However, the schema also supports "flattening" records in a child table so that they can be treated as if they were singular elements. The following are examples of each:

Example of a child table. This is a snippet of the Instructions collection on the migration plan business object. You can see that the list attribute defines the child table and all elements within it map to the appropriate column in that table.

```
   <migrationPlanInstruction type="list" mapChild="F1_MIGR_PLAN_INSTR">
         <migrationPlan mapField="MIGR_PLAN_CD" suppress="true"/>
         <sequence mapField="PLAN_INSTR_SEQ" suppress="true"/>
         <instructionSequence mapField="INSTR_SEQ"/>
         <instructionType mapField="INSTR_TYPE_FLG"/>
         <parentInstructionSequence mapField="PARENT_INSTR_SEQ"/>
         <businessObject mapField="BUS_OBJ_CD" fkRef="F1-BOMO"/>
...
```

Example of a simple "flattened" field. The business object for Status Reason includes an element called Usage, which maps to a pre-defined characteristic of type **F1-SRUSG**. The "row" defines which child table is being flattened and the attributes of the row in that child that uniquely identify it.

```
    <usage mdField="STATUS_RSN_USAGE" mapField="CHAR_VAL">
        <row mapChild="F1_BUS_OBJ_STATUS_RSN_CHAR">
            <CHAR_TYPE_CD is="F1-SRUSG"/>
            <SEQ_NUM is="1"/>
        </row>
    </usage>
```

Example of a "flattened row". This business object for Account includes a single row for the Person collection where only the "financially responsible, main" customer is defined. The "accountPerson" attribute defines one field from that row (the Person Id) and includes the "˜flattening" criteria in the "row" information. In addition, a second field from that same row ("accountRelType") is defined. Instead of having to repeat the flattening criteria, the "rowRef" attribute identifies the element that includes the flattening.

```
    <accountPerson mapField="PER_ID">
        <row mapChild="CI_ACCT_PER">
            <MAIN_CUST_SW is="true"/>
```

Copyright © 2026, Oracle and/or its affiliates.

```
            <FIN_RESP_SW default="true"/>
          </row>
      </accountPerson>
      <accountRelType mapField="ACCT_REL_TYPE_CD" rowRef="accountPerson"
dataType="string"/>
```

Example of a "flattened list". The business object for Tax Bill Type includes an list of valid algorithms for "bill completion". The Sequence and the Algorithm are presented in a list. The list element identifies the child table and the "˜rowFilter" identifies the information about the list that is common.

```
       <taxBillCompletion type="list" mapChild="C1_TAX_BILL_TYPE_ALG">
         <rowFilter suppress="true" private="true">
             <TAX_BILL_TYPE_SEVT_FLG is="C1BC"/>
         </rowFilter>
         <sequence mapField="SEQ_NUM"/>
         <algorithm mapField="ALG_CD" fkRef="F1-ALG"/>
     </taxBillCompletion>
```

In addition, many maintenance objects support an XML structure field within the entity. These fields may be of data type CLOB or XML. One or more business object elements may be mapped to the MO's XML structure field. These elements may be defined in different logical places in the business object schema based on what makes sense for the business rules. When updating the MO, the system builds a type of XML document that includes all the elements mapped to the XML structure and stores it in one column. The following is an example of elements mapped to an XML column:

```
        <filePath mdField="F1_FILE_PATH" mapXML="MST_CONFIG_DATA"
required="true"/>
        <characterEncoding mdField="F1_CHAR_ENCODING"
mapXML="MST_CONFIG_DATA"/>
```

> **Note**
>
> If the MO's XML structure field is of the data type XML, the database will allow searching for records based on that data, assuming appropriate indexes are defined. If the MO's XML structure field is of the data type CLOB, indexing or joining to elements in this column via an SQL statement is not typically supported. Note that most MOs are currently using the CLOB data type for the XML structure column, if provided.

Some business objects may have child tables that allow data to be stored in an XML structure field. The schema language supports defining elements from those fields in your schema as well.

Besides including information about the physical "mapping" of the element to its appropriate table / field location in the maintenance object, the schema supports additional syntax to provide the ability to define basic validation and data manipulation rules, including:

- Identifying the primary key of the record or the primary key of the a row in a list.
- Identifying which elements are required when adding or changing a record.
- Default values when no data is supplied on an Add.

Copyright © 2026, Oracle and/or its affiliates.

- For elements that are lookup values, the lookup may be specified to validate that the value of the element is a valid lookup value.
- For elements that are foreign keys to another table, the FK Reference may be specified to validate the data.

The system will check the validity of the data based on the schema definition obviating the need for any special algorithm to check this validation.

In addition, the schema language may include some attributes that are used to auto-render the view of the record on the user interface, such as the `suppress` attribute. Refer to BO Defines its User Interface for more information.

> **Note**
>
> Refer to Schema Syntax for the complete list of the XML nodes and attributes available to you when you construct a schema.

A business object's schema may include a subset of the fields and tables defined in the maintenance object. There are two reasons for this:

- The fields or tables may not be applicable to the type of record the business object is governing. For example, a field that is specific to gas may not be included on a Device business object that is specific to electric meters.
- The information is not maintained through the business object, but rather maintained separately. For example, many BO based maintenance objects include a Log table. The records in the log table are typically not included the BO because they are viewed and maintained separately from the business object.

A Business Object May Define Business Rules

A business object may define business rules that govern the behavior of entities of this type. The following table describes supported system events that can be associated with such rules.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Audit	Optional	Algorithms of this type may be used to audit certain changes made to business object instances. The system hands over to the algorithms a summary of all the elements that were changed throughout a specific call to update an object. For each element its original value before the change as well as its new value are provided. It is the responsibility of such algorithms to log the changes if and where appropriate, for example as a log entry in the maintenance object's log table or an entry in the business event log. These plug-ins are executed after all the post-processing rules are executed. The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information. By default all elements of the business object are subject to auditing. You can however mark certain elements to be excluded from the auditing process using the **noAudit** schema attribute. Marking an element as not auditable will prevent it from ever appearing as a changed element in the business object's audit plug-in spot. In addition, if the only elements that changed in a BO are ones marked to not audit, the audit algorithm is not even called. Refer to Schema Syntax for more information on this attribute.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
Information	Optional	We use the term "Business Object Information" to describe the basic information that appears throughout the system to describe an entity defined by the business object. The data that appears in this information description is constructed using this algorithm. The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number found on the business object closest to the current business object in the inheritance hierarchy. Refer to Business Object inheritance for more information.
`Post-Processing`	Optional	Algorithms of this type may be used to perform additional business logic after a business object instance has been processed. For example, such an algorithm may be used to create a To Do Entry or add a log record as part of the business object logical transaction. These plug-ins are executed after all the validation rules are executed. The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.

Copyright © 2026, Oracle and/or its affiliates.

System Event	Optional / Required	Description
`Pre-Processing`	Optional	Algorithms of this type further populates a request to maintain a business object instance right before it is processed. Such algorithm may be used to "massage" a business object's elements prior to any maintenance object processing. For example, although simple element-level defaulting is supported by schema attributes. you may use this type of algorithm to default element values that are more sophisticated. The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.
Validation	Optional	Algorithms of this type may be used to validate a business object instance when added, updated or deleted. Simple element-level validation is supported by schema attributes. Note that element-level validation is executed before any maintenance object processing. For more sophisticated rules you create validation algorithms and associate them with your business object. BO validation algorithms are only executed after "core validation" held in the MO is passed. The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.

The system applies business object rules (schema based and algorithms) whenever a business object instance is added, changed or deleted. This is only possible when the call is made via the maintenance object service. For example, when made via business object interaction ("invoke BO"), the MO's maintenance page or inbound web services that reference the BO. In addition the system must be able to determine the identifying business object associated with the actual object being processed. If the business object cannot be determined for a maintenance object instance business object rules are not applied.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Pre-Processing is special.** The pre-processing algorithm plug-in spot is unique in that it only applies during a BO interaction. It is executed prior to any maintenance object processing. It means that when performing add, change or delete via the maintenance object service, the pre-processing plug-in is not executed.

> **Caution**
>
> Direct entity updates bypass business rules! As mentioned above, it is the maintenance object service layer that applies business object rules. Processes that directly update entities not via the maintenance object service bypass any business object rules you may have configured.

> **NOT_SUPPORTED**
>
> Refer to BO Algorithm Execution Order for a summary of when these algorithms are executed with respect to lifecycle algorithms.

The plug-in spots described above are available for all business objects and they are executed by the system when processing adds or updates to the business object. It is possible for a specific maintenance object to define a special plug-in spot for business objects of that MO. When this happens, the maintenance object identifies the special algorithm entity lookup value as an MO option: **Valid BO System Event**, causing the BO Algorithm collection to include that system event in its list.

A Business Object Defines its User Interface

One of the responsibilities of an identifying business object is to define its user interface rules for viewing and maintenance of its record. The standard implementation for maintaining a business object is that a maintenance portal is used to display a record. This portal includes a "map" zone that displays the information about the business object. To add or make changes to a record, the user clicks a button that launches a maintenance BPA script which displays a maintenance "map".

The display and maintenance "maps" are driven by the business object.

- **Schema based UI.** This is the preferred option. The BO's schema definition and UI Hints define user interface behavior that results in generated HTML. The schema language includes some basic display attributes such as **label** and **suppress**. UI hints provide many additional tags and elements that allow dynamic generation of formatted UI Maps. For more complex behavior in the user interface, for example where javascript is needed, UI map fragments may be defined within the schema via UI hints. In this way only complex UI behavior warrants small snippets of javascript and HTML. However the rendering of standard fields can be dynamically rendered. UI map fragments also allow for derived fields to be included in the user interface.
- **Explicit UI map.** The BO may rarely define a full UI map where all the information is displayed based on the map's HTML. Note that for a child BO, the maps may be inherited by a parent BO (or any BO "up the chain"). This technique is less flexible for describing a business object and as such is mainly supported for backward compatibility.

Copyright © 2026, Oracle and/or its affiliates.

A business object schema may include data areas for segments of its schema definition to allow for reusable components. In this case the data area would also include schema attributes and UI hints for the elements that it is including.

> **Note**
>
> Refer to UI Hint Syntax for detailed information about the supported syntax.

As mentioned in Business Object Inheritance, schemas are not inherited on a child business object. As such, when using UI hints for automatic UI rendering, the child BO must define the full schema with all the definitions. A good business object hierarchy will be designed for reuse meaning that the child BO will include the parent BO schema or alternatively, the BO schemas will include reusable data areas.

By default, the input form used to add or update an entity is presented in the large drawer panel. If the small or medium drawer panel fits better to display this form, you can configure the **Maintenance Drawer Size** BO option accordingly.

A Business Object Defines Options

A business object may be associated with configuration options that control specific features. For example, the scripts used to maintain and display a business object are defined as options. Refer to the detailed description of each option type for more information on the functionality it controls.

> **Note**
>
> **You can add new options types**. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do that, add your new values to the customizable lookup field `BUS_OBJ_OPT_FLG`. If you add a new option type for a business option, you must update its maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Option Type** maintenance object option.

Some options may be defined for a specific lifecycle status. For example, marking a status specific base algorithm as inactive is defined as an option on that staus definition record.

> **Note**
>
> **You can add new options types**. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do that, add your new values to the customizable lookup field `BO_OPT_FLG`. If you add a new option type for a status, you must update the business object's maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Status Option Type** maintenance object option.

Copyright © 2026, Oracle and/or its affiliates.

Invoking A Business Object

We have talked about defining a business object. This section describes how business objects are used throughout the system to view, add and update records.

- Various parameters for zones that are used to display data in the system include support for retrieving data by referencing a business object. The zone code will "invoke" the BO, meaning that the record will be retrieved using the referenced BO.
- The system's scripting language includes a step type to "invoke BO". This allows for BPA scripts, service scripts and plug-in scripts to retrieve information and add or update records using BO interaction.
- Inbound web services may reference a business object in its operations collection. This allows external systems to add or update records in our product via web service interaction.

Often when configuring a zone or writing a script, the BO to use in the "invoke BO" statement should be the identifying BO of the record. As such, often the script will include steps prior to the "invoke BO" step to "determine the identifying BO of the record" and once the identifying BO is found, the script step will invoke that BO. Note that zones and inbound web services reference a BO directly. In each case, if the BO to use should be dynamic, then the zone / inbound web service should reference a service script that can perform the steps to identify the BO and then invoke that BO.

It should be noted however that the BO used in an "invoke BO" statement (or referenced in an inbound web service) **does not have to match** the identifying BO for the record. Here are some examples of where this may be true:

- A script may only require a subset of elements for a record and not the entire record. In this case, it is better for performance purposes to define a special BO (sometimes called a "lite" BO or a "mini" BO) that only defines the needed elements. When the system retrieves the data, it will only access the tables that are included in the BO's schema definition. In addition, if there are no elements that map to an XML structure field, the system will skip any parsing of that column. Similarly, if a script is **updating** a subset of elements on a record, it may be beneficial to use a "mini" BO to do the updates.

  > **Note**
  >
  > Please note the following with respect to using a mini BO. This BO is only used for its schema. This type of BO would not define algorithms or a lifecycle. Because the BO is special, it often should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to Determine the Identifying BO for more information.

- The maintenance object to be added or updated in a script may not support business objects as "identifying BOs". For example, Batch Control maintenance object does not have an identifying BO. However, scripts may still wish to retrieve data (or make updates) to these types of records. An easy way to achieve that goal is to define a business object and use "invoke BO" to access the data.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Not all maintenance objects support being maintained through a business object interaction. This is true in a small number of older objects where the underlying maintenance service includes additional functionality besides simply updating the database tables. These maintenance objects are identified via the MO option **BO Maintenance**, set to N.

- Some functionality may be trying to add or update records for a maintenance object in a 'physical' manner and do not want or need to use the object's identifying BO. Or the MO may not have an identifying BO. For example, revision control takes a snapshot of a record for audit purpose and to be able to restore a previous version. In this case, the system wants to capture a full "physical" view of the record. To do this, a special "physical" BO may be created that includes all (or most of) the columns and the child tables.

> **Note**
>
> Like the mini BO, the physical BO would not define algorithms or a lifecycle and should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to Determine the Identifying BO for more information.

> **Note**
>
> To reiterate, the BO referenced in the "invoke BO" statement or referenced in an inbound web service does not have to match the identifying BO and does not have to be configured to "allow new instances".

Determine the Identifying BO

As mentioned in other topics, the identifying BO is the business object that governs the business rules for a record. This is the business object that the record will be validated against when any additions or changes are made to the record as long as updates are made via the maintenance service. This includes using "invoke BO" for add or update, using inbound web service interaction and for access to the maintenance page service (via an old style fixed page or via a business service).

How does the system determine the identifying BO? An algorithm plugged into the maintenance object (the **Determine BO** plug-in spot) is responsible for this. If the maintenance object is not configured with an algorithm for this plug-in spot, or no BO is found by the algorithm, no BO business rules are applied.

Most maintenance objects in the system capture the record's identifying BO directly on the record. However, it is possible to define the identifying BO somewhere else. For example, there may be some maintenance objects that are master or transaction objects with an associated "type" object where the identifying BO is defined on its "type" object. Note that the standard Determine BO algorithm plugged into most maintenance objects (**F1-STD-DTMBO - Determine Standard Business Object**) checks for these two conditions.

There may also be cases where a single identifying BO is used for all BOs for a given MO. This may be an option used for some older maintenance object created prior to the business object functionality when implementations wish to introduce custom business rules that are

Copyright © 2026, Oracle and/or its affiliates.

common for all records of that MO. The product provides a base algorithm type (**F1–MOBO - Determine Specific Business Object**) that captures the BO as a parameter.

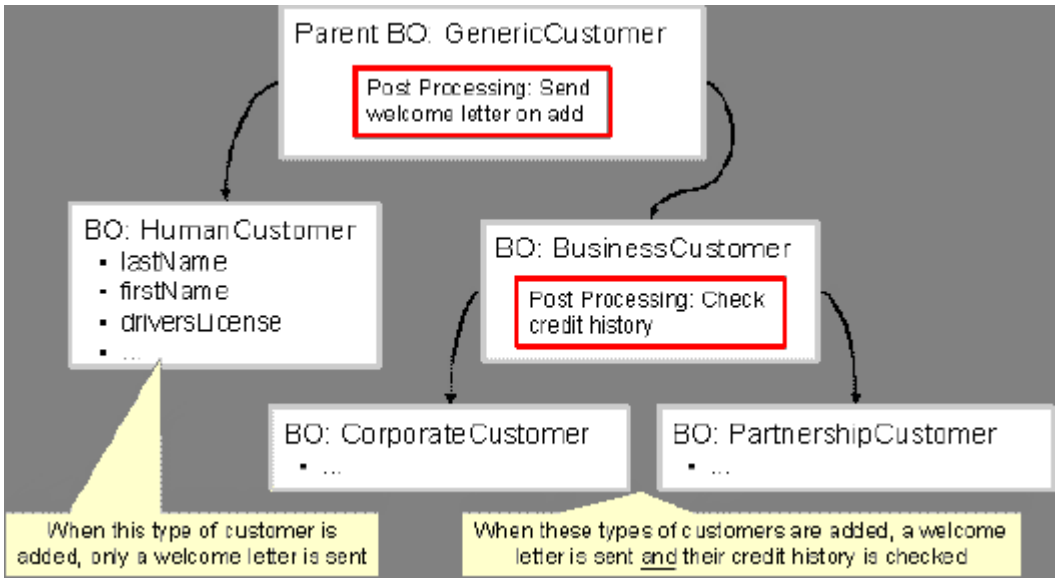
Base Business Objects

For each maintenance object (MO) that supports an "identifying" business object, the type of business object provided by the product depends on the functionality and expected use by implementations. The following are some common patterns.

- There are MOs where the product provides base BOs that implementations may use if applicable for their business rules. In addition, it is expected that implementation will define custom BOs to support their business needs. Good examples of this type of MO are any of the various "rule" MOs. For example, calculation rule in Oracle Utilities Customer Care and Billing or the usage rule in Oracle Utilities Meter Data Management. The product provides business objects for common rules but each implementation could have special rules that they need to implement and will need to create custom business objects.
- There are MOs where the product provides base BOs that supply common behavior for an object. Implementations may find that supplied the business objects match their business requirements and use the BOs as is. It is expected, however that for many implementations, their business rules will require additional elements to be captured or have special rules to apply. In this case the base business objects may be extended. This scenario may apply to 'master' data objects in various products such as the Device or Meter.
- There are MOs where the product may deliver a base BO that is not expected to satisfy most implementations because different jurisdictions or different implementations will typically have their own rules. In this case the base delivered BO can be used as a template or starting point for custom defined BOs. Some examples of this are Rebate Claim in Oracle Utilities Customer Care and Billing.
- There are MOs where the expectation is that every implementation will have different requirements for the type of data to capture and the product will not supply base BOs that can be used as the "identifying" BO. However, it may supply a "parent" BO that defines the lifecycle and many of the business rules that it expects all records to follow. In these scenarios, the implementations will create "child" BOs that will serve as the "identifying" BOs and refer to the base "parent" BO for many of its rules through inheritance. An example of this is the Activity in Oracle Utilities Mobile Workforce Management.
- There are some scenarios where the base product provides business objects and the expectation is that implementations will use the business objects as delivered with little or no customization. This is a case where the system used business objects to implement product functionality, not because there is an expectation that the implementers will extend the functionality, but because the business object model is the favored development tool even for the product. The objects delivered for Content Migration Assistant are an example.

> **Note**
>
> Not all maintenance objects in the product support business objects as a "identifying" or "governing" tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

For all maintenance objects, the base product may provide additional BOs that are not meant to be "identifying" BOs, but instead are provided to support functionality to interact with the MO using the BO as a tool as described in Invoking a BO.



Copyright © 2026, Oracle and/or its affiliates.

- One or more "mini" or "lite" BOs may be supplied for a maintenance object. This may be found when the product has functionality to retrieve a subset of elements for the maintenance object via scripting or via a user interface.
- A "physical" BO may be supplied. This a BO that typically includes all tables and all fields of the maintenance object in there "physical" form. In other words, there is no "flattening" of child tables and any XML structure fields are defined as a single field. Physical BOs are used in system processing where the full record needs to be captured as is. Some functionality that uses a physical BO includes bundling, revision control and the pre-compare algorithm for CMA to adjust data prior to comparing. If there are any maintenance objects that do not have a base supplied physical BO, refer to Creating a Physical Business Object for steps on how to provide one.
- A "bundling add" BO may be supplied. Refer to Recursive Key References for more information as to why this type of BO may be supplied.

Business Object Inheritance

A business object may inherit business rules from another business object by referencing the latter as its parent. A child business object can also have children, and so on. A parent's rules automatically apply to all of its children (no compilation - it's immediate). A child business object can always introduce rules of its own but never remove or bypass an inherited rule.

The following is an illustration of multiple levels of business object inheritance.

Notice how the "Business Customer" business object extends its parent rules to also enforce a credit history check on all types of customers associated with its child business objects.

Most types of business object system events allows for multiple algorithms to be executed. For example, you can have multiple **Validation** algorithms defined for a business object. For these, the system executes all algorithms at all levels in the inheritance chain starting from the highest-level parent business object moving on to lower levels.

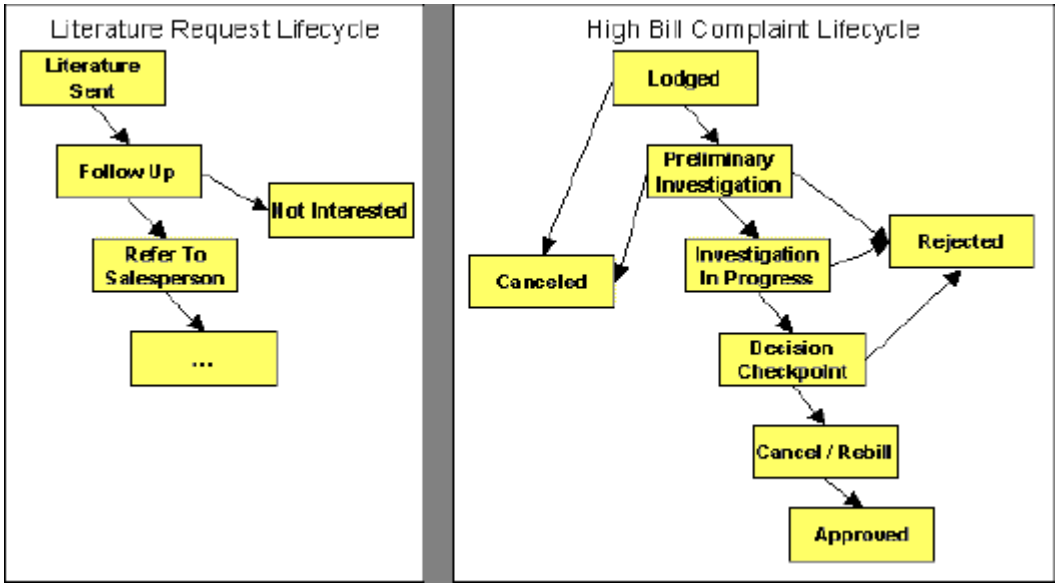
Other types of system events allows for a single algorithm to be executed. For example, you can only have one **Information** algorithm to format the standard description of a business object instance. For these, the system executes the one at the level nearest to the business object currently being processed.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The parent and its children must reference the same maintenance object.

> **Note**
>
> **Data structures are not inherited.** While you can declare schemas on parent business objects, their children will not inherit them. A good practice is to design child business object schemas to **include** their parent business object's schema.

> **Note**
>
> **User interface maps are inherited.** When determining if the business object has a UI map to use for UI rendering, the system looks for display and maintenance maps linked to the BO as options. If the identifying BO does not have maps defined, the system follows “up the chain” of inheritance until it finds a map to use. This allows for a child BO to be used to extend business rules of a parent BO but inherit its user interface behavior. Refer to Business Object Defines its User Interface for more information.



> **Note**
>
> **Use Inheritance Wisely.** While it is intellectually attractive to abstract behavior into parent BOs to avoid redundant logic and simplify maintenance, before doing this weigh the reuse benefits against the cost in transparency, as it is not easy to maintain a complex hierarchy of business objects.

Each Business Object Can Have A Different Lifecycle

Many maintenance objects have a status column that holds the business entity's current state within its lifecycle. Rules that govern lifecycle state transition (what is its initial state, when can it transition to another state, and so on.) and the behavior associated with each state are referred to as lifecycle rules. Older Maintenance Objects, such as To Do Entry, have predefined lifecycles whose rules are governed by the base-package and cannot be changed. The lifecycle of newer Maintenance Objects exists in business object meta-data and as such considered softly defined. This allows you to have completely different lifecycle rules for business objects belonging to the same maintenance object.

Here are examples of two business objects with different lifecycles thast belong to the same maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

The boxes in the above diagram show the potential valid states a business entity of the above business object can be in. The lines between the boxes indicate the state transition rules. These rules govern the states it can move to while in a given state. For example, the above diagram indicates a high bill complaint that's in the **Lodged** state can be either **Canceled** or moved into the **Preliminary Investigation** state.

When you set up a business object, you define both its valid states and the state transition rules, including the label for the Action to display on a button for users that may initiate a transition. For example, the action label to transition to the 'Approved' state could be configured as 'Approve'.

> ⓘ **Note**
>
> The status description and the action label of base delivered values may be overridden by your implementation.

> ⓘ **Note**
>
> A Maintenance Object supports soft lifecycle rules if it is defined with a **Status Field** Maintenance Object option and that field is not a lookup field (which denotes a hard-coded lifecycle).

The topics that follow describe important lifecycle oriented concepts.

- Opening UI Maps Before Entering A State

One Initial State and Multiple Final States

When you set up lifecycle states, you must pick one as the initial state. The initial state is the state assigned to new entities associated with the business object. For example, the above high-bill complaint business object defines an initial state of **Lodged**, whereas the literature request one defines an initial state of **Literature Sent**.

You must also define which statuses are considered to be "final". Typically when an entity reaches a "final" state, its lifecycle is considered complete and no further processing is necessary.

> **Note**
>
> **Allowing An Entity To Be "Reopened".** You can set up your state transition rules to allow a business entity to be "reopened" (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure your business object accordingly.

State-Specific Business Rules

For each state in a business object's lifecycle, you can define the following types of business rules.

System Event	Optional / Required	Description
Enter	Optional	Algorithms of this type apply business rules when a business object instance enters a given state.
Exit	Optional	Algorithms of this type apply business rules when a business object instance exits a given state.
Monitor	Optional	Algorithms of this type monitor a business object instance while in a given state. Typically these are used to auto-transition it to another state.

The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object Inheritance for more information.

> **NOT_SUPPORTED**
>
> Refer to BO Algorithm Execution Order for a summary of when these lifecycle algorithms are executed with respect to BO level algorithms.

Copyright © 2026, Oracle and/or its affiliates.

- Entering A State
- Exiting A State
- Monitor Rules

Entering A State

You can define algorithms that execute before a business entity enters a given state. For example, you could develop an algorithm that requires a cancellation reason before an entity is allowed to enter the **Canceled** state.

You can also incorporate state auto-transitioning logic within this type of algorithms. Refer to auto-transition for more information.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an enter algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

Exiting A State

You can define algorithms that execute when a business entity exists a given state. For example, you could develop an algorithm that clears out error messages when a given entity exits the **Error** state.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an exit algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

Monitor Rules

You can define algorithms to monitor a business entity while it is in a given state. This type of logic is typically used to check if the conditions necessary to transition the entity to another state exist (and, if so, transition it). For example, transition an entity to the **Canceled** state if it's been in the **Error** state too long. Another common use is to perform ancillary work while an entity is in a given state. For example, update statistics held on the object while it's in the **Active** state.

Monitor algorithms are invoked when a business entity first enters a state and periodically after that in batch. You have the option to defer the monitoring of a specific state until a specific monitoring batch job runs. You do so by associating the state with a specific monitoring process. In this case the system will only execute the monitoring rules of this state when that specific batch process runs. This is useful when processing one type of record typically creates another type of record. You may want the processing of the second set of records to be deferred to a later time.

A monitor algorithm can carry out any business logic. In addition it can optionally tell the system to do either of the following:

- Stop monitoring and transition to another state. The system will not call any further monitoring algorithm plugged in on the state and attempt to transition the entity to the requested new state.
- Stop monitoring. Same as above except that no transition takes place. You may want to use this option to prevent transitions while some condition is true.

If none of the above is requested the system keeps executing subsequent monitoring algorithms.

Copyright © 2026, Oracle and/or its affiliates.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for a monitor algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

NOT_SUPPORTED

Refer to Business Object - Lifecycle for more information on how to set up state-specific algorithms.

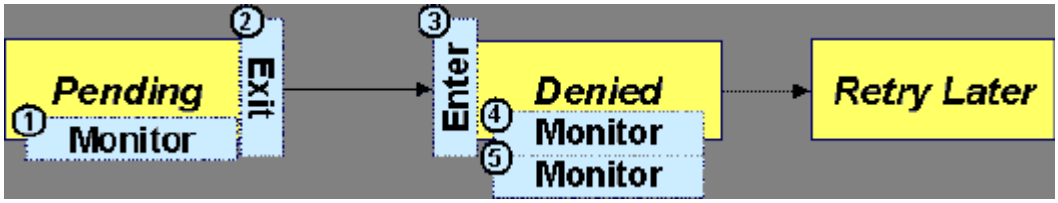
Maintaining Market Contracts

You use the **Market Contract** portal to view and maintain market contracts.

Refer to About Market Contracts for additional functional information.

You can access the portal from the **Main > Market > Market Contract**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:



- **Market Contract**: This zone displays basic information about the market contract.
- **Related Market Awards**: This zone displays a list of market awards related to the market contract.

Auto-Transition

In a single transition from one state to another, the system first executes the **Exit** algorithms of the current state, transitions the entity to the new state, executes the **Enter** algorithms of the new state followed by its **Monitor** algorithms. At this point if a **Monitor** algorithm determines that the entity should be further automatically transitioned to another state the remaining monitoring algorithm defined for the current state are not executed and the system initiates yet another transition cycle.

Notice that an **Enter** algorithm can also tell the system to automatically transition the entity to another state. In this case the remaining **Enter** algorithm as well as all **Monitor** algorithms defined for the current state are not executed.

The following illustration provides an example of an auto-transition chain of events.

In this example a business entity is in a Pending state. While in that state a **Monitor** algorithm determines to auto-transition it to the Denied state. At this point the following takes place:

- No further **Monitor** algorithms of the Pending state are executed
- Pending state **Exit** algorithms are executed
- The system transitions the entity to the Denied state

Copyright © 2026, Oracle and/or its affiliates.

- Denied state **Enter** algorithms are executed. No further auto-transition is requested.
- Denied state **Monitor** algorithms are executed. No further auto-transition is requested.

Keeping An Entity In Its Last Successful State

By default, any error encountered while transitioning a business entity from one state to another rolls back all changes leaving the entity in its original state.

When applicable, the Maintenance Object can be configured to always keep an entity in its last successful state rather than rolling all the way back to the original state. This practice is often referred to as "taking save-points". In case of an error, the entity is rolled back to the last successfully entered state and the error is logged on the maintenance object's log. Notice that with this approach no error is returned to the calling process, the error is just logged.

The logic to properly log the error is in a **Transition Error** Maintenance Object plug-in. The system considers a maintenance object to practice "save-points" when such an algorithm is plugged into it.

Even if the maintenance object practices "save-points", in case of an error the system will not keep an entity in the last successfully entered state if that state is either marked as transitory or one of its **Enter** algorithms has determined that the entity should proceed to a next state. The system will roll back to the first previous state that does not match these conditions.

Monitoring Batch Processes

A monitor batch process may be used to transition a business object into its next state by executing the monitor algorithms associated with the current state of the entity. The use cases for performing the monitor logic in batch are as follows:

- The record may be waiting for something else to occur before transitioning. The monitor algorithm may be coded to determine if the condition is satisfied and initiate the transition then. For example perhaps when entering a state, a field activity is generated and the record should exit the state when the field activity is complete. The monitor algorithm can check the status of the field activity.
- Perhaps a record is added or updated manually and the next step in the BO lifecycle includes a large amount of processing such that the logic should occur in batch. In this case the BO status is configured with an explicit reference to a batch control (referred to as "deferred"), which indicates to the system that the monitor algorithms should not be performed automatically (but should be deferred to batch). Later when the batch process runs, it selects all the records to process to progress the records.

> **Note**
>
> When a status includes a deferred batch control, it may also be configured to allow a user to manually transition the record to the next state rather than waiting for batch. When a user manually transitions a record that includes monitor algorithms, those algorithms are not executed.

- Perhaps a record is added or updated in batch, but a subsequent step in the overall lifecycle should be processed later. This may be accomplished by ensuring that the batch control linked to the state to process later does not match the batch control that added or updated the record.
- Monitor processes may also be used to periodically perform some logic related to the record without actually transitioning the record.

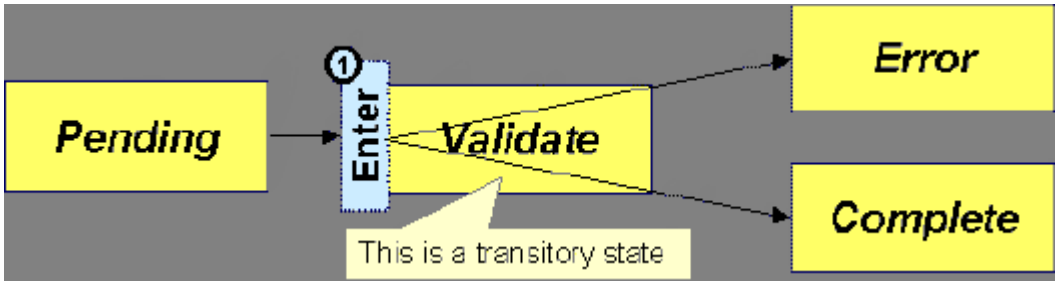
Copyright © 2026, Oracle and/or its affiliates.

Note that only the parent business object may refer to a deferred monitor batch process. However, any business object in the "inheritance" chain may be configured with monitor algorithms, which will all be executed.

The base package provides a periodic monitoring batch process for each maintenance object that supports a configurable BO lifecycle. The process periodically executes the monitoring algorithms associated with the current state of an entity, excluding states explicitly referencing a deferred monitoring batch process that is for a different batch control.

A deferred monitoring process selects records whose current state references this particular batch control as their monitor process. Deferred monitor process is only needed when an object has different use cases for monitoring the same type of records with different schedules. In this case only one periodic monitor batch should be configured. Other monitors should be configured to restrict by batch control so that there is no overlap in processing.

> **Note**
>
> **MO option configuration**. The maintenance object includes options to indicate the batch controls delivered for periodic and deferred monitor batch controls.



Your business rules will dictate the execution frequency of each monitoring process and the order in which they should be scheduled. Refer to Monitor Background Processes in the background process chapter for more information about the parameters supported for this type of batch process.

> **Note**
>
> **Updates to the business object.** When the monitor algorithms indicate that the business object should transition, the monitor batch processes are responsible for ensuring the business object is transitioned appropriately and that the appropriate exit, enter and monitor algorithms are executed. Please note that the business object is not updated using a call to the maintenance object service and therefore by default the business rules plugged in to the business object are not executed. However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the "force post processing" indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

Transitory States

You can define a state as **Transitory** if you do not wish the business entity to ever exist in that particular state.

The following illustrates a lifecycle with a transitory Validate state.

Copyright © 2026, Oracle and/or its affiliates.

In this example, the business entity is saved still not validated in the Pending state. At some point, the user is ready to submit the entity for validation and transitions it into a transitory state Validate whose **Enter** rules contain the validation logic. The responsibility of the transitory state's **Enter** algorithms is to decide if the entity is valid or in error and then transitions it into the appropriate final state. In this scenario, you may not ever want the business entity to exist in the Validate state.

Let's also assume that the maintenance object in this example is practicing "save-points" and requires the entity to be kept in its last successful state. If an error were to occur during the transition from **Validate** to the next state, the system would roll back the entity back to Pending, and not Validate even though the entity has successfully entered the Validate state. Refer to the Auto Transition section for more information.

State Transitions Are Audited

Most Maintenance Objects that support soft lifecycle definition also have a log to hold significant events throughout a business entity's lifecycle. For example, log entries are created to record:

- When the business entity is created (and who created it)
- When its status changes (and who changed it)
- If a transition error occurred (and the error message)
- References to other objects created throughout the entity's lifecycle. For example, if a To Do entry is created as part of processing the entity, the To Do Entry is referenced in the log.
- Manual entries added by a user (think of these as "diary" entries)

When a business entity is first created and when it transitions into a new state the system calls **Transition** algorithm(s) plugged in on the Maintenance Object to record these events. If the maintenance object supports a log these events can be captures as log entries.

> **Note**
>
> Most base package maintenance objects supporting a log may already provide state transition logging as part of their core logic. In this case you only need to provide a **Transition** plug-in if you wish to override base logging logic with your own.

Required Elements Before Entering A State

You can define additional elements that are required before a business entity can enter a given state. For example, let's assume that a Cancel Reason must be defined before an object can enter the *Canceled* state. You do this by indicating that element as a **Required Element** state-specific option on the appropriate state on the business object.

Capturing a Reason for Entering a State

Some business objects support configuring certain states to allow or require a status reason when an object enters the state. The product provides a centralized status reason table that may be used to define the valid BO status reasons for various business objects and various states. The status reasons are defined using the Status Reason portal.

The following sections provide additional information about the BO status reason functionality.

Copyright © 2026, Oracle and/or its affiliates.

Maintenance Object Must Support Status Reason

In order for a business object to use the centralized status reason table to define reasons, the maintenance object must first support the status reason. MOs that support status reason have the following characteristics:

- The primary table includes a column for Status Reason. This represents the status reason for the record's current status, if applicable.
- The log table includes a column for Status Reason. The standard logic for capturing a log record when entering a state also captures the status reason, if applicable. This allows a user to review the history of the changes in status and the status reason captured for a previous state transition, if applicable.
- The maintenance object option collection includes an option that defines the Status Reason field. This setting is a trigger for business objects of this MO to be able to configure states to allow or require status reason.

Business Object State Indicates if Reasons are Applicable

Once the MO is configured to support status reason, configuration on the business object is required to indicate the states where a reason is applicable. States may be configured to require status reasons, allow status reasons as optional or not allow status reasons. With this configuration, the framework will automatically get the list of valid reasons for a state that allows or requires them and then prompt the user for a status reason when a manual state transition occurs for that state. It also automatically triggers an error if the state requires a status reason and no reason is provided.

> **Note**
>
> The status reason configuration on the business object state is customizable. That means that for a product owned business object, an implementation may opt to change the delivered configuration.

Status reasons are defined for the parent (or "lifecycle") business object. All business objects in the hierarchy of the parent business object have the same valid reasons for their states.

The status reason code must be unique for the centralized status reason table. Business object and status are required fields, so it is not possible to share a common reason code (like "Not applicable") across multiple business objects or states. If multiple BOs / states want to support a reason "Not applicable" then each must define a unique record for it. This point should be considered when planning for your status reasons.

Override Description

The description of product owned status reasons may be overridden by your implementation.

Selectable vs. Not Selectable

When defining a status reason, you may indicate whether it's **Selectable** or **Not Selectable**. When a manual transition is performed and a user is prompted for a status reason, only the **Selectable** reasons are presented. The **Not Selectable** reasons may be defined to support transitions that occur via algorithm processing.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The Selectable setting is customizable. That means that if a product provides a base owned status reason for a business object state, an implementation may opt to change whether it is selectable or not. Careful consideration should be made before changing a base delivered status reason from **Not Selectable** to **Selectable** as this may affect base provided algorithm functionality that could be relying on the setting of **Not Selectable**.

Status Reason Business Object

The status reason maintenance object, as with many maintenance objects in the product, references a business object used to define attributes and behavior related to defining status reasons. The framework provides a business object for status reason (`F1-BOStatusReason`). For the business objects that have states that require a status reason (let's call these "transactional BOs"), if there is some special logic required for defining the status reasons, it is possible to define a different status reason BO. In this situation, the override status reason BO to use for capturing status reasons should be defined as a BO option on the transactional BO using the **Status Reason Business Object** option type. If a transactional BO does not define any status reason BO option, then the `F1-BOStatusReason` is used when adding a status reason.

Defining a Usage

The base product status reason BO provides the ability to define a "usage" value. This is useful for algorithms that perform state transitions where a status reason is needed and where the algorithm is usable by more than one business object. In this case, the status reason to use cannot be provided as a parameter because each business object must define its own set of status reasons for each state. The Usage value can be used instead. Each business object can configure the status reason to use in the algorithm and set the appropriate usage value. The algorithm can reference the usage value and retrieve the correct status reason to use based on the record's transactional BO.

The status reason business object provided with the framework product (`F1-BOStatusReason`) supports capturing a usage. The valid usage values are defined in the **Status Reason Usage** characteristic type.

Alternatives for Defining Reasons

There may be business objects in the system that capture reasons that are defined somewhere besides the BO status reason table. For example, some objects may have an explicit administrative table for status reasons. Some objects may use a Lookup or an Extendable Lookup to capture reasons. Refer to the business object description for information about how valid reasons are defined, if applicable.

If a business object supports a reason that is not related to a state transition (such as a creation reason), the BO status reason would not be used. One of the alternate methods for defining a reason, described above, would be used.

Opening UI Maps Before Entering A State

You can define a UI Map to capture additional elements before a business entity can enter a given state. You do this by configuring the **State Transition UI Map** state-specific option on the appropriate state on the business object.

Copyright © 2026, Oracle and/or its affiliates.

There may be circumstances in which the status pre-processing logic can determine the value of the elements, in which case it is not necessary to invoke the map. The system provides a data area (`F1-StateTransitionCommon`) which contains a boolean element to indicate if the state transition map can be skipped. This data area can be included in your pre-processing script to allow the element to be set according to your business logic. The base maintenance script (`F1-MainProc`) references this element to determine whether to open the state transition map.

BO Algorithm Execution Summary

This table highlights the processing steps that occur when adding or changing a record that is governed by a business object.

Invoke BO	
Event	**Comments**
BO Pre-processing algorithms executed	These algorithms are only executed when Invoke BO is used. The business object in the Invoke BO is the one whose rules are executed.

MO Processing	
Event	**Comments**
Determine if status has changed.	The system keeps a note of the new status value but initially proceeds with the old value.
MO Processing.	Standard MO processing, including MO validation is executed.
Determine BO algorithm executed.	The MO level algorithm is executed to determine the identifying BO.
BO Validation algorithms executed.	
State transition rules are performed if the status has changed.	BO Status Exit algorithms for the "old" status executed. Status updated to the new value. BO Status Enter algorithms for the "new" status executed. If no error â€” MO Transition algorithms are executed.

NOT_SUPPORTED

Refer to State Transitions are Audited for more information.

Copyright © 2026, Oracle and/or its affiliates.

MO Processing	
	If error and there are "save points" the MO Transition Error algorithms are executed.
	NOT_SUPPORTED Refer to Keeping An Entity In Its Last Successful State for more information.
	Otherwise, the error is reported.
BO Status Monitor algorithms are executed.	If the record transitions again, the prior step (State transition rule step) is repeated for the new transition.
BO Post-processing algorithms are executed.	
BO Audit algorithms are executed.	These algorithms are only executed if the system detects a change in elements that are not marked with "no audit".

Note

To emphasize, the steps in the MO Processing table are only executed when the maintenance object service is invoked. Any add or update initiated by an "invoke BO" statement will invoke the MO service. This is also true for web service that invoke the business object. The Monitor Batch Process does not invoke the maintenance service. By default the monitor batch process only executes the monitor algorithms and the state transition rules (if the monitor algorithms indicate that a status change should occur). However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the "force post processing" indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

Note

For records that do not have a status, the state transition rules and the monitor rules are not applicable.

Granting Access To Business Objects

Every business object must reference an application service. When you link a business object to an application service, you are granting all users in the group access to its instances. You can prevent users from transitioning a business object into specific states by correlating each business object status with each application service action (and then don't give the user group rights to the related action).

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture Of Application Security for information about granting users access rights to an application service.

The system checks if a user has access rights each time the application is invoked to add, change, delete, read, or transition a business object. However, if a business object invokes another business object, we assume that access was controlled by the initial business object invocation and we do not check access for other business objects that it invokes. In other words, access rights are only checked for the initial business object invoked in a service call.

In order to apply business object security the system must be able to determine the business object associated with the actual object being processed. To do that the Maintenance Object itself has to have a **Determine BO** algorithm plugged in. If this algorithm is not plugged in or it cannot determine the BO on the MO, the system will not invoke any BO rules. If the business object cannot be determined for a maintenance object instance, business object security is not checked. In this case the system checks the user's access rights using standard maintenance object security.

Note

Parent business objects are ignored. If a child business object exists, a user need only have access to the child business object's application service (not to every application service in the business object hierarchy).

Defining Business Objects

This portal is used to view and maintain information about a business object.

You can access the portal from the **Admin Menu**, and then **System**, and then **Business Object**. You are brought to a query portal with options for searching for a specific business obejct. Once a business object has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to Understanding Business Objects for more information.

Caution

Important! If you introduce a new business object, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Business Object.** This zone provides information about the selected business object.
- **Schema Editor.** This zone describes the business object’s schema and supports basic edits in plain text. Refer to the **Schema** tab below for additional schema editor information.

The following zones may appear as part of the portal's **Schema** tab page.

- **Schema Editor.** This zone allows you to edit the business object's schema using the Schema Designer tool. The purpose of the schema is to describe the business object's properties and map them to corresponding maintenance object fields.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Schema Syntax and UI Hint syntax for a complete list of the XML nodes and attributes available to you when you construct a schema.

Tip

Click the **View Schema** hyperlink to view the business object's expanded schema definition. Doing this opens the schema viewer window.

The following zones may appear as part of the portal's **Algorithms** tab page. Refer to A Business Object May Define Business Rules for more information.

- **Algorithms.** This zone is used to maintain the algorithms associated with the current business object.
- **Hierarchy Algorithms.** This zone displays all algorithms associated with the business object's inheritance hierarchy. The zone is visible when the current business object is part of a hierarchy and such algorithms exist.

The following zones may appear as part of the portal's **Options** tab page. Refer to A Business Object Defines Options for more information.

- **Options.** This zone is used to maintain various configuration options associated with the current business object.
- **Hierarchy Options.** This zone displays all options associated with the business object's inheritance hierarchy. The zone is visible when the current business object is part of a hierarchy and such options exist.

The following zones may appear as part of the portal's **Lifecycle** tab page. This tab is only available when the maintenance object supports lifecycle definition.

- **Lifecycle.** This zone describes and maintains the current business object's lifecycle definition. Broadcast a specific status to review its complete configuration.
- **Status Details.** This zone is used to maintain basic definition information for a selected status within the current business object's lifecycle.
- **Status Algorithms.** This zone is used to maintain algorithms for a selected status within the current business object's lifecycle.
- **Status Options.** This zone is used to maintain various configuration options for a selected status within the current business object's lifecycle.
- **Hierarchy Status Algorithms.** This zone displays all algorithms associated with the business object's inheritance hierarchy for a selected status. The zone is visible when the current business object is part of a hierarchy and such algorithms exist.
- **Hierarchy Status Options.** This zone displays all options associated with the business object's inheritance hierarchy for a selected status. The zone is visible when the current business object is part of a hierarchy and such options exist.
- **Status Reasons.** This zone is used to maintain reasons for a selected status. The zone is visible when the maintenance object supports a reason field and usage of reasons is allowed by the status definition.

The following zones may appear as part of the portal's **Lifecycle View** tab page. This tab is only available when the maintenance object supports lifecycle definition.

Copyright © 2026, Oracle and/or its affiliates.

- **Lifecycle View.** This zone provides a schematic view of the current business object's lifecycle definition. Broadcast a specific status to review its complete configuration.
- **Status Details.** This zone is used to maintain basic definition information for a selected status within the current business object's lifecycle.
- **Status Algorithms.** This zone is used to maintain algorithms for a selected status within the current business object's lifecycle.
- **Status Options.** This zone is used to maintain various configuration options for a selected status within the current business object's lifecycle.

The following zones may appear as part of the portal's **Hierarchy** tab page. This tab is only available when the current business object is part of a hierarchy.

- **Business Object Hierarchy.** This zone lists the inheritance hierarchy of business objects up to and including the current business objects. The zone is visible if the current business object is not the top level business object of the hierarchy.
- **Business Object Tree.** This zone describes the entire hierarchy of the current business object.
- **Hierarchy Algorithms.** This zone lists all algorithms defined for the current business object. The zone is visible if algorithm information exists for the current business object.
- **Hierarchy Lifecycle Algorithms.** This zone lists all algorithms associated with the current business object's inheritance hierarchy. The zone is visible if the current business object is not the top level business object of the hierarchy and algorithm information exits. Refer to Inheriting Lifecycle for more information.
- **Hierarchy Options.** This zone lists all configuration options for the current business object's lifecycle. The zone is visible if options information exists for the current business object.
- **Hierarchy Lifecycle Options.** This zone displays all options associated with the current business object's inheritance hierarchy. The zone is visible if the current business object is not the top level business object of the hierarchy and options information exits. Refer to Inheriting Lifecycle for more information.

The following zones may appear as part of the portal's **References** tab page.

- **Business Object References.** This zone list various configuration entities referencing the current business object or its schema.

Actions

The page supports the following special actions:

- **Generate User Interfact Configuration Artifacts.**When creating a new buisiness object or editing an existing one, you may request to generate the user interface configuration artifacts needed to properly maintain and display the business object on an existing portal. For example, if a display script is needed to further prepare the business object's details for presentation then request to generate such script. You can then navigate to the script from the **User Interface Configuration** section and adjust it as needed.
- **Subclass a Business Object.** Use the **Subclass** action to create a new business object that is a child of an existing business object. The action generates the new business object's schema as inherited from the existing business object. Refer to Business Object Inheritance for more information.
  Once created, you may extend and adjust the new business object's schema and rules as needed.

Copyright © 2026, Oracle and/or its affiliates.

- **Create an Algorithm.** Use this action, on the Algorithm tab or the Lifecycle tab for a specific status, to creates a script based algorithm related to this business object. You are prompted for information regarding the plug-in spot (BO or BO Status) and the system event, the name, description, etc. Once all the information is provided, the system creates an algorithm type, a script, an algorithm and links the algorithm to the business object. You may then navigate to the script to adjust it as needed.
- **Inactivate / Activate Base Algorithms.** You can inactivate algorithms on base Business Objects. Your implementation may want to use a business object provided by the base product, but may want to inactivate one or more algorithms provided by the base business object. To do that, use the "Inactivate" action on the appropriate algorithm entry on the Algorithm tab. Use use the "Activate" action to mark an inactive algorithm as active. Note that these actions add and remove the "Inactive Algorithm" businesss option as needed.
- **View Schema.** Click the hyperlink to view the business object's expanded schema definition. Doing this opens the schema viewer window.

Advanced BO Tips and Techniques

The topics in this section describe some advanced tips and techniques for configuring business objects.

- Creating a Physical Business Object
- Managing To Do Entries
- Submitting a Batch Job

Creating a Physical Business Object

The physical business object's schema represents the complete physical structure of the maintenance object, and includes elements for all fields in the maintenance object's tables. There are several processes in the system that may use a maintenance object's physical BO.

To create a physical business object for the maintenance object:

1. Navigate to Business Objectand add a business object for the maintenance object. Do not fill in any of the UI oriented configuration.
2. The business object is created with a schema that looks like the physical structure of the maintenance object.
3. Save the physical business object.
4. Navigate to Maintenance Object and search for the maintenance object.
5. On the **Option** tab, add a new option with the type **Physical Business Object**. The value is the name of the physical business you just created.

Managing To Do Entries

The product provides several base algorithm types that may be used to manage To Do entries through status changes for a given record via BO lifecycle plug-ins.

Create To Do Entry

The product supplies a BO status Enter algorithm type **Generic To Do Creation** (`F1-TDCREATE`) that creates a To Do entry based on parameter configuration. Refer to the algorithm type description for more information about how it determines the To Do type or To

Copyright © 2026, Oracle and/or its affiliates.

Do role and how to populate the appropriate message text onto the To Do. This algorithm may be used in conjunction with the Retry Logic (below).

If your implementation has a business rule that requires a To Do entry to be created when entering a given BO status and the logic provided by the algorithm type meets the needs of the business rule, this algorithm type may be used. Create an algorithm for the algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Retry Logic

The algorithm type **Retry for To Dos** (`F1-TODORETRY`) is supplied for a special use case. It is a BO status monitor plug-in and may be used for a state that is a type of 'error' or 'waiting' state. It relies on the To Do entry creation logic to set a Retry Frequency. The algorithm transitions to the originating state to retry the logic. The idea is that the condition that caused the record to enter the 'error' or 'waiting' state may be resolved after some period of time has passed, allowing the record to progress in its lifecycle. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as a Monitor algorithm. The state should also have an algorithm for the **Generic To Do Creation** algorithm type plugged in as an Enter algorithm (or something equivalent) that sets the appropriate Retry Frequency.

To Do Completion

It is common that one or more To Do entries associate with a given record should be completed when exiting a state (if it is not already completed). The system supplies the algorithm type **Generic To Do Completion** (`F1-TODOCOMPL`) that may be used for this purpose. Note that the algorithm type functionality is not tied to any To Do creation logic. It may be used for any use case where To Do entries should be completed on exiting a state. Refer to the algorithm type description for more information about its functionality and how to prevent certain To Do entries from being automatically completed.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Exit algorithm.

Submitting a Batch Job

The product provides a base algorithm type that submits a batch job when entering a BO state. This functionality allows for "event driven" batch submission where the event is the lifecycle transition for a certain record.

The algorithm type is **Create Batch Job Submission Entry for Batch Control** (`F1-SCHEDJOB`). The batch control code is a parameter for the algorithm. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameter with the batch control that should be submitted and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Defining Status Reasons

Status Reasons are used to provide more information about why a business object transitioned to a given state. The status reason table provides a centralized place where status reasons can be defined across many different business objects and states.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Refer to Defining Reasons for Entering a State for overview information.

If a business object has one or more states that are configured to capture a status reason, you may configure the valid reasons by navigating to the status reason portal using **Admin**, and then **System**, and then **Status Reason**.

The topics in this section describe the base-package zones that appear on the Status Reason portal.

Business Objects with Status Reason List

This zone displays the business objects that have one or more status values that allow status reasons to be defined.

Click the broadcast icon to open other zones that contain more information about the business object's status reasons.

Status Reasons

The **Status Reasons** zone contains a list of the existing status reasons for the broadcasted business object.

Data Areas

The data area has no business purpose other than to provide a common schema location for re-used schema structures. It exists solely to help eliminate redundant element declaration. For example, if you have multiple schemas that share a common structure, you can set up a stand-alone data area schema for the common elements and then include it in each of the other schemas.

Be aware that a stand-alone data area can hold elements that are mapped to true fields. For example, you might have 50 different types of field activities and all might share a common set of elements to identify where and when the activity should take place. It would be wise to declare the elements that are common for all in a stand-alone data area and then include it in the 50 field activity business objects.

It's strongly recommended that you take advantage of stand-alone data areas to avoid redundant data definition!

> **Caution**
>
> **Dynamic inclusion!** When the system renders a schema, all schemas included within it are expanded real-time. This means that any change you make to a data area will take effect immediately within all schemas it is referenced within. Therefore, changing a schema that is referenced in a large number of schemas may be too large to be performed online. In this situation, the change should be performed in batch. Refer to "Update Object Schema (F1-SCMUP)" batch control for more information.

This section describes additional topics related to designing and working with data areas.

Copyright © 2026, Oracle and/or its affiliates.

Dynamic Extension

You may use a custom data to extend a base product data area. To extend another data area, reference that data area in the **Extended Data Area** field. By extending a data area you can add additional elements to a base product data area.

Here's an example of an extended data area:

- The product releases with data area A, which contains elements a, b, and c.
- Your implementation creates data area CM-A, which contains element z, and references data area A as the extended data area.
- At run time, everywhere data area A is included it will contain elements a, b, c, and z.
- Defining Data Areas

Defining Data Areas

Use this page to define basic information about a data area.

You can access the portal from the **Admin Menu**, and then **System**, and then **Data Area**. You are brought to a query portal with options for searching for a specific data area. Once a data area has been selected you are brought to the maintenance portal to view and maintain the selected record.

> ⚠ **Caution**
>
> Important! If you introduce a new data area, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Data Area.** This zone provides information about the selected data area.
- **Extending Data Areas.** This zone lists all data areas extending the current data area. The zone appears if such data areas exist.
- **Schema Editor.** This zone describes the data area's schema and supports basic edits in plain text. Refer to the **Schema** tab below for additional schema editor information.

The following zones may appear as part of the portal's **Schema** tab page.

- **Schema Editor.** This zone allows you to edit the data area's schema using the Schema Designer tool. The purpose of the schema is to describe the data area's properties and map them to the underlying internal service fields .

> **NOT_SUPPORTED**
>
> Refer to Schema Syntax and UI Hint syntax for a complete list of the XML nodes and attributes available to you when you construct a schema.

Copyright © 2026, Oracle and/or its affiliates.

> **Tip**
>
> Click the **View Schema** hyperlink to view the data area's expanded schema definition. Doing this opens the schema viewer window.

The following zones may appear as part of the portal's **References** tab page.

- **Data Area References.** This zone list various configuration entities referencing the current data area or its schema.

Actions

The page supports the following special actions:

- **View Schema.** Click the hyperlink to view the data areas's expanded schema definition. Doing this opens the schema viewer window.

Business Services

A business service is used to expose a back-end service so that it may be invoked by a script or a zone or a map to retrieve information or perform functions, depending on the related service.

As with the business object, the business service's interface to the internal service is defined using its schema. The schema maps the business service's elements to the corresponding elements in the internal service program's XML document. Just as a business object can simplify the schema of its maintenance object by only defining elements that it needs and "flattening" entries in a child collection to be defined as a singular element, a business service schema may simplify its service XML in a similar way.

> **NOT_SUPPORTED**
>
> Refer to Schema Syntax for a complete list of the XML nodes and attributes available to you when you construct a schema.

Inbound web services and scripts support interaction with business services. You can also invoke a business service from a Java class.

- Defining Service Programs
- Defining Business Services

Defining Service Programs

This transaction defines services available in the system. These include user interface services as well as stand-alone services that perform a specific function. A service may be referenced by a business service. Use this transaction to view existing service and introduce a new stand-alone service to be made available to a Business Service.

You can access the portal from the **Admin Menu**, and then **System**, and then **Service Program**. You are brought to a query portal with options for searching for a specific service program. Once a service program has been selected you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

> **⚠ Caution**
>
> Important! When adding new service programs, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Service Program.** This zone provides information about the selected service program.
- **Service Program References.** This zone list various configuration entities referencing the current service program.

Application Service is the application service that is used to provide security for the service. If the service is related to a maintenance object, the access modes for the application service should be the standard **Add**, **Change**, **Delete** and **Inquire**. For other services, the application service should have the **Execute** access mode.

Service Type indicates whether the service is a **Java Based Service** or a **Java (Converted) Service**. Note that services generated to support a portal in the system will not have a service type populated.

The **Programs** grid shows the list of program user interface components associated with the service. For a stand-alone service, this list is typically not applicable.

Defining Business Services

Use this page to define basic information about a Business Service.

You can access the portal from the **Admin Menu**, then **System**, then **Business Service**. You are brought to a query portal with options for searching for a specific business service. Once a business service has been selected you are brought to the maintenance portal to view and maintain the selected record.

> **⚠ Caution**
>
> Important! If you introduce a new business service, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Business Service.** This zone provides information about the selected business service.
- **Schema Editor.** This zone describes the business service's schema and supports basic edits in plain text. Refer to the **Schema** tab below for additional schema editor information.

The following zones may appear as part of the portal's **Schema** tab page.

- **Schema Editor.** This zone allows you to edit the business service's schema using the Schema Designer tool. The purpose of the schema is to describe the business service's properties and map them to the underlying internal service fields.

> **ⓘ Note**
>
> Refer to Schema Syntax and UI Hint syntax for a complete list of the XML nodes and attributes available to you when you construct a schema.

Copyright © 2026, Oracle and/or its affiliates.

> **Tip**
>
> Click the **View Schema** hyperlink to view the business service's expanded schema definition. Doing this opens the schema viewer window.

The following zones may appear as part of the portal's **References** tab page.

- **Business Service References.** This zone list various configuration entities referencing the current business service or its schema.

Actions

The page supports the following special actions:

- **View Schema.** Click the hyperlink to view the business service's expanded schema definition. Doing this opens the schema viewer window.
- **Test.** Use this action to test your business service. Enter input values and save. The service is performed and output information is presented, but the system issues a roll-back so that the changes are not committed. Note that if your service uses the save-point dispatcher to perform any actions or if it issues a call to an external system, the roll-back does not apply to those actions. If the service issues an error the corresponding message is displayed. Note that the input and output testing user interface is dynamically rendered based on UIHints embedded in the business service's schema. As such, the user interface may be as elaborate or basic as the UIHints in that schema.

> **Note**
>
> This action is secured by a designated "Test a Service" application service and the "Generic Service Executor" application service and also requires security rights for creating a script, which is the alternative way for testing any service. It is recommended to allow access to this function in non-production environments only.

- Useful Services and Business Services

Useful Services and Business Services

The following section highlights some business services and services provided by the product that may be useful for implementations to use.

Data Explorer Service

The system provides a mechanism for performing an SQL select statement for use in scripting, Java plug-ins, or via a web service call. This is done by creating a zone using one of the data explorer zone types where the SQL is defined. Then, create a business service using the Data Explorer service (**FWLZDEXP**).

> **Note**
>
> There are numerous business services delivered with the base product that reference this service that may be used as a template.

Copyright © 2026, Oracle and/or its affiliates.

The following points highlight how to create your own business service for this service. Note that typically a separate business service exists for each zone.

- Enter a **Business Service** code and a **Description**. It is recommended to define the business service code to match the zone code so that it's easier to manage which business service invokes which zone.
- Select the **Service Name FWLZDEXP**.
- On the **Schema** tab, under the ***<schema>*** node, enter mapping for the fields that are required for the Data Explorer service:
  - The **Zone** should be mapped into service field ***ZONE_CD*** . Define the zone code as the default value.
  - For every **user filter** defined on the zone, create a schema mapping into the service field ***Fx_VALUE***, where "x" is the filter number (from the zone parameters).
  - For every **hidden filter** defined on the zone, create a mapping into the service field ***Hx_VALUE***, where "x" is the filter number (from the zone parameters).
  - The search results are returned as a list by the data explorer service. Each column value is in the service field ***COL_VALUE*** with an appropriate sequence number (***SEQNO***). The results can be flattened based on sequence number allowing for a logical element name to be defined.
  - Another useful field is ***ROW_CNT***, which provides the number of rows retrieved by your search.

The following is an example of the schema for a BS that receives a business object code and returns a list of status values and their descriptions that allow status reasons to be defined.

```
<schema>
     <zone mapField="ZONE_CD" default="F1-BOSTSLST"/>
     <bo mapField="H1_VALUE" />>
     <rowCount mapField="ROW_CNT"/>>
     <results type="list" mapList="DE">>
          <status dataType="string" mapField="COL_VALUE">
               <row mapList="DE_VAL">>
                    <SEQNO is="1" />>
               </row>>
          </status>>
          <description dataType="string" mapField="COL_VALUE">
               <row mapList="DE_VAL">>
                    <SEQNO is="2" />>
               </row>>
          </description>>
      </results>>
</schema>
```

Maintenance Object Log Service

Many maintenance objects support a log table that follows a pattern of column names and behavior. The system provides a service called Generic MO Log Service (F1MOLOGP) that may be used to perform common functions related to log entries:

- Read log entries. If you pass a certain MO, primary key and log sequence number, the service will return the details of that log entry. The product provides a generic business service that may be used for this purpose — Generic MO - Retrieve Log Details (F1–

Copyright © 2026, Oracle and/or its affiliates.

ReadMOLog). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.

- Add log. The service may be used to add a log entry. If a user log is added, then the comments from the user are populated in the detailed description. System generated log entries typically supply a message category / message number along with other information such as the status, a specific log type and optionally a related object reference (via a characteristic). The product provides a generic business service that may be used for this purpose — Add Generic MO Log (F1–AddMOLog). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.

Base Business Services

The following table highlights some business services provided by the product that may be useful for custom logic for an implementation.

> ⚠ **Caution**
>
> This is not intended to be a complete reference of Business Services. Refer to the business service page to find all the supported business services.

Business Object Related Services

Business Service Name	Description
F1-AutoTransitionBO	Performs monitoring algorithms associated with the current state of a given business object instance (which may result in subsequent state transitioning).
F1-CompareBusinessObjectData	Compares two versions of a given business object instance.
F1-DetermineBo	Determines the business object of a given instance of a maintenance object by executing the MO's Determine BO logic.
F1-GetRequiredFieldsForBOState	Returns the required fields for a given business object status.
F1-RetrieveBOOption	Returns BO option values for a given BO and option type.
F1-RetrieveBOStatusOption	Returns BO option values for a given BO, status and option type.
F1-RetrieveBOStatusOption	Retrieves a list of BOs for a given MO that are accessible for the current user.
F1-RetrieveBoStatusDescription	Return the description of a given BO status.
F1-RetrieveBusinessObjectLabel	Return the label appropriate for a given path (e.g. element) within a BO schema.
F1-RetrieveNextStates	Return a list of next possible states based on the input of a MO and its prime key, or a BO and one of its statuses.

Email Related Services

Copyright © 2026, Oracle and/or its affiliates.

Business Service Name	Description
F1-EmailService	Sends an email message in real time.
F1-RetrieveEmailAddress	Retrieves the email addresses of users belonging to a To Do Role.
F1-RetrieveEnvironmentURL	Retrieves the current environment URL information for the installation.

Tools for Maps and Scripting

Business Service Name	Description
F1-AddWarning	This business service may be used to log a warning by providing the message details. The system gathers all the warning and displays them to the user all at once.
F1-CheckOnlineConnection	Check if Connection is Online or Batch.
F1-CheckWarning	Used to check if any warnings have been accumulated. If warnings have been accumulated, any logic that cannot be rolled back (when the warnings are shown) should not be performed.
F1-DateMath	Performs various date and time math calculations. Refer to the BS description for more details.
F1-DateTimeFormattingService	Formats a given date / time based on the user's display profile settings.
F1-ExecuteScriptInNewSession	Executes a Service Script in a new processing session/transaction.
F1-GetFieldLabel	Retrieves the label for a given field.
F1-GetForeignKeyReference	Returns foreign key reference information for a given FK Reference and primary key, including info description, navigation option, and context menu.
F1-GetFKReferenceDetails	Returns foreign key reference information for a given MO and primary key, including FK reference code, info description, navigation option, search zone and context menu.
F1-GetLookupDescription	Returns lookup description for a lookup field value given the lookup field name.
F1-GetExtLookUpVal	Returns the list of values for a given extendable lookup BO.
F1-GetMonthInYearAbbreviation	Returns a 3-character month abbreviation for an input date in system format.
F1-NumberAmountFormatter	Formats a given amount or number based on the user's display profile settings. It also may receive input to adjust the scale and optionally apply currency settings.
F1-OutmsgDispatcher	Dispatches a real-time message giving the user the option of whether to persist the message on the database, and whether to trap errors that may take place during the call. Refer to Real Time Messages for more information.

Copyright © 2026, Oracle and/or its affiliates.

Business Service Name	Description
F1-OutmsgMediator	Alternative to F1-OutmsgDispatcher and may be a better option if the sender does not require an outbound message record to be instantiated. Refer to Real Time Messages for more information.
F1-RethrowError	Issues an application error using the input message category / number / parameters.
F1-RetrieveMODescription	Retrieves the description for a maintenance object.
F1-ReturnMessage	Returns the expanded message given a message category, number, parameters, and parameter types.
F1-SavePointDispatcher	Allows for a service script to be executed where exceptions are trapped and the transaction is rolled back to a save point set before the service script execution.

User Related Services

Business Service Name	Comments
F1-CheckApplicationSecurity	Checks a user's security for a given application service / access mode
F1-CheckUserAuthorization	Determine whether a given user is authorized for access based on the input application service, security code, and authorization level.
F1-DetermineIfUserCanApproveTD	Determine if the current user can approve a given To Do.

User Interface (UI) Options

Your implementation may create input forms and output maps that closely match your customer's business practice within the following user interface areas:

- Content presented in portal zones. For example, a map that displays the details of a business object or any other informational content. Refer to Map Zones for more information.
- An input form presented via Business Process Assistant (BPA) scripts for data entry and update purposes. For example, a form that captures business object information or prompts the user for additional information related to a task they perform.
- An input form presented as a panel within a process flow.

The HTML for these forms and maps may be provided using the following options:

- **UI Map.** Compose your HTML and store it as a UI map, which is a repository for an HTML document. The UI Map HTML gives you the ability to craft the display by any method that an HTML document can support, including JavaScript and full CSS functionality.
- **UI Hints.** With this technique you do not compose the HTML. Instead, the HTML is generated at run time based on a schema that describes the data being displayed and embeds user interface rendering instructions known as "UI Hints".
- Understanding UI Maps

Copyright © 2026, Oracle and/or its affiliates.

- Understanding UI Hints
- UI Hint Syntax
- Defining UI Maps

Understanding UI Maps

The preferred method for creating input and output HTML maps is by leveraging the schema-based HTML rendering technique known as UI Hints. For more complex requirements, you may craft an HTML that closely matches your customer's business practices and capture it as a User Interface (UI) map.

The User Interface (UI) map is a repository for a single HTML document paired with an XML schema where the schema defines the data that the HTML document displays and/or modifies. The UI Map HTML gives you the ability to craft the display by any method that an html document can support, including JavaScript and full CSS functionality.

The topics in this section describe concepts and guidance relevant to UI map configuration.

Output Maps and Input Forms

UI maps are typically crafted as output tables when used in conjunction with portal zones - please refer to Map Zones for more information. When referenced within BPA scripts or process flows, UI maps are typically crafted as forms for the capture and update of data.

Figure Customer HTML Rendered (Output Data for Zone)

UI Map Fragments

A UI map may represent a complete HTML map or a fragment that can be embedded in a complete map.

You may use a UI map fragment in the following use cases:

- To share and reuse the same HTML/JavaScript across multiple complete UI maps. The UI map fragment is referenced as part of the HTML definition of the complete UI maps.
- To embed complex HTML/JavaScript logic as part of a map that its HTML is otherwise rendered using UI Hints.
- To implement a filter map for a data explorer search zone where basic filter definition syntax does not handle your business requirements.

Configuration Tool Support

Configuration tool support for UI Maps hinges around the ability to inject and extract an XML document from the HTML. For more information on the specialized support for HTML and JavaScript functionality refer to UI Map Attributes and Functions.

- Ensuring Unique Element IDs for UI Maps

Ensuring Unique Element IDs for UI Maps

The following describes how to modify JavaScript code to ensure the proper rendering of unique element IDs for UI Maps.

The modification is required only for code that renders HTML using a getElementById() (or similar) function to generate list IDs and avoid account verification or related errors.

The following sample snippet contains the necessary modifications:

```
...
function getElementsFromList(namePrefix) {
    var ret = [];
    var elements = document.getElementsByTagName("INPUT");
    for(var i=0;i<elements.length;i++) {
        var elemID = elements[i].id;
        if((id) && (id.startsWith(namePrefix + '_')) {
            ret.push(elements[i]);
```

Copyright © 2026, Oracle and/or its affiliates.

```
        }
    }
...
return ret;
```

Since IDs aren't necessarily unique in generated UI Map IDs, the code shown above ensures uniqueness at runtime by appending an underscore and row number (e.g., myField_1, myField_2) for proper handling by Framework in the rendered HTML, while still allowing you to reference the unmodified IDs contained in the generated UI Map.

A switch in the spl.properties file also permits you to disable the generation of unique IDs for elements in a grid (as described below), though, for standards compliance reasons, it is highly recommended that this switch be left at is default value.

```
Property Name: spl.runtime.compatibility.uiMapDisableGenerateUniqueHtmlIDs
File Name: spl.properties (under web project in FW)
Default Value: false
Accepted Values: true or false
Description: This property controls the generation of unique IDs for all
input elements inside
a list. When this value is set to true it disables the generation of unique
IDs, thus
replicating the old behavior. When this property is set to false or this
property is missing
it enables the generation of unique IDs, thus enabling the list to be
standards-compliant.
```

Understanding UI Hints

A schema may be used to describe the structure of a business object or any other XML document. When applicable, the same schema may also embed user interface (UI) "hints" that are interpreted at run time and render the HTML needed to display or maintain that document. Refer to UI Hint Syntax for more information.

The main advantages of this technique are as follows:

- **Less error prone.** A tighter correlation between the data structure and its presentation layer keeps the latter up to date, for example:
  - Adding an element to the schema or removing an element from it result in a corresponding change to the presentation layer. Note that you can explicitly exclude elements from the presentation layer as needed.
  - The HTML widget that is most appropriate to present or input data for an element is determined by its data type as defined by the schema. For example, a date picker is used for an input date element. If the element's data type changes in the schema its presentation adjusts accordingly.
- **Faster to implement.** No HTML skills are needed. The schema definition along with its embedded UI hint instructions is used to render the HTML at run time. Eliminating the need of crafting HTML and maintaining it as a UI Map reduces implementation and maintenance costs.
- **Supports business object inheritance.** Incorporating the presentation layer into the business object schema allows each business object in a hierarchy to contribute their part to the complete HTML that displays the entity. In other words, the complete HTML used to

Copyright © 2026, Oracle and/or its affiliates.

display a subclassed business object is made of the HTML rendered by the included schema of its parent business object, followed by elements extended by the subclass.

The topics in this section describe concepts and guidance relevant to the UI Hints functionality.

Display vs. Input Modes

The same schema may be used to generate either a display version of its HTML map or an input map. In the display version, element values are presented as read-only, corresponding descriptions are shown instead of codes, and additional artifacts such as links are available for navigation to related pages. In the input version, the element is editable, using the appropriate HTML widget for its data type. For example, a foreign key element is rendered along with search components, and a date element incudes a date picker widget.

The type of map generated depends on the context in which it is used:

- The display map is generated when the schema is used to present content in a map zone.
- The input map is generated when the schema is used for data entry as part of a BPA script step or a process flow panel. Refer to Generate Edit Map Statements and process flows for more information.

By default, each element in the schema is assumed to be included in both the display and input presentation maps. UI hints allow an element to be excluded from presentation altogether, included only in the display map or included only in the input map.

Not Just Business Object Schemas

While mostly used to describe the display and maintenance maps of business objects, UI Hints may also be embedded as part of other schema based objects:

- You may use a data area to describe an input form and prompt the user to fill it in using a BPA script step or a process flow panel.
- You may embed UI hints in a business service or service script schema for the purpose of displaying the content prepared by the service in a portal zone. Refer to map zones for more information.
- You may embed UI hints in a service script's schema to prompt for user input before calling the script to perform a task and presenting results. Refer to Generate Edit Map Statements for more information.

Definition Order is Presentation Order

Elements are presented in the order they are defined in the expanded schema. For example, a subclassed business object that includes its parent business object followed by extension elements is presented with the parent portion of the HTML, followed by the extension fields.

Use UI Map Fragments for Complex HTML

The following items describe basic capabilities supported by the UI Hints functionality:

- Control which elements are presented in the display and input maps.
- Provide a title for the input map.
- Introduce sections around elements by injecting start and end section instructions. The order in which the elements are defined within a section is also their presentation order.
- Basic visibility rules are supported at the element and section level.

For more complex requirements around a specific element, you may craft the necessary HTML/JavaScript for the element, capture it as a UI Map Fragment, embed the fragment as

Copyright © 2026, Oracle and/or its affiliates.

part of the schema in the appropriate presentation order, and suppress the element from basic rendering for the corresponding input or display map.

> **Note**
>
> You may also use this technique to display elements in a different presentation location. For example, when a business object's display script needs to display additional elements that are not part of the business object's schema. In this situation, the script's schema introduces the elements as suppressed and the business object schema includes an embedded HTML UI map fragment to display them in the appropriate section. Note that this may only work when both the business object and script are owned by your organization.

Refer to UI Hint Syntax for more information.

UI Hint Syntax

Working Examples

For working examples of uiHint functionality, refer to the following business objects:

BOs with User Assigned Keys

The following examples illustrate the patterns used to enable uiHints on an object with a user specified key.

- `F1-OutcomeStyleLookup`. This extendable lookup BO does not require state transition, but does allow duplicate and delete actions.
- `F1-TodoSumEmailTyp`. This request type illustrates the hints required to support state transition on a display map.
- `F1-WebSvc`. This web service BO is a good example for management of complex JavaScript requirements. Both display and input maps have functionality that requires specialized javascript.

BO with System Generated Key

The following example illustrates the pattern used to enable uiHints on an object with a system generated key.

- `F1-GenericAttachment`. This attachment BO has a system assigned key, which entails the following special handling:
  - `F1-AttachmentMain`. This is the main section data area contains the elements common to all attachments, including the key, bo, and version. Because this data area is used to define the main section of the generated maps, the main section of the map can be extended by an implementation via data area extension functionality.
  - `F1-AttachmentActions`. This record actions map contains the standard actions, Edit and Delete, plus custom actions used only by attachments, View and Upload.
  - `F1-AttachmentIDFrag`. This record information map contains the primary key of the attachment.

Display Map Service Script

Display map service scripts can be fully supported via dynamic HTML generation. However, to help eliminate the need for a display service script, self-contained uiHint functionality has been

Copyright © 2026, Oracle and/or its affiliates.

developed to write the business object status and determine valid state transitions. So the two most common reasons to craft a display service script have been eliminated.

A typical reason to use a display pre-script is if you have an embedded map fragment that contains a business service schema. The display service script can be used to invoke the business service. Both the map fragment and the display service script must declare the business service schema to support this scenario.

> **Warning**
>
> The zone used to display the object's map must have a derivation script, like `F1-GncDsMpDZ` or `F1-GenDss`, that will invoke a display service script for the business object if it has been defined as a BO option - but not require an explicit display map BO option. In addition, the display service script's schema must be enabled for uiHint functionality - as the script's schema will be dynamically rendered by the zone - and not the BO schema.

- `F1-ExcelSpreadsheet`. This attachment BO has a display service script used to manipulate the attachment business object before displaying it:
- `F1-AttchDtlU`. This display map service script's schema has been defined with the uiHint namespace, and will have a display map generated for it.

Maintenance Pre-Processing Service Script

Maintenance pre-processing service scripts can be used with uiHints.

- `F1-ExcelSpreadsheet`. This attachment BO has a maintenance pre-processing service script used to manipulate the attachment business object before rendering the maintenance map:
- `F1-AttchPre`. This pre-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked before the maintenance map is rendered.

Maintenance Post-Processing Service Script

Maintenance post-processing service scripts can be used with uiHints.

- `F1-ExcelSpreadsheet`. This attachment BO has a maintenance post-processing service script used to manipulate the attachment business object after rendering the maintenance map:
- `F1-AttchPost`. This post-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked after the maintenance map is rendered.

Technical Notes

The following prerequisites are required to support dynamic HTML generation:

Schema Requirements

To support automated UI generation, the business object schema must contain the following:

- <schema **xmlns:uiHint="http://oracle.com/ouafUIHints"**>. The schema node must name the uiHint namespace.
- **isPrimeKey="true".** Every element of the business object schema that is part of the primary key must be identified.

Copyright © 2026, Oracle and/or its affiliates.

Maintenance Script Requirements

The maintenance script for the MO must be enabled for dynamic generation.

> **⚠ Caution**
>
> The business object maintenance BPA script must be declared as an MO Option for uiHint maintenance functionality to work!

If the script performs `F1-BOProc` then it is likely no special functionality is needed. However, if the maintenance script contains its own call to `F1-GetValOpt` then the following statement is required prior to that call:

```
move 'false' to "F1-GetBOOpts/input/maintenanceMapRequired";
performScript 'F1-GetValOpt';
```

After the call to `F1-GetValOpt` the following logic must be included to dynamically declare the map schema if the business object does not have a maintenance map of its own:

```
 // Perform Main Processing
if ("F1-GetBOOpts/output/maintenanceMap = $BLANK")
  declareBOWithBOGroup "$bo" as 'map_schema';
else
  declareMap "F1-GetBOOpts/output/maintenanceMap" as 'map_schema';
end-if;
```

Format an Input Map Title

> **ⓘ Note**
>
> Throughout this topic the term "field" to refer to both the generic concept of displaying and capturing data in a 'field' as well as referring to the meta-data object supplied in the product to define Fields. When referring to the latter, the term "MD Field" (meta-data Field) is used.

A uiHint element can be used to build a title for a maintenance map. The title will only print on the maintenance map, not on the display map. It will be printed as the first line in the map, centered, with a heading style.

Syntax	Description	Examples
`<uiHint:title mdField=""/>`	Displays the label of a referenced MD field as the title.	`<schema xmlns:uiHint="http://oracle.com/ouafUIHints"> <uiHint:title mdField="STATUS_RSN_LBL"/> ... </schema>`

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Description	Examples

`<uiHint:title text=" "/>`	Displays the indicated text as the title. (Do not use this mechanism when multiple languages are supported.	`<schema xmlns:uiHint="http://oracle.com/ouafUIHints">`
		`<uiHint:title text="Status Reason"/>`
		`...`
		`</schema>`

Create a Section

The uiHint namespace supports the definition of a UI map section. Note that sections are currently created in generated UI Maps when the schema has a group or list node with a label or mdField. The functionality described here enables the creation of a section without requiring a labeled group or list node within the schema. Every section must be bounded by **startSection** and **endSection** element pair.

Syntax	Supporting Attributes	Description
`<uiHint:startSection .../>`	`sectionColumn="left | right | fullWidth | float"`	The default is that the section will be the full width in display maps. To override that setting, specify if you want a half-width section to appear in either the left (**left**) or right (**right**) column or to float (**float**). Sections that are marked as 'float' will display half-width and be aligned according to whether prior sections are displayed or conditionally hidden. For example, if a left-aligned section is followed by a floating section, the floating section will appear in the right column if the left section is populated but will display in the left column if the left section is hidden / collapsed.
	`editColumn="left | right | fullWidth | float"`	By default a section appears as full width in maintenance maps. To override that setting, specify if you want a half-width section to appear in either the left (**left**) or right (**right**) column or to float (**float**). The behavior is the analogous to the **sectionColumn** behavior.
	`sectionOpen="false"`	By default a section is open on initial display. Specify this attribute to initially display the section as closed (collapsed).
	`mdField=" "`	Specify the name of a MD field whose label should be used as the section heading.
	`label=" "`	Specify the explicit text to use as the section heading.
	`visibleOn="displayMap | inputMap"`	By default a section appears on both the display and the input maps. Use this attribute to limit the display of the section to either the display map (**displayMap**) or input map (**inputMap**).

The syntax for the end section attribute is `<uiHint:endSection/>`

Copyright © 2026, Oracle and/or its affiliates.

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
    <uiHint:startSection label="Main" sectionColumn="left"/>
    ...
    <uiHint:endSection/>
</schema>
```

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
    <uiHint:startSection mdField="F1-ADD-INFO" sectionColumn="fullWidth"
editColumn="float" sectionOpen="false" visibleOn="displayMap"/>
    ...
    <uiHint:endSection/>
</schema>
```

> **Note**
>
> The sectionColumn, editColumn and sectionOpen attributes are available for group and list nodes as well.

Include a Map Fragment

You can specify a UI map fragment to inject HTML into a generated map using the **includeMap** element name. This allows for you to support more sophisticated behavior on your user interface. For any element that is included for rendering in the map fragment, be sure to suppress the element in its schema definition, otherwise HTML will automatically be generated for the element.

Syntax	Supporting Attributes	Description
`<uiHint:includeMap ../>`	`map=" "`	Specify the name of the map.
	`visibleOn="displayMap | inputMap"`	By default the details from the map fragment appear on both the display and the input maps. Use this attribute to limit the display of the section.

Example:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap"/>
  ...
</schema>
```

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Important note on the map fragment schema:** If a map fragment contains a schema, then the fragment schema structure will be injected into the dynamically generated schema when the business object is rendered for input. Technically, the fragment schema will be inserted after the boGroup structure within the map's schema. This method may be used to support the implementation of maintenance pre and post script processing for a business object and oraInvokeBS function calls within embedded JavaScript.

If JavaScript is required within an XHTML UI Map fragment, it is necessary to bound it within a **![CDATA[ ]]** tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/* <![CDATA[ */
//
//javascript
//
/* ]]> */
</script>
```

Flush the cache: For performance reasons, the Framework automatically caches business object schemas, data areas, and UI maps. When you update a business object, the cache is automatically flushed. However, if the business object includes either a data area or embedded UI map fragment, the cache must be manually flushed in order for your changes to be recognized. Refer to Server Cache for more information.

Build A Dropdown

Syntax is provided to build a dropdown list in an edit map. The dropdown may be built using data returned from a service script, a business service or a table.

Syntax	Description
`uiHint:select="ss: "`	Specify the name of the service script after the colon.
`uiHint:select="bs: "`	Specify the name of the business service after the colon.
`uiHint:select="table: "`	Specify the name of the table after the colon.

When specifying a service script or a business service, extra mapping information is needed to pass data to and from the service.

Syntax	Values	Description
`uiHint:selectIn=" "`	serviceXPath:element	Used to pass the value of another element into the service (mapping to the service's XPath).
	serviceXPath:'Literal'	Used to pass a constant or literal to the service (mapping to the service's XPath).

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Values	Description
`uiHint:selectOut="valuePath: ; descPath: "`	See examples below.	Used to indicate which element in the service's output holds the values and which one holds the descriptions.

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
    <boStatus mapField="BO_STATUS_CD" uiHint:select="bs:F1-BOStateReasonList"
    uiHint:selectIn="boStatusBO:boStatusBO"
uiHint:selectOut="valuePath:results/status;
    descPath:results/description"/>
    ...
    <algorithm mdField="ALG_CD" uiHint:select="bs:F1-
RetrieveSysEvtAlgorithms"
     uiHint:selectIn="algorithmEntity:'F1AA';"
uiHint:selectOut="valuePath:results/algorithm;
     descPath:results/description"/>
    ...
    <outboundMsgType mdField="OUTMSG_TYPE_CD" required="true" fkRef="F1-
OMTYP" uiHint:select="table:F1_OUTMSG_TYPE"/>
</schema>
```

Conditionally Hide Elements

The **displayNone** attribute is used to suppress elements on the map based on conditions.

Syntax	Values	Description
`uiHint:displayNone=`	"'XPath','value','!=' | '='"	Used to conditionally hide this element based on the value of another element (referenced using its XPath). Enter a value of `' '` to interrogate a blank value. By default the operator is `'='`. This may be overridden using `'!='`.
	"function name, **true** | **false**"	Used to indicate a JavaScript function, which must return a Boolean.

> **Warning**
>
> Embedded spaces are not supported within the comma separated string values of this attribute.
>
> This setting may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be hidden conditionally.

The following example illustrates that two elements (currency reference and lookup) that will be hidden or displayed based on the value of the data type element. Note that this example also

Copyright © 2026, Oracle and/or its affiliates.

illustrates Trigger Dependent Behavior because the data type element's value may change and if it does, the condition for hiding the subsequent elements should be re-evaluated.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
    ...
    <dataType mdField="F1_SE_DATA_TYPE" dataType="lookup"
lookup="F1_SE_DATA_TYPE"
     uiHint:dependents="currencyRef;lookup; "/>
     <currencyRef mdField="F1_SE_CURR_REF_LBL"
uiHint:displayNone="'dataType','F1MO','!='"/>
     <lookup mdField="F1_SE_LOOKUP_LBL" fkRef="F1-LKUPF"
uiHint:displayNone="'dataType','F1LP','!='"/>
     ...
</schema>
```

The following example illustrates referring to a function where the function receives parameters:

```
<uiHint:startSection mdField="F1_SE_DEFAULT_SECT"
    uiHint:displayNone="isApplicableForSchemaType(item,'F1MP'),true"/>
```

Conditionally Protect Elements

The protect attribute is used to protect elements on the map based on other factors.

Syntax	Values	Description
`uiHint:protect=`	"'XPath','value','!=' | '='"	Used to conditionally protect this element based on the value of another element (referenced using its XPath). Enter a value of ' ' to interrogate a blank value. By default the operator is `'='`. This may be overridden using `'!='`.
	"function name, **true** | **false**"	Used to indicate a JavaScript function, which must return a Boolean.
	"'**action**','A' | 'C','!=' | '='"	Use the `'action'` setting to protect the element based on the current action. For example, certain elements may only be specified when adding a record. Any subsequent changes to the record should protect the element from being changed. When using this option, the valid values for the *'value'* are `A` (add) and `C` (change).

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> Embedded spaces are not supported within the comma separated string values of this attribute.
>
> The protect UI Hint may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be protected conditionally.

The following UI Hint will protect the statistics category when the action is 'C'.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
     ...
     <statisticsCategory dataType="lookup" mapField="STAT_CATEGORY_FLG"
    lookup="STAT_CATEGORY_FLG" uiHint:protect="'action','C','='"/>
     ...
    </schema>
```

Trigger Dependent Behavior

The dependents attribute is used to trigger behavior on a child element when a parent element is changed.

Syntax	Values
`uiHint:dependents=" "`	A list of one or more dependent elements separated by semicolons.

The following example illustrates that the dropdown list of one element is driven by the value of another element. In this example, when the Country changes, the list of States to choose from should change to only show the states for the indicated country.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <country label="Country" uiHint:select="table:CI_COUNTRY"
uiHint:dependents="state"/>
  <state label="State" uiHint:select="ss:CM-RetrieveCountryStates"
   uiHint:selectIn="input/country:country;"
uiHint:selectOut="valuePath:output/state/stateCode;
   descPath:output/state/stateDesc"/>
    ...
</schema>
```

> **Note**
>
> Dependent targets may only name elements, not group or list nodes.
>
> Do not modify the "id" attribute value of dependent and parent element. Data population in dependent is done based on the "id" attribute value.

Copyright © 2026, Oracle and/or its affiliates.

Control Rendering Target

By default all elements that are not suppressed are visible on both the display map and the input map. Use the **visibleOn** attribute to limit the inclusion of an element to either the display or input map.

Syntax	Values
`uiHint:visibleOn=`	`"displayMap"` `"inputMap"`

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap"
  ...
</schema>
```

Generate a Text Area

By default, a standard text box is rendered in an input map for any string element. If the field is larger and you wish to have a bigger text area (with a scroll bar), use the **textArea** attribute.

Syntax
`uiHint:textArea="true"`

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
   ...
  <message label="Message" uiHint:textArea="true"/>
  ...
</schema>
```

Modify FK Reference Defaults

By default, when an element with **fkRef** is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

Syntax
`uiHint:fkRef="info:false;context:false;navigation:false;search:false;"`

Only the feature that you wish to turn off needs to be specified. The following example illustrates turning off the navigation capability, meaning the text will not be rendered as hypertext.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
   ...
   <attachmentID fkRef="F1-ATTCH" primeKey="true" suppress="input"
uiHint:fkRef="navigation:false;"/>
```

Copyright © 2026, Oracle and/or its affiliates.

```
   ...
</schema>
```

> **NOT_SUPPORTED**
>
> Refer to FK Reference Formatting in the UI Map Attributes section for more information on each FK reference setting.

Suppress Automatic Number Formatting

By default numeric fields (`dataType="number"`) are formatted as numbers. An attribute is provided to instead apply alphanumeric formatting.

Note: If **dataType** is not specified explicitly, it is be derived from **mdField** or **mapField**.

Syntax
`uiHint:alphaFormat="true|false"`

By default, its value is **false** (and therefore can be left out altogether).

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
     ...
     <numberCount mdField="" dataType="number" uiHint:alphaFormat="true"/>
        ...
    </schema>
```

Auto Capitalize the Input Data

The uiHint provides syntax to automatically capitalize input data.

Syntax
`uiHint:capitalize="true|false"`

By default, its value is **false** (and therefore can be left out altogether).

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
     <toDoTypeCd mdField="TD_TYPE_CD" uiHint:capitalize='true'
isPrimeKey="true"/>
</schema>
```

> **Note**
>
> This attribute is ignored if `uiHint:textArea="true"` is configured.

The attribute is only available in the schema designer when the **isPrimeKey** is set to **true**. The attribute may be added to any string element when using the source viewer.

Copyright © 2026, Oracle and/or its affiliates.

Override Row Header for Accessibility Purposes

When generating the HTML for a list, the default is to assign scope="row" to the non-suppressed primary key elements, if any, or the first non-suppressed element in the list. This uiHint provides syntax to override the defaults when they are not the appropriate elements to be used by a screen reader.

Syntax
`uiHint:rowHeader="true|false"`

```
<iwsAnnotationTypeParameter mdField="F1_ANN_TYPE_PARMS_LBL" type="list"
mapChild="F1_IWS_ANN_TYPE_PARM">
        <sequence dataType="number" mapField="SEQ_NUM"
uiHint:rowHeader="false"/>
        <parameterName mapField="PARM_NAME" uiHint:rowHeader="true"
dataType="string"/>
        <parameterValue mapField="PARM_VALUE" dataType="string"/>
        <isRequired dataType="lookupBO" mapField="REQUIRED_SW" lookupBO="F1-
BooleanValues"/>
        <javaPackage mapField="JAVA_PACKAGE" dataType="string"/>
        <version suppress="true" dataType="number" mapField="VERSION"/>
        <description mapField="DESCR" dataType="string"/>
        <longDescription mapField="DESCRLONG" uiHint:textArea="true"
dataType="string"/>
        <owner suppress="input" dataType="lookup" mapField="OWNER_FLG"
lookup="OWNER_FLG"/>
    </iwsAnnotationTypeParameter>
```

The attribute is only applicable to elements in a list.

Defining UI Maps

Use this page to define basic information about a user interface (UI) Map.

You can access the portal from the **Admin Menu**, and then **System**, and then **UI Map**. You are brought to a query portal with options for searching for a specific UI Map. Once a UI Map has been selected you are brought to the maintenance portal to view and maintain the selected record.

> ⚠ **Caution**
>
> Important! If you introduce a new UI Map, carefully consider its naming convention. Refer to System Data Naming Convention for more information.

Refer to Understanding UI Maps for more information.

Use **UI Map Type** to indicate the map type. The system recommends using a **Complete XHTML Document** (the default) or **XHTML Fragment**. The values **Complete HTML Document** and **HTML Fragment** remain for backward compatibility but are not recommended.

The following zones may appear as part of the portal's **Main** tab page.

Copyright © 2026, Oracle and/or its affiliates.

- **UI Map.** This zone provides information about the selected UI Map.
- **HTML Editor.** This zone allows you to edit the HTML document of the map.

> **Note**
>
> Refer to UI Map Attributes and Functions and UI Map Standards for more information about HTML definition syntax. These topics describe good ways to produce simple HTML, however, they are not an HTML reference. Note that you can use a variety of HTML editors to compose your HTML, which you can then cut and paste into your UI map.

> **Note**
>
> **Providing Help.** A tool tip can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map. Refer to UI Map Attributes and Functions for more information on how to enable and provide UI map help.

- **HTML Override Editor.** This zone allows you to provide an override HTML document for a base product map.

The following zones may appear as part of the portal's **Schema** tab page.

- **Schema Editor.** This zone allows you to edit the UI Map's schema using the Schema Designer tool. The purpose of the schema is to describe the UI Map's properties.

> **NOT_SUPPORTED**
>
> Refer to Schema Syntax and UI Hint syntax for a complete list of the XML nodes and attributes available to you when you construct a schema.

> **Tip**
>
> Click the **View Schema** hyperlink to view the UI Map's expanded schema definition. Doing this opens the schema viewer window.

The following zones may appear as part of the portal's **References** tab page.

- **UI Map References.** This zone list various configuration entities referencing the current UI Map, its HTML or its schema.

Actions

The page supports the following special actions:

- **View Schema.** Click the hyperlink to view the UI Map's expanded schema definition. Doing this opens the schema viewer window.
- **Test UI Map.** Use the hyperlink to render your HTML in a test window. This action also exercises the proprietary functionality that binds an XML element with an HTML element so you can get immediate feedback on your HTML syntax.
- UI Map Attributes and Functions

Copyright © 2026, Oracle and/or its affiliates.

- UI Map Standards

UI Map Attributes and Functions

> **Note**
>
> Use the UI Map Query's Additional Information option to review HTML examples provided by the product.

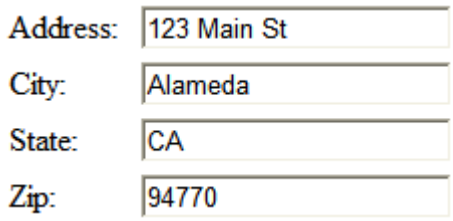
Bind XML to HTML

Only two different attributes are required to bind a UI Map's XML to its HTML. Both of these attributes require an XML document embedded within the HTML, where the XML is bounded by <xml> nodes.

> **Warning**
>
> You must embed a pair of <xml></xml> tags within your HTML document for binding to occur.

Linking a Field

Syntax	Values	Description
oraField=" "	Field element XPath	This attribute is used to link an HTML element directly with an XML element, where the XML element is defined within the UI Map's XML schema. The attribute can be used with any *rendering* HTML element, such as: , , and <input>.



- HTML for input element:

```
<html>
<body>
<table>
   <tr>
      <td>Address:</td>
      <td><input type="text" oraField="address"/></td>
   </tr>
   <tr>
      <td>City:</td>
      <td><input type="text" oraField="city"/></td>
   </tr>
   <tr>
      <td>State:</td>
      <td><input type="text" oraField="state"/></td>
   </tr>
   <tr>
      <td>Zip:</td>
      <td><input type="text" oraField="zip"/></td>
```

Copyright © 2026, Oracle and/or its affiliates.

```
   </tr>
</table>
</body>
<xml>
   <root>
      <address>123 Main St</address>
      <city>Alameda</city>
      <state>CA</state>
      <zip>94770</zip>
   </root>
</xml>
</html>
```

Rendered HTML

- HTML for span and div elements:

```
<html>
<body>

<div oraField="address"></div>
<span oraField="city"></span>
<span>,</span>
<span oraField="state"></span>
<span oraField="zip"></span>
<span oraField="country"></span>

</body>
<xml>
   <root>
      <address>123 Main St</address>
      <city>Alameda</city>
      <state>CA</state>
      <zip>94770</zip>
   </root>
</xml>
</html>
```

HTML rendered:

123 Main St
Alameda, CA 94770

Linking a List

Copyright © 2026, Oracle and/or its affiliates.

This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the framework to replicate the table's HTML for each occurrence of the list.

Syntax	Values	Description
oraList=" "	List element XPath	This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the framework to replicate the table's HTML for each occurrence of the list.

> **Note**
>
> The oraField attributes embedded within the list must contain XPath navigation relative to the list. See below for an example.

```
<html>
<head><title>Bind xml list element</title></head>
<body>
<table oraList="payment">
   <thead>
      <tr>

HTML rendered:

Pay Date	Amount
01-01-2008	$44.28
02-01-2008	$32.87
03-01-2008	$21.76

Build a Dropdown List

The following attributes are provided to build an HTML ‘select’ element, also called a dropdown, based on various sources.

Source	Syntax	Values	Examples

Lookup	`oraSelect="lookup: ;"`	Lookup field	`...`
			`<td>House Type:</td>`
			`<td>`
			`<select oraField="houseType" oraSelect="lookup:HOUSE_TYPE;" >`
			`</select>`
			`</td>`

Extendable Lookup	`oraSelect="lookupBO: ;"`	BO code	`...`
			`<td>UI Device Display Type:</td>`
			`<td>`
			`<select oraField="uiDeviceType" oraSelect="lookupBO: F1-DeviceDisplayTypes;"></select>`
			`</td>`

Characteristic Type (pre-defined)	`oraSelect="charType: ;"`	Characteristic Type code	`...`
			`<td>Usage:</td>`
			`<td>`
			`<select oraField="statusReasonUsage" oraSelect="charType:F1-SRUSG;"></select>`
			`</td>`
			`...`

Copyright © 2026, Oracle and/or its affiliates.

Source	Syntax	Values	Examples
Control Table	`oraSelect="table: ;"`	Table name	``` ... <td>Currency: </td> <td> <select oraField="currency" oraSelect="table:CI_CURRENCY_CD;"> </select> </td> ... ```

Note

This attribute only works with tables that follow the esta

Source	Syntax	Values	Examples

Page Service	`oraSelect="service: ;"`	Page Service name	`...`
			`<td>Country:</td>`
			`<td>`
			`<select oraField="country" oraSelect="service:CIPTCNTW;">`
			`</select>`
			`</td>`
			`...`

Embedded List	Used to build a select dropdown based on a list within the map's XML. `oraSelect="valuePath: ;descPath: "`	After the valuePath, indicate the XPath of the element that holds the values. After the descPath, indicate the XPath of the element that holds the descriptions.	`<html>`
			`<body>`
			`<table summary="" border="0" cellpadding="1" cellspacing="1">`
			`<tr>`
			`<td>Select: </td>`
			`<td><select oraSelect= "valuePath:list/value; descPath:list/desc" oraField="target"></ select></td>`
			`</tr>`
			`</table>`
			`</body>`
			`<xml>`
			`<root>`
			`<target>10</target>`
			`<list>`
			`<value>10</value>`
			`<desc>Ten</desc>`
			`</list>`
			`<list>`
			`<value>20</value>`
			`<desc>Twenty</desc>`
			`</list>`
			`<list>`
			`<value>40</value>`
			`<desc>Forty</desc>`
			`</list>`
			`</root>`
			`</xml>`
			`</html>`

Service Script	`oraSelect="ss: ; "`	Service Script code	See below for additional syntax needed when using this function.
Business Service	`oraSelect="bs: ; "`	Business Service code	See below for additional syntax needed when using this function.

Copyright © 2026, Oracle and/or its affiliates.

When specifying a service script or a business service, extra mapping information is needed to pass data to and from the service.

Syntax	Values	Description
oraSelectIn=" ;"	serviceXPath:element;	Used to pass the value of another element into the service (mapping to the service's XPath).
	serviceXPath:'Literal';	Used to pass a constant or literal to the service (mapping to the service's XPath).
oraSelectOut= "valuePath: ; descPath: "	See examples below	Used to indicate which element in the service's output holds the values and which one holds the descriptions.

Example using a business service:

```
...
<td>External System: </td>
<td>
   <select oraField="externalSystem"
    oraSelect="bs:F1-RetrieveExternalSystems"
    oraSelectIn="outboundMsgType:boGroup/parameters/outboundMsgType;"
    oraSelectOut="valuePath:results/externalSystem;
    descPath:results/description">
   </select>
</td>
...
```

This method for building dropdowns is often used when there is a dependency between elements and the list of valid values in a dropdown (for the child element) is based on another element in the map (the parent element). When the parent element is changed, it may be required to refresh the child element. This behavior can be implemented using the function called within an **onChange** event in the map. The syntax is **oraHandleDependentElements('dependent element');**. Multiple target elements (dependents) can be named.

The following example is related to the above business service example where the list of external systems is specific for a given outbound message type, which is passed in as input. The snippet below shows the configuration for the outbound message type element to trigger a refresh of the external system’s dropdown list.

```
...
<div>
   <label oraLabel="boGroup/parameters/outboundMsgType"></label>
      <span>
         <select oraSelect="table:F1_OUTMSG_TYPE"
          oraField="boGroup/parameters/outboundMsgType"
          onChange="oraHandleDependentElements('boGroup/parameters/
externalSystem');">
         </select>
      </span>
</div>
...
```

Format Input and Output Fields

The following attributes are designed to apply data type formatting for input and output fields.

Automatic Formatting

Syntax
`oraSchemaDataTypes="false"`

This attribute is used to trigger automatic formatting in the rendered HTML document. The automated formatting will occur according to the data type attributes defined in the UI map's schema. For details on specific data type formatting, please refer to the oraType attribute descriptions below.

> **Warning**
>
> The attribute **oraSchemaDataTypes="true"** will be automatically injected into the UI map's HTML! If you do not wish to apply the schema's data types to the rendered HTML then you must specify this attribute in the body node with a value of false. The attribute **<body oraSchemaDataTypes="false">** is required to avoid automatic formatting!

- UI Map schema:

```
<schema>
    <schemaDate dataType="date"/>
    <schemaDateTime dataType="dateTime"/>
    <schemaFkRef fkRef="F1-MOTBL"/>
    <schemaLookup dataType="lookup" lookup="ACCESS_MODE"/>
    <schemaMoney dataType="money"/>
    <schemaNumber dataType="number"/>
    <schemaTime dataType="time"/>
</schema>
```

- UI Map HTML:

```
<html>
<body oraSchemaDataTypes="true">
<table border="1" cellpadding="1" cellspacing="1">
   <tr><th>dataType</th><th>input result</th><th> display-only result</
th></tr>
   <tr>
      <td>date</td>
      <td><input oraField="schemaDate"/></td>
      <td><span oraField="schemaDate"></span></td>
   </tr>
   <tr>
      <td>dateTime</td>
      <td><input oraField="schemaDateTime"/></td>
      <td><span oraField="schemaDateTime"></span></td>
   </tr>
   <tr>
```

```
      <td>fkRef</td>
      <td><input oraField="schemaFkRef"/></td>
      <td><span oraField="schemaFkRef"></span></td>
   </tr>
   <tr>
      <td>lookup</td>
      <td><input oraField="schemaLookup"/></td>
      <td><span oraField="schemaLookup"></span></td>
   </tr>
   <tr>
      <td>money</td>
      <td><input oraField="schemaMoney"/></td>
      <td><span oraField="schemaMoney"></span></td>
   </tr>
   <tr>
      <td>number</td>
      <td><input oraField="schemaNumber"/></td>
      <td><span oraField="schemaNumber"></span></td>
   </tr>
   <tr>
      <td>time</td>
      <td><input oraField="schemaTime"/></td>
      <td><span oraField="schemaTime"></span></td>
   </tr>
</table>

</body>
<xml>
<root>
   <schemaDate>2007-11-02</schemaDate>
   <schemaDateTime>2007-11-02-23.45.00</schemaDateTime>
   <schemaFkRef>CI_MD_TBL</schemaFkRef>
   <schemaLookup>A</schemaLookup>
   <schemaMoney>1000000</schemaMoney>
   <schemaNumber>5661976.11548</schemaNumber>
   <schemaTime>23.45.00</schemaTime>
</root>
</xml>
</html>
```

HTML rendered.

dataType	input result	display-only result
date	11-02-2007	11-02-2007
dateTime	11-02-2007 11:45:00PM	11-02-2007 11:45:00PM
fkRef	CI_MD_TBL Table	Table
lookup	A	Add
money	$1,000,000.00	$1,000,000.00
number	5,661,976	5,661,976
time	11:45:00PM	11:45:00PM

Date and Time Formatting

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Valid Values	Description
`oraType="date"`		This function is used to display a date according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.
`oraType="time"`		This function is used to display a time according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.
`oraType="dateTime; time:suppress"`		This function is used to display a timestamp according to the user's display profile. If this function is used for an input element, it is broken into two pieces, one for date and one for time. Optionally, the time portion of the date time element can be suppressed using the attribute value 'time:suppress'.
`oraType="dateTime; stdTime:true;"`		This function is used to render a date / time element that is stored in standard time according to the daylight savings time schedule of the 'base' time zone. The 'base' time zone is specified on the Installation table and represents the database time zone. For input elements with this setting, all time entered is assumed to correspond with the daylight savings time schedule of the base time zone. If a time is entered that cannot be unambiguously translated to standard time, then the user will be required to provide a time zone label to indicate whether daylight savings time, or standard time, has been entered.
`oraType="dateTime; stdTimeRef:;"`	Reference an XPath after the colon.	This function is used to render a date / time element according to the daylight savings time schedule of a time zone whose XPath is referenced. Note that the time processed is assumed to have been stored in the standard time of the referenced time zone - so only daylight savings time shifting will execute - not time zone shifting.
`oraType="dateTime; legalTime:true;"`		This function is used to render a date / time element that is stored in legal time of the 'base' time zone. The 'base' time zone is specified on the Installation table and represents the database time zone.
`oraType="dateTime; legalTimeRef: ;"`	Reference an XPath after the colon.	This function is used to render a date / time element according to the daylight savings time schedule of a time zone whose XPath is referenced. Note that the time processed is assumed to have been stored in the legal time of the referenced time zone.
`oraType="dateTime; … ; displayRef:;"`	Reference an XPath after the colon.	This function is used to display a date/time element that is explicitly defined as stored in standard or legal time (using either stdTime | stdRef | legalTime | legalRef) from its storage time zone to the referenced time zone in legal time before display and vice versa, from the display time zone to the storage time zone on save.

HTML rendered.

Copyright © 2026, Oracle and/or its affiliates.

dataType	input result	display-only result
date	11-02-2009	11-02-2009
time	12:28:54AM	12:28:54AM
dateTime	11-02-2009 12:28:54AM	11-02-2009 12:28:54AM
dateTimeSuppress	11-02-2009	11-02-2009
Base Time Zone (Standard) - Duplicate hour	11-01-2009 1:28:54AM PDT	11-01-2009 1:28:54AM PDT
Base Time Zone (Standard)	11-02-2009 12:28:54AM PST	11-02-2009 12:28:54AM PST
Base Time Zone (Legal)	11-02-2009 12:28:54AM PST	11-02-2009 12:28:54AM PST
Referenced Time Zone (Standard)	11-02-2009 12:28:54AM EST	11-02-2009 12:28:54AM EST
Referenced Time Zone (Legal)	11-02-2009 12:28:54AM EST	11-02-2009 12:28:54AM EST
Stored in Base Time Zone (Standard) - displayed in another Time Zone	11-02-2009 2:28:54AM CST	11-02-2009 2:28:54AM CST
Stored in Base Time Zone (Legal) - displayed in another Time Zone	11-02-2009 2:28:54AM CST	11-02-2009 2:28:54AM CST
Stored in a Referenced Time Zone (Standard) - displayed in another Time Zone	11-01-2009 11:28:54PM CST	11-01-2009 11:28:54PM CST
Stored in a Referenced Time Zone (Legal) - displayed in another Time Zone	11-01-2009 11:28:54PM CST	11-01-2009 11:28:54PM CST

When an element is associated with a time zone the corresponding time zone name is displayed along with the value. This is specifically useful in the example referenced as "Base Time Zone (Standard) - Duplicate hour". The time 1:28 is ambiguous without a time zone label. Legally, November 1, 2009 1:28 AM occurs twice because daylight savings time (DST) is removed at 2:00 AM. The time zone name indicates whether the first or second hour is specified for the time zone.

Duration Formatting

Syntax

```
oraType="duration"
```

This function is used to display time duration. For an input element, the value entered by the user is translated from minutes to hour and minutes as appropriate. For example, an entered value of '90', is converted to '00:01:30' when tabbing out of the input field.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
   <tr>
      <td>Duration: </td>
      <td><span oraField="duration" oraType="duration"></span></td>
   </tr>
   <tr>
      <td>Duration: </td>
      <td><input oraField="duration" oraType="duration"/></td>
   </tr>
</table>
</body>
<xml>
<root>
   <duration>90</duration>
</root>
</xml>
</html>
```

HTML rendered.

Duration: 00:01:30

Duration: 00:01:30

Copyright © 2026, Oracle and/or its affiliates.

Day in Month Formatting

Syntax
`oraType="dayInMonth"`

This function is used to display a concatenated day and month.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
   <tr>
      <td>Day In Month: </td>
      <td><span oraField="dayMonth" oraType="dayInMonth"></span></td>
   </tr>
   <tr>
      <td>Day In Month: </td>
      <td><input oraField="dayMonth" oraType="dayInMonth"/></td>
   </tr>
</table>
</body>
<xml>
<root>
   <dayMonth>0228</dayMonth>
</root>
</xml>
</html>
```

HTML rendered.

Day In Month: 02-28

Day In Month: 02-28

Month In Year Formatting

Syntax
`oraType="monthInYear"`

This function is used to display a concatenated month and year.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
   <tr>
      <td>Month In Year: </td>
      <td><span oraField="month" oraType="monthInYear"></span></td>
   </tr>
   <tr>
      <td>Month In Year: </td>
      <td><input oraField="month" oraType="monthInYear"/></td>
   </tr>
</table>
</body>
```

Copyright © 2026, Oracle and/or its affiliates.

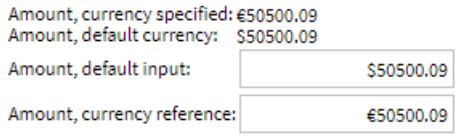
```
<xml>
<root>
   <month>200811</month>
</root>
</xml>
</html>
```

HTML rendered.

Monetary Formatting

This function is used to display a number as a monetary amount. See the table for configuration options with respect to the currency. For input elements, an error is issued if a non-numeric value is entered.

Syntax	Description
`oraType="money: "`	Directly specify a currency code after the colon.
`oraType="money;currencyRef: "`	Reference an XPath (after the colon) for an element that references a currency code.
`oraType="money"`	If no currency or currency reference is specified, the installation currency is used.



> **Note**
>
> You must specify the stylesheet reference cisDisabled in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the oraMoney style.

```
<html>
<head>
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Amount, currency specified:</td>
      <td><span oraType="money:EUR" oraField="totalAmt"></span></td>
   </tr>
   <tr>
      <td>Amount, default currency:</td>
      <td><span oraType="money" oraField="totalAmt"></span></td>
   </tr>
   <tr>
      <td>Amount, default input:</td>
      <td><input oraType="money" oraField="totalAmt"/></td>
   </tr>
   <tr>
      <td>Amount, currency reference:</td>
      <td><input oraType="money;currencyRef:cur" oraField="totalAmt"/></td>
```

Copyright © 2026, Oracle and/or its affiliates.

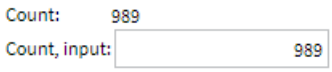
```
   </tr>
</table>
</body>
<xml>
<root>
   <totalAmt>50500.09</totalAmt>
   <cur>EUR</cur>
</root>
</xml>
</html>
```

HTML rendered

Number Formatting

This function is used to display a number or validate an input value. For input elements, the system will return an error if a non-numeric value is entered.

Syntax
`oraType="number"`



> **Note**
>
> You must specify the stylesheet reference cisDisabled in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the oraNumber style.

```
<html>
<head>
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Count:</td>
      <td><span oraType="number" oraField="count"></span></td>
   </tr>
   <tr>
      <td>Count, input:</td>
      <td><input oraType="number" oraField="count"/></td>
   </tr>
</table>
</body>
<xml>
<root>
   <count>989</count>
</root>
```

Copyright © 2026, Oracle and/or its affiliates.

```
</xml>
</html>
```

HTML rendered.

FK Reference Formatting

By default, when an element with an **fkRef** oraType is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

Note that you can enable the foreign key hyperlink separately as well, refer to Embed Framework Navigation for more information. The various attributes used to control foreign key reference functionality are as follows. Note that in every case, the default value is **true**. A value of **false** should be used to disable the feature.

Syntax
`oraType="fkRef:true|false; info:true|false; context:true|false; navigation:true|false; search:true|false"`

- **fkRef**. A value of 'true' enables all of the following foreign key reference processing. Use a value of 'false' to disable automatic FK Reference processing.
- **info**. A value of 'true' renders an information string on the UI map, if applicable.
- **context**. A value of 'true' renders a context menu to appear before the foreign key reference element, if applicable.
- **navigation**. A value of 'true' causes the information string to be rendered as a hyperlink, if applicable. Clicking the hyperlink navigates to the appropriate page.
- **search**. A value of 'true' displays a search icon that launches the search zone if applicable.

> **Note**
>
> Foreign key navigation and context menu functionality is only available for UI maps presented in a portal zone. UI Maps presented during BPA script processing cannot support navigation options. Search functionality is only available for input HTML elements.

- UI Map schema:

```
<schema>
  <bo fkRef="F1-BOMO"/>
</schema>
```

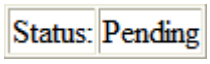
- UI Map HTML:

```
<html>
<body>
```

Copyright © 2026, Oracle and/or its affiliates.

```
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Business Object</td>
      <td><span oraField="bo" oraType="fkRef:true; info:true;
context:true; navigation:true;"></span></td>
   </tr>
</table>
</body>
<xml>
<root>
   <bo>F1-COUNTRY</bo>
</root>
</xml>
</html>
```

- HTML rendered.



Lookup Formatting

This function is used to display the description of a lookup value.

Syntax	Valid Values
`oraType="lookup: "`	Lookup field name after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Status:</td>
      <td><span oraField="status" oraType="lookup:BATCH_JOB_STAT_FLG"></
span></td>
   </tr>
</table>
</body>
<xml>
<root>
   <status>PD</status>
</root>
</xml>
</html>
```

HTML rendered.

Extendable Lookup Formatting

This function is used to display the description of an extendable lookup value.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Valid Values
`oraType="lookupBO: "`	Business Object code name after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Value:</td>
      <td><span oraField="status" oraType="lookupBO:F1-DeviceDisplayTypes"></
span></td>
   </tr>
</table>
</body>
<xml>
<root>
    <status>oraTablet</status>
</root>
</xml>
</html>
```

HTML rendered.

Value:	Tablet size

Characteristic Type Formatting

This function is used to display the description of a predefined characteristic value.

Syntax	Valid Values
`oraType="charType: "`	Characteristic Type code after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
    <tr>
        <td>Skill:</td>
        <td><span oraType="charType:CM-SKILL" oraField="skill"></span></td>
    </tr>
</table>
</body>
<xml>
<root>
    <skill>10</skill>
</root>
</xml>
</html>
```

HTML rendered.

Copyright © 2026, Oracle and/or its affiliates.

Control Table Formatting

This function is used to display the description of a control table that has an associated language table.

Syntax	Valid Values
`oraType="table: "`	Table code after the colon.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Currency:</td>
      <td><span oraType="table:CI_CURRENCY_CD" oraField="curr"></span></td>
   </tr>
</table>
</body>
<xml>
<root>
   <curr>USD</curr>
</root>
</xml>
</html>
```

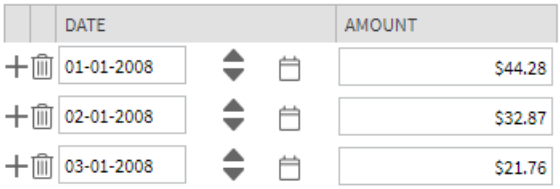
HTML rendered.

Add / Remove Grid Formatting

Syntax	Description
`oraType="addGridRow"`	The addGridRow function is used to build "insert row" dialog into the UI map. • An 'add' image is displayed. • Clicking the image inserts a new row in the grid. • If the list is empty, by default, an empty grid row is automatically be added. This means that the user will always see at least one grid row when this attribute is used.
`oraType="deleteGridRow"`	The deleteGridRow function is used to build "delete row" dialog into the UI map. • A 'delete' image is displayed. • Clicking the image removes the adjacent row from the grid.

> **Note**
>
> Because add and delete dialogs are relevant only inside a table, these attributes must be specified within a <td> element.

Copyright © 2026, Oracle and/or its affiliates.



> **Warning**
>
> These attributes are designed to work with the business object action of 'replace' rather than 'update'. Therefore, if the map contains a grid, the business object action of 'replace' must be used to update the business object. Refer to BO Replace Action for more information.

Example:

```
<html>
<head>
<title>Demonstrate Grid Add and Grid Delete OraTypes</title>
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table oraList="listEntry">
   <thead>
      <tr>
         <th/>
         <th/>
         <th><span>Date</span></th>
         <th><span>Amount</span></th>
      </tr>
      <tr/>
   </thead>
   <tr>
      <td oraType="addGridRow"></td>
      <td oraType="deleteGridRow"></td>
      <td>
         <input oraField="date" oraType="date"></input>
      </td>
      <td align="right">
         <input oraField="amount" oraType="money"></input>
      </td>
   </tr>
</table>
</body>
<xml>
<root>
   <listEntry>
      <date>2008-01-01</date>
      <amount>44.28</amount>
   </listEntry>
   <listEntry>
      <date>2008-02-01</date>
      <amount>32.87</amount>
   </listEntry>
   <listEntry>
      <date>2008-03-01</date>
      <amount>21.76</amount>
   </listEntry>
</root>
</xml>
</html>
```

Copyright © 2026, Oracle and/or its affiliates.

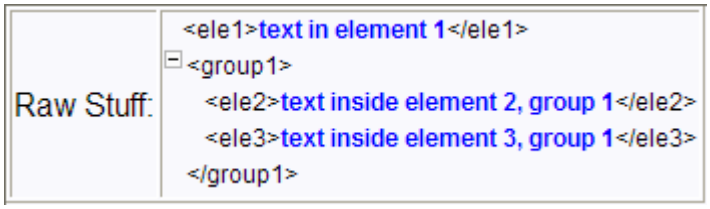
HTML rendered.

Unformatted Elements

This function is used to display the contents of an element that contains 'raw' data as defined for the schema element being rendered.

Syntax
`oraType="raw"`

- UI Map schema:



```
<schema>
    <rawStuff type="raw"/>
</schema>
```

- UI Map HTML:

```
<html>
<head>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>Raw Stuff:</td>
      <td><span oraType="raw" oraField="rawStuff"></span></td>
   </tr>
</table>
</body>
<xml>
<root>
   <rawStuff>
      <ele1>text in element 1</ele1>
      <group1>
         <ele2>text inside element 2, group 1</ele2>
         <ele3>text inside element 3, group 1</ele3>
      </group1>
   </rawStuff>
</root>
</xml>
</html>
```

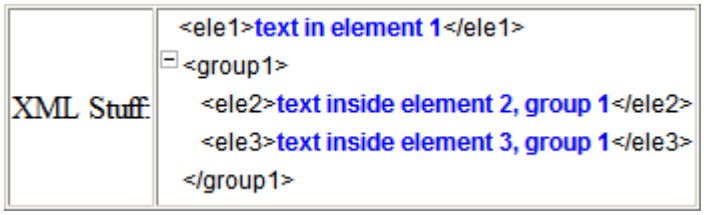
HTML rendered.

Copyright © 2026, Oracle and/or its affiliates.

String Formatting

This function is used to display the contents of an element, as XML pretty-print, when the element contains escaped XML.

Syntax
`oraType="xmlString"`



> **Note**
>
> It is not required, but the pretty print of the rendered XML is enhanced if you specify the stylesheet reference cisDisabled in the map's header.

Example:

```
<html>
<head>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>XML Stuff:</td>
      <td><span oraType="xmlString" oraField="xmlStuff"></span></td>
      </tr>
</table>
</body>
<xml>
<root>
   <xmlStuff>
      <ele1>text in element 1</ele1>
      <group1>
         <ele2>text inside element 2, group 1</ele2>
         <ele3>text inside element 3, group 1</ele3>
      </group1>
   </xmlStuff>
</root>
</xml>
</html>
```

HTML rendered.

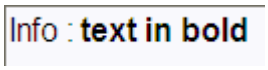
Copyright © 2026, Oracle and/or its affiliates.

HTML rendered without oraType="xmlString"

XML Stuff:	<ele1>text in element 1</ele1><group1><ele2>text inside element 2, group 1</ele2><ele3>text inside element 3, group 1</ele3></group1>

HTML Formatting

This function is used to display the contents of an element as HTML as opposed to plain text. An element defined as oraType="fkref" is automatically rendered as HTML.



Syntax
`oraType="html"`

> **Warning**
>
> To avoid execution of malicious HTML not all HTML tags are supported. The list of supported tags is defined in the "F1-HTMLWhiteList" managed content definition.
>
> If unsupported HTML is detected the entire element is escaped and rendered as plain text. It is therefore recommended to properly escape any source string that contributes to the final HTML element if it is not expected to contain valid HTML. This way only the offending string is escaped and not the entire element.
>
> If the HTML element is composed in scripting refer to the 'escape' function described in the Edit Data Syntax for more information. Use the WebStringUtilities.asHTML java API for escaping text composed in Java.

```
<html>
<head>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
   <tr>
   <td>Info :</td>
   <td><span oraType="html" oraField="info"></span></td>
   </tr>
</table>
</body>
<xml>
<root>
   <info><b>text in bold</b></info>
</root>
</xml>
</html>
```

HTML rendered.

HTML rendered without oraType="html"

Display Labels

Derive Label from an Element

This attribute is used to obtain a language sensitive label for a , <td>, or <input> HTML element.

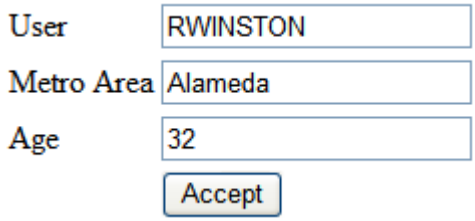
Syntax	Valid Values
`oraLabel=" "`	XPath of an element in the UI map schema. The element must reference either the `mapField=` , `mdField=` , or `label=` attribute.

> **Note**
>
> You can also define a field directly in your HTML for label definition, refer to Deriving Label from a Field for more information.

> **Note**
>
> If the schema contains multiple attributes, the oraLabel attribute will pick the label to render according to the following hierarchy: The label attribute overrides the mdField attribute, which in turn will override the mapField attribute.

- UI Map schema:

```
<schema>
   <user mapField="USER_ID"/>
   <info type="group" mapXML="CLOB">
      <city label="Metro Area"/>
      <age mdField="AGE_LBL"/>
   </info>
</schema>
```



- HTML:

```
<html>
<head><title oraMdLabel="BUS_LBL"></title></head>
<body>
```

Copyright © 2026, Oracle and/or its affiliates.

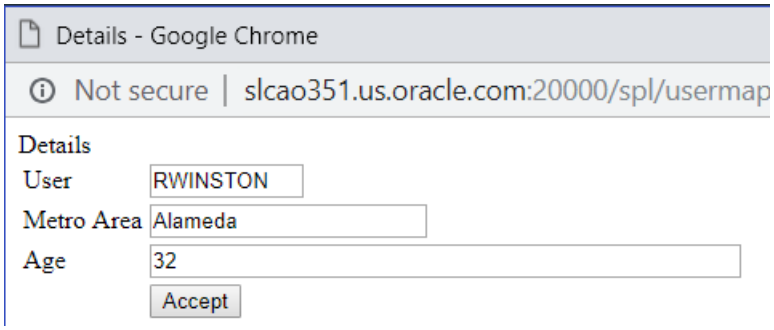
```
<table>
   <tr>
      <td oraLabel="user"></td>
      <td><input oraField="user"/></td>
   </tr>
   <tr>
      <td oraLabel="info/city"></td>
      <td><input oraField="info/city"/></td>
   </tr>
   <tr>
      <td oraLabel="info/age"></td>
      <td><input oraField="info/age"/></td>
   </tr>
   <tr>
      <td/>
      <td><input type="button" oraMdLabel="ACCEPT_LBL"/></td>
   </tr>
</table>
</body>
<xml>
<root>
   <user>RWINSTON</user>
   <info>
      <city>Alameda</city>
      <age>32</age>
   </info>
</root>
</xml>
</html>
```

HTML rendered:

Deriving Label from a Field

This attribute is used to obtain a language sensitive label for a , <td>, <input>, or <title> HTML element. The label text is derived from the field referenced.

Syntax	Valid Values
`oraMdLabel=" "`	MD Field code.



> **Note**
>
> You can also define labels derived from the map's schema definition, refer to Derive Label from an Element for more information.

Copyright © 2026, Oracle and/or its affiliates.

- HTML:

```
<html>
<head><title oraMdLabel="F1_DETAILS_LBL"></title></head>
<body>
<table>
   <tr>
      <td oraLabel="user"></td>
      <td><input oraField="user"/></td>
   </tr>
   <tr>
      <td oraLabel="info/city"></td>
      <td><input oraField="info/city"/></td>
   </tr>
   <tr>
      <td oraLabel="info/age"></td>
      <td><input oraField="info/age"/></td>
   </tr>
   <tr>
      <td/>
      <td><input type="button" oraMdLabel="ACCEPT_LBL"/></td>
   </tr>
</table>
</body>
<xml>
<root>
   <user>RWINSTON</user>
   <info>
      <city>Alameda</city>
      <age>32</age>
   </info>
</root>
</xml>
</html>
```

HTML rendered:

Enable UI Map Help

The Display Labels section describes ways to derive the label for an element using an underlying MD Field. In addition, if the same MD field contains help text, the system will automatically generate a tool tip adjacent to the element label. Clicking the tool tip allows the user to view the help text.

Copyright © 2026, Oracle and/or its affiliates.

It is possible to change the rendering of the tool tip. Refer to Custom Look And Feel Options for more information

Search Using a Pop-Up Explorer Zone

Search Option

This attribute is used to enable search zone functionality for input HTML elements.

Syntax	Valid Values
`oraSearch=" "`	Zone code.

> **Note**
>
> The oraSearch attribute is similar to the oraType attribute, because it will be 'automatically' included into HTML via the oraSchemaDataTypes attribute. This means that coding the oraSearch attribute into UI Map HTML is only required if a search zone has not been specified in the schema, or in the schema element's FK reference.

- Example of defining the search in the HTML. UI Map's Schema:

```
<schema>
   <uiMap/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>UI Map with Search </td>
      <td><input oraField="uiMap" oraSearch="F1-UISRCH"></td>
   </tr>
</table>
</body>
<xml>
<root>
   <uiMap/>
</root>
</xml>
</html>
```

- Example of defining the search in the schema. UI Map's Schema:

```
<schema>
   <uiMap search="F1-UISRCH"/>
</schema>
```

Copyright © 2026, Oracle and/or its affiliates.

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>UI Map with Search </td>
      <td><input oraField="uiMap"></td>
   </tr>
</table>
</body>
<xml>
<root>
   <uiMap/>
</root>
</xml>
</html>
```

- Example where the FK reference defines the search zone. UI Map's Schema:

```
<schema>
   <uiMap fkRef="F1-UISRC"/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>UI Map with Search </td>
      <td><input oraField="uiMap"></td>
   </tr>
</table>
</body>
<xml>
<root>
   <uiMap/>
</root>
</xml>
</html>
```

In all cases, the HTML rendered is the same.

Initializing Search Fields

This optional attribute is used to initialize search zone filters. Multiple filters may be initialized. This attribute can only be used in conjunction with the oraSearch attribute.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Valid Values	Field Value Options	Comments
`oraSearchField=" "`	One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon. `oraSearchField="fieldName:fieldValue: ..."` The field name is used to identify the zone filter to initialize when the search is launched. The field name must match the value of the searchField mnemonic specified on a search zone user filter or hidden filter parameter.	No value	If you do not specify a field value, then the value of the input element containing the oraSearchField attribute will be used.
		XPath	Indicate the XPath to the schema element that contains the value to use.
		'literal'	Indicate a literal value to supply.

> **Note**
>
> If you do not specify an oraSearchField attribute and the schema element has a search enabled fkRef specified, the framework automatically builds an oraSearchField where the field name is equal to the FK reference's key (MD) fields.

> **Warning**
>
> The pop-up explorer zone can be invoked one of two ways: By clicking on the search button, or by hitting the enter key from the field to the left of the button. If you click on the button then no search field information will be passed to the zone. Search field information is only used to initialize zone filter values when enter is pressed.

Two filter values are initialized as shown in the following example:

```
<schema>
   <bo/>
   <uiMap/>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>UI Map with Search </td>
      <td><input oraField="uiMap" oraSearch="F1-UISRCH"
oraSearchField="MAP_CD; BUS_OBJ_CD:bo;"></td>
    </tr>
</table>
</body>
```

Copyright © 2026, Oracle and/or its affiliates.

```
<xml>
<root>
   <bo/>
   <uiMap/>
</root>
</xml>
</html>
```

Mapping Returned Search Fields

This optional attribute is used to direct values returned by the search zone. Multiple fields may be specified. This attribute can only be used in conjunction with the oraSearch attribute.

Syntax	Valid Values	Field Value Options	Comments
`oraSearchOut=" "`	One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon. `oraSearchOut="field name:xpath target; ..."` The field name is used to identify the search result returned from the query zone. The field name must match the ELEMENT_NAME mnemonic defined within the explorer zone's search results parameter.	No value XPath	If you do not specify a field value, then the input element containing the oraSearchField attribute receives the returned value. Indicate the XPath to the schema element that should receive the returned value.

> **Note**
>
> If you do not specify an oraSearchOut attribute, the framework will build a default where the field name will be set equal to the oraSearchField's field name.

Two values are returned in the following example:

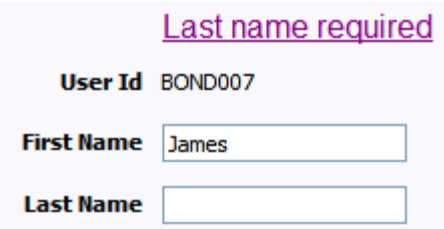
```
<schema>
   <bo/>
   <mo/>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
   <tr>
      <td>BO Search </td>
      <td><input oraField="bo" oraSearch="Z1-BOSRCH"
oraSearchOut="BUS_OBJ_CD; MO_CD:mo;"></td>
```

Copyright © 2026, Oracle and/or its affiliates.

```
   </tr>
</table>
</body>
<xml>
<root>
   <bo/>
   <mo/>
</root>
</xml>
</html>
```

Display Errors



Display Error Variables

One of the following error variables may be displayed.

Syntax
`oraErrorVar="ERRMSG-TEXT"` `oraErrorVar="ERRMSG-LONG"`
`oraErrorVar="ERRMSG-CATEGORY"`
`oraErrorVar="ERRMSG-NUMBER"`

```
...
<table width="100%" cellpadding="12">
   <tr class="oraErrorText">
      <td>
         <a href="" onclick="oraShowErrorAlert(); return false;">
            <span  class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
         </a>
      </td>
   </tr>
</table>
...
```

HTML rendered

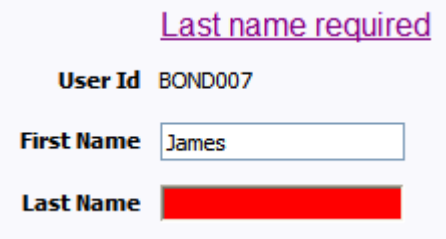
Highlight a Field in Error

> **Note**
>
> For more information on throwing an error, refer to the Terminate Statement in the Edit Data Syntax.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Comments
`oraError="automate :true|false; prefix: "`	Specifying `automate:true` automatically enables highlighting of the element in error when issuing an error. Note that **true** is the default and doesn't need to be specified. Specify `automate:false` to turn off field highlighting. The system uses a match on the element name referenced in the error to the element names in the UI map. If the elements in the schema are within an XPath that may not match what is referenced by the error, use `prefix:XPath` to specify that.

> **Note**
>
> The stylesheet reference cisDisabled must be specified for reference of the oraError style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the oraError style.



The following HTML example shows that the elements in the map are defined within a group called **boGroup**. The element name returned by the error will not include this group so in order for the field highlighting to work properly the `prefix:` attribute must indicate the group name.

```
<html>
<head>
   <title>User Zone Input</title>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body oraError="automate:true; prefix:boGroup">
<table width="100%" cellpadding="12">
   <tr class="oraErrorText">
      <td>
         <a href="" onclick="oraShowErrorAlert(); return false;">
            <span  class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
         </a>
      </td>
   </tr>
</table>
<table width="100%" border="0" cellpadding="4">
   <tr style="padding-top:30px;">
      <td align="right" class="label">User Id</td>
      <td>
         <span oraField="boGroup/userId" class="normal"/>
      </td>
   </tr>
   <tr>
      <td align="right" class="label">First Name</td>
      <td>
         <input oraField="boGroup/firstName" class="normal"/>
      </td>
```

Copyright © 2026, Oracle and/or its affiliates.

```
   </tr>
   <tr>
      <td align="right" class="label">Last Name</td>
      <td>
         <input oraField="boGroup/lastName" class="normal"/>
      </td>
   </tr>
</table>
</body>
<xml>
<root>
   <boGroup>
      <userId>BOND007</userId>
      <firstName>James</firstName>
      <lastName></lastName>
   </boGroup>
</root>
</xml>
</html>
```

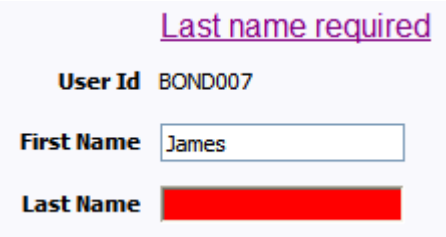
HTML rendered, where the error element thrown is equal to 'lastName':

Overriding the Error Element Name

In the rare occasion where the element name returned by the error doesn't match the element name in the map, you can add an explicit attribute to indicate the error element name.

Syntax	Valid Values	Comments
`oraErrorElement=`	"element name"	The element name referenced here must exactly match the name of the error element assigned when the error was thrown. More than one HTML field can be referenced by the same error element name.

> **Note**
>
> The stylesheet reference cisDisabled must be specified for reference of the oraError style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the oraError style.



This illustrates a scenario where the element name associated with the error differs from the element name on the map.

```
<html>
<head>
   <title>User Zone Input</title>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
```

Copyright © 2026, Oracle and/or its affiliates.

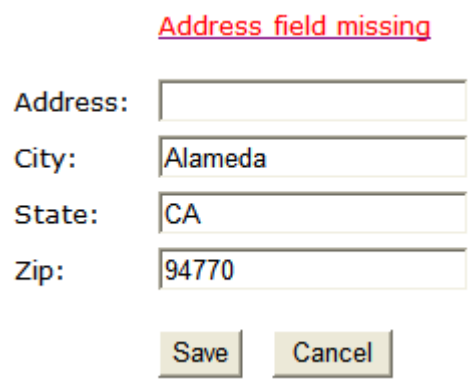
```
</head>
<body>
<table width="100%" cellpadding="12">
   <tr class="oraErrorText">
      <td>
         <a href="" onclick="oraShowErrorAlert(); return false;">
            <span  class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
         </a>
      </td>
   </tr>
</table>
<table width="100%" border="0" cellpadding="4">
   <tr style="padding-top:30px;">
      <td align="right" class="label">User Id</td>
      <td>
         <span oraField="userId" class="normal"/>
      </td>
   </tr>
   <tr>
      <td align="right" class="label">First Name</td>
      <td>
         <input oraField="firstName" class="normal"
oraErrorElement="firstName"/>
      </td>
   </tr>
   <tr>
      <td align="right" class="label">Last Name</td>
      <td>
         <input oraField="familyName" class="normal"
oraErrorElement="lastName"/>
      </td>
   </tr>
</table>
</body>
<xml>
<root>
   <userId>BOND007</userId>
   <firstName>James</firstName>
   <familyName></familyName>
</root>
</xml>
</html>
```

HTML rendered.

Display Error Pop-Up

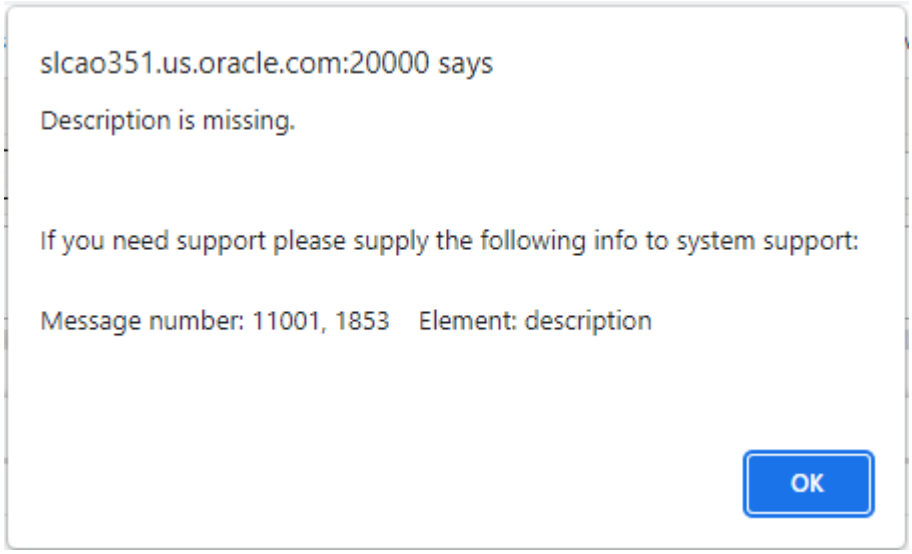
Copyright © 2026, Oracle and/or its affiliates.

When the error text is displayed, this function may be used to pop-up the standard error dialog (which displays more information) when a user clicks the error message.



Syntax

```
oraShowErrorAlert(); return false;
```



```
<html>
<head>
   <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
   <tr class="oraErrorText">
      <td>
         <a href="" onclick="oraShowErrorAlert(); return false;">
            <span  class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
         </a>
      </td>
   </tr>
</table>
<table>
   <tr>
      <td >Address:</td>
      <td><input type="text" oraField="address"/></td>
   </tr>
   <tr>
      <td>City:</td>
      <td><input type="text" oraField="city"/></td>
   </tr>
   <tr>
      <td>State:</td>
      <td><input type="text" oraField="state"/></td>
   </tr>
   <tr>
      <td>Zip:</td>
      <td><input type="text" oraField="zip"/></td>
   </tr>
   <tr>
      <td/>
      <td style="padding-top=15px;">
         <oraInclude map="F1-SaveCancelButtons"/>
      </td>
   </tr>
</table>
</body>
<xml>
<root>
   <address>123 Main St</address>
   <city>Alameda</city>
   <state>CA</state>
   <zip>94770</zip>
</root>
</xml>
</html>
```

Standard error pop-up dialog launched via click on error message:

Fire JavaScript for Browser Events

Working with the JavaScript Framework

There are many JavaScript events that can be used within the HTML/Javascript environment. These include events such as onLoad, onBlur, onChange, etc. The UI Map Framework also makes use of some of these events. It is important that any UI Map you develop works with the framework in order to obtain consistent results (events may not always be executed in the same order at all times!).

Copyright © 2026, Oracle and/or its affiliates.

Warning

The following describes the recommended approach for safely handling loading and processing field updates in your UI Maps.

If JavaScript is required within an XHTML UI Map or fragment, it will be necessary to bound it within a `![CDATA[ ]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/* <![CDATA[ */

//
// javascript
//

/* ]]> */

</script>
```

Element Change Event

Syntax	Valid Values
`oraChange=" "`	A JavaScript function.

At the time of UI Map load, if there is an event handler already attached to an HTML element, the framework removes it and attaches a combined event handler. The combined handler calls any **framework handler first** and then calls the other (custom) handlers.

Warning

Note that the function must not be used to execute logic that will modify the associated field data value again - or an endless loop will occur.

In the following example the **oraInvokeBS** function is executed when the button is clicked.

```
<html>
  <head>
    <title>oraInvokeBS test</title>
  </head>
  <body>
    <table>
      <tr>
        <td>User Id:</td>
        <td>
          <input oraField= "xmlGroup/userId"/>
          <input type="button" value="Search"
oraChange="oraInvokeBS('UserSearch','xmlGroup');"/>
```

Copyright © 2026, Oracle and/or its affiliates.

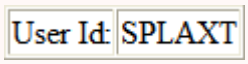
```
          </td>
        </tr>
        <tr>
          <td/>
          <td>Search Results</td>
        </tr>
        <tr>
          <td/>
          <td>
            <table oraList="xmlGroup/searchList">
              <tr>
                <td><span oraField="userId"></span>
                </td>
              </tr>
            </table>
          </td>
        </tr>
      </table>
    </body>
    <xml>
      <root>
        <xmlGroup>
          <userId/>
          <searchList>
              <userId></userId>
          </searchList>
        </xmlGroup>
      </root>
    </xml>
</html>
```

Page Load Event

Syntax	Valid Values
`oraLoad=" "`	A JavaScript function.

Warning

When executing oraLoad within a fragment UI map, and you need to execute a JavaScript function during page load (where the function invokes a business object, business service, or service script) you can use the special syntax "`oraLoad[$SEQUENCEID]`". For other special syntax used for map fragments, refer to theConstruct Portal Zone Map Fragments section.



- In the following example, the oraDisplayNone function is executed during page load:

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
    <tr>
        <td oraLoad="oraDisplayNone(item,'userId','')">User Id:
```

Copyright © 2026, Oracle and/or its affiliates.

```
    </td>
            <td><span oraField="userId"></span></td>
        </tr>
    </table>
    </body>
    <xml>
    <root>
        <userId>SPLAXT</userId>
    </root>
    </xml>
    </html>
```

- HTML rendered

After Page Load Event

Syntax	Valid Values
`oraAfterLoad=""`	A JavaScript function.

In the following example the oraGetValueFromScript function is executed after page load.

```
<div>
  <label for="boGroup_parameters_externalSystem" oraLabel="boGroup/
parameters/externalSystem">
  </label>
    <span>
      <select oraSelect="bs:F1-RetrieveExternalSystems"
class="oraInput"
        id="boGroup_parameters_externalSystem" oraField="boGroup/
parameters/externalSystem"
        oraSelectOut="valuePath:results/externalSystem;
descPath:results/description"
        oraSelectIn="outboundMsgType:boGroup/parameters/
outboundMsgType"
        oraAfterLoad

="oraGetValueFromScript(document.getElementById('boGroup_parameters_ext
ernalSystem');">
      </select>
    </span>

</div>
```

Hide Elements

Hide Using a Function

The system provides multiple techniques for hiding an HTML element.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Valid Values	Comments
`oraDisplayNone(item );`	(item, 'XPath', 'value', 'operator')	Used to hide an element based on the value of another element (referenced using its XPath). Enter a value of ' ' to interrogate a blank value. By default the operator is `'='`. This may be set instead to another operator such as `'!='`, `'>'`, or `'<'`.
	(item, function name,**true** | **false**)	Used to indicate a JavaScript function, which must return a Boolean.
`oraIsSuppress="true"`		Use this option for fields that need to be hidden always and not dependent on something else. Set this attribute on the HTML element (div element).

- Example where the User Id label is hidden when no User Id value exists.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
    <tr>
        <td oraLoad="oraDisplayNone(item,'userId','')">User Id: </td>
        <td><span oraField="userId"></span></td>
    </tr>
</table>
</body>
<xml>
<root>
    <userId></userId>
</root>
</xml>
</html>
```

- Example where the Save button is hidden when the user does not have security access to the action of change ('C') for the application service 'F1-DFLTS'.

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
    <tr>
   <td oraLoad="oraDisplayNone(item, oraHasSecurity('F1-DFLTS', 'C'),
false );">
      <input name="Save" type="button" onclick="oraInvokeBO('CM-
IndividualTaxpayer', null, 'replace')"/>
   </td>
    </tr>
</table>
</body>
```

Copyright © 2026, Oracle and/or its affiliates.

```
<xml>
<root>
    <userId></userId>
</root>
</xml>
</html>
```

Check User's Security Access

The system provides two functions to check a user's security access to a given application service and access mode. These are commonly used for hiding elements.

Syntax	Parameters
`oraHasSecurity( )`	'Application Service code' 'Access Mode'
`oraHasSecurityPath('x','y')`	'Application Service XPath' 'Access Mode XPath'

See the previous section for an example of the `oraHasSecurity` function. The following shows an example where the status button is hidden when the user does not have security access to the access mode 'ACT' of the application service 'FORMTST'.

```
<html>
<body>
<table>
    <tr>
   <td oraLoad="oraDisplayNone(item, oraHasSecurityPath('appService',
'accessMode'), false );">
      <input oraField="statusLabel" type="button"
onclick="oraRunScript('UpdateState','status');"/>
   </td>
    </tr>
</table>
</body>
<xml>
<root>
    <status>ACTIVATE</status>
<statusLabel>Activate</statusLabel>
<appService>FORMTST</appService>
    <accessMode>ACT</accessMode>
</root>
</xml>
</html>
```

Invoke Schema Based Services

The system provides functions for invoking a business object, business service or service script.

Invoke BO Function

This function is used to perform a BO interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Parameters	Comments
`oraInvokeBO( )`	'BO Name'	
	'XPath' or **null**	Identifies a group element via XPath. If you specify the word **null**, then the entire embedded XML object will be passed.
	'action'	Indicate the action to use. Valid values are **add**, **delete**, **read**, **update**, **replace**, **fastAdd** and **fastUpdate**.

NOT_SUPPORTED

Refer to BO Actions for more information about the various BO actions.

Example with the statement invoked in a JavaScript function.

```
function invokeBO {
     if (!oraInvokeBO('F1-User','xmlGroup','read')) {
          oraShowErrorAlert();
          return;
}
}
```

Example with the statement invoked within onClick.

```
<input type="button"  class="oraButton" oraMdLabel="DISPLAY_LBL"
onClick="oraInvokeBO('F1-User');"/>
```

Invoke BS Function

This function is used to perform a business service interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Syntax	Parameters	Comments
`oraInvokeBS( )`	'BS Name'	
	'XPath' or **null**	Identifies a group element via XPath. If you specify the word **null**, then the entire embedded XML object will be passed.

Example with the statement coded within a JavaScript function.

```
function invokeBS {
     if (!oraInvokeBS('F1-UserSearch','xmlGroup')) {
          oraShowErrorAlert();
          return;
  }
}
```

Copyright © 2026, Oracle and/or its affiliates.

Example with the statement invoked via onClick.

```
<input type="button"  class="oraButton" oraMdLabel="DISPLAY_LBL"
onClick="oraInvokeBS('F1-RetrieveInfo');"/>
```

Invoke SS Function

This function is used to perform a service script interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

Syntax	Parameters	Comments
`oraInvokeSS( )`	'Service Script Name' 'XPath' or **null**	Identifies a group element via XPath. If you specify the word **null**, then the document belonging to the parent node will be passed. If the parent node is not enough, then the entire document can always be passed using the following syntax: `oraInvokeSS('service script', null, null, [$SEQUENCEID])`

Example with the statement invoked within a JavaScript function:

```
function invokeSS {
     if (!oraInvokeSS('F1-GetUsers','xmlGroup')) {
          oraShowErrorAlert();
          return;
}
}
```

Example with the statement invoked within onClick.

```
<input type="button"  class="oraButton" oraMdLabel="DISPLAY_LBL"
onClick="oraInvokeSS('F1-GetUserInfo');"/>
```

Refresh a Rendered Map or Portal Page

Refresh Map

This function is used to 'Refresh' only the map zone issuing the command.

Syntax
`oraRefreshMap;`

```
...
    <tr>
        <td/>
        <td><input type="button" onclick="oraRefreshMap();"
value="Refresh"/></td>
```

Copyright © 2026, Oracle and/or its affiliates.

```
    </tr>
...
```

Refresh Page

This function is used to refresh all zones in the portal.

Syntax
`oraRefreshPage;`

```
...
    <tr>
        <td/>
        <td><input type="button" onclick="oraRefreshPage();"
value="Refresh"/></td>
    </tr>
...
```

Embed Framework Navigation

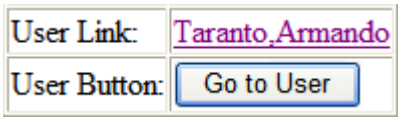
Navigate using Navigation Option

This function is used to navigate to another page using the information defined on a navigation option.

Syntax	Parameters
`oraNavigate( );`	'Navigation Option code' 'Key XPath'

> **Warning**
>
> This function is only intended for a UI map defined within a portal zone. It should not be used within a UI map launched by a BPA script.

The following example exhibits two possible uses of this function: as a URL and as a button. Note that the UI Map schema must contain a fkRef attribute. Refer to FK Reference Formatting for more information.



```
<schema>
    <userId fkRef="CI_USER"/>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
    <tr>
       <td>User Link: </td>
       <td><a href="" onclick="oraNavigate('userMaint','userId'); return
false;">
         <span oraField="userId" oraType="fkRef:CI_USER"></span></a>
```

Copyright © 2026, Oracle and/or its affiliates.

```
      </td>
    </tr>
    <tr>
        <td>User Button: </td>
        <td><input type="submit" onclick="oraNavigate('userMaint','userId')"
          value="Go to User"/></td>
    </tr>
</table>
</body>
<xml>
<root>
    <userId>SPLAXT</userId>
</root>
</xml>
</html>
```

HTML rendered.

Launch a View Details Drawer

Launch a drawer to view additional details for a specific context.

This function is used for a specific element to launch a side panel Drawer to present related extended information. The launched drawer references a panel name defined by the current portal and that may include one or more zones.

A drawer may be launched from a display zone or a row in a data explorer zone.

> **Warning**
>
> This function is only intended for a UI map defined within a portal zone. It should not be used within a UI map launched by a BPA script. Launching a drawer is also not supported from the Sidebar nor the Assistant portals.

Syntax	Parameters in UI Map	Parameters in Data Explorer	Comments
Add the following attribute to an HTML element `viewDetails="..."`	`detailPanelName:LITERAL | x[xpath] | c[CONTEXTNAME];`	`detailPanelName:LITERAL | Cx ;`	You must supply a reference to either a panel name defined for the current portal or a zone that is not defined on the portal.

> **Note**
>
> When referencing a panel name, the

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Parameters in UI Map	Parameters in Data Explorer	Comments
	`detailZoneCode:LITERAL | x[xpath] | c[CONTEXTNAME];`	`detailZoneCode:LITERAL | Cx ;`	drawer width is explicitly defined on the portal for that panel. When referencing a zone, drawer width is determined by the zone's width. Use a 1/3 width for a small drawer, a 2/3 width for a medium drawer, and a full width for a large drawer. From a UI map, the panel name or zone may be specified as a literal without any quotes, as an xpath to an element in the schema or a reference to a global or portal context name. From a data explorer column the non-literal reference may be to another column.

Copyright © 2026, Oracle and/or its affiliates.

Syntax	Parameters in UI Map	Parameters in Data Explorer	Comments
	`CONTEXTNAME: LITERAL | x[xpath] | c[CONTEXTNAME];` The context name can also be a reference to an element `x[xpath]`	`CONTEXTNAME: LITERAL | Cx;`	Optionally provide values to one or more portal context names that should be set before the drawer is launched. From a UI map, the value may be specified as a literal, an xpath, or a context name. From a data explorer column the non-literal reference may be to another column.
