- Setting Up Payment Arrangement Request Reasons
- Setting Up Payment Arrangement Request Status Reasons

Setting Up Payment Arrangement Request Types

A payment arrangement request type defines properties that control how a request for payment arrangement is processed.

Refer to The Big Picture Of Payment Arrangement Requests for an overview of payment arrangement request functionality.

To maintain payment arrangement request types, open **Admin**, and then **Credit & Collection**, and then **Payment Arrangement Request Type**, and then **Search**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information on the fields.

Setting Up Payment Arrangement Request Reasons

A payment arrangement request can capture the specific reason why a customer is asking to go on a payment arrangement. This reason is optional if using the base-owned Payment Arrangement Request (**C1–PARequest**) business object and the Payment Arrangement Request Process Flow Type (**C1-PAREQUEST**) on your Payment Arrangement Request Types.

To use Payment Arrangement Request Reasons, configure your specific values on the **C1-PARequestReasonLookup** extendable lookup. No base values are supplied for this lookup.

Setting Up Payment Arrangement Request Status Reasons

The Payment Arrangement Request (**C1–PARequest**) base business object provides the option to specify the reason for the request going into the **Denied** or **Canceled** state.

A few base-owned status reasons are supplied. To add other reasons for payment arrangement request cancellation/denial, go to the Status Reason portal and update the **C1–PARequest** business object's status reasons for the Denied and Canceled states.

Copyright © 2026, Oracle and/or its affiliates.

Automatically Cancelling Inactive Payment Arrangement Requests

The system is delivered with a batch process, Cancel Inactive PA Requests (C1-ACPAR), that can be used to cancel payment arrangement requests that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the Plug-in Driven Background Processes framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the payment arrangement request. Adjust the batch parameters according to your custom logic, if needed.

The Big Picture Of Pay Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

> **Note**
>
> **Nomenclature.** Some people refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the customer's bill only contains charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

- Creating Payment Arrangements
- Installment, Payoff and Current Amounts
- Monitoring Payment Arrangements

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed.
- When a payment is received, the service agreement's debt is reduced.
- If the service agreement becomes delinquent, a collection process is initiated to collect the overdue debt.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent service agreements (SAs) at the inception of the payment arrangement.

When you transfer delinquent debt from the delinquent SAs to the PA SA, the debt is removed from the delinquent SAs. If you transfer all debt from the delinquent SAs, the customer will no

Copyright © 2026, Oracle and/or its affiliates.

longer be in arrears in a given debt class (and if the customer is no longer in arrears, active collection and severance processes will be cancelled).

> **Note**
>
> **Use the Payment Arrangement Request Transaction.** You could do the above functions by adding a new service agreement and creating transfer adjustments. However, this is tedious. Rather, use the Payment Arrangement Request process. This process is recommend when requests for payment arrangements require eligibility checking and other prerequisites such as down payments and approvals. When a payment arrangement request is granted, it creates the PA SA, transfers debt to it, and sets up the installment amount.
>
> You can also create the payment arrangement service agreement directly using the Payment Arrangement transaction if you don't require any prior eligibility checks, down payments or approvals. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

> **Warning**
>
> If you do not understand the difference between payoff balance and current balance, refer to Current Amount versus Payoff Amount.

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, neither the original service agreements nor the PA SA have delinquent debt. If the customer neglects to pay their payment arrangement, the PA SA will fall into arrears and a collection process will ensue. If the customer neglects to pay their previously delinquent SAs, they will again fall into arrears and a collection process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes $500 on their electric and water service agreements and they want to pay this off in 10 installments, you'd set up the installment amount to be $50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their normal service agreements, you can transfer additional delinquent debt to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off $500 with 10 installments of $50 would have an initial payoff balance of $500 and a current balance of $0. After the first bill, the PA SA would still have a

Copyright © 2026, Oracle and/or its affiliates.

payoff balance of $500, but its current balance would be $50. When the customer pays, the PA SA's payoff balance would fall to $450 and its current balance would return to $0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff $1,000 of debt in $10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed ($50 for new debt and $10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays $60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Monitoring Payment Arrangements

The PA SA should belong to its own debt class (let's call it Payment Arrangement Debt) so that you can have stricter collection criteria for payment arrangement debt (as compared to normal SAs). Because there will be a new debt class, there will be a unique collection class control (CCC) for payment arrangements. This CCC will have debt criteria associated with payment arrangement debt. If these criteria are violated, we will kick off a collection process that should have 1 collection event - Start Severance.

The severance process template for PA SAs will have 1 severance event that calls the Break Payment Arrangement Event algorithm. This algorithm does the following:

- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement (identified by the XFER adjustment type on the PA SA's SA type). When these are cancelled, the original arrearage will be reinstated under the original SAs - this debt should be rather old by this point.
- Syncs up current balance with payoff balance on the PA SA.

Copyright © 2026, Oracle and/or its affiliates.

- Makes the PA SA pending stop (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the account's debt using the standard distribution algorithm. Because the payment arrangement debt that was reinstated should be rather old, it should get relieved first. This relief will occur via transfer adjustments from the PA SA to the original SAs.
- If there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), the debt will be transferred back to one of the SAs from which the arrangement was originally created.
- Inserts a characteristic under the PA SA to indicate that it has been broken (we need this for the account debt monitor (ADM) a few steps down).
- Inserts a row on the account debt monitor trigger. This trigger will cause the account to be reviewed by the ADM the next time it runs.

> **Note**
>
> **The PA SA must final bill before it closes.** The PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the ADM next runs, it will analyze the account's reinstated debt. We recommend creating a new override collection criteria for the normal debt class that will return a value of true if the account has a closed payment arrangement that has been broken in the last X days (where X is a parameter of the override collection criteria's algorithm). If this algorithm returns a true, kick off a unique collection process template (that has nasty events). A sample algorithm of this type is supplied in the base package - COLL COND PA.

To complete this discussion, we have to worry about the situation when the final bill of a payment arrangement goes unpaid. In this situation, the payment arrangement is stopped and will therefore not be processed by the ADM. In this case, the write off monitor will process the PA SA after its final bill's due date and a write-off process will start. This write off process will have a single event that calls the Break Payment Arrangement algorithm (described above). After the FT's are issued in this event, the SA will close (because it's been final billed and its balance will go to zero).

The Big Picture Of Pay Plans

A pay plan (PP) is an agreement with a customer to make payments on specific dates. Pay plans differ from payment arrangements in that pay plans have user-defined scheduled payment dates, which are independent from the customer's billing dates. In other words, payment arrangements appear on the customer's bills, pay plan scheduled payments do not.

If a customer is in arrears and you want to receive payments on specific dates (as opposed to with the customer's regular bills), you would set up a pay plan and define the dates on which you expect the payments.

The topics in this section describe how pay plans work.

- A Pay Plan Has One Or More Scheduled Payments
- Automatic Payments Can Be Created On The Scheduled Payment Dates

- Collection Process / Severance Process Cancellation
- Interesting Pay Plan Facts

A Pay Plan Has One Or More Scheduled Payments

When you create a pay plan for an account, you must define the number of scheduled payments and their respective amounts. There is no limit to the number of scheduled payments that may be set up under a pay plan.

Automatic Payments Can Be Created On The Scheduled Payment Dates

The system will create automatic payments on a pay plan's scheduled payment dates if:

- The account is set up for automatic payment (as described under How To Set Up A Customer To Pay Automatically), and
- The payment method defined on the pay plan indicates automatic payment is being used

The background process called PPAPAY is responsible for creating these automatic payments. It does this by calling the automatic payment creation algorithm plugged in on the installation record.

> **Note**
>
> If the **Autopay Creation Option** on the installation record is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process (APAYDSFR) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to Automatic Payment Dates for more information on how this date is calculated). Refer to Automatic Payments for more information.

A Pay Plan Insulates Overdue Debt From The Account Debt Monitor

A pay plan's scheduled payments are used by the account debt monitor as "pseudo payments" that relieve the account's debt before it is subjected to the collection criteria (refer to How Does The Account Debt Monitor Work for more information about collection criteria).

It's important to understand that a pay plan only insulates the account's debt that belongs to the pay plan's debt class. Therefore, if a customer has debt that belongs to two debt classes

Copyright © 2026, Oracle and/or its affiliates.

(e.g., normal debt and 3 rd party pass through debt), you would need to set up a separate pay plan for each debt class (assuming both types of debt are covered by a pay plan). Refer to Different Collection Criteria For Different Customers and Different Debt for more information about debt classes.

A Pay Plan Must Reference A Pay Plan Type

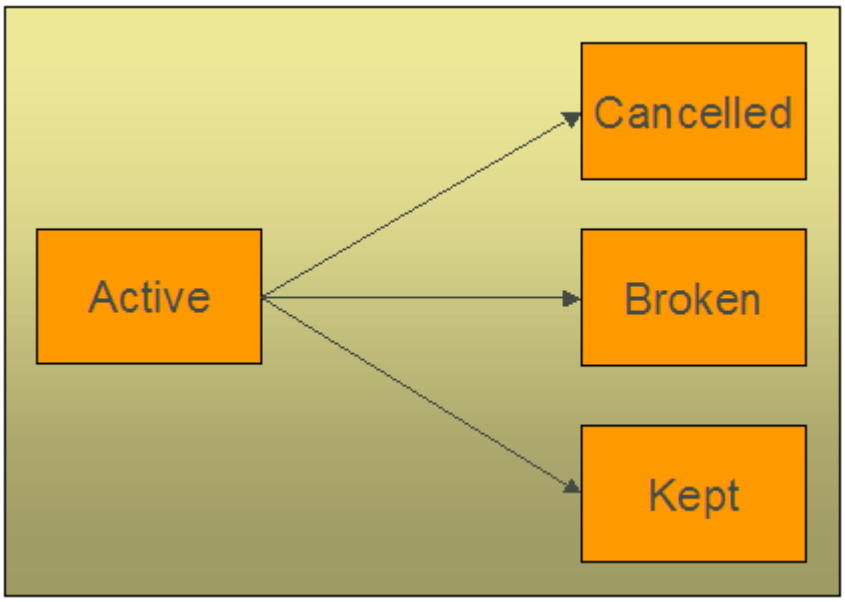
When you create a pay plan, you must define its pay plan type. The pay plan type controls the following functions:

- The debt class whose debt is insulated by the pay plan.
- The type of algorithm (if any) that is executed when the pay plan is broken. You might use such an algorithm to affect the customer's credit rating when the pay plan is broken.

A Pay Plan May Reference A Third-Party Payor

In addition to referencing the account whose debt is insulated by the pay plan, the pay plan must also reference the account that is responsible for making the payments. We refer to this second account as the pay plan's "payor".

While the payor's account is typically the same as the account whose debt is insulated by the pay plan, you can indicate a third-party payor (e.g., a social service agency) is responsible for making the pay plan's scheduled payments.



If your organization allows third-party payors, you can define each on the third-party payor control table. This control table exists to simplify the data-entry effort when you create a pay plan (as it defines the account associated with the third-party payor).

> **Note**
>
> If a pay plan does not reference a third-party payor, any non-third-party payor (i.e., any account that is not defined in the third-party payor control table) can make payments on behalf of the customer. If a pay plan references a third-party payor, only payments made by the third party on behalf of the customer are counted towards the fulfillment of the pay plan.

The Lifecycle Of A Pay Plan

The following diagram shows the possible lifecycle of a pay plan:

Copyright © 2026, Oracle and/or its affiliates.

The following points explain this lifecycle:

- Pay plans are initially created in the active state. Active pay plans are monitored for compliance by The Pay Plan Monitor.
- A pay plan may be cancelled as follows:
  - A user can cancel a pay plan at will.
  - When a SA is stopped AND there are no other active SAs in the same debt class, all **Active** pay plans associated with the account and debt class will be will be **Canceled** .
  - The activation of a collection event that calls the "cancel pay plan" algorithm will cancel all active pay plans associated with the collection process's debt class. You may want to use such a collection event if your organization cancels active pay plans when new debt causes a collection process to kick-off. Note, the base package algorithm that performs this function will not cancel the pay plan if it's associated with a 3rd party payor.
- The Pay Plan Monitor causes active pay plans to become broken if sufficient payments have not been made to satisfy the pay plan's scheduled payments.
- The Pay Plan Monitor causes active pay plans to become kept when it detects that sufficient payments have been made to satisfy the pay plan's scheduled payments.

Highlighting The Existence Of Broken / Kept / Active and Denied Pay Plans

You can define on the installation record plug-in algorithms that format alert messages. (Refer to Installation Options - Algorithms for additional information.) We recommend that you take advantage of the following algorithms to highlight pay plans:

- Highlight pay plans in a given status. This algorithm is used to highlight pay plans in a given state (broken, kept, cancelled) that were started within the last X days.
- Highlight customer contacts of a given type. This algorithm would be used to highlight customer contacts of a given type that were created within the last X days. This would be useful if you create a specific type of customer contact when you deny a pay plan. Some utilities do this to prevent customers from shopping around.

Copyright © 2026, Oracle and/or its affiliates.

In addition, you can define account-specific alerts to highlight customers that should never be allowed to have a pay plan (for whatever reason).

A Pay Plan Must Reference A Payment Method

When you create a pay plan, you must define how the customer will make the payments be referencing a payment method. Examples of payment methods include: In Person , Wire Transfer, By Post, Express Mail, etc.

The payment method is more than just documentation as it defines the number of grace days the customer has to make the pay plan's scheduled payments. For example, if you set up the payment method control table to indicate that payments made By Post have 3 grace days, then the customer has up to 3 days after each scheduled payment date to make the payment. If payment is not received by the scheduled payment date plus the grace days, the pay plan will be marked as broken (and the ADM will be triggered).

The Pay Plan Monitor

NOT_SUPPORTED

Please understand the concepts described in The Lifecycle Of A Pay Plan and The Tendering Account May Differ From The Account Whose Debt Is Relieved before reading this section.

The Pay Plan Monitor background process (referred to as PPM) is responsible for monitoring active payment plans. This process can cause a pay plan (PP) to become kept or broken (or being left as active).

Note

When is a pay plan marked as broken / kept? It's important to understand that only the PPM can cause a pay plan to become kept or broken. This means that if a customer makes a payment that satisfies a pay plan, the pay plan will only be marked as kept when the pay plan monitor next runs. Analogously, if a payment is cancelled, nothing will happen to an active pay plan until the PPM next runs. When the PPM next runs, it will see that the scheduled payment was not kept and it will break the pay plan and schedule the ADM to be executed. When the ADM next executes, it will create a collection process (because the customer's debt will no longer be insulated by the pay plan's scheduled payments).

NSF Cancellations After A Pay Plan Is Kept. If a payment is cancelled due to non-sufficient funds (NSF) after a pay plan is marked as kept, the pay plan will remain kept. But keep in mind that the pay plan's account is scheduled for review by the ADM when a payment is cancelled due to NSF. When the ADM reviews the account's debt, it will no longer have an active pay plan to insulate it and the account's debt will likely trigger a new collection process. Refer to How Pay Plans Affect The Account Debt Monitor for more information.

Copyright © 2026, Oracle and/or its affiliates.

The following points describe, at a high level, how the PPM monitors a pay plan (PP) for compliance.

- The system selects all frozen, non-cancelled payment segments associated with the PP's account and debt class where:
  - The payment date is after the start date of the pay plan, and
  - The payment's pay event has at least one tender that references the pay plan's payor.
- The system logically reduces / removes past and current scheduled payments (starting with the earliest scheduled payment) until the total amount of payment segments is exhausted (or there are no more historical / current scheduled payments).

> **Note**
>
> **Paying pay plans in advance.** Scheduled payments with a future date are not logically removed / reduced. This means that if a customer makes advance payments on a pay plan, it will not be marked as kept until all scheduled payment dates are in the past.

- If all scheduled payments have been logically removed, the pay plan is marked as kept.
- If there exist scheduled payments where the pay date + grace days (grace days are defined on the pay plan's payment method) is before the current date (i.e., a payment doesn't exist for a scheduled payment):
  - The pay plan is marked as broken.
  - The PP's break algorithm (if any) is called (note, for European / Australian pay plans, there are scenarios where the break algorithm can cause the pay plan to become unbroken - when there aren't at least two missed, historical scheduled payments).
  - An ADM trigger is stored for the PP's account. This will cause the account to be reviewed by the ADM the next time it runs. And because the pay plan is broken, its scheduled payments will no longer insulate the account's arrearage.

> **Important**
>
> It's important that you schedule the PPM to run before the ADM so that it can break unpaid payment plans prior to the ADM subjecting the account's debt to collection criteria. Refer to How Pay Plans Affect The ADM for more information.

How Pay Plans Affect The Account Debt Monitor

As described under A Pay Plan Insulates Overdue Debt From The Account Debt Monitor, a pay plan's scheduled payments insulate an account's debt from the ADM. This section describes how this is accomplished.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> You should understand the concepts in How Does The Account Debt Monitor Work and The Tendering Account May Differ From The Account Whose Debt Is Relieved before reading the following.

> **Note**
>
> **The ADM will be triggered when a pay plan is broken.** Refer to The Pay Plan Monitor for an explanation of how the ADM is triggered when a pay plan is broken.

Before the ADM subjects an account's debt to the collection criteria, it calls the debt's debt class's Override Arrears Algorithm (this is an optional plug-in spot on Debt Class). This algorithm is passed the debt class's aged debt and manipulates it as follows:

- First, a list of all past, present and future scheduled payments associated with the account and debt class's active pay plans is constructed.
  - If multiple payors are encountered (because the customer has multiple pay plans and these have different payors), a separate list of scheduled payments is maintained for each payor.
- Next, for each payor, retrieve the total amount of frozen, non-cancelled payment segments made on behalf of the pay plan's account and debt class.
  - Select all frozen, non-cancelled payment segments associated with the pay plan's account and debt class whose pay date is >= pay plan's start date and the pay segment's event has at least one tendering account associated with the pay plan's payor.
- Next, logically reduce / remove past and current scheduled payments (starting with the earliest scheduled payment) until the payor's payment amount is exhausted (or there are no more historical / current scheduled payments). Future scheduled payments cannot be remove / reduced.
- Finally, reduce the passed in aged debt with any unpaid scheduled payments.

> **Note**
>
> **This logic is not "hard coded".** Rather, the mechanism used to use a pay plan's scheduled payments to reduce debt is defined in an algorithm defined on the pay plan's debt class. The contents in this section describe how a base package algorithm works. Because it's an algorithm, you can introduce whatever logic you please.

The following is an example of how pay plans affect aged debt.

Date	Event	SA's Arrears	SA's Balances	Scheduled Payments

Copyright © 2026, Oracle and/or its affiliates.

Prior to creation of the PP 1/18/2000		$1,000 - 90 days old $1,600 - 60 days old $1,900 - 30 days old	Current: $4,500 Payoff: $4,500	
1/18/2000	Pay Plan created. The $4,500 in future scheduled payments offsets the existing $4,500 of aged debt.	$1,000 - 90 days old $1,600 - 60 days old $1,900 - 30 days old **De facto ADM debt: $0**	Current: $4,500 Payoff: $4,500	1/20/2001 $1,500 2/01/2001 $1,500 2/07/2001 $1,500
1/20/2001	The customer pays $1,500. There exists $3,000 of future scheduled payments that offset the arrears	$1,100 - 62 days old $1,900 - 32 days old **De facto ADM debt: $0**	Current: $3,000 Payoff: $3,000	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
1/20/2001	ADM runs. The $3000 in future scheduled payments offsets the Current Balance of $3000, so CC events not created.	$1,100 - 62 days old $1,900 - 32 days old **De facto ADM debt: $0**	Current: $3,000 Payoff: $3,000	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
1/24/2001	A new bill is created for $400	$1,100 - 62 days old $1,900 - 32 days old $400 - 1 day old **De facto ADM debt: $400 - 1 day old**	Current: $3,400 Payoff: $3,400	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
2/2/2001	Pay Plan Monitor runs. PP marked as Broken because the 2/1/2001 scheduled payment has not been paid (assuming no grace period on the pay plan's payment method)	$1,100 - 74 days old $1,900 - 44 days old $400 - 8 days old	Current: $3,400 Payoff: $3,400	1/20/2001 $1,500 "Paid" **2/01/2001 $1,500 "Late"** 2/07/2001 $1,500 Future

Copyright © 2026, Oracle and/or its affiliates.

2/2/2001	ADM runs. There are no active pay plans and therefore there is nothing to insulate the customer's debt. Therefore the aged debt will be subjected to the collection criteria and an appropriate collection process will be created.	$1,100 - 74 days old $1,900 - 44 days old $400 - 8 days old **De facto ADM debt is the same as above (i.e., rather old)**	Current: $3,400 Payoff: $3,400	**Pay plan is broken and therefore its scheduled payments cannot be used.**

Collection Process / Severance Process Cancellation

When a pay plan (PP) is created, the system determines if it can cancel active collection and severance processes associated with the pay plan's account and debt class. It does this because a pay plan's scheduled payments act as "pseudo payments" that relieve the account's debt (temporarily). The following points describe how this works:

- The system attempts to cancel collection processes by calling the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm is meant to cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see How Pay Plans Affect The Account Debt Monitor for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.
- It attempts to cancel severance processes by calling the Severance Process Cancel Criteria Algorithm defined on the debt class that is associated with the severance process. This algorithm is meant to cancel a severance process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see How Pay Plans Affect The Account Debt Monitor for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

If collection / severance processes still exist for the account / debt class associated with the pay plan, a warning is issued.

Interesting Pay Plan Facts

The following points describe a variety of interesting facts about pay plans (PP):

- An account may have many active pay plans. However, only 1 pay plan may be active for a given account / debt class / payor at any point in time.
- The existence of a pay plan has no impact on payment distribution.

Copyright © 2026, Oracle and/or its affiliates.

- When a SA is stopped, if the SA's debt class has an active PP AND there are no other active SAs in the same debt class, the PP will be cancelled
  - The cancel reason will be "cancelled by system" (as opposed to "cancelled by user")
- If necessary, different collection / severance processes can be triggered if a broken PP is detected (via the override algorithms on CCC and write-off control - we do NOT provide such algorithms).

Setting Up Pay Plan Control Tables

This section describes the control tables needed to set up pay plans.

- Setting Up Pay Plan Types
- Setting Up Payment Methods
- Setting Up Third Party Payors

Setting Up Pay Plan Types

Pay plan types control what is done by a given pay plan. Open **Admin**, and then **Credit & Collection**, and then **Pay Plan Type** to define your pay plan types.

> **NOT_SUPPORTED**
>
> For more information refer to The Big Picture Of Pay Plans for more information.

Description of Page

To modify a pay plan type, simply move to a field and change its value. To add a new pay plan type, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Plan Type The name of the pay plan type.

Description A meaningful description of the pay plan type.

Broken Algorithm This algorithm is called when a pay plan is broken. Refer to The Pay Plan Monitor for more information about how pay plans are broken.

If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that breaks a pay plan.

Debt Class The debt class covered by pay plans of this type. Refer to Setting Up Debt Classes for more information.

Setting Up Payment Methods

Payment methods are used to describe how a customer intends to make their pay plan's scheduled payments. Open **Admin**, and then **Credit & Collection**, and then **Pay Method** to define your payment methods.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information refer to A Pay Plan Must Reference A Payment Method for more information.

Description of Page

To modify a pay method, simply move to a field and change its value. To add a new pay method, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Method The name of the payment method.

Description A meaningful description of the payment method.

Grace Days The number of days added to the scheduled payment date. The ADM will consider the pay plan to be broken if payment is not made by the scheduled date plus the grace days.

Auto Pay If the pay method is marked as being for **Auto Pay**, the PPAPAY background process will automatically create an automatic payment on the pay plan's scheduled payment dates IF the account has been set up for automatic payment.

Setting Up Third Party Payors

Pay plans support optional third-party payors. Open **Admin**, and then **Credit & Collection**, and then **Third Party Payor** to define your third-party payors.

Note

A third-party payor refers to an account. You must set up the account before you can create a third-party payor.

NOT_SUPPORTED

Refer to A Pay Plan May Reference A 3rd Party Payor for more information.

Description of Page

The following fields display for each third party payor:

Third Party Payor Provide a meaning id for the third-party payor that can be easily recognized when setting up a pay plan.

Description A meaningful description of the payor.

Account ID The account that is used for this payor. It is this account that is tracked as the "payee" of any payments made towards a third party payor's pay plan.

Active Check this box if the payor is currently available to participate in pay plans.

Creating Collection, Severance & Write-Off Procedures

Your collection procedures define how your organization collects overdue debt. Your severance procedures define how your organization severs service agreements when collection attempts fail. Your write-off procedures define how your organization writes off finaled debt. In this section, we describe how to set up the data that controls these procedures.

NOT_SUPPORTED

For more information about collection, severance and write-off procedures, see The Big Picture Of Credit & Collections (C&C).

Warning

There are innumerable ways to design your collection, severance and write-off procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production collection, severance and write-off procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

- Designing Your Collection Procedures
- Setting Up Collection Procedures
- Designing Your Severance Procedures
- Designing Your Reconnection Procedures
- Setting Up Severance Procedures
- Designing Your Write-Off Procedures
- Setting Up Write-Off Procedures
- Setting Up Feature Configuration

Designing Your Collection Procedures

The design of your collection procedures is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the collection process control tables.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about how the information in this matrix is used to monitor your customers' debt, refer to Different Collection Criteria For Different Customers And Different Debt.

- Designing Your Debt Classes
- Designing Your Collection Classes
- Designing Collection Class Controls
- Designing Your Collection Class Control Overrides
- Designing Collection Process Templates & Collection Event Types
- Defining Cancellation Process Auto Cancellation Criteria

Designing Your Debt Classes

Multiple debt classes are needed when you have different collection procedures for different types of service agreements. If all service agreement debt is collected the same way, then you'll have just one debt class (call it Generic). However, if you're like many organizations, you will have multiple debt classes. The following points will help you understand why:

- If you have both regulated and unregulated service, you probably have different debt classes for each type of service. Why? Because your local regulators control how you collect and cutoff overdue, regulated debt. For unregulated debt, your organization controls how overdue debt is collected.
- If your customers make charitable donations, you will have a charitable contribution debt class. Why? Because you probably send a different type of letter when the customer falls into arrears on their charitable contributions. You also can't cut off their water service if they don't make their charitable contributions.
- If you levy deposits, you will probably have a deposit debt class. Why? Because you probably respond differently if the customer doesn't pay their deposit (e.g., you may decide to cut off their electric service until the deposit is paid).
- If you allow customers to make payments on Non-Billed Budgets, you will probably have a Non-Billed Budget debt class. Why? Because you probably respond differently if the customer doesn't pay their Non-Billed Budget (e.g., you may decide to expire the Non-Billed Budget but not affect their other service since the Non-Billed Budget is a way for customers to prepay for upcoming bills).
- If you write-off uncollectable debt, you will need another debt class for write-off service agreements. Why? Because when you write-off debt in the system, you transfer the uncollectable debt from the original service agreement(s) to a write-off service agreement. The write-off service agreement holds this debt forever (or until it is paid). You need to use a different debt class for the write-off service agreements because they aren't subject to collection criteria.
- If you use the system to charge your organization's company usage, you'll need another debt class (we refer to it as the "N/A" debt class below). Why? Because all service agreements must have a debt class, even those that will never have debt.

SA's Debt Class	Account's Collection Class	Account's Collection Class

Copyright © 2026, Oracle and/or its affiliates.

Regulated
Unregulated
Charitable Contribution
Deposit
Non-Billed Budget
Write Off
N/A

Designing Your Collection Classes

Multiple collection classes are needed when any debt class has different collection rules depending on the type of customer. If all customers within all debt classes are collected the same way, then you'll just have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

Consider unregulated debt. For commercial/industrial customers, you probably don't worry until they owe you more than, say, $100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, $5 after 20 days. In this situation, you will have at least two collection classes: one for large customers, the other for residential customers.

In our example, we are assuming you have two collection classes: Residential and Commercial/Industrial.

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Charitable Contribution		
Regulated		
Unregulated		
Write Off		
Company Usage		

Designing Collection Class Controls

At this point we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Each cell should have a "collection class control" that defines its collection criteria and what to do if the criteria are violated. If a cell doesn't have a collection class control, this means you don't have any debt associated with that combination of collection class and debt class. So, we'll mark each cell without debt with "N/A".

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A

Copyright © 2026, Oracle and/or its affiliates.

Deposit		
Write Off		
N/A		

Next, we'll mark each cell for debt classes whose debt isn't collectable (i.e., the write-off and N/A debt classes).

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off	N/A	N/A
N/A	N/A	N/A

> **Note**
>
> If the Account Debt Monitor encounters debt associated with a non-existent collection class control, it will issue an error.

Determining the collection criteria in each remaining cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For charitable debt, if the customer is more than $0 in arrears by more than 20 days, kick off the "charity reminder" collection process. We'll talk more about this collection process later.
- For regulated / residential debt, if the customer is more than $15 in arrears by more than 20 days, kick off the Normal Regulated collection process. We'll talk more about this collection process later.
- For unregulated / residential debt, if the customer is more than $5 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For unregulated / commercial-industrial debt we have multiple criteria:
  - Highest priority. If the customer is more than $10,000 in arrears by more than 20 days, kick off the Large Overdue Debt collection process. We'll talk more about this collection process later.
  - Lower priority. If the customer is more than $100 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For deposit debt (regardless of collection class) we have multiple criteria:
  - Highest priority. If the customer is more than $5 in arrears by more than 50 days, kick off the Deposit Severely Overdue collection process. We'll talk more about this collection process later.

Copyright © 2026, Oracle and/or its affiliates.

- Lower priority. If the customer is more than $15 in arrears by more than 20 days, kick off the Deposit collection process. We'll talk more about this collection process later.

Given the above, our matrix will look as follows:

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Charitable Contribution	If > $0 is older than 20 days, start Charity Reminder collection process.	N/A
Regulated	If > $15 is older than 20 days, start Normal Regulated collection process.	N/A
Unregulated	If > $5 is older than 20 days, start Normal Unregulated collection process.	Highest priority: If > $10,000 is older than 20 days, start Large Overdue Debt collection process. Lower priority: If > $100 is older than 20 days, start Normal Unregulated collection process.
Deposit	Highest priority: If > $5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > $15 is older than 20 days, start Deposit collection process.	Highest priority: If > $5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > $15 is older than 20 days, start Deposit collection process.
Write Off	N/A	N/A
N/A	N/A	N/A

Designing Your Collection Class Control Overrides

> **Warning**
>
> Your collection needs may not require any overrides for your collection class control matrix and therefore this section may not be relevant.

The following matrix will help you design your collection class overrides. When the matrix is complete, you're ready to set up the collection class control tables.

Notice that the matrix has two dimensions: one is dependent on collection condition algorithms; the other is dependent on the collection class controls designed in the previous section. Collection condition algorithms are confusing. Think of them as optional conditions that, if met, will subject the collection class control's debt to different collection criteria.

Each cell in the matrix contains the collection criteria that will be applied to the account's debt when the collection condition is met (i.e., the same type of criteria - dollars and days and collection process - are defined in each cell).

Copyright © 2026, Oracle and/or its affiliates.

We label the first collection condition as the Default. The collection criteria associated with this column will be used to analyze an account's debt when none of the other conditions applies. We'll start by indicating the Default collection criteria (this was defined in the previous section).

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

If a different collection process OR criteria should be used when other conditions are met, you should indicate such by defining the collection criteria in the cell. For example, if we assume that all unregulated residential debt has a different collection process when the account's credit score is less than the threshold credit rating on the installation record or the account’s CIS Division, our matrix will look as follows:

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	Override: If Credit Rating is lower than the credit rating threshold: If > $5 is older than 15 days, start Risky Unregulated collection process.
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

Once the matrix is complete, you're ready to design your collection process and collection event types.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The collection conditions are limited by your imagination (and business requirements).** We have provided the collection conditions you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors. For example, if you have different collection criteria that apply during winter months, you should add a new collection condition (called Winter Season). Or if you have different criteria based on years of service, you could have another condition.
>
> **New collection conditions may require programming.** See How To Add A New Algorithm for more information.

Designing Collection Process Templates & Collection Event Types

The following table shows the collection process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Collection Process Template	Collection Event Template	Triggered X Days From Start Of Collection Process
Charitable Contribution Reminder	Charity courtesy reminder letter	0
	Start severance	15
Normal Regulated	Regulated courtesy reminder letter	0
	Regulated second notice letter	10
	Start severance	15
Large Overdue Debt	Large debt courtesy reminder letter	0
	To Do for large overdue debt	3
	Large debt second notice letter	10
	Start severance	15
Normal Unregulated	Unregulated courtesy reminder letter	0
	Unregulated second notice letter	5
	Start severance	10
Risky Customer Unregulated	Unregulated risky letter	0
	Start severance	5
Deposit	Deposit reminder	0
Deposit Severely Overdue	Create To Do entry	0

If we extract each unique event type from the above table, we end up with the following:

Collection Event Type	Event Type

Copyright © 2026, Oracle and/or its affiliates.

Charity courtesy reminder letter	Send Letter - CHARIT REMIN
Start severance	Start Severance Process
Regulated courtesy reminder letter	Send Letter - REGUL REMIN
Regulated second notice letter	Send Letter - REGUL second
Large debt courtesy reminder	Send Letter - LARGE REMIN
Risky debt courtesy reminder	Send Letter - RISKY REMIN
To Do for large overdue debt	Issue To Do
Large debt second notice letter	Send Letter - LARGE second
Unregulated courtesy reminder letter	Send Letter - UNREG REMIN
Unregulated second notice letter	Send Letter - UNREG second
Deposit reminder	Send Letter - DEPOS REMIN
To Do for deposit severely overdue	Issue To Do

Now you're (almost) ready to set up your collection procedures.

Defining Cancellation Process Auto Cancellation Criteria

The topics in the section How Are Collection Processes Cancelled describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your Debt Classes, and optionally, on your Collection Process Templates.

Setting Up Collection Procedures

In the previous section, Designing Your Collection Procedures, we presented a case study that illustrated a mythical organization's collection procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Collection Event Types
- Setting Up Collection Process Templates
- Setting Up Collection Classes
- Setting Up Debt Classes
- Setting Up Collection Class Controls

Setting Up Collection Event Types

Collection event types control what is done by a given collection event. Open **Admin**, and then **Credit & Collection**, and then **Collection Event Type**, and then **Add** to define your collection event types.

Description of Page

Enter a unique **Collection Event Type** and **Description** for the collection event type.

Copyright © 2026, Oracle and/or its affiliates.

Enter the **Collection Event Type**. Permissible values are: Affect Credit, Rating/Cash-Only, Cancel Budget, Generic Algorithm, Send Letter, Create To Do Entry, Start Severance Process. The following discussion describes the parameters that must be defined for each type of collection event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Credit Rating Points** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Credit Rating Months** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

> **NOT_SUPPORTED**
>
> For more information, refer to Account - Credit Rating.

The Send Letter collection event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

> **Note**
>
> **Letter creation is triggered via a customer contact.** You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the collection event. Refer to Setting Up Letter Templates for more information.

The Cancel Budget collection event type cancel an account's budget plan (if the account is on such a plan). When a budget plan is cancelled, adjustments are issued to synchronize every service agreement's current balance with its payoff balance and each applicable SA's recurring charge amount (i.e., budget amount) is set to zero.

The Generic Algorithm collection event type causes the algorithm defined in the **Collection Event Alg** to be executed. You use this type of algorithm when the standard types of collection events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).

Copyright © 2026, Oracle and/or its affiliates.

- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type of activated.

The Create To Do Entry collection event type causes a To Do entry to be issued. A good example of where this is used is when the collection event requires that the customer be called on the phone. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-CEVT for the type of To Do entry that's created).

The Start Severance Process type will start a severance process for every service agreement linked to the collection process. No parameters are needed for this type of event.

Enter a **Long Description** to fully describe the collection event type.

Setting Up Collection Process Templates

Collection process templates define the collection events that will be executed when a collection criteria rule is violated. Open **Admin**, and then **Credit & Collection**, and then **Collection Process Template**, and then **Add** to define your collection process templates.

Description of Page

Enter a unique **Collection Process Template** and **Description** for the collection process template.

Select a **Cancel Criteria Algorithm** if your organization allows individual service agreements to be "removed" from a collection process regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM. If this algorithm is specified, it is executed by the collection process monitor when it detects that a credit has been applied to a service agreement linked to an active collection process. This algorithm will indicate if the specific service agreement that has been credited no longer has debt that warrants a collection process. Refer to How Are Collection Processes Cancelled for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that "removes" a service agreement from a collection processes if the service agreement's debt so warrants.

The **Response** grid contains an entry for every collection event that will be created when a collection process that references this template is created. The following information must be defined for each event:

Event Sequence controls the order in which the collection event types appear under the collection process template. The sequence number is system-assigned and cannot be changed. If you have to insert a collection event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Collection Event Type Specify the type of collection event to be generated.

Days After Process Creation Specify the number of days after the creation of the collection process that the related collection event will be triggered. Refer to Calendar vs Work Days for a description of how this system uses this information to set the trigger date on the respective collection events.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about collection event types, see Setting Up Collection Event Types. For more information about trigger dates, see Collection Event Trigger Date.

Setting Up Collection Classes

Every account has a collection class. This class is one of several fields that control the collection method applied to the account's debt. Open **Admin**, and then **Credit & Collection**, and then **Collection Class** to define your collection classes.

NOT_SUPPORTED

For more information about collection classes, see Designing Your Collection Classes.

Description of Page

Enter a unique **Collection Class** code and **Description** for each collection class.

Indicate which method is used to monitor the member accounts' unpaid debt:

- If you practice balance-forward accounting for accounts belonging to this collection class, select Collection, Severance & Write-Off. This method of collection is described throughout this chapter.
- If you practice open-item accounting for accounts belonging to this collection class, select Overdue. This method of collection is described under Defining Overdue Processing Options.
- If accounts belonging to this collection class are not subject to either of the above collection methods, select Not Eligible For Collection. Please be aware that these accounts will NOT be reviewed for overdue debt.

Setting Up Debt Classes

Every SA type has a debt class. This class is one of several fields that control the collection criteria applied to the service agreement's debt. Open **Admin**, and then **Credit & Collection**, and then **Debt Class**, and then **Add** to define your debt classes.

NOT_SUPPORTED

For more information about debt classes, see Designing Your Debt Classes.

Description of Page

Enter a unique **Debt Class** and **Description** for the debt class.

Copyright © 2026, Oracle and/or its affiliates.

Turn on **Eligible for Collection** if service agreements belonging to this debt class have their debt monitored by the collection process. This should only be turned off if this debt cannot be collected, e.g., write-off debt.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to an arbitrary number as only one algorithm for each system event is allowed in this case.

> **Warning**
>
> These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
Collection Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a collection process can be canceled, and if so, it cancels it. Refer to How Are Collection Processes Cancelled for more information.
Severance Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a severance process can be canceled, and if so, it cancels it. Refer to How Are Severance Processes Cancelled for more information.

Copyright © 2026, Oracle and/or its affiliates.

Override Arrears Due to Pay Plan	Required if you use Pay Plans	This algorithm is called to temporarily override a customer's arrears using a pay plan's scheduled payments when the system looks at an account's debt from a credit & collections perspective (i.e., the ADM calls this algorithm before it subjects a customer's debt to the collection criteria and when a pay plan is created). It does not actually change any data, but overlays the current arrears with the pay plan scheduled payments. This algorithm is also called by the above algorithms when a pay plan is created in order to evaluate if the scheduled payments actually cover the arrears (if so, the collection / severance processes are cancelled). It is also called periodically by the ADM in order to establish if the current state of the pay plan still covers the arrears. Refer to How Pay Plans Affect The Account Debt Monitor.

Setting Up Collection Class Controls

The topics in this section describe the windows on which you set up your collection class control information.

> **Warning**
>
> The information in this page is what controls how the system analyzes your customer's debt. The flexibility of this control information provides you with almost unlimited options. This is very powerful, but it requires careful analysis. Refer to Designing Your Collection Procedures **for more information**.

- Collection Class Control - Main Information
- Collection Class Control - Debt Criteria

Collection Class Control - Main Information

The information on this transaction defines the conditions that will be checked by the Account Debt Monitor when it checks if an account has violated your debt criteria.

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Credit & Collection**, and then **Collection Class Control**, and then **Add** to define this information.

> **NOT_SUPPORTED**
>
> For more information about collection class control, refer to Designing Collection Class Controls.

Description of Page

Enter a unique **Collection Class Control** code and **Description** for the collection class control (CCC).

Enter the **CIS Division** to which the CCC's criteria applies.

Enter the **Collection Class** to which the CCC's criteria applies.

Enter the **Debt Class** to which the CCC's criteria applies.

Enter the **Currency Code** in which the CCC's criteria are denominated.

Use **Long Description** to further describe the CCC.

> **NOT_SUPPORTED**
>
> The information in the following grid is not intuitively obvious. Refer to Designing Collection Class Controls and Designing Your Collection Class Control Overrides for more information.

The grid which follows contains the conditions that are checked by the Account Debt Monitor (ADM) to determine the type of criteria (defined on the next tab) that will be applied against an account's debt. In other words - the ADM will check each condition (from highest to lowest **Priority**). The first condition that returns a value of true will cause the system to compare the account's debt against the debt criteria defined on the next tab.

Multiple conditions may be defined if different conditions result in a different type of debt thresholds (or a different type of collection process). The following fields are required for each condition:

Collection Condition Priority The priority controls the order in which the ADM checks if a collection condition applies (the lower the number, the higher the priority). Higher priorities are checked before lower priorities.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is COLL_CAT_PRIO_FLG.

Condition Algorithm Define the algorithm used to check if an account should be subject to the collection criteria defined on the next tab. If the algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** (defined

Copyright © 2026, Oracle and/or its affiliates.

on the next tab) and start a collection process if the account has debt that violates these criteria.

You must have at least one collection condition; otherwise the system will not have criteria against which to compare the account's debt. This entry should have the lowest priority code and reference the "default" algorithm. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that references the "default" collection condition algorithm type (COLL COND DF).

If you have other conditions that should be checked before the default condition, you must create an entry for each in this grid. Each entry should have a priority consistent with your business requirements (and this priority should be higher than the default condition's priority). In addition, you should reference an algorithm that contains the conditions that will be checked to determine if the account should be subject to the debt criteria (defined on the next tab). The system is supplied with many additional algorithm types. In order to take advantage of them, you will need to create an algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that references one of the collection condition algorithm types.

Where Used

Collection class controls contain the data that controls the Account Debt Monitor. Refer to How Does The Account Debt Monitor Work? for more information.

Collection Class Control - Debt Criteria

The information on this page defines the debt and age thresholds used by the Account Debt Monitor when it checks if an account has violated your acceptable levels of debt. Open **Admin**, and then **Credit & Collection**, and then **Collection Class Control**, and then **Search** and navigate to the **Debt Criteria** page to define this information.

> **Note**
>
> **The information on this page is not intuitively obvious.** Refer to Designing Collection Class Controls and Designing Your Collection Class Control Overrides for more information.

Description of Page

The **Debt Criteria** scroll contains an entry for each collection criteria algorithm defined on the **Main** tab. The following information appears

The **Collection Condition Priority** controls the order in which the Account Debt Monitor (ADM) checks if a collection condition applies. Higher priorities are checked before lower priorities.

The **Condition Algorithm** is called by the ADM to determine which collection criteria should be applied to the account's debt. If this algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** defined below. If the account violates any criteria, a collection process will be started (using the respective **Collection Process Template**).

The grid that follows contains the debt age and amount of debt that must be violated by the account in order for the ADM to create a collection process template. The following fields should be defined:

Copyright © 2026, Oracle and/or its affiliates.

Arrears Priority controls the order in which the arrears criteria will be checked by the Account Debt Monitor (the lower the number, the higher the priority). The first criteria, if any, that is met will cause a collection process to be created (using the **Collection Process Template**).

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: Collection Class Control, Severance Criteria, Write Off Control, and Workflow Process Profiles .

Collection Process Template If the Account Debt Monitor determines that the account's debt violates the corresponding criteria, it creates a collection process using the specified collection process template.

Arrears Amount When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than "> Number of Days" (the next field) AND the debt exceeds "> Arrears Amount". If so, a collection process is started.

Days When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than **Days** AND the debt exceeds **Arrears Amount**. If so, a collection process is started.

Where Used

Collection class controls contains the data that controls the Account Debt Monitor.

Designing Your Severance Procedures

The following matrix will help you design your severance procedures. When the matrix is complete, you're ready to set up the severance process control tables.

Notice that the matrix has two dimensions: one is dependent on severance criteria algorithms; the other is dependent on the SA type of the service agreement being severed. The number and type of SA types is dependent on how your organization sets up the SA type table (the SA types shown below are characteristic of those used by a simple utility).

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support
Electric Residential		
Electric Commercial		
Gas Residential		
Gas Commercial		
Charitable Contribution		

Once you know the values of each dimension, you fill in each cell with its respective severance events. We've completed the sample matrix with some characteristic events.

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support

Copyright © 2026, Oracle and/or its affiliates.

Electric Residential	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	Create a To Do entry asking a collection rep to call the customer. 5 days later, create a 72-hour warning field activity. 2 days after completion, create a To Do entry telling collection rep of impending life support cutoff. 3 days after completion of warning, create a disconnect service field activity AND generate a To Do entry informing a collection agent of such. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection expire the service agreement.
Electric Commercial	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	N/A
Gas Residential	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.
Gas Commercial	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	N/A
Charitable Contribution	Expire service agreement	Expire service agreement

Copyright © 2026, Oracle and/or its affiliates.

Once the matrix is complete, you determine the severance process templates needed to implement your severance procedures. The following table shows the severance process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Utility severance - default	10	Field activity - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Electric life support residential severance	10	Generate delinquent life support customer To Do entry	N/A - first event	0
	20	Field activity - 72 hour disconnect for non-payment warning	10	5
	30	Generate impending life support cutoff To Do entry to C&C rep	20	2
	40	Field activity - cut for non-payment	20	3
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Just expire severance	10	Expire service agreement	N/A - first event	

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
48-hour warning	Generate Field Activity - Disconnect Warning
72-hour warning	Generate Field Activity - Disconnect Warning
Disconnect for non payment	Generate Field Activity - Cut For Non-Payment
Delinquent life support customer	Create To Do Entry - C&C Rep Role

Copyright © 2026, Oracle and/or its affiliates.

Impending life support cutoff	Create To Do Entry - C&C Rep Role
Service has been disconnected letter	Send Letter - Customer Contact Type is Disconnect Letter
Expire service agreement	Expire Service Agreement

> **Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

Now you're (almost) ready to set up your severance procedures.

- Defining Severance Process Auto Cancellation Criteria

Defining Severance Process Auto Cancellation Criteria

The topics in the section How Are Severance Processes Cancelled describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your Debt Classes, and optionally, on your Severance Process Templates.

Designing Your Reconnection Procedures

If a customer pays for a service agreement after the service has been cut for non-payment AND BEFORE THE SA HAS BEEN EXPIRED, they need to be reconnected. Counter-intuitively, you must set up a severance process to initiate the field activities to reconnect service.

> **Note**
>
> **Why do you use a severance process to reconnect service?** Because a severance process is nothing more than a series of events that take place one after another. Some of the events create field activities, others send letters, others create To Do entries. So, why not use a severance process? You just have to send different letters and perform different field activities.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> The system will automatically create a reconnection process if a severance process is cancelled as a result of a payment (or other credits). Please note that this will only happen if you plug-in the appropriate post cancellation algorithm on your severance process templates. Refer to What Happens When A Severance Process Is Cancelled? **for more information**.

While you don't define the reconnect procedures for an SA type, we recommend you think about the reconnection steps for each of your SA types that can be disconnected for nonpayment. We've completed the sample matrix with some characteristic events.

SA Type	Steps
Electric Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Electric Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.

Once the matrix is complete, you determine the severance process templates needed to implement your reconnection procedures. Notice each SA type has the same reconnection steps. This means you just need one severance process. The following table shows this severance process template and its events.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Reconnect	10	Field activity - reconnect service	N/A - first event	0
	20	Service has been reconnected letter	10	0

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
Reconnect	Generate Field Activity - Reconnect
Service has been reconnected letter	Send Letter

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

> **Important**
>
> If you want the system to automatically create a reconnection process if a customer pays after they have been cut, you must specify the appropriate post cancellation algorithm on your severance process templates.

And now you're ready to set up your severance (and reconnection) procedures.

Setting Up Severance Procedures

In the previous section, Designing Your Severance Procedures, we presented a case study that illustrated a mythical organization's severance procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Severance Event Types
- Setting Up Severance Process Templates

Setting Up Severance Event Types

Severance event types control what is done by a given severance event. Open **Admin**, and then **Credit & Collection**, and then **Severance Event Type**, and then **Add** to define your severance event types.

> **NOT_SUPPORTED**
>
> For more information refer to Designing Your Severance Procedures.

Description of Page

Enter a unique **Severance Event Type** code and **Description** for the severance event type.

Enter the Severance **Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Send Letter, Generic Algorithm, Create To Do Entry, Create Field Activities, Expire Service Agreement. The following discussion describes the parameters that must be defined for each type of severance event.

Copyright © 2026, Oracle and/or its affiliates.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- account debt monitor.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

The Send Letter severance event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Generic Algorithm severance event type causes the algorithm defined in the **Sev. Event Algorithm** to be executed. You use this type of algorithm when the standard types of severance events won't do what you need done.

The Create To Do Entry severance event type causes a To Do entry to be created. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-SEVT for the type of To Do entry that's created).

The Generate Field Activities severance event type causes one or more field activities to be generated. Enter the following **Parameters** for this type of event:

- Select the **Customer Event** associated with the field activity. Valid values are: Cut For Non-Payment (CNP), Disconnect Warning (Disc Warn), Reconnect for Payment (Reconn), Start Service (Start) , Start/Stop Service (Start/Stop), Stop Service (Stop), Reread (Reread).
- The system uses the **Customer Event** to select the appropriate field activity type(s) from the field activity type profile associated with the service points linked to the service agreement.

> **⚠ Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter off) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

The Expire Service Agreement severance event type causes the service agreement to be moved to the pending stop state (it also populates the service agreement's stop date). Refer to Finalizing Pending Stops for how the system will eventually stop the service agreement (and then final bill it). There are no parameters for this type of event.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Cut for non-payment field activities are special.** The Expire Service Agreement severance event type also makes any "cut for non-payment" field activities created by earlier severance events available to stop service. Specifically, it changes the linkage type of the field activities from Severance Activity to Stop Activity. You can see a service agreement's service points' field activities and their respective linkage type on Service Agreement - Service Point.

Enter a **Long Description** to fully describe the severance event type.

Setting Up Severance Process Templates

Severance process templates define the severance events that will be executed when a service agreement is severed. Open **Admin**, and then **Credit & Collection**, and then **Severance Process Template**, and then **Add** to define your severance process templates.

Description of Page

Enter a unique **Severance Process Template** and **Description** for the severance process template.

If severance processes of this type should be automatically canceled when the customer pays the collection amount on the severance, turn on **Auto Cancel**. This switch would typically only be turned off for severance processes used to reconnect a cut service because you don't want such a reconnection process to be canceled when a payment is made. Refer to Designing Your Reconnection Procedures for more information.

In addition to turning on the **Auto Cancel** switch, specify a **Cancel Criteria Algorithm** if your organization allows a severance process to be cancelled regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM.

If the **Cancel Criteria Algorithm** is specified, it is executed when a credit is posted to the service agreement associated with a severance process. This algorithm will indicate if the service agreement no longer has debt that warrants a severance process. Refer to How Are Severance Processes Cancelled for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

If you wish to perform any special processes after a severance process is canceled, specify a **Post Cancel Algorithm**. This can be used to start a reconnection in case the severance process was canceled too late to stop the disconnection. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

When a service agreement is to be severed due to non-payment, the system creates a severance process and links to it one or more severance events based on the **Event Types** entered here. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event:

Copyright © 2026, Oracle and/or its affiliates.

Event Sequence controls the order in which the severance event types appear under the severance process template. The sequence number is system-assigned and cannot be changed. If you have to insert a severance event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Severance Event Type Specify the type of severance event to be generated.

Dependent On Other Events Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. For example, you would turn this switch on for the event that initiates the field activity to disconnect service. Why? Because you only want to disconnect service after the preceding event that warned the client of impending disconnection is complete.

Days After Prev Response Specify the number of days after the completion / cancellation of the dependent events on which the severance event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of days after the creation of the severance process that the related severance event will be triggered. Refer to Severance Event Dependencies and Trigger Date and Calendar vs Work Days for a description of how the system uses this information to set the trigger date on the respective severance events.

When the **Dependent On Other Events** switch is on, use the grid to define the events on which this event is dependent. If multiple events are specified in the grid, all such events must be completed or cancelled before the event will be triggered.

Sequence is system-assigned and cannot be specified or changed.

Dependent On Sequence Specify the sequence number of the severance event on which the above severance event depends.

NOT_SUPPORTED

For more information about severance event types, see Setting Up Severance Event Types. For more information about trigger dates, see Severance Event Dependencies & Trigger Date.

Designing Your Write-Off Procedures

The design of your write-off procedures is relatively straightforward. Simply follow the instructions in the following topics.

- Designing Your Write-Off Debt Classes
- Designing Write-Off Controls
- Designing Write Off Process Templates & Write Off Event Types

Designing Your Write-Off Debt Classes

Multiple write-off debt classes are needed when you have different write-off procedures for different types of service agreements. If all service agreement debt is written-off the same way, then you'll have just one write-off debt class (call it Generic). However, if you're like many

Copyright © 2026, Oracle and/or its affiliates.

organizations, you will have multiple write-off debt classes. The following points will help you understand why:

- If you bill for 3 rd parties, you probably have different write-off debt classes for the 3 rd party service agreements. Why? Because you probably treat 3 rd party uncollectable debt differently from your own debt.
- You will need a separate write-off debt class for service agreements whose debt cannot be written off. Why? Because there is a switch on the write-off debt class control table that controls if service agreements in the write-off debt class are eligible for write-off processing. Given that you will have some service agreements that hold debt that aren't eligible for write-off processing (e.g., service agreements that hold written-off debt and service agreements that overpayments), you will need at least one other write-off debt class.
- If you use the system to calculate charges for your organization's company usage, you'll need another write-off debt class (we refer to it as the "N/A" write-off debt class below). Why? Because all service agreements must have a write-off debt class, even those that will never have debt.

SA's Write-Off Debt Class	**Account's Collection Class**	**Account's Collection Class**
Normal W/O		
N/A		

Designing Write-Off Controls

Set up a matrix using the collection classes you designed when you were designing your collection procedures (Designing Your Collection Procedures).

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**
Normal Write Off		
N/A		

Each cell should have a "write-off control" that defines what to do when the system detects finaled debt that hasn't been paid. This is true even of the "N/A" write-off debt class. Why? Because you may want the system to write-down these stopped SAs when they have a small balance. For example, if you have a write-off service agreement that subsequently receives a partial payment that leaves a small amount owing, you probably want the system to generate a write-down adjustment (so that the write-off service agreement will close). We'll initially fill in the matrix for the "N/A' write-off debt class.

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**
Normal Write Off		

Copyright © 2026, Oracle and/or its affiliates.

N/A	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment.

> **Note**
>
> If the Write Off Monitor encounters debt associated with a non-defined collection class and write-off debt class, it will issue an error.

For each cell that isn't designated as N/A, you need to answer the following questions:

- Are you allowed to transfer debt to other non-closed service agreements linked to the account? If so, you need to define the algorithm used to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- Are you allowed to write-down small amounts of debt (or small credits)? If so, you need to define the algorithm used to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- Should you refund credit balances with a check? If so, you need to define the algorithm to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- If debt remains after doing the above, how do you write it off (e.g., do you first refer the debt to a collection agency and only write it off after waiting 30 days)?

We'll fill in the above matrix with our assumptions:

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**

Copyright © 2026, Oracle and/or its affiliates.

Normal Write-Off	Attempt to reduce the SA's balance to zero using the following methods: Attempt to transfer debt to another active service agreement linked to the account. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. If the debt is <= $-1, create an A/P adjustment to refund the credit to the customer. If debt remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process. Otherwise, create the default write-off process for residential debt.	Attempt to reduce the SA's balance to zero using the following methods: Attempt to transfer debt to another active service agreement linked to the account. If the debt / credit is < $10 and > $-10, write down the debt using a write-down adjustment. If the debt / credit is <= $-10, create an A/P adjustment to refund the credit to the customer. If debt remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process. Otherwise, create the default write-off process for commercial debt.
N/A	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.

We can now use the information in the above matrix to design the necessary Write Off Process Templates and Write Off Event Types.

Designing Write Off Process Templates & Write Off Event Types

The following table shows the write-off process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Write Off Process Template	Write Off Event Type	Triggered X Days From Start Of Write Off Process
Residential	Refer to collection agency	0
	Letter notifying customer of referral	0
	Cancel collection agency referral	60
	Write off	60

Copyright © 2026, Oracle and/or its affiliates.

Non-Cash Deposit Exists	To Do for non-cash deposit redemption	0
	To Do to highlight unpaid SA(s) still exist (and they will be reconsidered for write-off processing)	10
Commercial	Refer to collection agency	0
	Letter notifying customer of referral	0
	To Do to check up on collection agency's efforts	30
	Cancel collection agency referral	60
	Write off	60

If we extract each unique event type from the above table, we end up with the following:

Write Off Event Type	Event Type
Notification of write-off referral	Send letter - Debt referred to a collection agency
Refer to collection agency	Refer to collection agency
Cancel collection agency referral	Cancel collection agency referral
Write off	Write off
To Do for non-cash deposit redemption	Generate To Do - Redeem non-cash deposit
To Do to highlight unpaid SA(s) still exist	Generate To Do - SA(s) linked to a non-cash deposit remain unpaid (and will be reconsidered for write-off processing)
To Do to check up on collection agency's efforts	Generate To Do - Check up on collection agency's efforts

And now you're ready to set up your write-off procedures.

Setting Up Write-Off Procedures

In the previous section, Designing Your Write-Off Procedures, we presented a case study that illustrated a mythical organization's write off procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Write Off Debt Classes
- Setting Up Write Off Event Types
- Setting Up Write Off Process Templates
- Setting Up Write Off Control
- Setting Up Collection Agencies

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Write Off Debt Classes

Every SA type has a write-off debt class. This class is one of several fields that control the write off criteria applied to the service agreement's debt. Select **Admin**, and then **Credit & Collection**, and then **Write Off Debt Class** to define your debt classes.

> **NOT_SUPPORTED**
>
> For more information about debt classes, see Designing Your Write-Off Debt Classes.

Panel controls

To modify a write-off debt class, simply move to a field and change its value. To add a new write-off debt class, click + to insert a row, then fill in the information for each field. The following fields display:

Write Off Debt Class Code The unique identifier of the write off debt class.

Eligible for Write Off Indicates if service agreements belonging to this write off debt class are eligible for write-off processing. This should only be turned off if this debt cannot be written off, e.g., write off debt.

Description The description of the write off debt class.

Setting Up Write Off Event Types

Write-off event types control what is done by a given write-off event. Select **Admin**, and then **Credit & Collection**, and then **Write Off Event Type**, and then **Add** to define your write-off event types.

Description of Page

Enter a unique **Write Off Event Type** code and **Description** for the write-off event type.

Select the **Write Off Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Cancel Agency Referral, Generic Algorithm, Refer to Agency, Send Letter, Create To Do Entry, Write Off using Distrib Code, and Write Off using SA Type. The following discussion describes the parameters that must be defined for each type of write-off event.

The Affect Credit Rating/Cash-Only write-off event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Affect Credit Rating By** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account’s CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account’s CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Affect Cash-Only Score By** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the

Copyright © 2026, Oracle and/or its affiliates.

cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

> **NOT_SUPPORTED**
>
> For more information, refer to Account - Credit Rating.

The Cancel Agency Referral event type will cancel previous collection agency referrals. No parameters are needed for this type of event.

The Generic Algorithm write-off event type causes the algorithm defined in the **Generic Algorithm** to be executed. You use this type of algorithm when the standard types of write off events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type are activated.

The Refer to Agency event type will refer the debt associated with the process' SAs to a collection agency. You must supply the **Agency Selection Algorithm** that is used to determine the collection agency associated with the referral. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines the collection agency to which bad debt should be referred.

> **Note**
>
> **Letters.** You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the write off event type. Refer to Setting Up Letter Templates for more information.

The Send Letter write-off event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following parameters for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Create To Do Entry write-off event type causes a To Do entry to be issued. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-WOEVT for the type of To Do entry that's created).

The Write Off using Distrib Code event type causes bad debt to be written off in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. Use this method if, for example, you want to write-off revenue differently than you write-off liabilities. When this type of event is activated, the system accumulates the distribution

Copyright © 2026, Oracle and/or its affiliates.

codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreements. The type of service agreements to which the debt is transferred is defined on the distribution codes. Refer to Setting Up Distribution Codes for more information.

The Write Off using SA Type event type causes all debt associated with the process' SAs to be transferred to a write-off service agreement linked to the account. Enter the following **Parameters** for this type of event:

- **CIS Division / SA Type** is the type of write-off service agreement to which the debt will be transferred. Note well,
  - The system will reuse an existing service agreement if an active SA of this type is already linked to the account; otherwise the system will create a new service agreement of this type.
  - The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on the write-offable SA Type. Refer to SA Type - Main Information for more information.
  - The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write off SA type. Refer to SA Type - Detail for more information.

Enter a **Comment** to fully describe the write-off event type.

Setting Up Write Off Process Templates

Write-off process templates define the write-off events that will be executed when a write-off criteria rule is violated. Select **Admin**, and then **Credit & Collection**, and then **Write Off Process Template**, and then **Add** to define your write-off process templates.

Description of Page

Enter a unique **Write Off Process Template** code and **Description** for the write-off process template.

The rows in the following grid define the events that will be created when a write off process is created using this template. The following fields display:

Event Sequence Controls the order in which the write-off event is executed. The sequence number is system assigned and cannot be changed. If you need to insert a write-off event between two existing events, you must remove the latter events, insert the new event, and then re-enter the removed events.

Write-off Event Type Code Specify the type of write-off event to be generated. The event type's description is displayed adjacent.

Days After Process Creation Specify the number of days after the creation of the write-off process that the related write-off event will be triggered. Refer to Calendar vs Work Days for a description of how this system uses this information to set the trigger date on the respective write-off events.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about write-off event types, see Setting Up Write Off Event Types. For more information about trigger dates, see Write-off Event Trigger Date.

Setting Up Write Off Control

Write-off controls define how the system handles finaled, unpaid debt belonging to a given collection class and write off debt class.

- Write Off Control - Main
- Write Off Control - Criteria

Write Off Control - Main

Select **Admin**, and then **Credit & Collection**, and then **Write Off Control**, and then **Add** to define basic information about a write-off control. After entering basic information, navigate to the **Criteria** tab to define the type of write-off process to start when given criteria are met.

NOT_SUPPORTED

For more information about write-off control, refer to Designing Write-Off Controls.

Panel controls

Enter a **Write Off Control** code and **Description** for the write-off control (WOC).

Enter the **Collection Class** to which the WOC applies.

Enter the **Write Off Debt Class Code** to which the WOC applies.

Enter general **Comments** to further describe the WOC.

Define the **Synch All Algorithm** used by the system to generate adjustments that cause current balance to equal payoff balance on the service agreements to be written off. This type of algorithm is issued before you actually start a write-off process as current balance is meaningless at write-off time (the customer owes you the payoff balance). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that synchronizes current and payoff balances.

Define the **Debt Transfer Algorithm** used by the system when it attempts to transfer the unpaid debt to another active service agreement linked to the stopped SA's account. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that transfers unpaid balances.

Copyright © 2026, Oracle and/or its affiliates.

Define the **Write Down Algorithm** used by the system when it attempts to write-down small debt and/or credit balances. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that writes down small amounts.

Define the **Credit Refund Algorithm** used by the system when it refunds a credit balance to a customer. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that refunds credit balances.

Write Off Control - Criteria

Select **Admin**, and then **Credit & Collection**, and then **Write Off Control**, and then **Search** and navigate to the **Criteria** page to define the type of write-off process to start when given criteria are met.

> **NOT_SUPPORTED**
>
> The following information is not intuitively obvious. Refer to Designing Write-Off Controls for more information.

Panel controls

The information in the grid defines the write-off process to be executed for debt belonging to the previously defined collection class and write off debt class. The type of write-off process may differ depending on some condition. For example, you may have a different write-off process if the customer has a non-cash deposit. You must have at least one entry in this collection otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **Write Off Criteria Algorithm** that references the WO CRIT DFLT the algorithm type.

The following fields display:

Priority controls the order in which the criteria will be checked by the Write Off Monitor (higher priorities are checked before lower priorities). The first criteria algorithm that is met (i.e., returns a value of *True*) will cause the associated write-off process to be initiated.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: Collection Class Control, Severance Criteria, Write Off Control, and Workflow Process Profiles .

Write Off Criteria Algorithm The Write Off Monitor checks if the condition defined by the W/O Condition Algorithm applies to the account whose debt is being analyzed. If a condition is met, a write-off process is created using the associated write-off process template.

Copyright © 2026, Oracle and/or its affiliates.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines if a customer's bad debt should be processed using the associated **Write Off Process Template**.

> **Important**
>
> You must have at least one entry in this grid otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **W/O Criteria Algorithm** that references the WO CRIT DFLT algorithm type.

Write Off Process Template If the Write Off Monitor determines the condition defined by the w/o condition algorithm applies, a write-off process is created using the associated write-off process template.

Where Used

Write-off controls contain the data that controls the Write Off Monitor. Refer to How Does The Write-Off Monitor Work? for more information.

Setting Up Collection Agencies

You must set up a collection agency for each such organization to which you refer delinquent debt. To define a collection agency, select **Admin**, and then **Credit & Collection**, and then **Collection Agency.**

Description of Page

Enter an easily recognizable **Collection Agency** code and **Description** for each collection agency.

A collection agency must be associated with a Person. Choose the **Person ID** of the organization from the prompt.

> **NOT_SUPPORTED**
>
> Information about how to set up persons is discussed in Maintaining Persons.

Turn on the **Active** switch if the collection agency is actively receiving referrals.

Specify the **Batch Control** that's used to route new and cancelled referrals to the collection agency. The batch control's description is displayed adjacent.

Where Used

Collection agencies get assigned to collection agency referrals when the collection agency referral background process executes. Refer to How Do Collection Agency Referrals Work? for more information.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Feature Configuration

You must set up a Feature Configuration if you use the champion / challenger functionality.

The following describes the various **Option Types** that must be defined:

Champion Template$Challenger Template$Percentage(1-100). You need only set up options of this type if your implementation implements Champion / Challenger functionality. Options of this type are entered in the format ABnnn where A is the collection process template of the champion template, B is the collection process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The collection monitor uses this option to override the champion collection process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

How To

The contents of this section describe how to set up various credit and collections scenarios.

- How Arrears History is Captured
- How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

How Arrears History is Captured

The system captures a history of arrears (amount owed) for accounts under an active collection activity – those with an active collection, severance, or overdue process. The data is maintained from the creation of the process to when it is set to inactive. Currently, there is no user interface to view the history records. Rather, they are stored in the system so they can be retrieved by other processes and APIs.

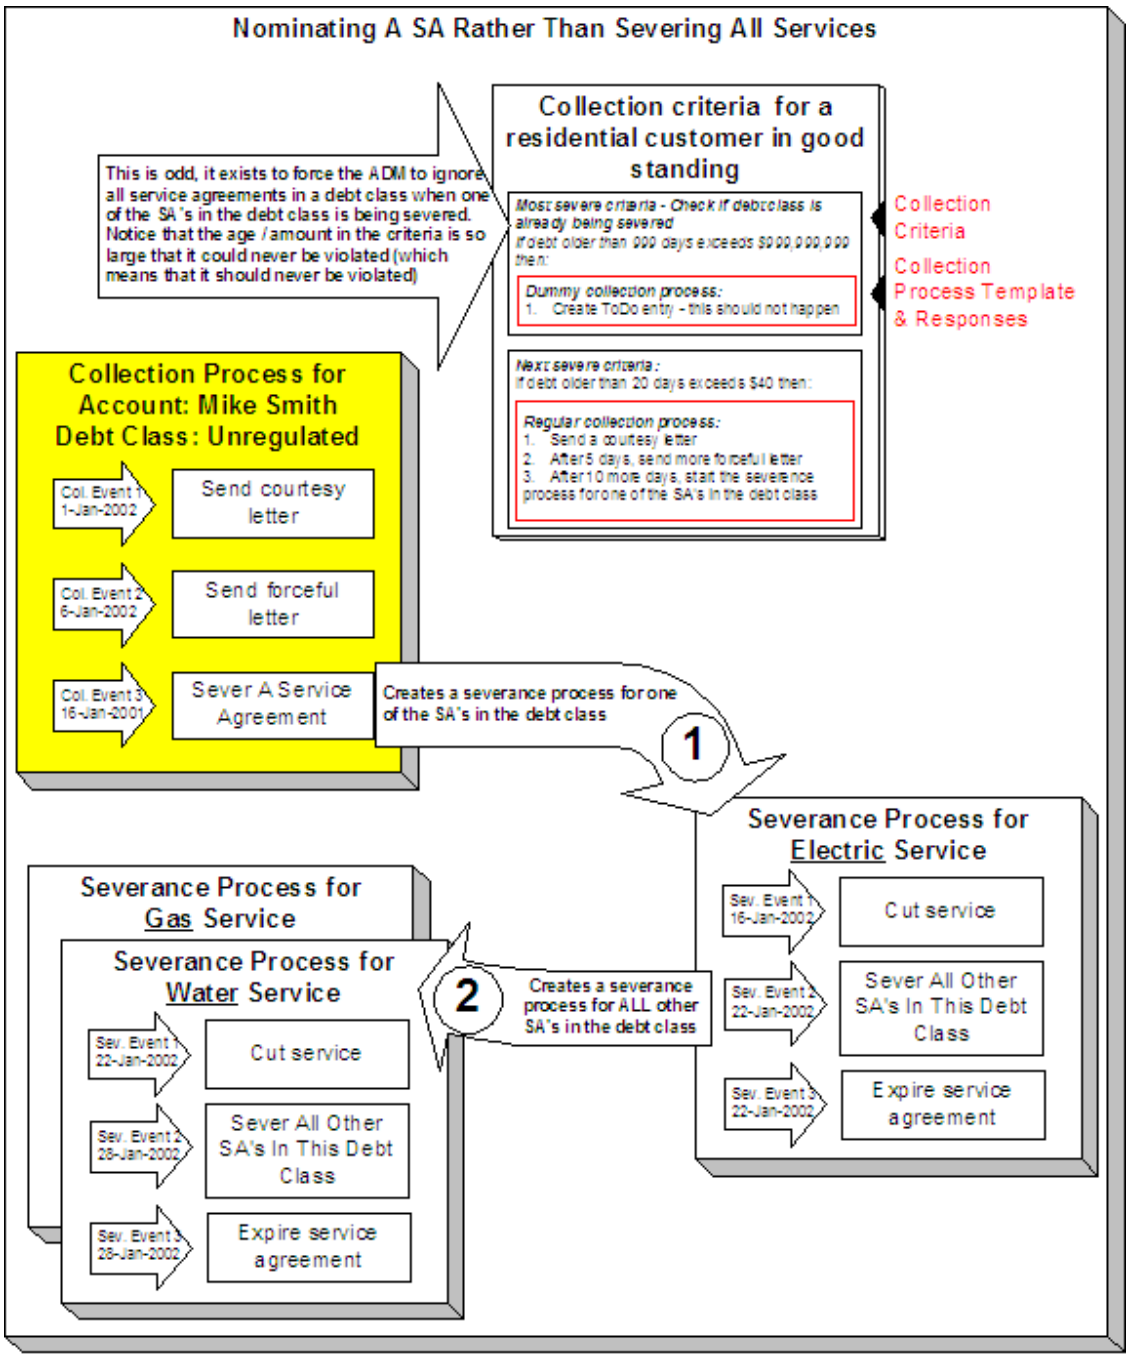
Where is this information captured? The system uses child maintenance objects that extend their parent object to capture this information. Arrears history records are stored in the following tables: Collection Process Arrears History, Collection Process SA Arrears History, Severance Process Arrears History and Overdue Process Arrears History. Arrears history is stored on the Collection Process SA Arrears History table when the system is configured to use service agreement-oriented cancel criteria. Refer to How Are Collection Processes Cancelled and How Are Severance Processes Cancelled for more information on debt class or service agreement-oriented cancel criteria configurations.

Why is this information captured? One reason is because it's difficult to derive real-time. The system relies on plug-in spots to know if a collection activity can be canceled. These plug-in spots calculate the amount owed under a collection activity, sometimes adjust that amount by promised future payments, and compare that amount to a threshold that is configured as an algorithm parameter. So, outside of the system processes that call these plug-in spots, it is difficult for an API or query to replicate the logic. Therefore, the system captures the information from the plug-in spot drivers – the programs that call the plug-ins. The drivers are base programs and will work with algorithms delivered with the system or your custom algorithms; just make sure they are populating the output elements for the plug-in spot.

Copyright © 2026, Oracle and/or its affiliates.

The above explains the technical aspect of this, but why or how can this data be used? One reason is to allow inquiries across many accounts belonging to the same person or business. Consider a large entity such as a local government with hundreds or even thousands of accounts and the desire to know how much debt is under collection at any moment. Aside from being difficult to replicate the logic that derives these amounts, that query could be a timely one to perform.

The most recent amount owed and related information should meet the business needs for cases like the one described above. However, instead of keeping a current snapshot of amount owed for each process, the system creates a record upon process creation and a new record each time there is a change in the amount owed or other data captured. One reason for this is to have the data to analyze the payment patterns for debt under collection. Is the debt paid in one lump sum or in small amounts? Is it paid close to the process creation or days or weeks later? Are customers paying the full amount owed or just enough to get below the threshold to cancel collection activity? This data makes these types of analytics possible.



What data is being stored? The key information is the amount still owed for the collection activity, the cancelation threshold amount, and the amount owed before being adjusted by future payments. Refer to How Pay Plans Affect The Account Debt Monitor for more information about how pay plans affect the amount owed. The system is also able to determine if debt class or service agreement-oriented cancel criteria configurations are used based on which plug-in spots are being used and this information is captured. This is important in knowing how to use and interpret the data. Refer to the system metadata for these tables to see exactly what data is captured.

What system processes call the plug-in spots responsible for capturing the arrears history? These plug-in spots are called when the processes that collect on debt are created. They are called in a special mode that does the calculations but doesn't take any action. This is to capture the initial record. These plug-in spots are also called by the processes that monitor ongoing collection of debt, some updates to these processes, and by system events such as payments or other credit financial transactions.

How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

Some organizations that offer multiple services do not sever all services when the customer falls into arrears. Rather, they nominate a single service agreement to sever in the hopes that the lack of service will cause the customer to remit payment. The following diagram illustrates the control tables values required to implement this type of requirement.

Copyright © 2026, Oracle and/or its affiliates.

The following important concepts are illustrated above:

- The collection process's last event does NOT sever all services. Rather, it calls an algorithm that selects a single service to sever. A base package algorithm allows you to define the primary service to sever and a secondary service to sever (if the customer does not have the primary service). If you sold electricity and gas, you would probably define the primary service as electricity and the secondary as gas (because electricity is easier to cutoff than gas).
- The severance process that is started for the primary service cuts service. If the customer doesn't remit what is owed, the second severance event calls an algorithm that severs all other service agreements in the debt class.

Copyright © 2026, Oracle and/or its affiliates.

- Because you are nominating a single service to sever, you must set up a special value in collection class control to force the ADM to ignore all service agreements in a debt class when one of the SAs in the debt class is being severed. Notice that the age / amount in the criteria is so large that it could never be violated.
- In addition, because the entire debt class must no longer be in arrears to stop the collection and severance processes, you must plug-in the appropriate collection process and severance process cancellation criteria on the debt class. Refer to How Are Collection Processes Cancelled and How Are Severance Processes Cancelled for more information about how these algorithms are used. Also note, you do not need service agreement cancellation criteria defined on your collection process templates and severance process templates (because cancellation is controlled at the debt class level).

Defining Meter & Item Options

Located at a premise's service points are the various meters, items and equipment that regulate and measure consumption. Before you can define meters, items and equipment you must set up the control tables defined in this section.

NOT_SUPPORTED

Refer to An Illustration Of A Premise for an illustration of how meters, items and equipment are related to the service points.

- The Big Picture of Meters, Items and Equipment
- Setting Up Meter Options
- Setting Up Metered Service Point Options
- Setting Up Metered Premise Options
- Setting Up Consumption Estimation Parameters

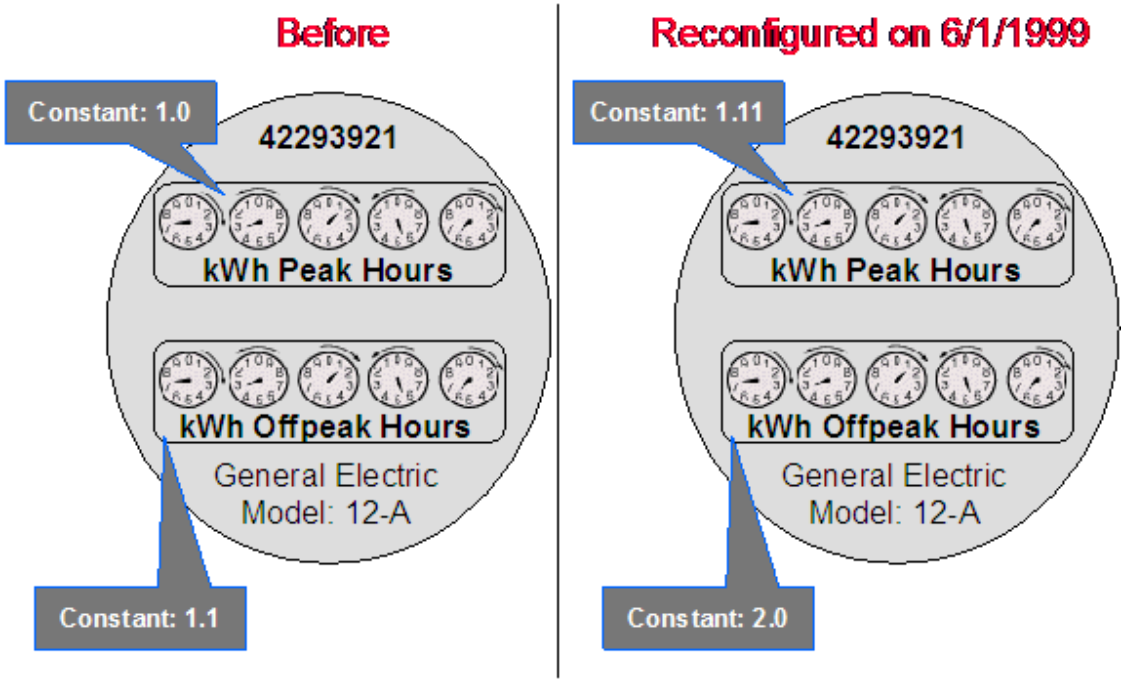
- Setting Up Device Test Options
- Defining Usage Options

The Big Picture of Meters, Items and Equipment



The topics in this section provide background information about meters, items and equipment.

- The Structure Of A Meter
- Items Are Used For Other Devices Associated With A Customer's Service

Copyright © 2026, Oracle and/or its affiliates.

The Structure Of A Meter

A customer's consumption is measured using a meter. What a meter measures and how it measures it can change over time. The following example illustrates a simple meter before and after a reconfiguration.

The system maintains how a meter looks over time so that it can reproduce bills using historical consumption. Information about this meter is recorded in the following tables:

- Every meter has a single **meter** record that contains information about the meter that doesn't change over time. For example, its meter number and manufacturer.
- A **meter configuration** record is required whenever something changes about what the meter measures. The meter shown above has two configurations - the original and the one effective on 1-June-1999.
- Every meter configuration contains one or more **registers**. Each register references the unit being measured and how the measured quantity is manipulated before it is billed.

NOT_SUPPORTED

Information about how to set up meters is discussed in Maintaining Meters.

Items Are Used For Other Devices Associated With A Customer's Service

In addition to meters, there are many other devices that can be involved with a customer's service. We refer to these other devices as "items".

Copyright © 2026, Oracle and/or its affiliates.

We purposefully use the ambiguous term *item* because items are used for many different devices including lamps, poles, current transformers, backflow devices, pulse initiators, etc. Refer to the diagram in An Illustration Of A Premise for an example of the various items that could be associated with a customer's service.

The topics in this section provide more information about items.

- Equipment versus Badged Items
- Meters May Have Equipment
- Items May Have Equipment
- Service Points May Have Equipment
- Chargeable Items Must Be Associated With Service Points
- Start/Stop and Items
- Billing and Items
- Generic Equipment

Equipment versus Badged Items

This is a rather confusing subject, but there are two notional types of items:

- **Equipment.** An item that is considered to be "equipment" is a physical device that regulates consumption; it does NOT measure consumption. You would only define equipment if it is of interest to your organization. For example, if your organization periodically tests the pulse initiators associated with your meters, you will need to set up items for each pulse initiator and link them to their respective meters. Equipment can be linked to either a service point (e.g., a current transformer, a backflow device), a meter (e.g., a pulse initiator), or an item (e.g., the components of an installation).
- **Non Equipment.** An item that is not considered to be "equipment" is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. These types of items are related to service points. Refer to Chargeable Items Must Be Associated With Service Points for information about the two types of items that may be linked to service points.

The topics that appear below provide more information about both types of items.

Meters May Have Equipment

If you have physical devices that are intrinsically associated with meters (but aren't meters), you can set up an item for each such device. For example, if you have pulse initiators linked to your meters, you would set up an item for each pulse initiator. After creating these items, you would update each meter's collection of equipment to include the respective pulse initiator.

Items May Have Equipment

If you have physical devices that are intrinsically associated with other non-metered devices, you can set up an item for each such device. For example, you could set up an item for an "installation" (an installation is a group of devices that work together to regulate electric

Copyright © 2026, Oracle and/or its affiliates.

consumption) and link to it the individual items that do the work. To do this, you would set up items for each individual piece of equipment in the installation. After creating these items, you would update the collection of equipment associated with the installation's item to include each piece of equipment.

Service Points May Have Equipment

If you have physical devices that don't have line item charges but are intrinsically associated with a service point, you can set up an item for each such device. For example, if you have voltage regulators linked to your service points, you would set up an item for each voltage regulator. After creating these items, you would update each service point's collection of equipment to include the respective voltage regulator.

Chargeable Items Must Be Associated With Service Points

If there are charges in your rates based on the number and type of items installed at a service point, you can use either of the following techniques:

- If the item is badged (i.e., uniquely identified), you would set up an item and link it to an **item** - ***based*** service point. An item-based service point may have zero or one item installed at any instant in time. Over time, an item-based service point may have many badged items installed and removed. Refer to Installing / Removing An Item for more information.
- If the item does not have a unique identifier, you do NOT have to set up phony items for it. Rather, you can use the system's multi-item functionality and simply define the number of each TYPE of item that is installed at a service point. Refer to Service Points With Multiple Items for an illustration of such a service point.

Start/Stop and Items

When a customer start or stops service at an **item** - ***based*** service point, it takes into account whether an item is currently installed at the SP and whether the item is on or off. Start/Stop does not concern itself with equipment.

Billing and Items

It's important to note that billing ignores equipment relationships when it constructs the snapshot of number and types of items associated with a service agreement's service points. In other words, billing constructs the item snapshot as follows:

- It inserts an entry into the item snapshot for every item type referenced in the service agreement's service points' multi-item collection.
- It inserts an entry into the item snapshot for every badged item linked to service points with an SP type of Item.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Item Snapshot for more information.

Note

Equipment and billing. Be aware that the only way equipment can impact billing would be if you develop a pre-processing calculation group that analyzed the equipment associated with a service point (directly or indirectly via the meters and items) and manipulated billed consumption accordingly. Refer to All Calculation Rule-Based Rates Share a Common Structure for more information about pre-processing calculation groups.

Generic Equipment

Some companies do not badge their equipment, but they still need to keep track of the type of equipment that is linked to service points, meters and badged-items. For example,

- You may want to keep track of the type of modem linked to a meter, but you don't care about the individual modem or pulse-initiator
- You may want to keep track of the type of backflow device linked to a water meter

Note

Why is generic equipment recorded in the system? Generic equipment gets linked to SP's / meters / items when the type of equipment linked to an SP / meter / item affects bill calculations. For example, some water companies charge extra if a backflow device is present at a service point.

If you encounter the need for generic equipment, do the following:

- Create an Item Type for each type of unbadged equipment. On this item type, indicate that items of this type may be linked to multiple SP's / meters / items. Note: we recommend suffixing the description of the item type with the word "generic".
- Update the relevant meter type(s) / SP type(s) / item type(s) to indicate that they may use equipment associated with the generic item type.
- Create one (1) item for each type of unbadged equipment. Note: we recommend suffixing the description of the item type with the word "generic".
- Link the generic item to the relevant SP's / meters / items.

Setting Up Meter Options

This section describes tables that must be set up before you can define meters.

Copyright © 2026, Oracle and/or its affiliates.

- Setting Up Meter Configuration Types
- Setting Up Meter Types
- Setting Up Manufacturers & Their Models
- Setting Up Meter ID Types
- Setting Up Read Out Types
- Setting Up Protocol Codes
- Setting Up Unit Of Measure Codes
- Setting Up Time-Of-Use Codes
- Setting Up TOU Groups
- Setting Up Retirement Reasons

Setting Up Meter Configuration Types

Every meter configuration must reference a meter configuration type. The meter configuration type indicates the valid (required or optional) unit of measure and time of use registers for the configuration.

Navigate to **Admin**, and then **Meter Configuration Type**, and then **Add** to set up valid meter configuration types.

Description of Page

Enter an easily recognizable **Meter Configuration Type** and **Description** for the meter configuration type.

Choose the **Service Type** associated with the meter configuration type. Refer to Setting Up Service Types for more information.

Use **Prepaid Meter** to indicate whether or not the meter configuration is used to record prepaid usage.

If you have set up a **TOU Group** to indicate your collection of time of use codes for the meter configuration, enter it here. Use the **Default TOU Registers** button to have the system build the collection of registers for you based on the TOU codes linked to the TOU group. Refer to Setting Up TOU Groups for more information

In the grid, specify the attributes of the collection of valid registers. If the register is **Interval**, put a check in the checkbox. For any register, indicate the valid **UOM**. For interval registers, indicate the **Interval Register Type**. If a **TOU** is applicable for the register, enter the TOU code. Finally, specify a **Validation** for each register. The register pair can be Optional or Required.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> In certain markets, registers with the same **UOM** and **TOU** combination or, for **Interval** meters, the same **UOM** and **Interval Register Type** combination may need to be defined under a single meter configuration. If your implementation is in one of these markets, add the Allow Duplicate UOM/TOU Combination **Option Type** on the Meter Management Options Feature Configuration and set its value to Y .
>
> **Attributes related to interval registers may not appear**. These attributes are suppressed if Meter Data Management module is turned off.

Setting Up Meter Types

Every meter references a meter type. The meter type defines the type of service and common characteristics shared by its meters. The meter type also controls the characteristics that may be specified on meters of a given type.

> **Note**
>
> **When a new meter type is added.** After adding a new meter type, you must define the SP types at which meters of this type can be installed.

The topics in this section describe how to maintain your meter types.

- Meter Type - Main
- Meter Type - Meter Characteristics
- Meter Type - Equipment Types
- Meter Type - Test Types
- Meter Type - Meter Configuration Type

Meter Type - Main

To define a meter type, open **Admin**, and then **Meter Type**, and then **Add.**

Description of Page

Enter an easily recognizable **Meter Type** and **Description** for the meter type.

Choose the **Service Type** associated with all meters of this type. Refer to Setting Up Service Types for more information.

Turn on **Allow Duplicate Meter Badges** if more than one meter of this type may have the same badge number.

Turn on **Prepaid-Capable** if meters of this type are used to record prepaid usage.

Turn on **Allow Interval Registers** if meters of this type may contain interval registers. Refer to The Big Picture of Raw Data Collection and Aggregation for more information.

Copyright © 2026, Oracle and/or its affiliates.

Indicate in **Track Location** whether you Track or Do Not Track the location of meters of this type. Refer to The Big Picture of Asset Inventory for more information.

Use the **Characteristic Values** collection to define **Characteristic Type**s and their respective **Characteristic Values** and **Adhoc Values** to describe characteristics common to all meters of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Meter Type Characteristics table.

> **Note**
>
> You can only choose characteristic types defined as permissible on the meter type record.

Meter Type - Meter Characteristics

To define characteristics that can be defined for meters of a given type, open **Admin**, and then **Meter Type**, and then **Search** and then navigate to the **Meter Characteristic** page.

Description of Page

Use the **Meter Characteristics** collection to define characteristics that can be defined for meters of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on meters of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Meter Type - Equipment Types

Open **Admin**, and then **Device**, and then **Meter Type**, and then **Search** and then navigate to the **Equipment Types** page to define the types of equipment that can be linked to meters of a given type. Refer to Equipment versus Badged Items for more information about equipment.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to meters of this type.

> **Note**
>
> **Item types are being specified.** There is no equipment type control table. Rather, items are used to define equipment and therefore you are actually defining item types rather than equipment types. Refer to Equipment versus Badged Items for more information about equipment.

Meter Type - Test Types

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Device**, and then **Meter Type**, and then **Search** and then navigate to the **Test Types** page to define the types of device tests that can be performed on meters of a given type. Refer to The Big Picture Of Device Testing for more information about device tests.

Description of Page

Use the **Device Test Type** collection to define the types of device tests that can be performed on meters of a given type.

Meter Type - Meter Configuration Type

Open **Admin**, and then **Device**, and then **Meter Type**, and then **Search** and then navigate to the **Meter Configuration Type** page to define the types of meter configurations that are allowed for this type of meter.

Description of Page

Use the **Meter Configuration Type** collection to define the types of meter configurations that can be used for this type of meter.

Setting Up Manufacturers & Their Models

When you set up a meter (or an item) you must define the manufacturer and model number of the meter / item. To define a manufacturer and its models, open **Admin**, and then **Manufacturer**, and then **Add.**

Description of Page

Enter an easily recognizable **Manufacturer** and **Description** for the manufacturer.

Enter a **Model** and **Description** for every model supplied by the manufacturer. Enter the **Service Type** with which the model is associated. Refer to Setting Up Service Types for more information.

If the model is associated with a meter, turn on **Use On Meter**. If the model is associated with an item, turn on **Use On Item**.

Setting Up Meter ID Types

A meter may have alternate ID's other than its badge number. If so, it will reference one or more meter ID types (one for each alternate form of ID). To define meter ID types, open **Admin**, and then **Meter ID Type.**

Description of Page

Enter a unique **Meter ID Type** and **Description** for every meter ID type.

Where Used

A meter may have alternate ID's other than its badge number. If so, it will reference one or more meter ID types (one for each alternate form of ID). Refer to Meter - Meter ID Information for more information.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Read Out Types

Every register has a read out type that defines how the register's measurements are physically displayed (e.g., circular dials, digital, n/a-electronic transmission, and so on). To define read out types, open **Admin**, and then **Device**, and then **Read Out Type.**

Description of Page

Enter a unique **Read Out Type** code and a **Description** for every read out type.

Setting Up Protocol Codes

Every register has a protocol code that defines the method used to record the register's measurements (e.g., visual, probe, AMR, modem). To define protocol codes, open **Admin**, and then **Device**, and then **Protocol.**

Description of Page

Enter a unique **Protocol** and **Description** for every protocol.

Setting Up Unit Of Measure Codes

You must create a unit of measure (UOM) for:

- Every UOM that is measured by your meters' registers.
- Every UOM in which your rates' prices are expressed.
- Every UOM in which your items' estimated consumption is expressed.

> **Note**
>
> Typically, the measured UOM is the same as the UOM in which the prices are expressed. However, there are instances where the UOM of the price is not measured by a meter's registers. Natural gas is a good example - the prices are expressed in an amount per therm, but the gas meters measure some volume (e.g., cubic feet, cubic meters).

> **NOT_SUPPORTED**
>
> For more information about UOM's, refer to UOM versus TOU versus SQI .

To define unit of measure codes, open **Admin**, and then **General**, and then **Rates**, and then **Unit of Measure**.

Description of Page

The following fields display for each unit of measure:

Copyright © 2026, Oracle and/or its affiliates.

UOM The unique identifier of the unit of measure.

Description The full description of the UOM.

Service Type The type of service (e.g., electric, gas, water, and so on.) associated with this UOM. This value controls the UOMs that may be referenced on meters belonging to a given service type. Refer to Setting Up Service Types for more information.

Decimal Positions The number of decimal positions that appear on bill lines that show consumption.

> **Note**
>
> **Suppression of trailing zeroes.** If you wish to suppress trailing zeroes in the consumption that appears on bill lines, you must set up the Allow Zero Suppression Of Consumption In Bill Description option type on the Financial Transaction Options Feature Configuration.

Allowed on Register Turn on this switch if the UOM can be referenced on a meter's register. A unit of measure may not be allowed on a register when it exists purely because there is a price in a rate expressed in this UOM. (For example, prices of natural gas are frequently express in therms, but it is rare to find a meter that measures gas in therms.)

Measures Peak Quantity Turn on this switch for UOMs that exist to record the peak amount of consumption, e.g., kW and kVar. Peak UOMs are treated differently by billing when determining the amount of consumption. They are also treated differently if rating has to prorate consumption.

Setting Up Time-Of-Use Codes

You will only create time of use (TOU) codes if your meters measure consumption in respect of broad time bands. For example, some electric meters measure consumption in respect of WHEN the power was used - peak period, off peak period, or partial peak period.

If you have "time of use" meters, then you must create TOU codes for:

- every TOU that is measured by your meters, and
- every TOU in which your rates' prices are expressed.

> **Note**
>
> Typically the measured TOU is the same as that in which the prices are expressed. However, there are instances where the TOU of the price is not measured directly by a meter's registers. A simple example is where the meter measures peak hours consumption and total consumption but there are prices in the rate for off peak consumption. In this situation, the peak hours consumption would have to be subtracted from the total consumption to derive off peak consumption. In this situation, you would need TOU codes for both peak (measured) and off-peak (derived) periods.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about TOU's, refer to UOM versus TOU versus SQI .

Time-of-use codes will also be needed if your company offers interval billing with TOU mapping. Refer to Designing Your Time of Use Options for more information.

To define time-of-use codes, open **Admin**, and then **Rates**, and then **Time of Use.**

Description of Page

Enter a unique **TOU** code and **Description** for every time of use code.

Setting Up TOU Groups

TOU Groups may be used to group together time of use codes, which are included in a meter configuration. It is also used in TOU mapping and pricing functionality.

NOT_SUPPORTED

Refer to Grouping of TOU Codes for more information about the TOU group's role in TOU mapping and pricing.

Open **Admin**, and then **TOU Group**, and then **Add** to define your TOU Groups.

Description of Page

Enter a unique **TOU Group** and **Description** for the TOU group.

Enter the Collection **Time of Use** codes. This is a list of time of use codes that define the time of use periods to be used for certain TOU maps. For each time of use code, you may indicate a **TOU Sequence** to indicate the relative order or relative priority of each TOU for the TOU group. Refer to Grouping of TOU Codes for more information.

Setting Up Retirement Reasons

When you change a meter or item's status to Retired, you must supply a retirement reason. To define retirement reasons, open **Admin**, and then **Devuce**, and then **Retire Reason.**

Description of Page

Enter a **Retire Reason Code** and **Description** for every retirement reason.

Setting Up Metered Service Point Options

Setting Up Meter Read Warnings

When you set up a premise you may define warnings to be supplied to the individuals who read the meters located at the premise. To define meter read warning codes, open **Admin**, and then **Geographic**, and then **Meter Read Warning.**

Description of Page

Enter a unique **Meter Read Warning** and a **Description** for every meter read warning.

Setting Up Consumption Estimation Parameters

The system estimates consumption under the following situations:

- At billing time, when "real" consumption cannot be computed due to the lack of a meter read, the system estimates how much the customer used assuming the following conditions are true:
  - The service agreement allows estimation.
  - The rate schedule allows estimation.
  - The bill cycle schedule (if one is being used) allows estimation.
  - The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption). Note that the base product estimation algorithms may attempt to estimate peak registers.
  - The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. But consider what would happen if we estimated a consumptive register, the consumption associated with the next real read will be billed in its entirety.
- When a meter read is added, the system verifies that the resultant consumption is congruous with historical consumption trends (i.e., high / low checks are performed).

This section describes the tables that must be set up to estimate consumption.

- Estimating Consumption
- Setting Up Trend Areas
- Setting Up Trend Classes
- Setting Up High / Low Factors
- Setting Up Trends

Estimating Consumption

How the system generates estimated consumption is up to you because a plug-in algorithm is called when it's time to estimate consumption. The identity of the plug-in algorithm is defined on the trend area of the premise at which the meter is installed.

Copyright © 2026, Oracle and/or its affiliates.

The base package is supplied with two algorithm types that you may use to estimate consumption:

- The TSMRE-LA algorithm type first tries to estimate consumption using historical data for the account and service point. If this is unsuccessful, it uses trend data to estimate consumption.
- The MR EST TREND algorithm type uses trend data to estimate consumption.

If neither of these algorithms works for your organization, you will need to write a new algorithm and plug it in on your trend areas.

The following discussion explains how the sample estimation plug-ins work.

- Estimating Using Historical Consumption
- Estimating Using Trends
- Tips for Consumption Estimation Using Trends
- Estimation and Negative Consumption

Estimating Using Historical Consumption

One of the sample estimation algorithms provided with the base package attempts to estimate consumption using historical data for the account and service point.

When you estimate consumption using historical data, you assume that the customer will have current consumption that is similar to their historical usage. For example, if you need to estimate consumption for the month of February of the current year, you could assume that the customer has similar consumption during the month of February of the previous year or that they have similar consumption to the previous month.

The base package algorithm type that uses a customer's historical data to estimate consumption is called TSMRE-LA (three-step meter read estimation). It makes three attempts to estimate consumption stopping at the first successful attempt.

First, it tries to estimate consumption using a bill segment for the service point from the previous year that covers a similar period to the one being estimated. The year-old bill segment can be used for estimation if it is for the same account AND the bill segment's end read is not a system estimate AND there are enough days in the bill segment for estimation (as defined by the algorithm).

If the year-old bill segment cannot be used for estimation, the system attempts to use the bill segment for the account and service point that immediately precedes the start date of the estimation period. Again, this bill segment must not have an estimated end read and it must have a sufficient number of days for estimation.

Once a historical bill segment that can be used for estimation is located (using one of the above methods), the estimation occurs as follows:

- If the register is non-peak, the system calculates the average amount of consumption per day on the historical bill segment and multiplies this by the number of days in the current estimation period. For example, if the customer averaged 30.350877 kWh per day in the historical bill period and there are 30 days in the current period, the estimated consumption is: 911 kWh.
- If the register is peak, the estimation amount is the same as the peak amount on the historical bill segment.

Copyright © 2026, Oracle and/or its affiliates.

If the system is unsuccessful in estimating consumption using the historical data for the previous year or the previous bill period, the system estimates consumption using trends .

Estimating Using Trends

> **Warning**
>
> The topics that appear below explain how the MR EST TREND sample estimation algorithm works. Another algorithm is also available in the base package. It attempts to estimate consumption using the customer's historical consumption; if historical consumption does not exist, it estimates using the logic described below (refer to Estimating Using Historical Consumption for the information about this algorithm).

- The Theory Behind Consumption Estimation Using Trends
- Consumptive Register Where UOM Does Not Measure Peak Quantity
- Subtractive Register Where UOM Does Not Measure Peak Quantity
- Consumptive Register Where UOM Measures A Peak Quantity
- Subtractive Register Where UOM Measures A Peak Quantity

The Theory Behind Consumption Estimation Using Trends

The following discussion explains how the sample estimation plug-ins use trend data. If you decide to create your own version of one of these plug-ins, you still have to set up trend areas and trend classes as these are required fields on premises and SP types.

The standard estimation plug-ins assume that if a customer historically used, say, twice as much as customers of a similar profile, then the customer should use twice as much in the current period. Therefore, to estimate consumption for any period of time the system needs to know:

A. How much the specific customer used in the previous consumption period.

B. How much the average customer in the customer's trend profile used in the previous consumption period.

C. How much the average customer in the customer's trend profile used in the period being estimated.

Once the above are known, estimated consumption for the specific customer equals (A/B) * C.

Knowing how much the specific customer used in the previous consumption period simply involves looking at the customer's previous readings (or reading, in the case of consumptive meters).

Knowing how much the average customer used requires consumption trend data. Consumption trend information is continuously updated behind-the-scenes using meter reads. A consumption trend is identified by a unique combination of:

Copyright © 2026, Oracle and/or its affiliates.

- **Trend area.** Trend areas are used to differentiate consumption trends in different geographic areas. If your service territory doesn't have appreciable differences based on geography, then you will have just one trend area.
- **Trend class.** Trend classes are used to differentiate consumption trends based on the type of service and the type of property. At a minimum, you would probably have a trend class to differentiate between residential, commercial, and industrial usage.
- **Unit of Measure and Time of Use.** All consumption in the system is identified using a unit of measure code and, optionally, a time-of-use code.

NOT_SUPPORTED

For more information about unit of measure codes, see Setting Up Unit Of Measure Codes . For more information about time-of-use codes, see Setting Up Time-Of-Use Codes . Trend areas, trend classes, and consumption trends are described later in this section.

Note

Bottom line. A separate consumption trend is maintained behind-the-scenes for every combination of trend area, trend class, unit of measure and time of use.

Consumptive Register Where UOM Does Not Measure Peak Quantity

The algorithm used to estimate consumption for a consumptive, non peak unit of measure is identical to Subtractive Register Where UOM Doesn't Measure Peak Quantity ; the only difference is that we don't have to find the previous, previous read in order to determine the customer's usage in the previous period.

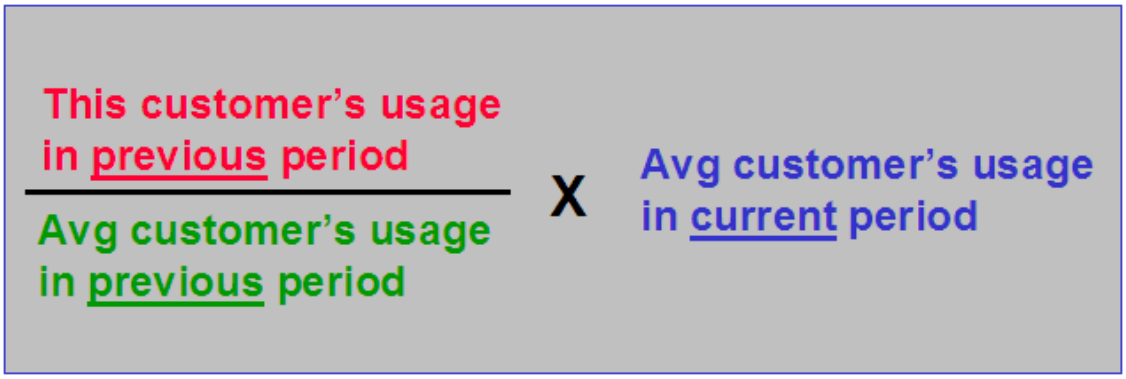
Subtractive Register Where UOM Does Not Measure Peak Quantity

Assume the following read history exists for a subtractive register (i.e., one where you have to subtract the previous read from the current read in order to derive consumption) where the register's unit of measure doesn't measure a peak quantity.

Read Date	Reading	Derived Consumption
15-Jan- 1999	1000	N/A (first read)
15-Feb-1999	3000	2000
15-Mar-1999	4500	1500

Next, assume the meter's trend profile looks as follows:

Read Date	Total Qty (Assume kWh)	No of Units (Total Days)	Number of Reads	Average Consumption (Per Day)
13-Mar-1999	6,000,000	135,000	4,500	44.444444



Copyright © 2026, Oracle and/or its affiliates.

14-Mar-1999	900,000	15,000	500	60
15-Mar-1999	5,000,000	137,750	4,750	36.297641
...				
13-Apr-1999	4,000,000	135,000	4,500	29.629630
14-Apr-1999	4,650,000	155,000	5,000	30

> **Note**
>
> The system keeps a separate trend for every combination of trend area, trend class, unit of measure and time of use code. Trend area comes from the premise at which a meter is installed. Trend class comes from the SP type of the service point at which a meter is installed. Unit of measure and time of use come from the register read's register.

Next, assume a new register read is recorded on 15-Apr-1999 with a value of 5000.

In order to calculate estimated consumption for this register read, we have to calculate average daily consumption using the following formula:

The following points describe exactly how the system calculates each variable in this formula:

- Determine **Average Customer's Usage In Current Period**:
  - Extract the number of reads from the meter's service point's SP type's trend class. We'll assume this is set to 7,500 reads.
  - Read trend records in reverse chronological order from the read date (assuming there is no trend record on 15-Apr-1999, we'll start amassing trends from 14-Apr-1999).
  - Read enough trend records until the number of reads is greater than or equal to the trend class' number of reads. We will have to read 2 trends records to amass this value (the ones on 14-Apr-1999 and 13-Apr-1999). We remember how many reads we extracted from the trend table for use a little later. In this case, we used 9,500 reads.
  - Divide **Total Qty** by **No of Units**. Using our example, we'd divide 8,650,000 kWh by 290,000 days to get 29.827586 kWh per day.
- Determine **This Customer's Usage In Previous, Non-Estimated Period**:
- Find the consumption associated with the previous, non-estimated read for the register's unit of measure / time of use codes at the service point. In this case, we'd find the read on 15-Mar-1999. Because this register is subtractive, we'd also need to find the previous,

Copyright © 2026, Oracle and/or its affiliates.

previous non-estimated read in order to calculate consumption. In this case, we'd find the read on 15-Feb-1999.

> **Note**
>
> **Minimum Days Between Readings**. The algorithm parameter Minimum Days Between Readings controls the minimum number of days needed between the previous non-estimated read and the "previous, previous" non-estimated read.

- Divide the total consumption by the number of days. Using our example, we'd divide 1,500 kWh by 28 days to get 53.571429 kWh per day.
- Note: if the customer doesn't have consumption in the previous, non-estimated period, e.g., if it's a meter at a new premise, the system assumes the customer uses the same as the average customer's usage in the previous period (see next point).
- Determine **Average Customer's Usage In Previous Period**:
- Read trend records in reverse chronological order from the read date of the previous reading (15-Mar-1999).
- Read enough trend records until the number of reads is greater than or equal to the number of reads amassed when determining the Average Customer's Usage In The Current Period (the first point). Using our example, we'd have to read 3 trends records (the ones on 15-Mar-1999, 14-Mar-1999 and 13-Mar-1999).
- Divide **Total Qty** by **No of Units**. Using our example, we'd divide 11,900,000 kWh by 287,750 days to get 41.355343 kWh per day.
- Next, determine the number of days of estimated consumption. This will be equal the number of days between the estimation date and the prior reading (note, the prior reading could have been estimated). Using our example, we'd have 31 days (the number of days between 15-Apr-1999 and 15-Mar-1999).
- At this point, we have everything we need to estimate consumption. This will equal ((53.571429 / 41.355343) * 29.827586) * 31 days. This is equal to 1,198 kWh.
- If we need to calculate high and low boundaries, we multiply 1,198 kWh by the high and low values defined for the register's unit of measure, the service point's service type and the read's read type.

Consumptive Register Where UOM Measures A Peak Quantity

The algorithm used to estimate consumption for a consumptive, peak unit of measure is identical to Subtractive Register Where UOM Measures A Peak Quantity with the exception that we don't have to find the previous, previous read in order to determine the customer's usage in the previous period.

Subtractive Register Where UOM Measures A Peak Quantity

The algorithm used to estimate consumption for a subtractive, peak unit of measure is identical to Subtractive Register Where UOM Doesn't Measure Peak Quantity the previous example except:

Copyright © 2026, Oracle and/or its affiliates.

- The No of Units on the trend table is not the number of days. Rather, it's the number of reads that contributed to the trend.
- Because we don't care about number of days, we don't have to multiply final estimated consumption by the number of days in the estimation period.

Tips for Consumption Estimation Using Trends

The quality of the trend information and setup impacts your estimation results (depending on your estimation algorithm) and this in turn impacts any estimated bills you send your customers. When you are setting up consumption estimation parameters keep the following guidelines in mind.

- Make Sure the Number of Reads on Trend Class Is Large Enough
- Trend Classes and Trend Areas Should be Defined Appropriately
- Customers Should Be Classified Into Appropriate Trend Classes and Areas

Make Sure the Number of Reads on Trend Class Is Large Enough

You should make the Number of Reads on the trend class is large enough that individual reads do not cause statistical anomalies. For example, assume that a "normal" read in a trend class is 500 kWh and, that within the trend class, there is one "abnormal" customer using 500 percent of normal:

- If the number of reads in the class is 10, the average read is calculated to be 700 kWh. The abnormal read causes a 40 percent increase in the average.
- If the number of reads in the class is 100, the average read is calculated to be 520 kWh. The abnormal read causes a 4 percent increase in the average.
- If the number of reads in the class is 1000, the average read is calculated to be 502 kWh. The abnormal read causes a 0.4 percent increase in the average.

By sizing the number of reads in a trend class appropriately, you can reduce the impact of statistical anomalies.

> **Note**
>
> **Example Values.** The example above is meant to illustrate the importance of using an appropriate number of reads in a trend class. The numbers used in the example should not be viewed as recommended values when setting up your trend classes.

Trend Classes and Trend Areas Should be Defined Appropriately

In addition to defining a large enough number of reads on the trend class, you want to make sure that the system can collect the number of reads in a relatively short period of time or the benefit of trends is diluted. For example, if the system collects the number of reads over a period of two days as opposed to two months, the seasonal trend information is better represented in your estimates.

Copyright © 2026, Oracle and/or its affiliates.

Consider the following example. Assume the number of reads required in the trend sample is 1000 and your system collects the following trend information for the area/class:

Month	Number of Reads	Average
March	400	200 kWh
April	400	300 kWh
May	400	500 kWh

The trended average in May is 333.33 kWh ((80000 + 120000 + 200000) / 1200).

However, if the number of reads required in the trend sample is 1000 and your system collects the following trend information for the area/class:

Month	Number of Reads	Average
March	1100	200 kWh
April	1100	300 kWh
May	1100	500 kWh

The trended average in May is 500 kWh (550000/1100), which is a more accurate representation of the trend in May.

> **Note**
>
> **Example Values.** The examples above are meant to illustrate the importance of ensuring that the system collects enough reads in a short enough time span to accurately capture trends. The values are summarized by month and do not represent actual records in a trend profile.

The collection of an appropriate number of reads is a function of the number of reads defined for a trend class and the number of customers who are in each trend class/trend area combination. Make sure that the number of reads is not too large for the number of customers who are in each trend class/trend area combination and that the trend class/trend area combinations do not create groups of customers that are too small to calculate accurate trends.

Customers Should Be Classified Into Appropriate Trend Classes and Areas

Make sure that your customers are classified into appropriate trend area/trend class categories. If a customer's actual usage does not follow the trend (within a certain percentage) for the area/class in which the customer is classified, the consumption estimates for that customer may be inaccurate. For example, a residential customer should not be in a trend class with industrial customers.

A customer's premise references the trend area in which the customer is classified. A customer's service point type references the trend class in which the customer is classified.

Estimation and Negative Consumption

Copyright © 2026, Oracle and/or its affiliates.

In some cases, a service point may be fitted with its own renewable energy source such as wind turbines or solar panels. The energy generated at this service point, as well as any energy used, could possibly be measured by a single meter, with the energy generated being netted against the energy used (a situation also referred to as net-metering). When the energy generated exceeds the energy used, negative consumption can result.

The possibility of negative consumption occurring at a particular SP/meter combination is indicated by the presence of a characteristic on the SP that identifies it as one that has generation capacity, as well as a characteristic on the meter type that identifies the meter as one capable of rolling backwards. Both characteristics must be present before negative consumption is allowed for that SP/meter combination. These characteristic types and values are defined on the Meter Management Options Feature Configuration. The following points describe the various **Option Types** that must be defined if negative consumption is allowed by your implementation:

- Negative Consumption SP Characteristic Type. This option indicates the characteristic type used on service points to denote generation capacity.
- Negative Consumption SP Characteristic Value. This option indicates the characteristic value used on service points to denote generation capacity.
- Negative Consumption Meter Type Characteristic Type. This option indicates the characteristic type used on meter types to identify meters capable of rolling backwards.
- Negative Consumption Meter Type Characteristic Value. This option indicates the characteristic value used on meter types to identify meters capable of rolling backwards.

Because the factors that cause a meter to roll forward are very different from the factors that cause it to roll backward, it is impracticable for the estimation algorithms to try to derive an estimate in situations where negative consumption is allowed. The estimation rules simply cannot combine the effects of all these disparate factors into one meaningful figure. By extension, the same issue applies to the determination of high/low factors. Besides the fact that high/low validation is impossible without first obtaining an estimate, a meaningful set of high/low factors cannot be determined when it is not known how energy generated at the service point may have affected the consumption in the first place. Therefore, no estimation is done by the system for SP/meter combinations that allow negative consumption. Reads that belong to these SP/meter combinations are also excluded from the trending process so as not to skew the rest of the estimates for a certain trend area and trend class.

Setting Up Trend Areas

When you set up a premise, you must define the consumption trend area in which it is located. This categorization matters when consumption trends differ across your service territory AND you want the system to estimate consumption in different areas differently.

This categorization does not have to be done in respect of classic geographic boundaries like cities and counties. Rather, trend areas may be based on economic factors, climatic conditions, or anything else related to geography that affects consumption.

> **Note**
>
> A premise's trend area will default based on its postal code. See Setting Up Premise & Service Point Postal Defaults for more information.

To define trend areas, open **Admin**, and then **Consumption**, and then **Trend Area.**

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Enter a unique **Trend Area** and **Description** for every trend area.

Define the **Meter Read Estimate Algorithm** that is used to estimate consumption for meters installed at premises associated with this trend area. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that performs meter read estimation.

Setting Up Trend Classes

When you set up an SP type, you must define the consumption estimation trend class in which its consumption will be categorized. This categorization matters when consumption differs based on the type of property AND you want the system to estimate consumption in different classes differently.

These categories could be the classic divisions of residential versus commercial versus industrial consumers. Alternatively, they could be finer-grained divisions: single family residence, versus duplex, versus triplex, versus medical office, versus grocery store.

To define trend classes, open **Admin**, and then **Consumption**, and then **Trend Class.**

Description of Page

Enter a unique **Trend Class** and a **Description** for every trend class.

Enter the **Number of Reads** that must be amalgamated to create a statistically significant sample when amassing the average customer's consumption. The system uses this number to determine the number of consumption trend records to amalgamate.

> **Note**
>
> **Don't worry.** The Number of Reads is not the number of rows that will be read when the system estimates consumption. This is because the total consumption from many reads is stored on a single consumption trend record.

Setting Up High / Low Factors

When consumption estimation is done for the purpose of meter read validity, the system checks if the meter read's consumption is reasonable. The High / Low Meter Read algorithm type (HILO-FACTBL) supplied with the base package uses the factors defined in this table to calculate the high / low values.

High and low factors are defined for every measurable unit of measure (UOM) and read type combination. The word measurable was underlined because some UOMs exist purely for pricing purposes and are never measured by a meter (e.g., a therm of gas).

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, refer to High / Low Checks.

To define high / low factors, open **Admin**, and then **Device**, and then **High Low Factor.**

Description of Page

Enter the **Unit of Measure** (UOM) for which the high / low factors are used.

Enter the **Read Type** for which the high / low factors are used. Valid values are: Billing Force, Customer Read, Office Estimate, No Read, Service Provider Estimate, System Estimate, Regular, and Verified.

Enter the **Low Factor** for the UOM and Read Type. This value will be multiplied by estimated consumption to derive the acceptable low value of a meter read with this UOM and read type.

Enter the **High Factor** for the UOM and Read Type. This value will be multiplied by estimated consumption to derive the acceptable high value of a meter read with this UOM and read type.

Where Used

This information is used by the High / Low Meter Read algorithm type (HILO-FACTBL) when the system calculates the low and high consumption amounts against which a meter read's consumption is compared when the read is added to the system.

Note

Detecting Theft Of Service. When the status of a meter is Off, the system sets the high and low read values equal to the previous register read. This catches any consumption activity at the service point after a meter has been turned off. However, for some implementations, a small amount of consumption trickle at the service point is acceptable. In this case, you would want to relax the high/low thresholds so that the reads are not constantly flagged to have failed high/low validation. To do this, you can add the Always Estimate And Apply High/Low Factors **Option Type** under Meter Management Options Feature Configuration and set its value to Y .

Setting Up Trends

NOT_SUPPORTED

Refer to Setting Up Trends for more information.

Setting Up Meter Read Options

This section describes tables that must be set up before you can enter a meter read.

Copyright © 2026, Oracle and/or its affiliates.

- Setting Up Meter Reader Remarks
- Setting Up Meter Read Sources

Setting Up Meter Reader Remarks

When you enter a meter read, you may define remarks using remark codes. The topics in this section describe how to set up meter reader remark codes.

- Meter Reader Remark - Main
- Meter Reader Remark - Bill Messages

Meter Reader Remark - Main

To define meter read remark codes, open **Admin**, and then **Device**, and then **Meter Reader Remark**, and then **Add.**

Description of Page

Enter a unique **Meter Reader Remark** and a **Description** for every meter read remark.

Turn on **Eligible for Processing** if meter reads marked with a given remark code should cause one or more **Action Algorithm**s to execute. For example, if you need a "reread" field activity to be created when a "high bill" remark is uploaded, you'd create an algorithm called "reread" and associate it with the "high bill" remark code. Then, whenever such a meter read with a "high bill" remark is recorded in the database, the system will execute the algorithm (and generate the field activity). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with a meter read remark special activity.

Meter Reader Remark - Bill Messages

To define bill messages to appear on bills that use a meter read that references a given meter reader remark code, open **Admin**, and then **Device**, and then **Meter Reader Remark**, and then **Search** and navigate to the **Bill Messages** tab.

Description of Page

Use the **Bill Messages** collection to define **Bill Message** codes that should appear on bills that use a meter read that references a given meter reader remark code. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps bill messages on a bill during bill completion. Refer to The Source Of Bill Messages for more information.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Meter Read Sources

When you add or upload a meter read, you may define the source of the meter read. The source could reference a specific reader, a meter reading agency, or any other possible source. To define meter read sources, open **Admin**, and then **Meter Read Source.**

Description of Page

Enter a **Meter Read Source** code and **Description** for every meter read source.

Setting Up Items

This section describes tables that must be set up before you can define items.

- Setting Up Item Types
- Setting Up Manufacturers and Models

Setting Up Item Types

Every item has an item type that defines characteristics common to all items with this type. The topics in this section describe how to set up your item types.

- Item Type - Main
- Item Type - Item Characteristics
- Item Type - Equipment Types
- Item Type - Test Types

Item Type - Main

To define item types, open **Admin**, and then **Item Type**, and then **Add.**

> **Note**
>
> **When a new item type is added.** After adding a new item type, you must define the SP types at which items of this type can be installed.

> **NOT_SUPPORTED**
>
> Refer to Service Points (SPs) for information about the difference between badged and non-badged items. Refer to Items Are Used For Other Devices Associated With A Customer's Service for more information about items in general.

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Enter an easily recognizable **Item Type** and **Description** for the item type.

Choose the **Service Type** associated with all items of this type. Refer to Setting Up Service Types for more information.

Turn on **Use Estimates** if estimated consumption is recorded for this type of item (e.g., lamps have estimated consumption that is used to calculate billable charges for these types of items). When this switch is turned on, also define the **Unit Of Measure** in which the estimated consumption is expressed.

> **NOT_SUPPORTED**
>
> For more information about estimated consumption, refer to Setting Up Estimated Consumption For Items .

Turn on **Summarize For Billing** if billing is supposed to summarize all items of this type on a customer's bill. If billing is supposed to show a separate bill line for every individual item of this type, turn this switch off.

> **Warning**
>
> The Summarize For Billing switch is only pertinent if badged items are linked to the service points being billed. If unbadged items are linked to the service points, the bill will contain a summary of items by item type regardless of the value of this switch. Refer to Metered versus Item-Based versus Non-Badged Service Points **for more information**.

Turn on **Multiple Equipment Assignment** if equipment of this type can be linked with more than one service point / meter / item at any instant in time.

Turn on **Billable** if billing should amalgamate items of this type when it calculates a bill segment. This switch would typically only be turned-off for items used to describe equipment and other non-billable items linked to a service point.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> If this switch is turned on, rates linked to service agreements used to bill for items of this type must include an Item Type Calculation Rule that references this item type. Why? Because we assume that a bill line should be produced for "billable" items (and bill lines are produced for items using "item type" calculation rules). If you neglect to have such a calculation rule, a bill segment error will be produced.
>
> If your organization bills for items of this type using Estimated Consumption rather than on a "per item" basis, you'll still need an "item type" calculation rule in these rates (otherwise billing will generate an error). In order to prevent the system from calculating a charge for such an "item type", make sure to indicate the calculation rule is "for calculation purposes only" (FCPO). Refer to Common Parameters for Calculation Rules for more information about FCPO's. Also note that you might also want to indicate that the calculation rule is not printable if you want to suppress the item type's description on the printed bill. Refer to How to Use Description on Bill for more information about printable calculation rules.

Indicate in **Track Location** whether you Track or Do Not Track the location of items of this type. Refer to The Big Picture of Asset Inventory for more information.

Use the **Characteristic Values** collection to define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics common to all items of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Item Type Characteristics table.

> **Note**
>
> You can only choose characteristic types defined as permissible on the item type record.

Item Type - Item Characteristics

To define characteristics that may be defined for items of a given type, open **Admin**, and then **Item Type**, and then **Search** and navigate to the **Item Characteristics** page.

Description of Page

Use the **Item Characteristics** collection to define characteristics that can be defined for items of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on items of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Item Type - Equipment Types

Open **Admin**, and then **Device**, and then **Item Type**, and then **Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to items of a given type. Refer to Equipment versus Badged Items for more information about equipment.

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to items of this type.

> **Note**
>
> **Item types are being specified.** There is no equipment type control table. Items are used to define equipment; therefore, you define item types instead of equipment types. Refer to Equipment versus Badged Items for more information about equipment.

Item Type - Test Types

Open **Admin**, and then **Device**, and then **Item Type**, and then **Search** and navigate to the **Test Types** page to define the types of device tests that can be performed on items of a given type. Refer to The Big Picture Of Device Testing for more information about device tests.

Description of Page

Use the collection to define the types of **Device Tests** that can be performed on items of a given type.

Setting Up Manufacturers and Models

When you set up an item (or a meter) you must define the manufacturer and model number of the meter / item.

> **NOT_SUPPORTED**
>
> Refer to Setting Up Manufacturers & Their Models for more information.

The Big Picture Of Device Testing

The topics in this section describe meter and item (i.e., device) testing at a high level.

We strongly recommend examining the demo data to see how the concepts explained in this section could be used in real life.

> **Warning**
>
> Setting up the device testing control tables is as challenging as your organization's business rules. If you don't test your devices, you don't have to setup anything. If you have sophisticated testing requirements, your setup process will be more challenging.

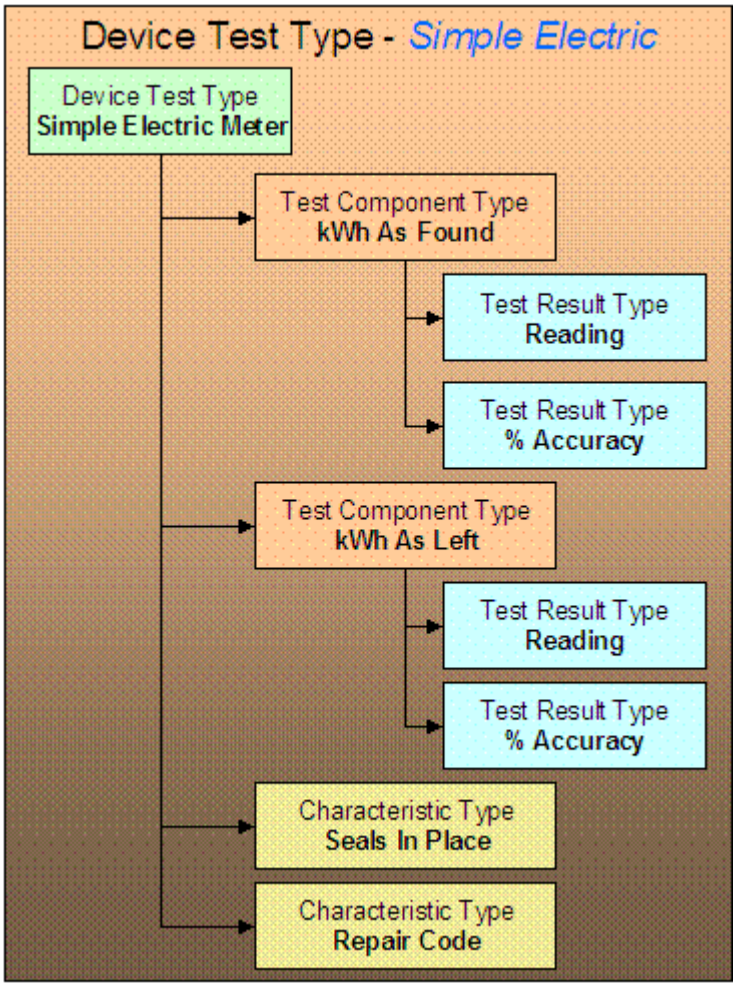
- The Level of Complexity Depends On What You Test and Your Record Keeping Requirements
- A Device Test Records Test Results
- Field Activities And Device Testing
- Device Test Validation

The Level of Complexity Depends On What You Test and Your Record Keeping Requirements

Every organization's device testing requirements are different. Consider the following:

- Some organizations simply use the CIS system to create and dispatch field activities when it's time to test devices. After the field activities are dispatched, the test results are maintained in a separate system. You can set up the system to work this way for you.
- Some organizations maintain very detailed test result records, others don't. For example, some organizations record both "as found" and "as left" test results, i.e., they test the meter in its "as found" state, then they recalibrate it and test it again and record the "as left" state. You can set up the system to work this way for you.
- Some organizations maintain separate test results for every individual register on a meter. For example, they might record 3 separate test results for an electric meter with kWh, kW, and kVar registers (and, if they recorded both "as found" and "as left" results, they would have 6 separate test results, at least, for this meter). You can set up the system to work this way for you.
- The type of information that can be recorded in respect of a test varies widely. Some organizations simply record if the test passed or failed. Other organizations keep track of a great deal of information about the test results. Consider the following examples:
  - Most organizations record who performed the test, the state of the seals on the meter, and whether or not a repair is necessary.
  - A company with gas meters might record the ambient air temperature, the temperature of the oil used in the test, the test spin time, the actual meter reading, the "chart" (should be) reading and the percent accuracy.
  - A company with electric meters might record the following information: meter reading at full capacity, meter reading a light capacity, meter reading with a power factor of 50%, and the percent accuracy.
- You can set up the system to work this way for you.



Given that the system supports the above disparate requirements, you can understand why the set up process is either straightforward or challenging. The remaining topics in this section provide some guidelines to help you through this setup process.

A Device Test Records Test Results

You create a device test each time you test a meter or item. The device test keeps track of when the test was conducted, who conducted it, and the results of the test. Every device test references a *device test type*.

Copyright © 2026, Oracle and/or its affiliates.

When you design your device test types, you are actually defining the type of information that can / must be recorded when such a device test is saved in the system. The following picture illustrates a device test type used for tests of simple electric meters.

Notice that the above device test type example uses two different mechanisms to record test results:

- **Component tests.** If your organization maintains the test results from individual registers, you will use component tests. In the above example, two different types of component tests can be recorded for this type of device test: one is used to record a register's accuracy before calibration (the "as found" component test), another is used to record the register's accuracy after calibration (the "as left" component test).
- The component test type controls the type of information that is recorded for a component test. In the above example, each component test type requires the same result types - a register reading and a percent accuracy. Note, the fact that these two test types require the same results is coincidental.

You have to set up a component test types and test result types to satisfy your organization record keeping requirements.

- **Characteristics.** If your organization doesn't keep register-specific test results, you don't have to use component tests. Rather, you can simply use characteristics to record test results. In the above device test type, characteristics are used to record whether the seals were in placed and a repair code (if the test results in a repair). Refer to Setting Up Characteristic Types & Their Values for more information about characteristics.

Copyright © 2026, Oracle and/or its affiliates.

Field Activities And Device Testing

Most device tests occur as a result of a field activity. The field activity is associated with the service point at which the device is currently installed. Refer to Examples of Device Testing Activity Types and their Steps for an overview of how these types of field activities look.

You can create device testing field activities manually OR you can take advantage of the Device Test Selection page. This page will generate field activities to test meters and items based on a user-defined Test Selection Algorithm. The system comes with a sample Test Selection Algorithm type that selects meters of a given manufacturer / model that haven't been test for a given number of months. In all likelihood, you or your implementer will have to develop other algorithms to meet the test selection requirements of your organization. For example, if you test all meters that generate more than $100,000 of revenue per annum every 6 months, you will have to write a new Test Selection Algorithm Type.

After defining which test selection algorithm types you need, you must set up Test Selection Algorithms that make use of them (these algorithms are specified by the operator on the Device Test Selection page). To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with a device test selection.

Device Test Validation

After entering the test results for a device test, some organizations want the system to analyze the test results and determine if the meter / item passed or failed the test. If your organization does this, you will have to determine the characteristic values and test result values associated with "passing the test". You will then have to design an algorithm that contains logic that determines if a device test contains the appropriate characteristic and test result values.

After developing your device test algorithms, you associate them with the appropriate device test types. The system invokes the respective algorithm when an operator pushes the Validate Device Test button on the device test page.

Setting Up Device Test Options

The topics in this section describe how to set up the control tables that must exist before a device test can be recorded.

- Setting Up Component Test Types
- Setting Up Device Test Types

Setting Up Component Test Types

Copyright © 2026, Oracle and/or its affiliates.

If you organization records component test results, you must set up a component test type for each type of component test. Refer to A Device Test Records Test Results for more information about component test types.

Open **Admin**, and then **Device**, and then **Device Test Component Type**, and then **Add** to define the type of information that must be recorded on a component test of a given type.

> **Note**
>
> **When a new component test type is added.** After adding a new component test type, you must define the device test types that make use of it.

Description of Page

Enter an easily recognizable **Test Component Type** and **Description**.

Turn on **Meter Test** if this type of component test is associated with a meter. If this type of component test is associated with an item, this switch should be off.

If **Meter Test** is on, turn on **Register Required** if a register must be referenced on component tests of this type. You would require a register if a) you keep component tests for individual registers, or b) if your component tests require the entry of register readings (as defined in the following grid).

The grid that follows defines the type of test results that are recorded.

Result Seq Result sequence controls the order in which the test results are captured.

Description Enter the prompt that is displayed for this type of test result.

Result Required Turn this switch on if a result must be specified on a test component of this type.

Validation Algorithm The validation algorithm controls how the test result is validated. Leave this field blank if no validation should be imposed.

Prompt For Read Turn on this switch if a user can enter a register read for this type of test result.

Setting Up Device Test Types

Every device test references a device test type. The device test type controls business rules associated its device tests. The topics in this section describe how to set up your device test types.

- Device Test Type - Main
- Device Test Type - Component Types
- Device Test Type - Characteristics

Device Test Type - Main

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Device**, and then **Device Test Type**, and then **Add** to define general business rules shared by device tests of a given type.

> **Note**
>
> **When a new device test type is added.** After defining your device test types, you must update your meter and item types to define their valid test types. This is what prevents a gas test from being performed on an electric meter.

Description of Page

Enter an easily recognizable **Test Type** and **Description**.

Turn on **Meter Test** if this type of test is associated with a meter. If this type of test is associated with an item, this switch should be off.

Turn on **Validation Required** if tests of this type use a **Validation Algorithm** to determine if the test results (and therefore the device test) are of a passing grade. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with a device test validation algorithm.

Define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics common to all tests of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Device Test Type Characteristics table. Note that you can also define characteristic types for which values are required to be entered when the device test is created (see Device Test Type - Characteristics).

> **Note**
>
> You can only choose characteristic types defined as permissible on a device test type record.

Device Test Type - Component Types

Open **Admin**, and then **Device**, and then **Device Test Type**, and then **Search** and navigate to the **Component Types** page to define the types of component tests (if any) that can be performed for device tests of a given type.

Description of Page

Use **Sequence** to define the relative order of each **Test Component Type** that can be performed during device tests of a given type.

Device Test Type - Characteristics

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Device**, and then **Device Test Type**, and then **Search** and navigate to the **Characteristics** page to define required and optional characteristics for device tests of a given type.

Description of Page

Define **Characteristic Types** to describe characteristics that might be entered for all tests of this type. Turn on **Required** if this type of characteristics must be specified on tests of this type, otherwise, the characteristic will be optional. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

> **Note**
>
> You can only choose characteristic types defined as permissible on a device test type record.

Defining Usage Options

This section describes concepts and common tasks related to usage administration.

- The Big Picture of Usage Requests
- The Big Picture of Time of Use Mapping and Pricing
- Designing Your Time of Use (TOU) Mapping and Pricing Options

The Big Picture of Usage Requests

Oracle Utilities Meter Data Management is used by some organizations who use a meter data management (mdm) system to record meter reading information. Since meter reads are not available in Oracle Utilities Customer Care and Billing to calculate consumption during the billing process, usage (or bill determinants) must be requested by Oracle Utilities Customer Care and Billing from the mdm system, Oracle Utilities Meter Data Management.

The following sections describe how the base-package usage request process works.

- Requesting Bill Determinants
- Usage Request Lifecycle
- Summary Billed Accounts and Usage Requests
- Corrected Read Notifications
- Configuring The System For Usage Request Integration
- Designing Your SA Types For Usage Requests
- Start and End Times for Billing
- Navigating To MDM

Copyright © 2026, Oracle and/or its affiliates.

Requesting Bill Determinants

The term bill determinant request is another way to refer to a usage request. These usage requests are created during the batch billing process, and also when a user generates an online bill segment or performs cancel / rebill. The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request.

- Batch Billing Usage Requests
- Online Billing Usage Requests
- Multi Cancel/Rebill — Usage Requests

Batch Billing Usage Requests

Batch billing usage requests are created and held in the initial pending state. A separate batch process is responsible for transitioning these requests and sending them to the MDM system. Here's how this works:

- The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request. These batch billing usage requests are held in the Pending state until the batch Usage Scheduled Monitor Process is executed
- Similarly, once a response is received from MDM, the usage request will not transition to the Bill Determinants Processed state until the batch Usage Scheduled Monitor Process is executed
- In addition to the standard MDM usage request elements, the system captures the bill cycle and window start date.

Online Billing Usage Requests

- Usage requests created from an online billing request are not held in the initial state. These usage requests are transitioned through their lifecycle resulting in the request being sent to the meter data management system (mdm) and, once a response is received, the bill segment is regenerated.
- The bill segment remains in the Freezable state until the user freezes the bill segment and completes the bill. If the freezable bill segment is regenerated, however, the system cancels the usage request and creates another usage request for the bill segment.
- In addition to the standard mdm usage request elements, the system captures the responsible user id.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **External Reference ID.** When creating a usage request, the external reference id is populated based on the version of MDM that your implementation integrates with. This is defined as the MDM Version MO option on the Usage maintenance object. If integrating with MDM 1, the system populates the external reference id using the batch run thread scheduler id to facilitate processing in the external system. Otherwise, the external reference id is left blank and may be updated on the response from the external system.

Multi Cancel/Rebill — Usage Requests

When online multi-cancel/rebill involves bill segments for service agreements that require bill determinants from Oracle Utilities Meter Data Management, an off cycle bill generator (OCBG) is created to perform the cancel/rebill.

The OCBG is created using the business object that is defined as OCBG Multi-Cancel/Rebill option on the Off Cycle Bill Generator maintenance object. It orchestrates the creation of usage requests for the specific bill segments being rebilled. Each bill segment needs to be successfully rebilled before the next bill segment can be rebilled. If a bill segment's usage request sits in waiting status, the following will occur:

- The original bill segment sits in Pending Cancel state.
- The new (rebill) bill segment is linked to both the usage request that is in the Awaiting Bill Determinants state and the Multi Cancel/Rebill OCBG in Processing Request state.
- Subsequent bill segments that were selected for rebilling stay in the Frozen state until the previous bill segment is successfully rebilled. Each will be linked to its own Multi Cancel/Rebill OCBG in Pending state.

The user will need to refresh the Multi Cancel/Rebill page, to see if any of the bill segments have progressed in rebilling.

If cancel/rebill of a bill segment results in an error, the system discards any non-final OCBGs for that service agreement.

Refer to the **C1-MultiCancelRebill** business object for more details on the OCBG processing.

Usage Request Lifecycle

The usage request business object (BO) contains the rules that govern the processing of a usage request. The base product provides the BO C1-UsageRequest which serves as a parent BO and contains the following lifecycle:

- All usage requests are created in the initial Pending state. If the usage request was created from the batch billing process, the batch Usage Scheduled Monitor Process must be executed to transition the usage request.
- If there are pending sync requests for the usage request's service agreement, the usage request is held in the Awaiting Data Sync state until the sync is processed.
- Once all pending sync requests related to the usage request have been processed, the usage request transitions to the Send Request state. An enter algorithm on this transitory

Copyright © 2026, Oracle and/or its affiliates.

state is responsible for sending the usage request to Oracle Utilities Meter Data Management (MDM). The base algorithm creates a JMS Queue outbound message. This outbound message is configured to not persist on the database.

- Once the outbound message has been successfully sent, the usage request sits in the Awaiting Bill Determinants state until a response is received from MDM, or a time out is encountered.
- When a response is received from the external system, the usage request is transitioned to either the Bill Determinants Received state, or the Error state. In the case of an error, the following occurs:
  - If the usage request was created from the batch billing process and the billing window is still open, a new usage request will be created the next time billing runs and the process is repeated. If however, the billing window is no longer open, a to do entry is created for manual follow up.
  - If the usage request was created from an online billing process, the user will be notified. The bill segment remains in the error state and the user can either delete the bill segment, or attempt to generate it again. If the bill segment is regenerated, a new usage request is created and the process is repeated.
  - The system transitions usage requests in the Bill Determinants Received state to the Bill Determinants Processed state. An enter algorithm on this final state is responsible for generating the bill segment. If the usage request was created from the batch billing process, the bill segment is frozen and the bill is completed. For online billing usage requests, the user is responsible for freezing the bill segment and completing the bill.

Summary Billed Accounts and Usage Requests

A "summary" account refers to an account with service agreements that cover more than one premise. If these premises are linked to service points that span different service cycle routes scheduled for reading on different dates, there's no guarantee that all the account's SAs will be billed at the same time. This is because batch billing for manually read meters is based on the meter's scheduled reading date.

For example, assume a summary account has two SAs each linked to a different premise. One is on route X, scheduled for reading every first of the month and the other is on route Y, scheduled for reading every 20th of the month. Assume that the account’s bill cycle is cycle X (which matches the schedule of premise/SP on route X). When billing runs on the first of the month, the service agreements tied to route Y won’t have any reads. And because route Y is not scheduled for reading, the system will not estimate the consumption. Instead, it will skip billing the route Y SAs until the next month. This means some SAs are always one billing cycle behind.

If your implementation maintains meters and meter reads in CCB, then the base get consumption algorithm called ***Get Consumption From SP's Linked To SA*** handles the skipping of a summary billed account's service agreements based on bill cycle and service cycle schedules. The remainder of this section describes how this works in a CCB-MDM integrated environment.

- Requesting Bill Determinants for Summary Billed Accounts

Requesting Bill Determinants for Summary Billed Accounts

Usage requests for summary billed accounts are handled as follows:

- On the first night of the billing window usage requests are created for each SA and sent to Oracle Utilities Meter Data Management (MDM). MDM then checks what the next schedule read date is for each service point.

Copyright © 2026, Oracle and/or its affiliates.

- Assuming Oracle Utilities Meter Data Management owns meter read schedules; when batch billing executes Oracle Utilities Customer Care and Billing (CCB) cannot determine whether a summary account's service agreement should be included on the bill or not.
- If MDM determines that an SA/usage subscription should be skipped from billing, it notifies CCB by including a skip indicator and reason on the usage response, as well as the SA's next scheduled read date. This date is captured as a ***MDM Next Scheduled Read Date*** characteristic on the SA, and the usage request is cancelled. The system still attempts to complete the bill since this might be the last outstanding usage request for the bill
- When billing next runs, the base ***Get bill segment consumption using a usage request*** algorithm first checks if the SA should be skipped as follows (Note that this check is also performed in first billing run):
- Get the ***MDM Next Scheduled Read Date*** characteristic on the SA. If this date is after the bill segment end date, we'll skip the SA from billing

If your implementation would like to wait until the bill cycle window end date before attempting to complete summary account's bills, ensure that the ***Complete Summary Bill at End of Bill Cycle*** pre-bill completion algorithm is defined on customer class. This is useful if scheduled reads are expected in the bill cycle window, but not necessarily on the window start date.

Corrected Read Notifications

If a read that was used for bill determinant calculations is modified in the mdm system, notification is sent to Oracle Utilities Meter Data Management.. Resulting in the creation of an off cycle bill generator. The system uses the business object defined as the OCBG Corrected Read BO MO option on the Off Cycle Bill Generator maintenance object to create the OCBG. If any errors are encountered while attempting to create the OCBG, the system sends a message to the external system using the Outbound Message Type and External System defined as BO options on the OCBG Corrected Read BO

What happens next depends on the lifecycle that your implementation has configured for the OCBG Corrected Read BO. Here are examples of what might occur:

- Create a To Do entry for manual follow up.
- Find any frozen bill segments that might be affected by the corrected read and perform cancel/rebill.

Configuring The System For Usage Request Integration

Oracle Utilities Customer Care and Billing sends usage requests to Oracle Utilities Meter Data Management (MDM) in the form of an xml message. These messages are transformed by the integration layer and then sent to MDM. Similarly, MDM sends responses to the integration layer so that the data can be transformed and sent to Oracle Utilities Customer Care and BillingMDM sends responses back to Oracle Utilities Customer Care and Billing.

The following sections describe at a high level the data setup required to send usage requests to an mdm system.

- Define the Outbound Message Type
- Define the Message Sender
- Define the External System and Configure the Messages

Copyright © 2026, Oracle and/or its affiliates.

Define the Outbound Message Type

An outbound message type is required for the batch billing usage request outbound message. This outbound message type must reference the base C1-CyclicalUsgReqOutMsg business object. The outbound message type must also be specified as a BO option on the base C1-CyclicalUsgReqOutMsg business object so the system knows which outbound message type to use when sending usage requests to MDM.

An outbound message type is required for the online billing usage request outbound message. This outbound message type must reference the base C1-NonCyclicalUsgReqOutMsg business object. The outbound message type must also be specified as a BO option on the base C1-NonCyclicalUsgReqOutMsg business object so the system knows which outbound message type to use when sending usage requests to MDM.

> **Note**
>
> **Defining the Usage Business Objects.** The business objects used by the get consumption algorithm when creating a batch or online billing usage request are defined as MO options on the Usage maintenance object.

Define the Message Sender

A Message Sender is required to define how to send usage requests to MDM. Use the context of the Message Sender to define the web service interface.

Define the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each. You will also need to select the appropriate XSLs to format the request for usage. The external system must also be specified as a BO option on the base C1-CyclicalUsgReqOutMsg and C1-NonCyclicalUsgReqOutMsg business objects so the system knows which external system to use when sending usage requests to Oracle Utilities Meter Data Management.

> **NOT_SUPPORTED**
>
> Refer to the *Oracle Utilities Customer Care and Billing - Meter Data Management Integration Implementation Guide* for more information.

Designing Your SA Types For Usage Requests

SA Types used to bill service agreements that require bill determinants from a meter data management system must have the following characteristics:

Copyright © 2026, Oracle and/or its affiliates.

- The SA Type must have a special role flag of Bill Determinants Required
- Bill segment type:
  - Reference the bill segment creation algorithm that creates a bill segment from a usage request.
  - Reference the bill segment get consumption algorithm that gets bill segment consumption using a usage request.

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to Ways To Control The Start Date Of A Bill Segment and Ways To Control The End Date Of A Bill Segment for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing uses the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

When integrating with a meter data management system, Oracle Utilities Customer Care and Billing lacks knowledge of the type of meter installed at a service point. Thus, both interval processing period as well as scalar processing information is captured on a usage request. Oracle Utilities Meter Data Management (MDM) then uses the appropriate period to calculate bill determinants based on the type of meter installed.

MDM returns the true usage period used to calculate bill determinants on the usage response. This usage period is captured on the bill segment.

NOT_SUPPORTED

Refer to Start and End Times for Billing for more information.

Navigating To MDM

It might be necessary for Oracle Utilities Customer Care and Billing users to navigate to MDM to view detailed read information for a service point. For example, a user may want to see the unbilled consumption that's available in MDM. The following is required to implement this:

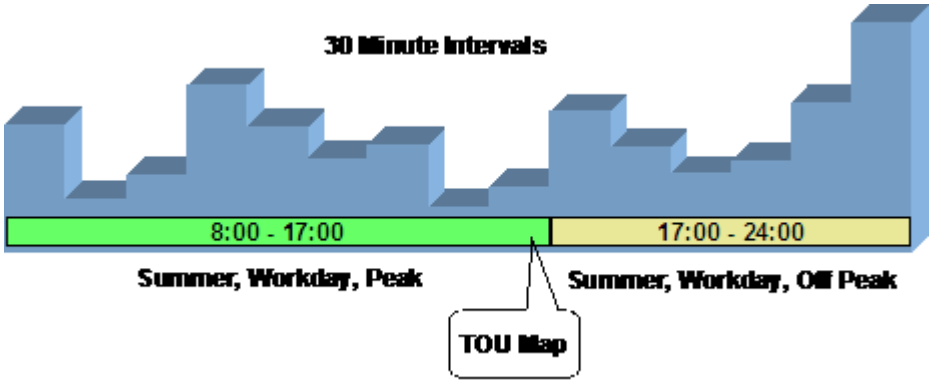
- Add a menu entry to the service point context menu. This menu item must reference the base Go To MDM From SP navigation option
- Add a menu entry to the service agreement context menu. This menu item must reference the base Go To MDM From SA navigation option
- Set up the MDM URL option type on the General System Configuration Feature Configuration. The MDM URL option must contain the URL for the MDM application.

Once configured, users should be able to launch the MDM system from these context menus with either a service point or service agreement id in context.

Copyright © 2026, Oracle and/or its affiliates.

The Big Picture of Time of Use Mapping and Pricing

This section provides an overview of the concepts related to setting up your control tables to support time of use mapping and pricing with the rates.



> **Note**
>
> Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.

- Mapping to Time of Use (TOU) Periods
- Grouping of TOU Codes for TOU Mapping
- Time of Use (TOU) Mapping and Pricing
- Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

Mapping to Time of Use (TOU) Periods

Many customers choose not to price their interval data using interval prices. Customers may choose for their interval data to be mapped into time of use (TOU) periods. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times). The TOU Map has a TOU Map Type, which defines the interval size between TOU map data rows.

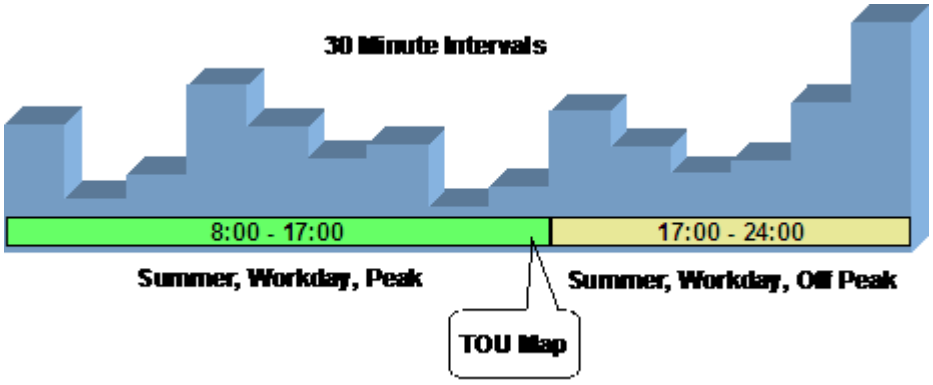
Time of use periods can (and often do) change during the year.

Copyright © 2026, Oracle and/or its affiliates.

Map #123 (TOU Group 2)	
Effective 1 Jan 2000	
Interval Date/Time	
30/Apr/00 16:30	On Peak/Winter
30/Apr/00 16:45	On Peak/Winter
30/Apr/00 17:00	Off Peak/Winter
30/Apr/00 17:15	Off Peak/Winter

01/May/00 7:45	Off Peak/Summer
02/May/00 8:00	On Peak/Summer
02/May/00 8:15	On Peak/Summer

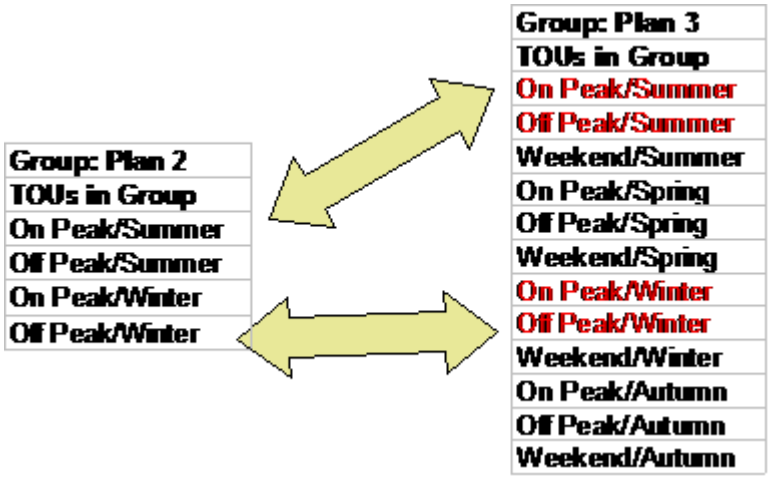
All the possible TOU codes for a given map are grouped together in a TOU group. Refer to Grouping of TOU Codes for TOU Mapping for more information.



Grouping of TOU Codes for TOU Mapping

This section describes the relationship between TOU Codes and TOU Mapping.

- Overview of TOU Codes and TOU Mapping
- TOU Sequence for TOU Mapping and Pricing

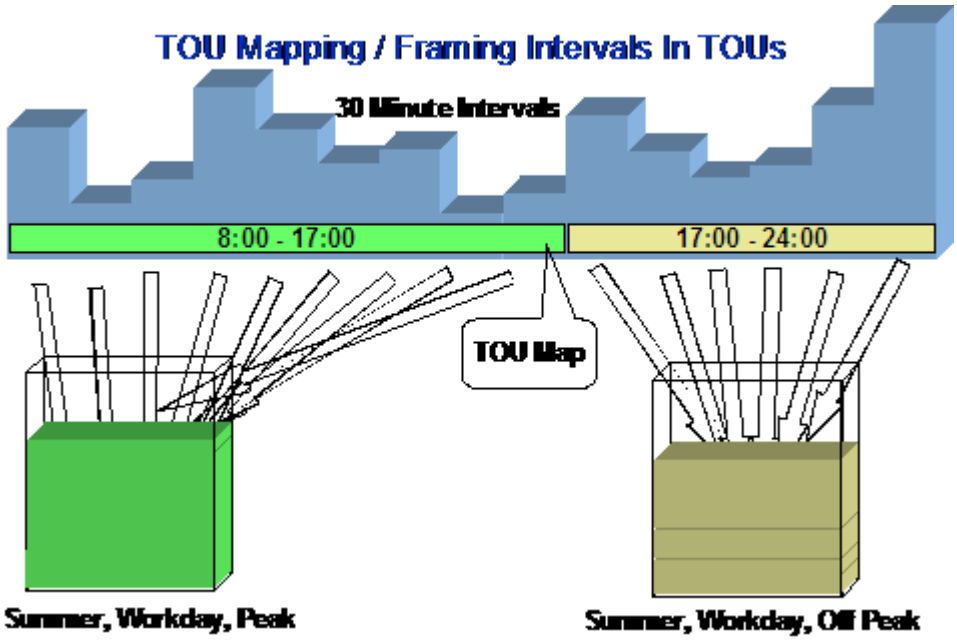


Overview of TOU Codes and TOU Mapping

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times).

Time of use codes or TOU codes (for example, "Off Peak/Winter", "Off Peak/Summer") are user-defined. Refer to Setting Up Time-Of-Use Codes for more information.

Copyright © 2026, Oracle and/or its affiliates.



TOU Sequence for TOU Mapping and Pricing

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Time of Use (TOU) Mapping and Pricing

The following section describes the logic used by the system to map an interval data curve to TOU periods using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take an interval data curve and will map the interval values to TOU periods based on a TOU Map. The interval data curve is retrieved from either a specific usage request or from the new rate engine buffer populated prior to calling the rate engine.

Copyright © 2026, Oracle and/or its affiliates.

This type of data manipulation is typically handled using a calculation rule based on the 'math' calculation rule type.

Once the interval data curve values have been mapped to TOU periods, prices can be applied to the time of use period quantities using calculation rules based on the 'service quantity' calculation rule type.

- Calculation Rules for TOU Mapping & Pricing
- TOU Map Used For Mapping

Calculation Rules for TOU Mapping & Pricing

Calculation Rules are used to perform time of use mapping and time of use pricing.

Time of Use Mapping

Time of use mapping will be typically handled using a calculation rule based on the 'math' calculation rule type. Calculation rules of this type can perform many functions. Two examples include:

- Applying a TOU map to an interval data curve to produce service quantities that will be added to the bill segment's SQ collection.
- Applying a TOU map to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the resultant curve.

For further details on the 'math' calculation rule type, refer to Base Package Math Calculation Rule for more information.

Time of Use Pricing

Time of use pricing will be typically handled using calculation rules based on the 'service quantity' calculation rule type. Calculation rules of this type can perform many functions. For example:

- Add or update a service quantity in the bill segments SQ collection
- Create bill calculations lines that levy charges based on some type of consumption. For example, applying a price to a specific service quantity in the bill segment's SQ collection

For further details on the 'service quantity' calculation rule type, refer to Base Package Service Quantity Calculation Rule for further information.

> **Note**
>
> Calculation rules are implemented using algorithms that contain the logic to be performed. If your implementation requires a new type of calculation rule, you can configure a new calculation rule type and reference the appropriate algorithm on it.

TOU Map Used For Mapping

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule.

Copyright © 2026, Oracle and/or its affiliates.

Attributes of TOU Maps

TOU map types define attributes shared by TOU maps of a given type. The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting.

Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

This section provides an overview of setting up your control tables to support time of use mapping and pricing with rates.

- TOU Codes
- TOU Groups
- Creating TOU Map Templates
- Creating TOU Map Types

TOU Codes

Refer to Setting Up Time of Use Codes for further information

TOU Groups

Refer to Setting Up TOU Groups for further information

Creating TOU Map Templates

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates and used for TOU map data generation.

Prerequisites: You must define TOU groups and work calendars before you can create TOU map templates. Refer to the Oracle Utilities Application Framework online help for more information about creating work calendars.

To maintain existing TOU map templates, select **Admin**, and then **Consumption**, and then **TOU Map Template**, and then **Search** then use standard actions to edit, duplicate, or delete a TOU map template.

To define a new TOU map template, follow these steps:

1. Select **Admin**, and then **Consumption**, and then **TOU Map Template**, and then **Add.** If your system supports more than one TOU map template business object, you will be prompted to select a business object for this TOU map template.
2. Enter a name and a meaningful description for the TOU map template.
3. Select the TOU group to be used by the TOU map template.
4. Select the default TOU for the TOU map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
5. Select the work calendar for the TOU map template. Work calendars define the days of the week on which work is performed, and specify holidays.

Copyright © 2026, Oracle and/or its affiliates.

6. Select the holiday TOU for the TOU map template (from the TOU Group).
7. Select the TOU map template used for holidays (if applicable).
8. Specify the interval size for TOU map data created from the map template. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
9. To specify TOU schedule's date ranges and which TOUs should be used for this TOU map template, click the + or - sign in the TOU Schedule Section and enter or select the following:
    - Start and End Dates for a specific date range
    - Start and End Days of the Week: To add or remove Start and End Days of the Week pairs, click the + or - sign and select the appropriate weekdays
    - Start and End Times: To add or remove Start and End Times within a Start and End Days of the Week pair, click the + or - sign and enter the appropriate times
    - TOU
10. Click **Save.**

Now you can use the TOU map template when creating TOU types.

Creating TOU Map Types

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule. TOU map types define attributes shared by TOU maps of a given type.

Prerequisites: You must define TOU map templates and time zones before you can create TOU map types. Refer to the Oracle Utilities Application Framework online help for more information about creating time zones.

To maintain existing TOU map types, select **Admin**, and then **Consumption**, and then **TOU Map Type**, and then **Search** then use standard actions to edit, duplicate, or delete a TOU map type.

To define a new TOU map type, follow these steps:

1. Select **Admin**, and then **Consumption**, and then **TOU Map Type**, and then **Add**

> **Note**
>
> If your system supports more than one TOU map type business object, you will be prompted to elect a business object for this TOU map type.

2. Enter a name and a meaningful description for the TOU map type.
3. Select the business object to use when creating TOU maps of this type
4. Select the time zone for the TOU map type.
5. Specify the interval size for TOU map data created from the map type. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
6. Select the default TOU map template for the TOU map type
7. To add or remove override TOU map templates for this TOU type, click the + or - sign in the Override TOU Map Templates section and select the TOU map template.

Copyright © 2026, Oracle and/or its affiliates.

8. Click **Save**.

Now you can use the TOU map type when creating TOU maps.

Designing Your Time of Use (TOU) Mapping and Pricing Options

This section provides an overview for designing your control tables to support time of use (TOU) mapping and pricing with the new rating engine.

- Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules
- Designing Your TOU Codes for TOU Mapping
- Designing Your TOU Groups for TOU Mapping
- Designing Your TOU Map Types for TOU Mapping
- Designing Your TOU Map Templates for TOU Mapping

Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules

As you know from the rates chapter, the system can handle mapping of interval data curve values into different time of use periods and pricing these quantities using the 'math' and 'service quantity' calculation rule types respectively. Refer to Base Package Calculation Rule Descriptions for more information.

The following guidelines provides a high level outline on how you should go about designing a rate schedule that involves time of use mapping and pricing.

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up exactly how the information should appear on the customers' printed bills.
- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. Which time of use map is used to define the time periods?
- In order to perform time of use mapping and pricing, calculation rules need to be designed
  - A calculation rule based on the 'math' calculation rule type may be used to map an interval data curve into time of use periods. This calculation rule must know the TOU map to apply to the interval data curve to map into the relevant time of use periods. The time of use period quantities are populated in the bill segments SQ collection.
  - Calculation rules based on the 'service quantity' calculation rule type may be used to apply prices to each mapped time of use period quantity. These calculation rules each require either a price or regular bill factor for pricing each time of use period quantity. The bill factor may contain the price directly, or may indicate that the price is customer specific and can be found as contract quantities for the service agreement.

Once you have your calculation rules designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Designing Your TOU Codes for TOU Mapping

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. It should be noted that it's possible that will not bill for every time of use period.

Copyright © 2026, Oracle and/or its affiliates.

For more information about time of use, refer to UOM versus TOU versus SQI.

Designing Your TOU Groups for TOU Mapping

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are available to be used in a single map. You must also decide if you want to use a sequence number to define the relative order of a TOU code within a TOU group.

When TOU data is created for a TOU map, only TOU periods defined on a specified TOU group can be specified.

Designing Your TOU Map Types for TOU Mapping

Now that you have your TOU groups defined, you can begin defining TOU map types. Recall that the TOU map type defines the attributes that may be shared by TOU maps of the same type.

The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting. Refer to Designing Your Time Options for more information.

TOU Map Type Interval Size

The interval size of a TOU map must divide evenly into the interval size of the interval data curve that uses the map (because the system joins the date/time of the interval data curve values to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute interval data curve. However, it is not OK to have a 60 minute TOU map used with a 15 minute interval data curve because the join will miss 3 out of 4 interval data curve values.

TOU Map Type Override Template

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support override templates. Refer to Designing Your TOU Map Templates for TOU Mapping for more information.

- A TOU map's TOU map type defines the default TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the default template.
- An individual TOU map can have override templates. If the TOU map doesn't have an override template, the default template defined on the TOU map type is used to generate the map's TOU data.

Refer to Creating TOU Map Types for further information.

Designing Your TOU Map Templates for TOU Mapping

In order to help your users to create and maintain data for TOU maps, you may define TOU map templates, which can be used to generate data for a TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates.

Copyright © 2026, Oracle and/or its affiliates.

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period. The system periodically generates TOU map data for TOU maps by interpreting the rules defined in the template.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays by specifying the following:

- A Work Calendar that defines when holidays start and end
- Either:
  - A Holiday TOU period for consumption on holiday
  - A Holiday TOU Map Template that defines the TOU codes to use for different times in the year

TOU Map Template Interval Size

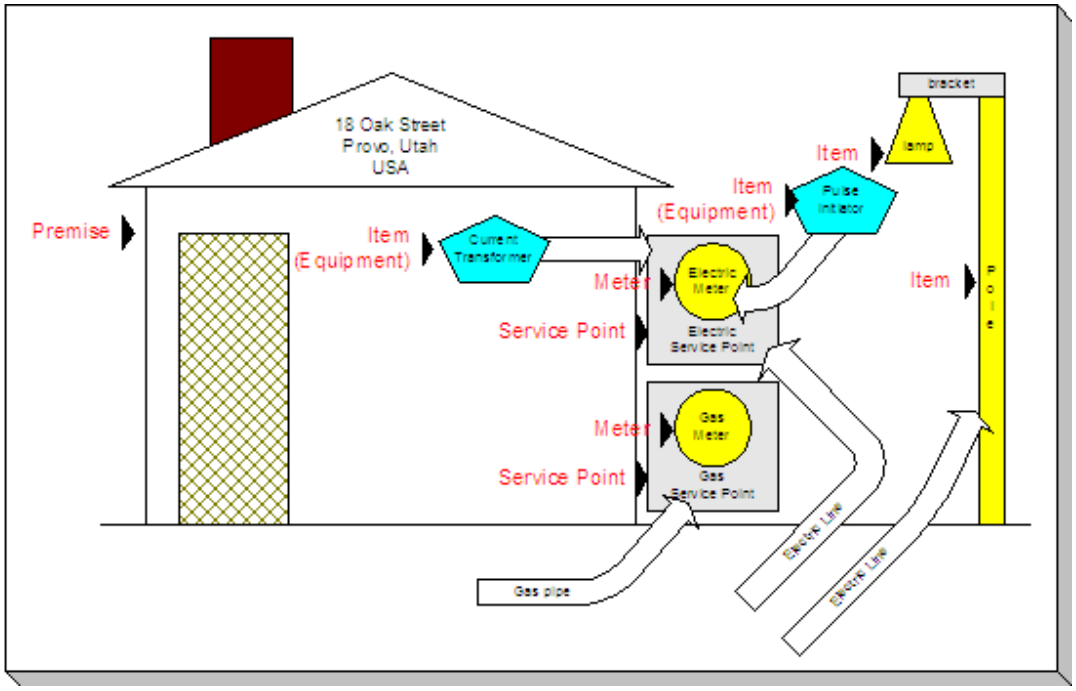
TOU map templates can also specify an interval size. This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose interval size is divisible by the template's interval size. For example, a 60 minute template can be used to generate TOU data for TOU maps with an interval size of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every interval size.

Refer to Creating TOU Map Templates for further information.

Defining Premise and Service Point Options

A premise is where a customer consumes the services supplied by your company. Located at a premise are the various devices that consume energy and measure consumption. Before you can define premises and devices, you must set up the control tables defined in this section.



Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> The topics in this section do not describe every table that must exist in order to set up premises and service points. Many premise and service point control tables are described in Defining Meter and Item Options , and Defining Field Order Options. The tables described in this section are those that must be set up regardless of the type of service.

- An Illustration Of A Premise
- Setting Up Premise Options
- Setting Up Generic Service Point Options
- Setting Up Premise & Service Point Postal Defaults
- Designing SP Types

An Illustration Of A Premise

The following picture illustrates a premise with 2 service points, 2 meters, and 2 badged items:

The following concepts are illustrated above:

Premise A premise describes a location at which your company supplies some type of service. In addition to the obvious address information, a premise also contains geographic coordinates, meter read instructions, and taxation jurisdiction information.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about the control tables that must be set up before you can define a premise see Setting Up Premise Options.

Service Point A service point (SP) is a geographic location at which service(s) are delivered to a premise. The SP record maintains information about the type of service, the service cycle (if the service is metered), the field office responsible for maintaining the service, the distribution company that supplies the service, etc.

There are three major categories of service points:

- Those where the rate of consumption and the total amount of consumption is measured (e.g., electricity, gas, water) by a meter. You can think of this type of service point as a "socket" into which a meter can be plugged. Over time, many meters may be plugged into the socket. We refer to these types of service points as metered.
- Those that hold badged items. A badged item is a physical device with a unique identity (e.g., a specific street light, a specific hydrant). You can think of this type of service point as a "socket" into which a badged item can be plugged. Over time, many items may be plugged into the socket. We refer to these types of service points as item-based.
- Those used to hold one or more non-badged items. For example, if your organization doesn't badge street lamps, you can use a single service point to hold an infinite number of lamps. We refer to these types of service points as non-badged.

NOT_SUPPORTED

Refer to Service Points (SPs) for more information about non-badged items.

An unlimited number of SPs may exist at a premise. However in reality, the number of SP's is related to the number of services supplied by your company. For example, an electric and gas company will typically have two SPs per premise.

NOT_SUPPORTED

For more information about the control tables that must be set up before you can define service points refer to Setting Up Generic Service Point Options, Defining Meter and Item Options .

Field activities may be dispatched to all types of service points.

Meter A meter is a physical device used to measure the amount of gas, water, or electricity used by a customer. While most meters measure consumption in a single unit of measure (e.g., gallons, cubic feet, kilowatt-hours), some electric meters are extremely sophisticated and measure several different factors. For example, some electric meters measure how much was used, when it was used, the efficiency of consumption, the maximum amount used, and a few other unusual things.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about the control tables that must be set up before you can define a meter, refer to Setting Up Meter Options , and Setting Up Consumption Estimation Parameters.

Item (Equipment) An item that is considered to be "equipment" is a physical device that regulates consumption; it does NOT measure consumption. You would only define equipment if it is of interest to your organization. For example, if your organization periodically tests the pulse initiators associated with your meters, you will need to set up items for each pulse initiator and link them to their respective meters. Equipment can be linked to either a service point (e.g., a current transformer, a backflow device), a meter (e.g., a pulse initiator), or an item (e.g., the components of an installation).

Note

Equipment and billing. Be aware that the only way equipment can impact billing would be if you developed pre-processing calculation groups that analyzed the equipment associated with a service point (directly or indirectly via the meters and items) and manipulated billed consumption accordingly. Refer to Understanding Calculation Groups and Rules for more information.

Item (NOT Equipment) An item is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. Items are related to service points and a service point can have one or more items linked to it.

NOT_SUPPORTED

For more information about the control tables that must be set up before you can define an item, refer toSetting Up Items .

For more information about premises and service points, refer to Understanding The "V".

Setting Up Premise Options

This section describes tables that must be set up before you can define premises.

- Defining Premise Types
- Implementing Address Validation

Defining Premise Types

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Geographic**, and then **Premise Type** to define the premise types used to categorize your premises.

Description of Page

Enter a unique **Premise Type** and a **Description** for every premise type.

Allow CIS Division controls whether premises of this type can use the CIS Division on the premise page. Valid values are Not Allowed, Optional, and Required.

If your implementation requires restricting data by CIS Division, it is recommended that Allow CIS Division be set to Required.

Implementing Address Validation

In order to set up address validation, you must ensure that the following Option Types are defined with their corresponding values on the General System Configuration – Feature Configuration page:

Option Type	Description
Address Validation Script	Indicates the name of the BPA script to invoke when a user clicks on the validate address button. This option is required if the Allow Address Validation option is set to Y. The base product includes sample script C1-ValAddr that uses Oracle Spatial procedures and functions to geocode an address and return its matching quality code.
Allow Address Validation	Indicates whether an integration with address validation software is implemented. If set to Y, the system will render a validate button along with the address fields displayed throughout the application to trigger address validation. Valid values are 'Y' and 'N'. If set to Y, the Address Validation Script to invoke must be specified.

As described in the above table, the base product includes sample script C1-ValAddr uses Oracle Spatial procedures and functions to geocode an address and return a matching quality code. To use this script, ensure that the Oracle Spatial Geocoding (F1-ORAGEOCD) algorithm is plugged in on installation options for the geocoding service system event. A data source containing the geocoding data must also exist on the database.

If your implementation uses something other than Oracle Spatial for address validation, you'll need to create a new address validation BPA script to specify on the General System Configuration feature configuration. For additional information about creating this script, see the steps descriptions for the C1-ValAddr script in the application. The new script should contain the following move step to update the page:

- If the calling page is an old style page, the move from the BPA to the page can be achieved by specifying a move step from a source field to a User Interface Field.
- If the calling page is a display map, the move from the BPA to the page can be achieved by specifying a step to read the Business Object, modify the values as returned by the validation software, and then update the BO.

Setting Up Generic Service Point Options

Copyright © 2026, Oracle and/or its affiliates.

This section describes tables that must be set up before you can define service points.

- Facility Levels
- Setting Up Service Point Types

Facility Levels

Every type of service tends to use a different mapping philosophy to designate the facility hierarchy that supplies service to the service point. For example, electric service typically uses a substation / feeder / node facility hierarchy to define how electricity is supplied to a service point (the substation is the highest level in the hierarchy, the feeder comes next, and finally the node). Whereas gas service uses a city gate / main / feeder hierarchy.

If your organization maintains this type of information on service points, you will set up your facilities and their interrelationships using 3 windows. On the first you set up the number and type of facility levels used for every service and you define the valid values for each facility level (you define these when you define your Service Types). On the second and third you define the values that may coexist in each level. After these set up tasks are complete, you're ready to enter facility levels on your service points.

> **Note**
>
> A service point's facility levels are used to help pinpoint problems and dispatch service crews during outages.

- Setting Up Facility Levels 1 & 2 Combinations
- Setting Up Facility Levels 2 & 3 Combinations

Setting Up Facility Levels 1 & 2 Combinations

To define which values of facility level 2 may be used with a given value of facility level 1, open **Admin**, and then **Geographic**, and then **Facility Level 1 to 2.**

Description of Page

Choose a **Service Type** and **Facility Level**, then use the **Facility Level 2** collection to define the level 2 facility levels that may coexist with the selected level 1 facility level.

Setting Up Facility Levels 2 & 3 Combinations

To define which values of facility level 3 may be used with a given value of facility level 2, open **Admin**, and then **Geographic**, and then **Facility Level 2 to 3.**

Description of Page

Choose a **Service Type** and **Facility Level 2**, then use the **Facility Level 3** collection to define the level 3 facility levels that may coexist with the selected level 2 facility level.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Service Point Types

Every service point must reference a service point (SP) type. The SP type controls almost all aspects of the service point's behavior (e.g., the type of field activity that may be dispatched to it, the type of service agreement that may be linked to it, the type of meter that may be installed at it).

The topics in this section describe the windows used to set up your SP types.

> **Warning**
>
> Setting up SP types requires careful analysis of your company's SA types, field activities, and its consumption estimation philosophy. Refer to Designing SP Types for more information about this design process.

- SP Type - Main
- SP Type - Meter Type
- SP Type - SA Type
- SP Type - Item Type
- SP Type - SP Characteristic
- SP Type - Equipment Type
- SP Type - FA Type Review

SP Type - Main

You begin to define a service point type by selecting **Admin**, and then **Geographic**, and then **SP Type**, and then **Add.**

> **Warning**
>
> You may find that your desire to use some of the more sophisticated control functions in the system will necessitate many SP types. For example, notice that one of the other windows on this group allows you to define the meter types that can be installed in service points of a given type. If you have many different types of meters and many restrictions as to the types of service points in which they can be installed, you will end up with many SP types.

Description of Page

Enter an easily recognizable **SP Type** for the service point type. This value will appear on many windows throughout your system as a "shorthand" for how the SP is used, so think carefully about the format. We recommend using a consistent format for all of your SP types. You should include the service type, an indication if it's metered or item-based, and the trend

Copyright © 2026, Oracle and/or its affiliates.

classification. For example, you might enter "E-M-RES", for an electric, metered, residential SP type.

Select the **Service Type**. Refer to Setting Up Service Types for more information.

Enter a **Description**.

Select the **Sub Type** to indicate the type of device that may be installed at service points of this type: Meter, Item, Unbadged.

Turn on the **Allow Service Route** switch if service points of this type should have a route. This switch would typically be turned on for metered service points.

Multiple Route Usage controls whether a service point can reference multiple service routes. Select Allowed if multiple service routes are allowed on service points of this type. Select Not Allowed if multiple service routes are not allowed on service points of this type. This switch would typically be turned on for garbage service points.

If this SP type is for metered service, select the **Trend Class** to define how to categorize this SP type's consumption for estimation and high / low validation purposes. This field will be gray for item-based services because items don't have meter reads that can be estimated or that are subject to high / low validation. Refer to Setting Up Trend Classes for more information.

If this SP type is for fieldwork that is managed by an external system, specify the external system in **Fieldwork Orchestration**.

If field activities are created for this SP type's service point, select the **Field Activity Type Profile** that controls which type of field activities may be linked to the service points. This Profile will also control which field activities are automatically generated by the system under various circumstances. Refer to Setting Up Field Activity Type Profiles for more information.

If a geographic type is used to identify individual service points of this SP type, select the **Identifying Geographic Type** used. You typically have an identifying geographic type if you refer to a service point using an identifier that is assigned by a third party. Refer to Defining Geographic Types for information on setting up geographic types.

Use the **SP Type Characteristic** collection and their respective **Characteristic Values** to describe characteristics common to all service points of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the SP Type Characteristics table.

> **Note**
>
> You can only choose characteristic types defined as permissible on an SP Type record. Refer to Setting Up Characteristic Types and Their Values for more information.

SP Type - Meter Type

Open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **Meter Types** page to define the types of meters that may be installed at service points belonging to this SP type.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

The **Meter Types** collection contains the types of meters that may be installed at service points belonging to this SP type. This collection is not relevant if the SP sub type is Item or Unbadged.

> **Note**
>
> You can connect meters with different service types to your SP Type. For example, a metering device such as a recorder can be used on both gas and electric service points.

SP Type - SA Type

Open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **SA Types** page to define the SA types that may be linked to (and therefore pay for) service points belonging to this SP type.

Description of Page

The following fields display:

CIS Division / SA Type Indicate the type of service agreement that may be linked to service points of this type.

Initial Turn on this switch if the Start Service process should default this SA type when service is initially started at a service point of this type. Multiple SA types may be marked as Initial if you want multiple service agreements created when service is initially started. For example, if you have both wastewater and water service agreements linked to the water service point.

SP Type - Item Type

Open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **Item Types** page to define the types of items that may be installed at service points belonging to this SP type.

Description of Page

The **Item Types** collection contains the types of items that may be installed at service points belonging to this SP type. This collection is not relevant if the SP sub type is Meter or Unbadged.

> **Note**
>
> You can connect items with different service types to your SP Type. For example, an item like a cell phone can be used on both gas and electric service points.

SP Type - SP Characteristic

Copyright © 2026, Oracle and/or its affiliates.

To define characteristics that may be defined for service points of a given type, open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **SP Characteristic** page.

Description of Page

- Use the **SP Characteristics** collection to define characteristics that can be defined for service points of a given type.
- Use **Sequence** to control the order in which characteristics are defaulted.
- Turn on the **Required** switch if the **Characteristic Type** must be defined on service points of a given type.
- When the **Default** switch is turned on, enter a **Characteristic Value** to use as the default for a given **Characteristic Type**

SP Type - Equipment Type

Open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to service points of a given type.

Open **Admin**, and then **Device Installation**, and then **SP Type**, and then **Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to service points of a given type.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to service points of this type.

> **Note**
>
> **Item types are being specified.** There is no equipment type control table. Rather, items are used to define equipment and, therefore, you define item types rather than equipment types. Refer to Equipment versus Badged Items for more information about equipment.

SP Type - FA Type Review

Open **Admin**, and then **Geographic**, and then **SP Type**, and then **Search** and navigate to the **FA Type Review** page to review the field activities that are allowed for the SP type.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Four dimensions.** For every **field activity type** that is eligible for dispatch, you define the **dispatch group** that performs the activity at every **SP type** located in every **operations area**. This information is maintained on the field service control page. This is a rather complex relationship because it involves the four dimensions highlighted in bold. Due to this complexity, we have provided review trees on the SP Type, Dispatch Group, and Field Activity Type windows to help you understand what you've set up.

Description of Page

This window is dedicated to a tree that shows the field activities allowed for this SP type. For each field activity type that is eligible for dispatch, you can view the dispatch group that will perform the activity at every operations area.

Setting Up Premise & Service Point Postal Defaults

You set up postal defaults if your company is able to default field values onto new premises and service points based on the premise's postal code. The topics in this section describe how to maintain postal defaults.

> **NOT_SUPPORTED**
>
> For more information about where these default values are used, refer to Maintaining Premises and Maintaining Service Points.

- Postal Defaults - Main
- Postal Defaults - Service Default

Postal Defaults - Main

To define premise postal defaults, open **Admin**, and then **Geographic**, and then **Postal Code Default**, and then **Add.**

Description of Page

Enter the **Country Code** and range of postal codes to which the default values apply using the **From Postal** and **To Postal**.

> **Note**
>
> You may not have postal defaults whose from / to postal codes overlap.

Select the **Trend Area** to be defaulted onto new premises located in this postal code range. The trend area is used to categorize premises into geographic areas when consumption

Copyright © 2026, Oracle and/or its affiliates.

estimation is controlled, in part, by where the customer lives. Refer to Setting Up Trend Areas for more information.

Enter the **County** to be defaulted onto new premises located in this postal code range.

Enter the **City** to be defaulted onto new premises located in this postal code range.

Enter the **CIS Division** to be defaulted onto new premises located in this postal code range.

Enter the **State** to be defaulted onto new premises located in this postal code range.

Enter the **Time Zone** to be defaulted onto new premises located in this postal code range.

Use the **Characteristic Types and Values** collection to define the **Characteristic Type**s and their respective **Characteristic Value**s to be defaulted on premises located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a premise.

> **NOT_SUPPORTED**
>
> For more information about characteristics, see Setting Up Characteristic Types & Their Values and An Illustration Of A Bill Factor And Its Characteristics .

Use the **Geographic Types and Values** collection to define the **Geographic Type**s and their respective **Value**s to be defaulted on premises located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

This information is defaulted when a new Premise is added. Characteristics and geographic values are also defaulted when the postal code for a Premise is changed. Refer to Maintaining Premises for more information.

Postal Defaults - Service Default

To define values to be defaulted for a service point located in a postal range, open **Admin**, and then **Geographic**, and then **Postal Code Default**, and then **Search** and navigate to the **Service Defaults** page.

> **NOT_SUPPORTED**
>
> For more information about where these default values are used, refer to Maintaining Service Points.

Description of Page

Use the **Service Defaults** collection to define values to be defaulted on service points located in a given postal code range belonging to a given **Service Type** (note, a service point's Service Type comes from its SP Type).

The following values may be defined per **Service Type**:

Copyright © 2026, Oracle and/or its affiliates.

- When a meter or item is removed from a service point located in this postal code range, the system assigns it by default to **Stock Location**. Note that this is only used if the meter's meter type or item's item type indicates that stock locations are tracked.

> **NOT_SUPPORTED**
>
> For more information about location history, refer to Stock Location History Is Created Behind The Scenes.

- Use the **Field Services** collection to define the **Field Service Classification**s and their respective **Operation Area** to be defaulted on new service points located in this postal range. Refer to Designing Field Service Classifications for more information.
- Use the **Characteristic Types and Values** collection to define the **Characteristic Type**s and their respective **Characteristic Value**s to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a service point.
- Use the **Geographic Types and Values** collection to define the **Geographic Type**s and their respective **Value**s to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

Information is defaulted when a new Service Point is added to a Premise. Refer to Service Point - Main Information for more information.

Stock Location is defaulted when a Meter or an Item is removed from a Service Point. For details see SP/Meter Installation and SP/Item Installation.

Designing SP Types

Every service point must reference an SP type. When you set up an SP type, you define how the system manages many aspects of its service points' behavior.

> **Note**
>
> **Perfect foresight.** In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SP types. In reality, setting up your SP types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing your SP types is an iterative process. To minimize the number of iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SP types.

SP Type	Service Type

Copyright © 2026, Oracle and/or its affiliates.

- Service Segmentation
- Device Segmentation
- Meter Read Estimation Trend Class Segmentation
- Field Activity Type Profile Segmentation
- SA Type Segmentation
- Meter Type Segmentation
- Item Type Segmentation

Service Segmentation

At a minimum, you will have one SP type for every different type of service that exists at your premises. If we assume that your organization sells gas, water, waste water and electricity services, you will need four SP types.

SP Type	Service Type
GAS	Gas service
WATER	Water service
WASTE WATER	Waste water service
ELECTRIC	Electric service

Device Segmentation

For each service, determine if there exist meters, badged items, or non-badged items at the service points. For example, if we assume:

- Electric service has service points with meters, badged lamps, and parking lots.
- Gas and water services just use meters.
- Waste water service doesn't actually have a meter installed at it (it uses the water consumption measured by the water service point's meter)

Then your SP types will be:

SP Type	Service Type	SP Sub Type
GAS - METERED	Gas service	Meter
WATER - METERED	Water service	Meter
WASTE WATER	Waste water service	Unbadged
ELECTRIC - METERED	Electric service	Meter
ELECTRIC - BADGED LAMP	Electric service	Item
ELECTRIC - PARKING LOT	Electric service	Unbadged

Meter Read Estimation Trend Class Segmentation

Copyright © 2026, Oracle and/or its affiliates.

When you set up a metered SP type, you must define the consumption estimation trend class in which its consumption will be categorized. This categorization matters when consumption differs based on the type of property AND you want the system to estimate consumption in different classes differently.

These categories could be the classic divisions of residential versus commercial versus industrial consumers. Alternatively, they could be finer-grained divisions: single family residence, versus duplex, versus triplex, versus medical office, versus grocery store.

> **NOT_SUPPORTED**
>
> Refer to The Theory Behind Consumption Estimation for more information about how trend class is used to estimate consumption.

If we assume you differentiate between residential and commercial service for all of your metered services, then your SP types will be:

SP Type	Service Type	SP Sub Type	Trend Class
GAS - METERED - RESID	Gas service	Meter	Residential
GAS - METERED - COMM	Gas service	Meter	Commercial
WATER - METERED - RESID	Water service	Meter	Residential
WATER - METERED - COMM	Water service	Meter	Commercial
WASTE WATER - RESID	Waste water service	Unbadged	N/A
WASTE WATER - COMM	Waste water service	Unbadged	N/A
ELECTRIC - METERED - RESID	Electric service	Meter	Residential
ELECTRIC - METERED - COMM	Electric service	Meter	Commercial
ELECTRIC - BADGED LAMP	Electric service	Item	N/A
ELECTRIC - PARKING LOT	Electric service	Unbadged	N/A

Notice that the non-metered service points don't use a trend class. This is because they don't have meters (and only meters have estimated consumption).

Field Activity Type Profile Segmentation

When you set up any type of service point that can have field activities, you must define the field activity type profile. This profile defines:

- The type of field activities that may be dispatched to the service points.

Copyright © 2026, Oracle and/or its affiliates.

- The type of field activity to be defaulted by the start/stop process given the condition of the service point.

Field activity type profiles should not impact your SP type design as these profiles should be designed after the SP types are designed.

NOT_SUPPORTED

Refer to Designing Your Field Activity Profiles & Types for more information about how field activity profiles are used.

SA Type Segmentation

Every SP Type whose service points can be linked to a service agreement has one or more SA types. These define which type of service agreements can pay for the service point's service. If different service points have different valid SA types, you will need to split the SP types accordingly.

The SA Type segmentation of SP Types is the most complicated design decision you'll have to make. Unfortunately, the decision making process is subjective and iterative. The iterations are caused by the fact that the number of SA types is dependent on the number of SP types (and vice versa). We recommend the following to help work your way through this conundrum:

- Design your SA types using the information in Defining Service Agreement Types.
- Return to your SP types and determine if, given the proposed SA types, you can define a list of valid SA types for each SP type. If you find the population of SA types (and their valid rates) could result in invalid rates paying for service at a service point, divide your SA types further.

Meter Type Segmentation

Every metered SP Type has one or more meter types. These define which type of meter can be installed at a service point of a given type. If different service points have different valid meter types, you will need to split the SP types accordingly.

For example, if you have 3-phase electric service points and you want to make sure that only 3-phase meters are installed in these service points, you will need to split the electric SP types accordingly.

NOT_SUPPORTED

Refer to Setting Up Meter Types for more information.

Item Type Segmentation

Copyright © 2026, Oracle and/or its affiliates.

All SP Types may have item types. These define which type of item can be installed at a service point of a given type. If different service points have different valid item types, you will need to split the SP types accordingly.

NOT_SUPPORTED

Refer to Setting Up Item Types for more information.

Defining Bill & Meter Read Cycles

This chapter is dedicated to issues related to defining cycles, routes and schedules in the system.

- Defining Bill and Service Cycles
- Defining Statement Cycles

Defining Bill and Service Cycles

Every account references a bill cycle. An account's bill cycle controls when it is billed.

Every metered service point references a service cycle. A service point's service cycle controls when a service point's meter is read.

The design of your meter read and bill cycles is inextricably linked because you probably want to bill your customers shortly after their meters are read.

In this section, we describe how to design and set up these cycles. In addition, we discuss how to set up bill period schedules. These are used to define the bill segment end date for special types of non-metered service agreements.

Note

Recommendation. We recommend reviewing Bill Frequency - Bill Cycle vs Bill Segment Duration before setting up this information.

Designing Cycles for Metered Services

The topics in this section provide background information about a variety of service cycle issues.

- A Description of the Cyclical Meter Read Process
- Designing Measurement Cycles, Routes, And Schedules

A Description of the Cyclical Meter Read Process

Manual meter readers using handheld devices record most meter reading measurements in the field. These meter reads are uploaded into the system for use by Oracle Utilities Meter Data Management.

A service point's installed meter device is measured due to the following data relationships:

- Every metered service point references a schedule route.
- A route references a measurement cycle.
- A measurement cycle has measurement cycle schedules that define when the service points in the cycle are measured.
- Every measurement cycle schedule contains two dates:
  - **Scheduled selection date.** This is the date Meter Data Management could use to select the service points in the cycle for download to your handheld software via custom algorithms to create handheld activities when pending measurement cycle schedules are proposed (refer to Measurement Cycle and Bill Determinants for more information).
  - **Expected work date.** This is the date the meter is expected to be read.

> **Note**
>
> **Overriding a route within a specific schedule.** Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to Designing Measurement Cycles, Routes, And Schedules for more information.

Copyright © 2026, Oracle and/or its affiliates.

- On the scheduled selection date, Meter Data Management could create a download file, via custom algorithms, containing information to be sent to your handheld software. This download file should contain information about every register or measuring component on every meter in the routes being downloaded.
- Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant measurements are uploaded into the system for subsequent use by other processes such as usage transactions for billing.

> **Warning**
>
> It is very important to create a measurement cycle schedule for every expected read date regardless of whether the cycle's routes are downloaded. Why do you have to do this? Because Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement during usage calculations. If it can't find a reading on or near this date, Oracle Utilities Meter Data Management may estimate consumption. Without a measurement cycle schedule, MDM wouldn't know when to look for readings. So, for example, if you estimate a given cycle's consumption EVERY OTHER MONTH, you must create a measurement cycle schedule for EVERY month. On each month's schedule, you must define if the routes should be downloaded.

> **NOT_SUPPORTED**
>
> For more information about the how to control when a cycle is read, refer to Setting Up Measurement Cycle Schedules.

Designing Measurement Cycles, Routes, And Schedules

The topics in this section provide information describing how to design your measurement cycles, routes, and schedules.

- Designing Measurement Cycles For Meter Reading
- Designing Schedule Routes For Meter Reading
- Designing Metered Measurement Cycle Schedules

Designing Measurement Cycles for Meter Reading

The criterion that affects the number of measurement cycles has nothing to do with when meter readers physically read your meter devices. Rather, the frequency that you bill the meter's consumption (real or estimated) is what controls the number of measurement cycles.

So, for example, if you bill every month, but read every OTHER month, you'll have 20 measurement cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 measurement cycles. If you bill quarterly, you'll have 60 measurement cycles. Etc.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Different billing frequencies are possible for different service points.** If you have different billing frequencies for your different types of metered service, you'll need a different set of cycles for each billing frequency. For example, if you bill water quarterly and electricity monthly, you'll have 20 bill cycles (one for each bill day during a month), but you'd need 60 quarterly measurement cycles for your water service points, and 20 monthly measurement cycles for your electric service points. This would result in a customer getting billed every month. However, four times a year, their bill would contain a charge for both electricity and water.

Top of the Page

Designing Service Routes For Meter Reading

The following points describe the relationship between a meter read, a route and a measurement cycle:

- A measurement cycle contains one or more routes.
- A route has one or more service points.
- A service point holds an installed meter device.
- And a device is what is measured.
- Therefore, the number of devices a person can read in a day limits the number of service points in a route.

> **Warning**
>
> If your company supplies electric service and uses MV90's, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because usage calculation is dependent on the route's cycle to determine the expected meter read date.

Top of the Page

Designing Metered Measurement Cycle Schedules

The process of designing your measurement cycle schedules is either easy or complicated. It will be easy if all routes within a cycle are downloaded when the measurement cycle is scheduled for download. It will be complicated if you download a subset of routes within a cycle on any given download date. We'll provide a few examples to help explain why.

If you download all cycles in a route whenever the cycle is downloaded, your measurement cycle schedule will look as follows.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bill cycles.** We've included each measurement cycle's related bill cycle to help you understand when the measurement cycle's consumption will be billed. Bill cycles are discussed in Bill Cycles.

Measurement Cycle	Download Date	Expected Work Date	Which Routes To Download	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	All	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	All	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	All	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	All	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc. to 20						

Now let's complicate life. If we assume you physically read your routes every other month (but bill monthly using estimated consumption), then you'll need the following measurement cycle schedule.

Measurement Cycle	Download Date	Expected Work Date	Which Routes	Bill Cycle	Bill Window	Estimation Date
1	30-May-99	31-May-99	1, 2, 3 - Download 4, 5, 6 - Estimate	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc. to 20						
1	29-Jun-99	30-Jun-99	1, 2, 3 - Estimate 4, 5, 6 - Download	1	30-Jun-99 to 2-Jul-99	2-July-99
2	30-Jun-99	1-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	2	1-July-99 to 3-Jul-99	3-July-99

Copyright © 2026, Oracle and/or its affiliates.

3	1-July-99	2-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	3	2-July-99 to 4-July-99	4-July-99
4	2-July-99	3-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	4	3-July-99 to 7-July-99	7-July-99
Etc. to 20						

Notice the following:

- You still have 20 measurement cycles even though you only read the meters every other month. Why? Because Oracle Utilities Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement. If it can't find a reading on this date, Meter Data Management estimates consumption. Without a measurement cycle schedule, Meter Data Management wouldn't know when to look for readings.
- Every other month you download half the routes in each cycle and estimate consumption for the other half.
- If you don't download all routes when a measurement cycle is scheduled, you have to indicate how to handle every route in the cycle.

The above design is infinitely flexible. You can use it to handle any number of requirements:

- Estimate consumption every seventh month.
- Bill every month, but only read once a quarter.
- Etc.

Designing Cycles for Waste Collection Services

The topics in this section describe how to design service cycles to support your waste collection requirements.

- A Description Of The Cyclical Waste Collection Process

A Description Of The Cyclical Waste Collection Process

Waste collection equipment (e.g., garbage trucks) travel from service point to service point using a predefined schedule. This schedule defines which groups of service points are collected by a given truck on a given day (we use the term "route" to define a group of service points that are collected by a given truck on a given day).

Waste service points tend to belong to multiple routes because they can be collected in a different order depending on a wide variety of factors:

- A service point may have one truck responsible for collecting recycling and a different truck responsible for collecting non-recyclable waste.
- A service point that is collected on Mondays, Wednesdays and Fridays may be on a different route on each day of the week.

Copyright © 2026, Oracle and/or its affiliates.

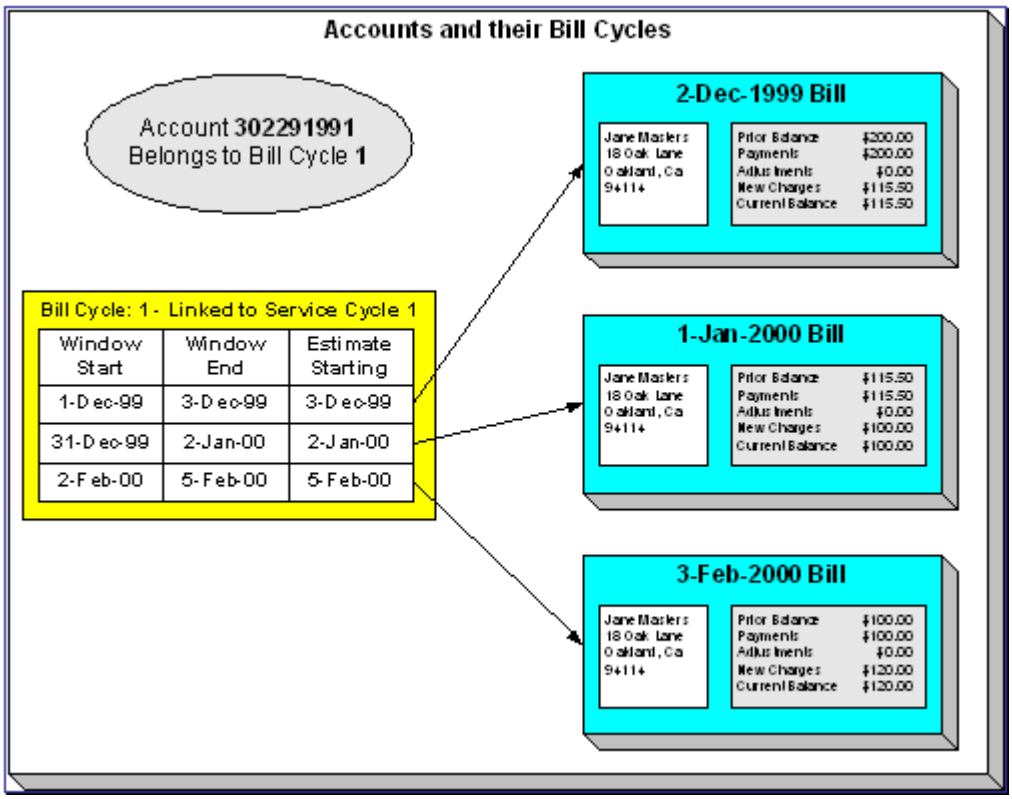
- Etc.

> **Note**
>
> Contrary to metered service points, the service schedules linked to your waste collection service cycles / route groups do not affect billing. Why? Because billing doesn't need to look for a read for these types of service points and therefore it doesn't need a schedule to know when to look for a read.

Bill Cycles

The topics in this section provide background information about a variety of bill cycle features.

- The Cyclical Billing Process & Window Billing
- Designing Your Bill Cycle
- The Relationship Between Metered Measurement Cycles and Bill Cycles
- How Does An Account Get Its Bill Cycle?
- Protecting An Account's Bill Cycle
- What Happens If An Account Has Service Agreements Spanning Metered Service Cycles?



The Cyclical Billing Process & Window Billing

The cyclical bill creation process creates most bills. This process works as follows:

- Every account references a bill cycle. The bill cycle's schedule controls WHEN the system attempts to create bills for the account.
- Every bill cycle has a bill cycle schedule that defines the dates when a cycle's accounts are to be billed. Rather than attempt to create bills on one evening, most bill cycles use a concept of "window billing" where the system attempts to produce bills for accounts over a few nights. The first night (i.e., the day the window opens) should be the earliest day on which meter reads for the account can enter the system. The last night (i.e., the day the window closes) should be the last possible day in which a meter read can enter the system. This concept of window billing allows you to start billing accounts on the earliest possible day and then bill the stragglers over successive evenings. This results in much better cash flow.
- When the bill cycle creation process runs, it looks for bill cycles with open bill windows. It then attempts to create bills for the accounts in each such cycle. If a bill is created, it will send it out that evening. If a bill cannot be created, the system will create a bill in the "error" state with a message that can be analyzed by your billing staff. The next day, your staff can either correct the problem or not. When the bill cycle creation process next runs, it deletes all "error" bills and attempts to recreate them. It continues this throughout the bill window. If bills are in error at the end of the window, they will remain in this state until a user fixes them. If the bills are still in error when the cycle's next window opens, a billing error will be generated.

The following diagram should help clarify the above.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about the how to control when bills are produced for a cycle, refer to Bill Cycle - Bill Cycle Schedule.

Designing Your Bill Cycle

The number of bill cycles is determined by the frequency that you bill your customers. So, for example, if you bill every month, you'll have 20 bill cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 bill cycles. If you bill quarterly, you'll have 60 bill cycles. Etc.

Keep in mind the following:

- You may need additional bill cycles if you allow customers to be billed off-cycle. For example, you could create a bill cycle called "Seniors" and link this to every senior citizen. You would set up this bill cycle's schedule to create bills shortly after social security checks are issued.
- You may need other bill cycles for customers with non-metered services (e.g., land leases, one time invoices).

Copyright © 2026, Oracle and/or its affiliates.

> **Important**
>
> An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to Bill Frequency - Bill Cycle vs Bill Segment Duration for more information.

The Relationship Between Metered Measurement Cycles and Bill Cycles

As you can deduce, a service point's measurement cycle is related to an account's bill cycle.

The following table is an example of how you would set up the various dates on the various schedules that control meter reading and billing.

Measurement Cycle	Download Date	Expected Work Date	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc.					

Notice the following about this example:

- The bill cycle code is the same as the measurement cycle. This is not necessary, it's just good practice.
- The bill window starts on the first date on which a meter read could be uploaded.
- The bill window ends on the day after the last possible day a read could be uploaded for the bill cycle.
- Oracle Utilities Meter Data Management only estimates consumption on the last day of the bill window.

> **NOT_SUPPORTED**
>
> For more information about the bill cycle schedule, refer to Setting Up Bill Cycles.

How Does An Account Get Its Bill Cycle?

Most accounts are created behind-the-scenes when a user uses the "add account" option on Person - Main Information. An account created like this doesn't have a bill cycle. Rather, it sits

Copyright © 2026, Oracle and/or its affiliates.

in limbo awaiting the activation of its first service agreement. When a service agreement is activated, the system populates the account's bill cycle using the following algorithm:

- If an account's bill cycle is protected, the activation of a service agreement will not affect an account's bill cycle. Refer to Protecting An Account's Bill Cycle for more information.
- If the service agreement being activated is for metered service, the account is given a bill cycle that will generate bills shortly after the service point is read. The route the system follows to get this bill cycle is a bit indirect:
  - A metered service agreement references one or more metered service points.
  - Every metered service point references a service cycle (the service cycle controls when the meter at the service point is read).
  - Every service cycle references a default bill cycle. It is this bill cycle that is populated on the account paying for service at the service point.
- If the service agreement being activated is not metered, the system cannot populate the account's bill cycle because there is no service cycle from which to default the bill cycle. This means the account's bill cycle will be blank until a user specifies a bill cycle for the account (using the Account page).

> **Note**
>
> **A To Do entry highlights accounts without a bill cycle.** A To Do entry highlights those accounts that require a user to specify a bill cycle. This entry is generated for accounts without a bill cycle that have active service agreements.

When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. Refer to What Happens At Finalization Time? for more information.

When a service point's service cycle is updated, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the service cycle. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options Feature Configuration is set to Y.

Protecting An Account's Bill Cycle

Over time, as a customer moves from premise to premise, their bill cycle is changed behind-the-scenes to be in sync with the latest service point's measurement cycle (as described in the previous section). If you do not want the system to change an account's bill cycle when a metered service agreement is activated, you need to turn on the account's **protect bill cycle** flag. You would do this if a customer liked to be billed at the start of the month regardless of when their device was read.

When the last service agreement for an account is stopped, the protect bill cycle flag is reset. This is to ensure that if the customer returns to start new service again, the bill cycle can be set based on How Does An Account Get Its Bill Cycle.

Copyright © 2026, Oracle and/or its affiliates.

What Happens If An Account Has Service Agreements Spanning Metered Service Cycles?

A single account can have service agreements that are in several service cycles. The bill cycle on such an account will default based on the last activated metered service agreement.

It's important to be aware that an account will only have bills created when its bill cycle schedule so indicates. This means that the consumption for some service points could remain unbilled for a few weeks.

Designing Bill Periods

Bill periods are used by non-metered service agreements whose bill end dates need to fall on strict dates. You need only set up this information if you have this type of service agreement.

> **NOT_SUPPORTED**
>
> Refer to Ways To Control The End Date Of A Bill Segment for more information.

Every bill period has a calendar that defines when bill segments are created for service agreements that use the bill period. Examples of bill periods include:

- Quarterly Bill - Last Day Of Quarter
- Quarterly Future Bill - Last Day Of Quarter
- Monthly - 15th Day Of Month.
- Monthly Future Bill - Last Day Of Month.

The Quarterly Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
1-Oct-1998	30-Sep-1998
1-Jan-1999	31-Dec-1998
1-Apr-1999	31-Mar-1999
1-Jul-1999	30-Jun-1999
...	

The Quarterly Future Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
15-Dec-1998	31-Mar-1999
15-Mar-1999	30-Jun-1999

Copyright © 2026, Oracle and/or its affiliates.

...

The remainder of this section provides examples using the above calendars.

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Future Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempt to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
18-Dec-1998	18-Dec-1998 thru 31-Mar-1999
15-Mar-1999	1-Apr-1999 thru 30-Jun-1999
...	

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempts to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
1-Jan-1999	18-Dec-1998 thru 31-Dec-1998
1-Apr-1999	1-Jan-1999 thru 31-Mar-1999
...	

NOT_SUPPORTED

Refer to Setting Up Bill Periods for information about how to define this information.

Setting Up Bill Cycles

An account references a bill cycle. The bill cycle defines when the account is billed and when the account's debt is checked to determine if it's overdue. To define a bill cycle and its bill cycle schedule, open **Admin**, and then **Billing**, and then **Bill Cycle**, and then **Add.**

Description of Page

Enter a unique **Bill Cycle** and **Description** for every bill cycle.

If your implementation requires restricting bill cycles to accounts by CIS Division, specify a **CIS Division** on the bill cycle.

Copyright © 2026, Oracle and/or its affiliates.

Use the **Bill Cycle Schedule** collection to define when bills are produced for the accounts in a given bill cycle. The following fields are required for each instance:

Window Start Date Specify the date on which the system should start trying to create bills for accounts in the cycle.

Window End Date Specify the last day on which the system will create bills for accounts in the cycle. This should be the last possible date on which a meter read could be loaded into the system for the account.

Accounting Date Specify the financial date associated with the bills' financial transaction. The accounting date defines the financial period(s) to which the bills will be booked in your general ledger.

Estimate Date The date on which the system is allowed to start estimating consumption if a real read cannot be found. Leave this date blank to inhibit consumption estimation. When specified, this date is typically on or shortly before the window end date.

The system will only estimate a service agreement's consumption if: 1) the bill cycle schedule allows estimation, and 2) the service agreement allows estimation.

Freeze and Complete Turn on this switch if the system should freeze and complete any bill that is created without errors. If this switch is turned off, all bills created by the billing process will be left in the unfinished state. You would only turn this switch off if you want to verify an entire bill run prior to freezing it (e.g., if you are introducing a new version of a rate). If you turn this off, you will need to return to this page after verifying a bill run and turn it back on for the customers to receive bills. When the system next runs, it deletes all unfrozen bills and recreates them as per the instructions on the bill cycle schedule.

The batch bill creation process uses this schedule to define the bill cycles for which it should create bills.

> **Note**
>
> **Don't forget.** After you set up the bill cycles that correspond with service cycles, go to Setting Up Service Cycle Schedules and update the service cycles accordingly.

Setting Up Service Route Types

Every route within a service cycle references a route type. The route type controls:

- The batch process used to download and upload a route's meter reads.
- Whether a route is downloaded as part of the service cycle schedule download process.

Open **Admin**, and then **Consumption**, and then **Service Route Type**, and then **Add** to define your route types.

Description of Page

The following fields display:

Route Type The unique identifier of the route type.

Description The description of the route type.

Copyright © 2026, Oracle and/or its affiliates.

Batch Control This defines the batch process used to download the meter reads for routes of this type. If you have multiple meter reading device formats you will have multiple batch processes - one for each format.

Process Routes In Cycle Turn this switch on if routes of this type have their meter reads downloaded when their service cycle is downloaded. This switch will be on for most types of routes. A classic example of a type of route where this switch is off would be a route containing translators (a translator sends in reads when it is polled).

Setting Up Service Cycles And Routes

When you set up a metered service point you must define its service cycle, route and sequence within the route. To define a service cycle and its routes, open **Admin**, and then **Service Cycle**, and then **Add.**

> **Note**
>
> Every service cycle has a calendar that defines when the service points in the cycle are read. For more information about this calendar, see Setting Up Service Cycle Schedules.

Description of Page

Enter a unique **Read Cycle** and **Description** for the service cycle.

Enter the **Bill Cycle** to populate on accounts with service points in this service cycle. The system updates an account's bill cycle when a service agreement is activated (assuming the account's bill cycle is not protected). Refer to How Does An Account Get Its Bill Cycle? for more information.

If the service cycle is associated with a **Service Provider** (rather than your own company's), define the owner of the cycle. Refer to MDMAs And Service Cycles for more information about service providers and their service cycles.

Use the **Service Routes** collection to define the routes within a given service cycle. The following fields display for each service route:

Service Route The unique identifier of the route within the cycle (you can use the same route ID in many cycles).

Description The route's description.

Route Type The type of route. This controls if and how the route's meter reads are downloaded. Refer to Setting Up Service Route Types for more information.

Characteristics

The **Characteristics** collection contains information that describes miscellaneous information about the service route.

The following fields display:

Effective Date Indicate the effective date for this characteristic.

Characteristic Type Controls the order in which characteristics of the same type are displayed.

Copyright © 2026, Oracle and/or its affiliates.

Characteristic Value Indicate the value of the characteristic.

Setting Up Service Cycle Schedules

The service cycle schedule defines when the service points in a given cycle are scheduled to be read. Open **Admin**, and then **Consumption**, and then **Service Schedule**, and then **Search** to maintain this information.

> **NOT_SUPPORTED**
>
> Refer to Designing Cycles for Metered Services for more information about service cycle. Refer to The Relationship Between Metered Service Cycles and Bill Cycles for more information about how service cycles are linked to bill cycles.

Description of Page

When you want to add a new service cycle schedule, you must specify the following information:

Service Cycle Enter the service cycle ID of the cycle whose routes will be downloaded.

Scheduled Selection Date Specify the date on which the system is meant to download information about the cycle's meters. This date should be a day or two before the scheduled work date.

Define the date the meters in the route are scheduled to be read using **Scheduled Work Date**. This date is extremely important as billing uses it when it looks for meter reads for service points in this cycle. If billing can't find a reading, consumption will be estimated as of this date (assuming the service agreement allows estimation).

Click **Pre-Generate Routes** if you need to finesse the cycle's routes on this Scheduled Selection Date (e.g., because some of the routes shouldn't be downloaded on a given date because the system is meant to estimate consumption). If you don't click this button, the system will create the routes on the scheduled selection date. It does this by creating a route extract for each downloadable route within the cycle (as defined by the route type). If you click this button, the system shows all routes within the cycle in the grid below. You must then define how the system is supposed to download each route on the scheduled selection date.

Click **Delete Routes** if you have pre-generated the routes and you was to remove them and allow the system to create the routes on the scheduled selection date.

Use the **Service Schedule Routes** to define how individual routes within the cycle should be handled during the download. The following fields are required for each schedule read date:

Service Route The unique ID of the service route. The route's route type is displayed adjacent.

Schedule Type This defines if and how the system is supposed to download the route's meter reads. Valid values are: Cust Read, Download, Estimate. Only those routes defined as Download will have meter reads downloaded. The other values are used to document why the route won't be downloaded.

Schedule Status This defines the download status of the route. Valid values are Pending and Complete. This value is only displayed for routes with a schedule type of Download.

Copyright © 2026, Oracle and/or its affiliates.

Where Used

This information is used by the meter read download process to determine which meter reads to download.

This information is used by the billing process to determine the date on which it expects to find a read. If it cannot find a read on or around this date, and it's OK to estimate consumption, consumption will be estimated as of the scheduled work date. The system uses the service agreement's rate schedule's frequency to determine the period of time around the scheduled work date in which it looks for a read. Refer to Defining Frequency Codes for more information.

Setting Up Bill Periods

Some SA types reference a bill period. The bill period defines when the service agreement's bill segments are produced and the respective end date of each bill segment.

> **NOT_SUPPORTED**
>
> Refer to Designing Bill Periods for more information.

To define a bill period and the bill period schedule, open **Admin**, and then **Billing**, and then **Bill Period**, and then **Add.**

Description of Page

Enter a unique **Bill Period** and a **Description** for every bill period.

Use the **Bill Period Schedules** collection when the system should create bill segments for service agreements that use a given bill period. It also defines the end date of each respective bill segment. The following fields are required:

Bill Date Specify the earliest date on which the system is allowed to create a bill segment for service agreements using this bill period.

Bill Seg End Date Specify the end date of the bill segment. For future bills, this will be after the bill date. For retro bills, this will be before the bill date.

This information is used by the bill segment creation process to determine the end date of service agreements that use a bill period.

Defining Statement Cycles

If you have persons set up in the system to receive statements with financial information, you will need to assign them to a statement cycle and define a schedule for the statement cycle.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture of Complex Statements for more information about statements.

Copyright © 2026, Oracle and/or its affiliates.

- The Big Picture Of Statement Cycles
- Setting Up Statement Cycles

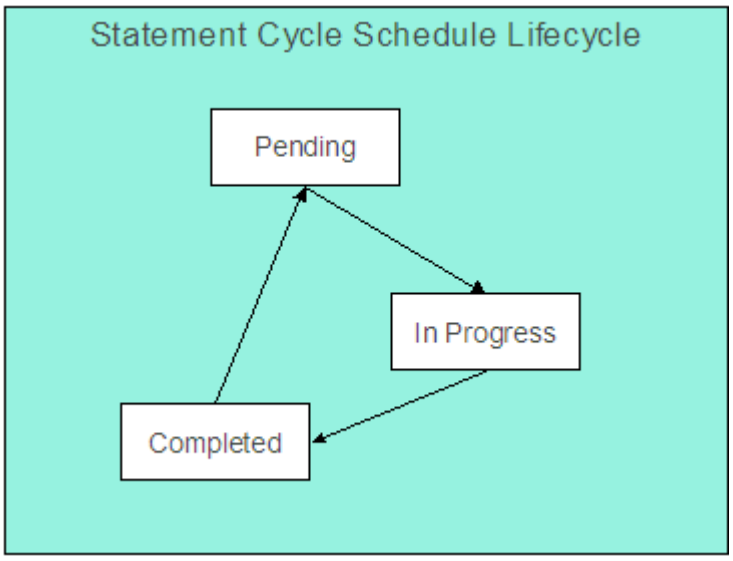
The Big Picture Of Statement Cycles

A statement cycle has a similar purpose to that of a bill cycle. It controls when statements will be produced.

- The Cyclical Statement Process
- Designing Your Statement Cycles
- Lifecycle of a Statement Cycle Schedule

The Cyclical Statement Process

Persons who wish to receive statements will work with you to determine how often these statements should be produced. Some persons may want a monthly statement, some a quarterly and some annually. For each unique schedule that is designed for your various statement persons, you will set up a Statement Cycle and its schedule.



Designing Your Statement Cycles

The number of statement cycles is determined by a combination of the frequency that you will send statements to the statement persons and how many statement cycles you wish to manage within the same frequency.

So, for example, for all the statement persons who wish to receive a monthly statement, will you create only one monthly Statement Cycle so that all monthly statements are produced the same day? Or will you have several monthly statement cycles scheduled throughout the month? The answer will depend on the volume of statements being produced and on how you want to manage the statement production.

Lifecycle of a Statement Cycle Schedule

Copyright © 2026, Oracle and/or its affiliates.

Pending The statement cycle schedule is added in this state. The Create Statements background process find records in this state to process on the appropriate date.

> **NOT_SUPPORTED**
>
> Refer to Create Statements Background Process for more information.

In Progress Records in this state are currently being processed by the Create Statements background process.

Completed Records in this state have already been processed by the Create Statements background process. If a problem occurs with the Create Statements background process and it needs to be rerun, simply change the status back to pending and rerun the process.

Setting Up Statement Cycles

A Statement Construct references a statement cycle. The statement cycle defines when the statement person will receive statements with financial information related to the accounts and service agreements linked to the statement construct. To define a statement cycle and its statement cycle schedule, open **Admin**, and then **Billing**, and then **Statement Cycle**, and then **Add.**

Description of Page

Enter a unique **Statement Cycle** and **Description** for every statement cycle.

Use the **Statement Cycle Schedule** collection to define when statements are produced for the persons with statement construct records in the given statement cycle. The following fields are required for each instance:

Processing Date Specify the date on which the system should create statements for persons with statement construct records in the cycle.

Copyright © 2026, Oracle and/or its affiliates.

Status Indicates the status of the cycle schedule. Refer to Lifecycle of a Statement Cycle Schedule for more information.

The batch statement creation process uses this schedule to determine which statement cycles for it should create statements for the statement construct records. Refer to Create Statements Background Process for more information.

Defining Service Agreement Type (SA Types)

Every service agreement must reference a SA type. The SA type defines what you sell, how much you sell it for, to whom you sell it, how overdue debt is collected, and how sales will be booked in your general ledger.

> **Note**
>
> **Perfect foresight.** In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SA types. In reality, setting up your SA types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

- Designing SA Types For Service Agreements With Service Points
- Designing SA Types For SAs Without Service Points
- Designing SA Type For Other Segmentations
- Designing Prepayment Billing Options
- SA Types And The Financial Design
- Setting Up SA Types

Designing SA Types For Service Agreements With Service Points

Designing your SA types is an iterative process. To minimize some iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SA types.

Division/SA Type	Service Type

The topics in this section provide guidelines describing how to fill in this table for SA types associated with service agreements that charge for service point-oriented services.

- CIS Division Segmentation
- Service Segmentation
- Receivable Segmentation

Copyright © 2026, Oracle and/or its affiliates.

- Revenue Segmentation
- Rate Segmentation
- Service Point (SP) Type Segmentation
- Company Usage Segmentation
- Debt Class Segmentation
- Budget Billing Segmentation

CIS Division Segmentation

A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

If we assume that you are located in a single jurisdiction - say California - we will need a single CIS division for all of our SA types.

CIS Division/SA Type
CA

Service Segmentation

At a minimum, you will have one SA type for every different type of utility service offered by your organization. If we assume you sell electricity, gas, water, wastewater and cable; your SA Types will be as follows:

CIS Division/SA Type	Service Type
CA/G	Gas service
CA/W	Water service
CA/E	Electric service
CA/WW	Waste water service
CA/CABLE	Cable

> **Note**
>
> **Non Utility Services.** Earlier in this manual, service types are discussed in respect of meters and items. However, you may require additional service types if you have non-utility services. In the above table, we have only shown utility oriented services and their respective CIS Divisions. Later in this section, we will encounter a few more service types. Refer to Setting Up Service Types for more information.

Copyright © 2026, Oracle and/or its affiliates.

Receivable Segmentation

Many organizations segregate their receivable balances in the general ledger. For example, the receivable amount associated with gas and water service may be maintained in separate GL accounts.

If your organization does this, you will probably have at least one SA type for each such receivable account because each SA type references a distribution code that typically contains the receivable account.

- The word *probably* is underlined because this is a rule of thumb. There are situations where the number of receivable accounts isn't directly related to the number of SA types. This happens when an organization maintains very detailed receivable accounts in the general ledger and maintaining a one-to-one relationship between SA types and distribution codes would lead to a massive proliferation of SA types (and you don't want this!). If your organization maintains very detailed receivable accounts, please speak to your implementers, they should be able to introduce a small customization to generate the appropriate receivable account rather than extract it from the distribution code.
- The word *typically* is underlined because there are several SA types that don't book to a receivable account when bill segments are generated. For example, company usage and charitable contributions. Refer to Company Usage Segmentation and Charitable Contribution Segmentation for examples of SA types that don't book to receivable accounts.

We'll simplify our example and assume your organization has one receivable account for all types of utility service. Given this, we won't need additional SA types to support receivable segmentation:

CIS Division/ SA Type	Service Type	Distribution Code
CA/G	Gas service	A/R-UTIL
CA/W	Water service	A/R-UTIL
CA/E	Electric service	A/R-UTIL
CA/WW	Waste water service	A/R-UTIL
CA/CABLE	Cable service	A/R-UTIL

Revenue Segmentation

Look at your rates and determine which rates can be used by each SA type. The following table shows the sample rates that can be used for each service:

CIS Division/ SA Type	Service Type	Distribution Code	Rates
CA/G	Gas service	A/R-UTIL	GALL-1
CA/W	Water service	A/R-UTIL	WALL-1

Copyright © 2026, Oracle and/or its affiliates.

CA/E	Electric service	A/R-UTIL	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	CABLE

Now, look at the rates' calculation rule GL Distribution window. You're looking for calculation rules whose GL distribution is affected by revenue class. If there are no revenue classes referenced on the calculation rules, this means that the revenue associated with the rate will be booked to a single GL account regardless of the type of customer. If you see revenue classes, this means that the revenue account associated with the calculation rule(s) differs depending on the SA type's revenue class. If revenue classes are used in the rates, you must create a different SA Type for every revenue class.

Let's assume the following:

- The gas rate (GALL-1) references the RESIDENTIAL, COMMERCIAL and INDUSTRIAL revenue classes in order to differentiate revenue based on the type of customer.
- None of the other rates differentiate revenue based on customer class.

Our SA types will now look as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Notice that we created new SA types for gas in order to specify the respective revenue class. We didn't do this for the other services because it isn't necessary. However, you should feel free to do this if it feels right or if you need it for reporting purposes. For example, if you want to report on all *residential* service agreements, but you differentiate only gas by residential versus commercial, you'll be in trouble.

Rate Segmentation

Every SA Type whose service agreements have their charges calculated with a rate must have one or more rates linked to it. These define which rates can be linked to the SA type's service agreements. If different service agreements have different valid rate combinations, you will need to split the SA types accordingly.

For example, look at the electric rates. If we assume:

- the RES rates can only be used for residential customer,

Copyright © 2026, Oracle and/or its affiliates.

- the IND rates can only be used for industrial customers,
- the COM rates can only be used for commercial customers,
- the LAMP rates can only be used for lamp customers

Then you might want to set up a new SA type to indicate such. The advantage of doing this is that you get more control over which rates can be used on a given SA type. The disadvantage is that you proliferate SA types. Unfortunately, it's really a question of taste.

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1
CA/LAMP	Electric service	A/R-UTIL	N/A	ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Warning

Don't be too specific in your analysis in respect of rate segmentation because you could end up with a separate SA type for every rate (and you don't want this). We understand this is a very subjective warning, but we recommend that you start out with broad bands of rates that can be used on a SA type and narrow it down if you end up unhappy with the results. For example, you don't have to set up a separate SA type for low-income residential gas customers just because they have a special rate. Rather, you can leave your SA types as they are and treat low-income gas customers as a subset of your residential gas customers. **For more information**, refer to Setting Up Start Options.

Note

Rate override. If a service agreement of this type may be linked to a terms of service record, you must also consider whether or not the rate schedule could be overridden by a template SA linked to the terms of service record. Refer to SA Type - Rate for information about the possible values for this field.

Service Point (SP) Type Segmentation

Copyright © 2026, Oracle and/or its affiliates.

Every SA Type whose service agreements exist to bill for service point-oriented service has one or more SP types. These define which type of service points can be linked to the SA type's service agreements. If different service agreements have different valid SP types, you will need to split the SA types accordingly.

For each service point-oriented SA type, determine if there are any restrictions in respect of the types of service points that can use the SA type's rates. For example, if we assume that only commercial SP types can be used by commercial customers, industrial SP types by industrial customers, residential SP types by residential customers, your SA types will be:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE

Notice the wastewater SA types reference both water and waste water service points. This is intentional as wastewater service uses the consumption from the water service to calculate some part of the wastewater charge.

Company Usage Segmentation

Up to now, we've discussed SA types associated with service agreements linked to your customers. The system has also been designed to keep track of the expenses associated with your company's use of power. If you want the system to do this, you must create at least one SA type for each service consumed by your organization.

For example, if we assume your organization consumes electric, gas, and water service; your SA types will now be as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES	SP-RATED

Copyright © 2026, Oracle and/or its affiliates.

CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM	SP-RATED
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND	SP-RATED
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES	SP-RATED
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM	SP-RATED
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND	SP-RATED
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	SP-RATED
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM	SP-RATED
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND	SP-RATED
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	SP-RATED
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	SP-RATED
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	SP-RATED
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE	SP-RATED
CA/E-COY	Electric service	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG
CA/G-COY	Gas service	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG
CA/W-COY	Water service	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG

Notice the three company usage SA types do not reference an A/R account as their distribution code. This is because when bill segments are created for these types of service agreements, the system must debit an expense account (or contra-revenue account) rather than a receivable account.

Also notice we introduced a new column - Bill Segment Type. Notice that the customer-oriented SA types use the SP-RATED bill segment type and the company usage SA types use the COMPUSAG bill segment type. Different bill segment types are necessary because company usage SA types use a different algorithm to calculate their bill segment's financial transaction algorithm because they don't affect either payoff or current balance.

NOT_SUPPORTED

For more information, refer to Designing and Defining Bill Segment Types.

Debt Class Segmentation

Copyright © 2026, Oracle and/or its affiliates.

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you will have to split the SA Type.

NOT_SUPPORTED

For more information about debt class, refer to Designing Your Collection Procedures.

If we assume that your residential services are regulated and your commercial and industrial services are deregulated, we won't have to introduce additional SA types.

CIS Division/ SA Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type	Debt Class
CA/G-RES	A/R-UTIL	R - residential	GALL-1	G-RES	SP-RATED	REGU
CA/G-COM	A/R-UTIL	C - commercial	GALL-1	G-COM	SP-RATED	UNRE
CA/G-IND	A/R-UTIL	I - industrial	GALL-1	G-IND	SP-RATED	UNRE
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	SP-RATED	REGU
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	SP-RATED	UNRE
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	SP-RATED	UNRE
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	SP-RATED	REGU
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	SP-RATED	UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	SP-RATED	UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	SP-RATED	REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	SP-RATED	UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	SP-RATED	UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	SP-RATED	UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the three company usage SA types do not have a debt class. This is because their bill segment type's FT algorithm doesn't cause debt to be created and therefore there is no reason to have a debt class. However, you'll need to create a "dummy" debt class - call it N/A - for these SA types because every SA type must reference a debt class.

Budget Billing Segmentation

Many utilities offer their customers levelized payment plans to smooth out the seasonal bill variations. We call this levelized amount the *budget amount*.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Budget Billing for more information about budgets in general. Refer to Billing - Current Balance versus Payoff Balance for an example of budget billing accounting.

If we assume that you only allow budget billing on the electric and gas residential services, then you'll need to update your CA/G-RES and CA/E-RES SA types:

CIS Division/ SA Type	Dist Code	Rev Class	Rates	SP Type	Bill Seg Type	Debt Class	Recurring Charge Control Info
CA/G-RES	A/R-UTIL	R	GALL-1	G-RES	SP-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/G-COM	A/R-UTIL	C	GALL-1	G-COM	SP-RATED	UNRE	
CA/G-IND	A/R-UTIL	I	GALL-1	G-IND	SP-RATED	UNRE	
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	SP-RATED	REGU	
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	SP-RATED	UNRE	
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	SP-RATED	UNRE	
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	SP-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	SP-RATED	UNRE	
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	SP-RATED	UNRE	
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	SP-RATED	REGU	
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	SP-RATED	UNRE	
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	SP-RATED	UNRE	
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	SP-RATED	UNRE	

Copyright © 2026, Oracle and/or its affiliates.

CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the following:

- We updated the two SA types to allow recurring charge information.
- The Recurring Charge Amount is Optional. Why? Because those customers who aren't on a budget plan won't have a recurring charge amount. Those customers on a budget will have a recurring charge amount.

> **Note**
>
> **Turn on Eligible for Budget.** Besides indicating that these SA types use recurring charges, you also need to turn on the Eligible for Budget switch on the SA type to indicate that this type of SA participates in budget processing.
>
> **Override Budget Eligibility**. You may plug in an override budget eligibility algorithm on an SA type that is configured to be Eligible for Budget if certain service agreements of this type are not eligible.

> **NOT_SUPPORTED**
>
> Refer to the Description of Page under SA Type - Billing for the definition of the recurring charge attributes.

Designing SA Types For SAs Without Service Points

The topics in this section provide guidelines describing how to design the SA types associated with your service agreements that don't have service points.

- Overpayment Segmentation
- Write Off Segmentation
- Connection Charge Segmentation
- Charitable Contribution Segmentation
- Payment Arrangement Segmentation
- Merchandise Segmentation - Installment Billing
- Deposit Segmentation - Installment Billing
- Billable Charge Segmentation
- Over/Under Cash Drawer Segmentation

Copyright © 2026, Oracle and/or its affiliates.

- Payment Upload Error Segmentation
- CIAC Segmentation
- Loan Segmentation
- Non-Billed Budget Segmentation

Overpayment Segmentation

When a customer pays more than they owe, you must decide what to do with the excess money. The following points describe two possibilities:

- You could create a new service agreement to hold the excess (let's call it an overpayment SA). The credit would be transferred from this service agreement to the billable service agreements when the next bill is completed. This means that all billable service agreements have the same opportunity to receive the overpayment when they are billed in the future.
- You could amalgamate the excess payment on one of the existing, billable service agreements. For example, if a customer has both electric and gas service, the excess funds could be kept on either the gas or the electric SA. This would result in the following:
  - The service agreements that do NOT receive the overpayment will have debt when they are next billed.
  - The service agreement that receives the overpayment could have its future debt offset by the overpayment (meaning that it could have a credit balance until the service agreement's future bill segments offset the overpayment amount).
- The above situation is not desirable unless the customer intentionally overpaid one service agreement. The first method (keeping the overpayment on a separate service agreement) obviates this potential problem. Obviously, if your organization sells a single service (and therefore your customers have a single service agreement) you would choose the second method.

You control which method is used by plugging in the appropriate Overpayment Distribution algorithm on each Customer Class (i.e., you can choose a different method for different customer classes). If you choose to hold overpayments on a separate SA, then you must set up an SA Type as described in the following table:

CIS Division/ SA Type	Service Type	Distrib. Code	Eligible for Billing	Debt Class	Pay Seg Type	Do Not Overpay	One-time
CA/ OVERPAY	Other	A/P - OVER	Not billed	N/A	Normal	No	Yes

Notice the following about the new overpayment SA type:

- It has an interesting distribution code. This is because when a payment segment is created for this type of service agreements, the system must credit a liability (an overpayment is a liability).
- It's important to indicate that the overpayment SA is a one-time service agreement. Why? Because this means that the system will automatically close the SA when it's balance falls to zero (i.e., when all of the overpayment has been used to satisfy future bills).
- A bill segment type is not needed because the system never creates bill segments for such service agreements (they exist only to hold excess credits).

Copyright © 2026, Oracle and/or its affiliates.

- You may also want to turn on the alert message
- You must plug-in a bill completion algorithm on this SA type. This bill completion algorithm will transfer the credit balance to the account's other service agreements when the bill is completed. Refer to The Credit Transfer Algorithm for more information about this algorithm.
- You must also reference this overpayment SA type as the parameter value on your overpayment algorithm (this algorithm is plugged in on the desired customer classes). Refer to Overpayment Algorithm for more information about this algorithm.

> **Note**
>
> **If overpayment means charitable contribution.** Some organizations sponsor a program that works as follows - if a customer overpays a bill by a given amount (say $5), this amount is assumed to be a charitable contribution. If you have this requirement, you will create another SA type to hold a customer's charitable contributions. This SA type will look similar to the one described below (see Charitable Contribution Segmentation) except it is not billable. The funds will be credited to this service agreement by creating a new overpayment algorithm that is similar to the base package Overpayment Algorithm. This new algorithm will be very similar to the existing algorithm. The main difference will be that it will have to check if the overpayment amount is an exact value (say $5). If so, it will create a payment segment for the charitable contribution SA type; otherwise it will create a payment segment for the overpayment SA.

Write Off Segmentation

When you write off non-collectable debt, you transfer the receivable from a "normal" service agreement onto one or more write-off service agreements. When the debt is transferred to a write-off service agreement, the distribution code on the "normal" service agreement is credited (typically an A/R GL account), and the distribution code on the write-off service agreement is debited.

You will almost always need a write-off service agreement whose distribution code is the write-off expense. However, you probably don't book all of the write-off amount to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you want to book the written off revenue to a write-off expense account and you want to reduce the liabilities (you don't owe the liability if you don't get paid). This means you'll need another SA type for the liabilities. Refer to The Ramifications of Write Offs in the General Ledger for a complete explanation.

The following table contains the minimum number of SA Types that you'll need to hold your write-offs.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class	Pay Seg Type	Do Not Overpay
CA/WO-STD	Other	EXP-W/O	Not billed	WO	Normal	Yes
CA/WO-LIA	Other	LIA-General	Not billed	WO	Normal	Yes

Notice the following about the new write-off SA types:

Copyright © 2026, Oracle and/or its affiliates.

- They have interesting distribution codes. This is because when debt is transferred to these types of service agreements, the system must debit either an expense account (i.e., write-off expense) or a liability account. It's important to note that in The Ramifications of Write Offs in the General Ledger we explain how this liability account may be overwritten with the liability account that was originally booked.
- Neither needs a bill segment type because the system never creates bill segments for such service agreements (they exist only to hold uncollectable debt)
- Even though the debt is not collectable, it still has a debt class. Why? Because the system shows a customer's debt on many inquiries by debt class and it's important to show write-off debt on these queries.
- The combination of Payment Segment Type and Do Not Overpay are important. Refer to The Ramifications of Write Offs in the General Ledger for a complete explanation.

> **Note**
>
> The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on each write-offable SA type. The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write-off SA type.
>
> **An Alternative.** If you have a limited number of liability accounts, you may decide to have a separate write-off service agreement for each liability account. Doing this would proliferate the number of service agreements created at write-off time. However, it would simplify the remittance of payment to the taxing authority if the reversed liability is ever paid.

Connection Charge Segmentation

If you levy connection charges, you have two options:

- You can create a SA type that exists purely to handle connect charge debt. After doing this, you'd create a start option for this SA type that causes an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had multiple services (e.g., a combined electric, gas, water utility) that only levies a single connection charge regardless of the number of services started. If you use this approach, make sure to indicate the SA type is non billable.
- You can levy a start adjustment on one of your existing SA types (e.g., CA/E-RES). The easiest way to do this is with a start option. On the start option you'd indicate an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had a single service offering (e.g., an electric-only utility). Refer to Setting Up Start Options for more information.

In the table below, we show what would be necessary if you want to have a separate service agreement for the connection charge.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class
CA/CONNECT	Other	A/R-UTIL	Not billed	REGU

Copyright © 2026, Oracle and/or its affiliates.

Notice the following about the new connection charge SA type:

- It has a normal receivable distribution code.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (its charged via an adjustment).
- The debt class is interesting - REGU (for regulated). We are intentionally linking the connection charge debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the connection charge debt the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

Charitable Contribution Segmentation

If your organization accepts charitable contributions made by your customers, you must create a SA type to hold these contributions.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/CHARITY	Other	A/P-CHAR	CHAR	RECUR	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Contrib. Amount

Notice the following about the new charitable contribution SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., charitable contribution payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the charitable contribution is created.
- It uses an interesting bill segment type - RECUR. This bill segment type was set up to create recurring charges that don't automatically stop at some point in time.
- The debt class is interesting - CHAR (for charity). This is done so that past due charitable contribution debt is treated separately from other types of debt.
- The recurring charge control information is set up as defined.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> It's important that you assign the charitable contribution SA type with a payment segment type that only affect current balance (as opposed to affecting current AND payoff balance). This is because there is no receivable recognized when the contribution is billed and therefore there is no payoff balance to relieve when it's paid.

Payment Arrangement Segmentation

If your organization allows customers to payoff outstanding debt using payment arrangements (e.g., current bill plus $X), you will need a new SA type for every debt class that can have a payment arrangement. If we assume you can have payment arrangements for both regulated and unregulated debt, then you'll need at least two more SA types (you may have more SA types if you need to segregate the payment arrangement receivable amount by utility type (or some other type)).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/PA-REGU	Other	A/R-ARRG	REGU	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount
CA/PA-UNRE	Other	A/R-ARRG	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount

Notice the following about the new payment arrangement SA types:

- They have an interesting distribution code. This is because when funds are transferred to these types of service agreements, the system must debit a receivable (i.e., payment arrangement receivable).
- They use an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- Each new SA type references the debt class whose debt it will pay off. We are intentionally linking the payment arrangement debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the arrangement debt as the

Copyright © 2026, Oracle and/or its affiliates.

same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

- The recurring charge control information is set up as defined.

> **NOT_SUPPORTED**
>
> Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use Start Options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Merchandise Segmentation - Installment Billing

If your organization allows customers to purchase merchandise using an installment plan, you must create a SA type for this.

> **Note**
>
> **No installments.** If the customer must pay for the merchandise in one lump amount, you'd create an SA type similar to the Connection Charge Segmentation example.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/MERCH-I	Merch	A/R-MRCH	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new merchandise SA type:

- It has a normal receivable distribution code.
- It uses an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- The recurring charge control information is set up as defined.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started. Refer to Start Option Considerations For SA Types That Use Initial Adjustments **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Deposit Segmentation - Installment Billing

If your organization allows customers to pay deposits using an installment plan, you must create an SA type for this.

Note

No installments. If the customer must pay for the deposit in one lump amount, you'd create an SA type similar to the Connection Charge Segmentation example. Just make sure the adjustment that's levied to charge for the deposit amount doesn't affect payoff balance (when you bill a deposit, the customer doesn't really owe anything because it's not a true receivable from an accountant's perspective).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/DEP-I	Other	A/P-DEPO	DEP	RECURATB	Amount to bill is Required Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new deposit SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., deposit payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the deposit is created.
- It uses an interesting bill segment type - RECURATB. This bill segment type was set up to create recurring charges that stop when the system has billed the Total Amount to Bill.
- The debt class is interesting - DEP (for deposit). This is done so that past due deposit "debt" is treated separately from other types of debt.

Copyright © 2026, Oracle and/or its affiliates.

- The recurring charge control information is set up as defined. Note well, the Amount to bill is Required.

> **NOT_SUPPORTED**
>
> Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

> **Note**
>
> **Bill messages on receipt of deposit in full.** The base package includes a special FT Freeze algorithm that can be specified on deposit SA Types. It recognizes when a deposit has been paid in full, and creates a bill messages to inform the customer. Refer to algorithm DEP PIF MSG in Algorithm Types for more information.

Billable Charge Segmentation

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line. You can also use billable charges to "pass through" other bill ready charges generated outside the system, by another application, or by a 3rd party supplier.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each service agreement with unbilled charges. If multiple unbilled charges exist for a given service agreement, only one bill segment will be created and it will contain details about all of the billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, you must set up at least one SA type to hold your billable charge debt. You may have multiple charges based on billing frequencies, A/R booking, debt monitoring, etc. It's really up to you.

The easiest way to determine how many billable charge SA types you'll need is to define every conceivable billable charge (which you should have done when you designed your billable charge templates). Then ask yourself if they have the same billing and payment behavior, if so, you'll have one SA type. If not, you'll need one SA type for each combination.

Copyright © 2026, Oracle and/or its affiliates.

We will assume your billable charges are all used to levy unusual one-off charges that can be collected in the same way, therefore we'll need one SA type.

CIS Division/ SA Type	Service Type	Distrib Code	Debt Class	Bill Seg Type	Billable Charge Templates	Rate
CA/ ONETIME	Other	A/R-UTIL	UNRE	BILLCHRG	TREETRIM DAMAGE	None
CA/ PASSTHRU	Electricity	A/R-OTHER	UNRE	BILLCHRG	None	None
CA/ADDON	Electricity	A/R-OTHER	EXTERNAL	BILLCHRG	None	TAXES

Notice the following about the new one time SA type:

- It has a normal receivable distribution code.
- Its debt class is unregulated.
- It uses an interesting bill segment type - BILLCHRG. This bill segment type was set up to create bill segments using billable charges.
- It references the valid billable charge templates that can be used on this SA type.

> **Note**
>
> **One Time Charge.** The ONE TIME example shown above implies this SA type exists to hold one-time charges. Because of this, you should turn on the One Time Charge switch on the SA type so that service agreement's of this type are automatically closed when final payment is received. You don't have to do this because a customer could have a single billable charge service agreement that is perpetually active for pass through charges (i.e., it doesn't have a stop date). If you do this, the system will create a bill segment for this service agreement whenever it finds an unbilled billable charge linked to the service agreement.

Notice the following about the pass through SA Type:

- It doesn't use the normal distribution code or debt class. This is done so that the debt and receivable can be tracked separately. If these charges were being pass through from another system, you might want to track these financial values separately.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- Templates are not relevant - these charges on not created on-line using templates, but are loaded via the Billable Charge Upload Staging.

Notice the following about the add on charges SA Type:

- This is an example of bill-ready charges (similar to pass through) to which the system adds on other charges, for example, taxes.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- It also uses a Rate. In this case, the bill creation algorithm (specified on the bill segment type) will take any billable charge lines and attach them to a bill. In addition, these billable charges will include billable charge service quantities (SQs). These service quantities will

Copyright © 2026, Oracle and/or its affiliates.

also be swept onto the bill segment, and the Rate (TAXES in this example) will be applied. In order for taxes to be calculated, the billable charge SQs must include the total taxable amount - the system is not able to apply the rate on top of the other billable charges. But, it can apply the tax rate to the SQs that are supplied.

- You can also use this technique to bill other rate-ready service quantities, like kWh, CCF, *etc.* This is a way to process rate-ready data for which you have a contract, but you do not know the meter (and therefore, cannot collect real meter reads).
- If the rate has pre-processing calculation groups, these will be applied as well.

NOT_SUPPORTED

For more information about billable charge templates, refer to Setting Up Billable Charge Templates.

Over/Under Cash Drawer Segmentation

In order to balance a tender control that is out-of-balance, your organization must set up an account with a service agreement whose SA type references the over/under expense account. You will probably only have one service agreement that references this SA type, but you still must have it if you remit funds via a cash drawer.

NOT_SUPPORTED

For more information about over/under processing, refer to How To Get An Unbalanced Tender Control In Balance (Fixing Over/Under).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/OVR UNDR	Other	EXP-OV/UND	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This is because when a payment segment is applied to this type of service agreement, the system must debit an expense account for under amounts (and credit it for over amounts).
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has over/under payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

Payment Upload Error Segmentation

If the payment upload process detects an invalid account on a payment upload record, it will create a payment for the suspense service agreement defined on the upload process' tender

Copyright © 2026, Oracle and/or its affiliates.

source (see Setting Up Tender Sources). You should create a special SA type for this service agreement.

> **NOT_SUPPORTED**
>
> For more information about the payment upload process, refer to Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/SUSPENSE	Other	EXP-MISC	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This code should probably be a suspense account. All payment segments that are created for this service agreement will eventually be transferred to a "real" service agreement and therefore this GL account's balance should be zero when no payments are in suspense.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has invalid account payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

CIAC Segmentation

If your company bills and refunds Contribution In Aid of Construction (CIAC) contracts, you must create one or more SA types. CIAC contracts are typically used to levy charges associated with line extensions. These types of service agreements are different from other service agreements because the initial amount charged is refunded to the original payee when new properties (or extensions) are added to the extension (or when the new properties are subsequently billed for service).

> **Note**
>
> **Billable charges are used for the original CIAC service agreement.** CIAC SA types are always Billable Charge SA types because an operator must specify the exact amount to charge the contractor using a billable charge. Refer to Billable Charge Segmentation for more information.

The following points describe how CIAC processing is implemented in the system:

- When a new line extension is build, you will create a new service agreement that references your CIAC SA type. This service agreement should be linked to a service point associated with the extension. The easiest way to create this service agreement and link it to the service point is by using the Start Account transaction. It's important to remember to define your CIAC SA type as a valid SA type for the SP type used to represent the line extension.

Copyright © 2026, Oracle and/or its affiliates.

- When a new premise / service point is built that "hangs" off the original extension, the new service point should be linked to the original service point. This can be done by referencing the original service point as the "parent" service point of the new service point using a foreign key value characteristic.
- The system periodically monitors the original CIAC service agreement. The process that performs this monitoring is referenced on the original CIAC service agreement's SA type. The exact processing that takes place during this monitoring is up to your organization's specific business requirement. For example, if you refund 10% of every bill produced for the "downstream" service points to the original contractor, you would have logic in your CIAC monitoring process that looks for recent bill segments produced for the "downstream" service agreements and then creates an adjustment for the master service agreement.

> **Note**
>
> **CIAC refunds are idiosyncratic.** Because CIAC refund processing is idiosyncratic, we do not supply any CIAC monitoring processes in the base package. This is because the likelihood that they could be used is extremely low because of your organization's unique requirements.

Therefore, if your organization performs CIAC processing, you should create a special SA type.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	CIAC Process	Bill Seg Type
CA/CIAC	Other	A/R - CIAC	UNRE	Refund based on percent of future bills	Billable Charge

Loan Segmentation

If you loan money to customers that is recouped using an amortization schedule, you need to set up an SA type for the loan service agreement.

CIS Division/SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/LOAN	Other	A/R - LOAN	A/R - STLN	UNRE	LOAN	

> **NOT_SUPPORTED**
>
> Refer to Setting Up The System To Enable Loans for more information.

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budget Segmentation

If you allow your customers to pay set amounts at specified intervals (e.g. every two weeks), you need to set up SA types for Non-Billed Budget service agreements. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. You may implement two types of Non-Billed Budgets monitored and unmonitored, each type requiring a different SA type. You may also implement different renewal options for Non-Billed Budgets.

CIS Division/SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/NBB-MON	Other	A/P - OVPY	Monitored	NBB	Optional	Not billed
CA/NBB-UNMON	Other	A/P - OVPY	Unmonitored	N/A	Optional	Not billed

NOT_SUPPORTED

For more information about monitored and unmonitored Non-Billed Budgets, refer to Defining Non-Billed Budget Options.

Designing SA Type For Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of SA Types. However, many obscure factors could cause the introduction of more SA Types. In this section, we explain these more obscure factors.

Warning

We strongly recommend not being too pedantic when considering the factors described in this section. If you can only think of a few strange situations that would necessitate a SA type, think carefully before you introduce it. It's better to be a little less than perfect than end up with large number of obscure SA types.

- Cash Distribution Segmentation
- Adjustment Profile Segmentation
- Late Payment Charge Segmentation
- Debt Classification Segmentation
- Allow Estimates Segmentation
- Severance Criteria Segmentation
- Deposit Class Segmentation

Copyright © 2026, Oracle and/or its affiliates.

- Sub SA Types
- Financial Settlement SA Types
- Interval Billing SA Types

- Initial Consumption Period Considerations
- Processing Sequence Considerations

Cash Distribution Segmentation

Every SA Type has a payment segment type. The payment segment type defines the cash account to which the SA type's payments should be booked. If different service agreements have different cash accounts, you will need to split the SA types accordingly.

Adjustment Profile Segmentation

Every SA Type has one or more adjustment profiles. These profiles define the valid adjustment types that can be booked to the SA type's service agreements. If different service agreements within an SA type have different mixtures of valid adjustment types, you must split the SA types accordingly.

Late Payment Charge Segmentation

An option exists on SA Type that causes the system to generate a late payment charge if payment is not received on time. If you don't levy late payment charges on all service agreements, you will need to determine when you do and design your SA types accordingly.

In addition, if you levy late payment charges, the percentage levied and the algorithm that defines the amount of the outstanding balance subject to the charge is defined on the SA type.

Debt Classification Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you must split the SA Type.

NOT_SUPPORTED

For more information about debt class, refer to Designing Your Collection Procedures.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Write Off Debt Class vs. Normal Debt Class.** An SA type references both write off debt class and normal debt class. An SA type's write-off debt class controls the write-off rules imposed on service agreements of a given type. An SA type's normal debt class controls the collection rules imposed on service agreements of a given type. Refer to Different Collection Criteria For Different Customers And Different Debt for more information about collection rules. Refer to Different Write-Off Criteria For Different Customers And Different Debt for more information about write-off rules.

Allow Estimates Segmentation

Every SA Type has a switch that controls whether the system estimates consumption if meter reads are missing at billing time. If a given SA Type has different situations when the system should and should not estimate, you will have to split the SA Type.

> **Note**
>
> **Override.** You can override the value of the SA Type's estimation switch on an individual service agreement. This means that if only a few service agreements don't abide by the SA Type's estimation switch, you can change the switch value of these service agreements.

> **NOT_SUPPORTED**
>
> For more information about estimation, refer to Setting Up Consumption Estimation Parameters.

Severance Criteria Segmentation

Every SA Type has severance criteria. The severance criteria define the severance process used to sever service if the customer doesn't pay. You can have multiple severance processes if different conditions warrant a different process. For example, you may have a different severance process if the customer has life support.

If you have a SA Type that requires different severance conditions other than those currently supported, you can make a programmatic change to introduce the additional conditions OR you can split the SA Type.

> **NOT_SUPPORTED**
>
> For more information about severance, refer to Designing Your Severance Procedures.

Copyright © 2026, Oracle and/or its affiliates.

Deposit Class Segmentation

Every SA Type that exists to hold a cash deposit will reference a deposit class. The deposit class defines the business rules that control various functions including interest calculation and refund criteria. You will need multiple deposit SA Types if any of the deposit class' rules / conditions differ for different types of deposits. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one SA type for residential deposits and another for commercial deposits (where the residential deposit SA type will reference the residential deposit class and the commercial deposit SA type will reference the commercial deposit class).

You will need additional deposit SA types if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one SA type for regulated deposits and another for unregulated deposits.

NOT_SUPPORTED

For more information about deposit class, refer to Designing and Defining Deposit Classes.

Sub SA Types

If you operate in a deregulated environment AND if you provide billing services for other service providers, you will need to create SA types to handle the billing of the service providers' charges.

NOT_SUPPORTED

Refer to Designing Your SA Types And Start Options For Sub SAs for more information.

Financial Settlement SA Types

If you operate in a deregulated environment, you may have to create financial settlement service agreements for the service providers. As explained in Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us service providers require a service agreement to hold adjustments used to increase how much you owe the service provider (or how much they owe you).

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Designing SA Types For Service Provider Financial Settlements for more information.

Interval Billing SA Types

If you have customers with interval meters, the SA types for these customers will require special setup.

NOT_SUPPORTED

Refer to Designing Your SA Interval Billing Options for more information.

Usage Request SA Types

If your organization uses a meter data management system to store meter reading information and the mdm is responsible for calculating bill determinants during billing, the SA types for these customers will require special setup.

NOT_SUPPORTED

For more information about usage requests, refer to The Big Picture Of Usage Requests.

Initial Consumption Period Considerations

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different utilities count the first day of a new service

Copyright © 2026, Oracle and/or its affiliates.

agreement differently than others. Because of this, a flag exists on SA Type called **Initial Start Date Option**. This flag controls whether the service agreement's start date is included in the consumption period in a service agreement's first bill segment.

The following table describes the ramifications of the options you can set for this flag.

Flag Value	Consumption Period Calculation	Use This Option When
Add 1 Day Always	The consumption period's start date is calculated by adding 1 day to the service agreement's start date. (The SA start date is never included in the consumption period for the first bill segment.)	You want the initial bill and all subsequent bills to have a consistently calculated consumption period (i.e., the consumption period for the first and all other bills is always one day less than the bill segment's period).
Add 1 Day for Back-to-back	A back-to-back occurs when any service point for this service agreement was previously linked to a different service agreement that was stopped on the same date that the new service was started (i.e., there is no gap in the service). If a back-to-back is detected, the consumption period start date is calculated by adding 1 day to the SA start date. If no back-to-back is detected, the start date of the consumption period is the SA start date.	You want to flexibly handle consumption period calculation. If you start customers on the same date as the stop date of the previous customer, billing does not include the SA start date in the consumption period. However, if you start a new customer one day (or more) after the stop date of the previous customer, billing includes the first day of the service agreement in the consumption period.
Include First Day	The start date of the consumption period is the service agreement start date. (The SA start date is always included in the consumption period.)	You want to always include the first day AND you will never encounter a back-to-back situation.

The example below shows how the consumption period would be calculated with the various options for a customer who starts service on January 1.

	First Bill **Meter Read: Jan 31** **Bill Segment Period: Jan 1 to Jan 31**	Second Bill **Meter Read: Feb 28** **Bill Segment Period: Jan 31 to Feb 28**	Third Bill **Meter Read: Mar 31** **Bill Segment Period: Feb 28 to Mar 31**
Consumption period using Add 1 Day Always	Jan 2 to Jan 31 (**30 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is detected	Jan 2 to Jan 31 (**30 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)

Copyright © 2026, Oracle and/or its affiliates.

Consumption period using Add 1 Day for Back-to-back when back-to-back is NOT detected	Jan 1 to Jan 31 (**31 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Include First Day	Jan 1 to Jan 31 (**31 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)

There may be SA types for which the value of this flag does not affect the consumption period calculation and still other SA types where this flag is never used. For example,

- For billable charge service agreements, the consumption period is equal to the start and end dates on the billable charge and therefore this flag is not applicable.
- A sub SA either inherits the consumption period from the master SA or it uses billable charges. As a result, billing does not use this flag.
- For some service agreements, the charges on the rate are not affected by the consumption period. For example, if you have a customer with a simple meter and a simple usage-based charge, billing calculates the amount of consumption between the start reading and end reading and applies the rate (i.e., the number of days in the consumption period doesn't impact the charges in some rates).
- Some service agreements are not billed, for example, overpayment service agreements. For this type of service agreement and other types of service agreements that are not billed, this flag is not applicable. However, the system does not prevent a value from being entered in these cases to allow for an implementation process to use the flag if needed.

Setting this flag to an appropriate value is significant for certain types of service agreements.

- For services whose rate includes daily charges, the configuration of this flag may impact the first bill segment for the service agreement. For example, if the first bill period is October 1st through October 31st, do you consider consumption period to be 31 days or 30 days? How you want to bill the customer on the first bill determines how you set this flag.
- For interval billing service agreements, the interval usage recordings typically begin on the first day of service. If you add 1 to the start date, you miss billing for intervals on the first day. In this case, you should set the value to Add 1 Day for Back-to-back.

NOT_SUPPORTED

Refer to Determine the Consumption Period for more information.

Processing Sequence Considerations

You may have customers with a complex collection of contracts such that the calculation for one bill segment relies on information calculated by another bill segment for the same account. For example, perhaps you need to process your bill segments as follows:

- Step 1: Calculate bill segments for all the account's "single site" service agreements (i.e., each service agreement related to a single premise)

Copyright © 2026, Oracle and/or its affiliates.

- Step 2: Calculate the bill segment for additional charges for the "head office" service agreement where the charges are based on the aggregated consumption of all premises from all bill segments (calculated in the first step).

To create the "head office" bill segment for the account, you must control the order in which the system creates the bill segments for each service agreement.

The SA type allows you to indicate a billing processing sequence that controls the order in which the service agreements are processed. The processing sequence is optional and service agreements are processed in ascending order of their SA type's billing processing sequence. As a result, SA Types with a processing sequence of zero are processed first, then 1, then 2, etc.

> **Note**
>
> If you have sub SAs linked to a master SA, the billing processing sequence is used first to order the creation of bill segments for the master SAs. If you populate a processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other. Refer to Designing Your SA Types And Start Options For Sub SAs for more information.

The billing processing sequence also controls the order of service agreements in the following other processes:

- Execution of pre bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the pre bill completion algorithms on its SA type are processed in the order of the algorithm's sequence.
- Execution of bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the completion algorithms on its SA type are processed in the order of the algorithm's sequence.
- Interval Data Creation. For interval service agreements linked to interval profiles with profile creation algorithms defined, the system processes each service agreement in the processing sequence order. Within each service agreement, the data creation algorithms are processed in the order of the creation priority on the profile type.

Designing Prepayment Billing Options

This section provides guidelines describing how to design service agreements that handle smart meter prepaid billing.

When a customer is subject to prepayment, normal cycle-based billing is not used to calculate the bill segments for their service. Rather, a prepay billing (PPB) process creates bill segments frequently (for example, daily) and periodically requests funds to maintain an adequate payoff balance. Bills will only be used to periodically inform the customer of the various financial transactions that have occurred since the last bill was produced.

Implementing prepayment billing requires the configuration of the following objects:

- SA Type
- Adjustment Types
- Bill Segment Type

Copyright © 2026, Oracle and/or its affiliates.

- Service Task Type

These configuration tasks are described below.

> **Note**
>
> For additional information, see the detailed descriptions in the application for the C1-PrepayBillerTaskType and C1-PrepayBillerTask business objects.

SA Type for Prepay Billing

To configure a prepay billing SA Type, create a new SA type with the following attributes:

- Set the Special Role flag to **Bill Determinants Required.** The Prepay Option should be set to **Prepaid Smart Meter.**
- Specify the SA Creation system event with the algorithm CI_CREATEPPB to create the service agreement's prepay biller.
- Specify the Payment Freeze system event with the algorithm STPZ-RMVC to set current amount to zero on a payment.
- If required, specify the Bill Completion system event with an algorithm of the type C1-CREPPBBM to add a bill message that informs an end customer of their prepaid charges for the period. You may need to create an algorithm of this type if it does not exist in your system.
- **Eligible for Budget** should be set to false.
- Reference a new **Prepay Bill Segment Type**, which is described below.

The following adjustment types must also be defined on the prepay SA type:

- **Adjustment Type (Xfer)** specifies the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement
- **Adjustment Type (Current=0)** specifies the type of adjustment used to set the prepaid current balance to zero after debt has been transferred
- **NSF Adjustment Type** specifies the type of adjustment used to levy an NSF charge. The NSF Adjustment Type is described in greater detail below.

The new SA types must be added to the data value mapping between CCB and MDM. This is to enable the synchronization of SAs of this type to MDM. The new CCB SA types can be mapped to existing US types in MDM. For additional information about this configuration, please see the integration documentation.

Adjustment Types for Prepay Billing

- **Funds Request Adjustment Type:** This adjustment type captures the type of adjustment used to request more prepaid funds. This adjustment type is specified on the prepaid biller task type. Specify the following algorithms on this adjustment type:
  - **Adj. Financial Algorithm** should reference the Adjustment FT creation algorithm ADJT-CA (Payoff=0/Current=Adj Amount (No GL)).
  - **Adjustment Freeze Algorithm** should reference an algorithm of the type C1-PPBADJFRZ (Set Prepaid Funds Request FT Details). You may need to create an algorithm of this type if it does not exist in your system.
- **NSF Adjustment Type:** For prepaid customers on autopay, when a user cancels an autopay tender the cancel reason must indicate that an NSF charge should be levied. The system invokes the NSF Charge algorithm specified on the tender's account's customer

Copyright © 2026, Oracle and/or its affiliates.

class which creates the NSF adjustment on the appropriate SA. The charge is levied using the NSF Adjustment Type specified on the SA's SA type. This adjustment type must reference the new adjustment freeze algorithm that will disable automatic payments on the PPB. This algorithm must be based on the algorithm type C1-DISPPBAP (Disable PPB's Automatic Payment). You may need to create an algorithm of this type if it does not exist in your system.

Bill Segment Type Required for Prepay Billing

Configure a new bill segment type for prepaid service agreements. This bill segment type should have the following attributes:

- **Create Algorithm** should be set to C1-BSBS-UR to create bill segment using a usage request.
- **Financial Algorithm** should be set to a new algorithm with algorithm type C1-NEM-GL (Payoff Amt = Bill Amt / Current Amt = 0 (GL affected)).You may need to create an algorithm of this type if it does not exist in your system.
- **Get Consumption Algorithm** should be set to C1-BSGC-USG to get bill segment consumption using a usage request.

Service Task Type for Prepay Billing

Configure a new service task type for prepay billing. This task type should reference the Prepay Biller (PPB)Task Type Business Object (C1-PrepayBillerTaskType). The task type must be specified on the new prepay billing SA creation algorithm. The task type captures the adjustment type used when an adjustment is created to request additional funds from the customer. Ensure that this adjustment type references the adjustment freeze algorithm (C1-PPBADJFRZ) that populates the financial transaction's arrears date.

SA Types And The Financial Design

In this section, we provide an example of how our SA Types map to Bill Segment Types, Payment Segment Types, and Adjustment Profiles. This example is meant to help solidify the power of the financial model, it is not necessarily indicative of how your specific implementation will look.

> **Warning**
>
> If you are not comfortable with the topics described in Defining Financial Transaction Options, the following table will not make sense.

Division/SA Type	Distribution Code	Bill Segment Type	Payment Segment Type	Adjustment Profiles
CA/G-RES	A/R-UTIL	SP-RATED	NORMAL	BALXFER, MISCFEES, BUDGET
CA/G-COM	A/R-UTIL	SP-RATED	NORMAL	BALXFER, MISCFEES
CA/G-IND	A/R-UTIL	SP-RATED	NORMAL	BALXFER, MISCFEES

CA/OVR UNDR	EXP-OV/UND		NORMAL	
CA/OVERPAY	A/P-OVER		NORMAL	BALXFER
CA/SUSPENSE	A/R-SUSP		NORMAL	
CA/NBB	A/P-OVPY		NORMAL	BALXFER, MISCFEES, NBB

Copyright © 2026, Oracle and/or its affiliates.

If you operate in a deregulated environment, you will also have additional SA types as described under Designing Your SA Types And Start Options For Sub SAs and Designing SA Types For Service Provider Financial Settlements you may have additional SA types.

Setting Up SA Types

In the previous section, Designing SA Types, we presented a case study that illustrated a mythical organization's SA types. In this section, we explain how to use the windows on the SA Type window group to maintain your SA Types.

> **Note**
>
> **When a new SA type is added.** When you add a SA type whose service agreements use service points, you must update the respective SP types if the new SA type is defaulted when service is initially started at the service points of a given SP type. Refer to SP Type - SA Type for more information.

- Configuring Cline in VS Code
  Cline is an open-source AI coding assistant for Visual Studio Code (VS Code) that supports MCP. Follow these steps to configure Cline for SQLcl MCP Server.
- SA Type - Detail
- SA Type - Billing
- SA Type - Rate
- SA Type - SP Type
- SA Type - Adjustment Profiles
- SA Type - C&C
- SA Type - Billable Charge Template
- SA Type - Characteristics
- SA Type - Algorithms
- SA Type - Billable Charge Overrides
- SA Type - Contract Option Type
- SA Type - Interval Info
- SA Type - NBB Recommendation Rule
- Setting Up Start Options
- Start Option Merge

Configuring Cline in VS Code

Cline is an open-source AI coding assistant for Visual Studio Code (VS Code) that supports MCP. Follow these steps to configure Cline for SQLcl MCP Server.

1. Download and install VS Code. See Download Visual Studio Code.
2. Install the Cline extension.

Copyright © 2026, Oracle and/or its affiliates.

a. Open VS Code, and click **Extensions** on the sidebar.

b. Enter `cline` in the search field. When it appears, click **Install**, then click **Trust Publisher and Install** to proceed.

The extension is installed and appears on the sidebar.

3. Configure API keys and select your preferred AI model.

> **Note**
>
> This step details API configuration for the first installation of Cline. After installation, you can update the API key or model anytime by clicking **Settings** in the top-right corner of the Cline extension view.

a. Click **Cline** on the sidebar.

b. Click **Use your own API key**.

c. Select your API provider, enter related details, and click **Let's go!**

The API Configuration page opens.

d. In the **Model** field, select the required AI model, and click **Save**.

4. Add the SQLcl MCP Server to Cline.

a. With the **Cline** extension selected on the sidebar, click **Manage MCP Servers** below the prompt box.

b. In the resulting dialogue, click **Settings**.

The MCP Servers page opens, with the **Installed** tab selected.

c. Click **Configure MCP Servers**.

The `cline_mcp_settings.json` file opens in the VS Code editor.

d. In the settings file, add a JSON configuration snippet in the following format. Replace `PATH/bin/sql` with the absolute path of your SQLcl installation, and press **Ctrl+S** on your keyboard to save the file.

```
{
   "mcpServers": {
    "sqlcl": {
            "command": "PATH/bin/sql",
            "args": ["-mcp"],
            "disabled": false
        }
    }
}
```

You'll now see the SQLcl MCP Server and its tools listed on the MCP Servers page.

e. Click **Done** on the MCP Servers page.

5. If necessary, restart VS Code for changes to take effect.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Detail

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Detail** page to define additional details about a given SA type.

Description of Page

Turn on **Display As Alert** if Control Central should display an alert if an account has a service agreement of this type that isn't Closed or Canceled. If this switch is on, also enter the **Alert Information** to appear on Control Central. We recommend only using this feature on unusual SA types (e.g., payment arrangements, write-offs) so that a CSR is not presented with an alert for every SA type.

If this SA Type is used for any of the **Special Roles**, defined in the dropdown, indicate which one. Valid values are: Billable Charge, Cash Deposit, Interval, Loan, Non-Billed Budget, Payment Arrangement, Write Off, Bill Determinants Required. This information is used on windows with functionality that can only be used by service agreements used for specific roles. For example, the Billable Charge window group can only reference Billable Charge service agreements.

If Special Role is Cash Deposit, you must define the **Deposit Class** of the deposit. You should also define a **Deposit Class** on every SA type to which a given deposit can be distributed.

NOT_SUPPORTED

Refer to What Do Deposit Classes Do? for more information.

If the Special Role is Loan, you must also define the following fields:

- Use the **Interest Bill Factor** to define the bill factor code for the loan interest rate.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the **Loan A/R Distribution Code** to define the distribution code to be used when posting the short-term receivable amount to the general ledger (the normal distribution code is used for the long-term receivable). If the normal distribution code is the same as the **Loan A/R Distribution Code**, the SA type does not differentiate between long- and short-term receivables. If the two distribution codes are different, the SA type differentiates between long- and short-term receivables.

NOT_SUPPORTED

Refer to Defining Loan Options for more information about **Interest Bill Factor**, **Override Interest** and **Loan A/R Distribution Code**.

If the Special Role is Non-Billed Budget , you must also define the following:

Copyright © 2026, Oracle and/or its affiliates.

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to the transfer accumulated credit from the Non-Billed Budget SA to the SAs covered by the Non-Billed Budget when the account is billed or the Non-Billed Budget SA is stopped.
- Use the **Non-Billed Budget Monitoring** to specify whether the Non-Billed Budget is monitored by the account debt monitor.

If the SA type is defined as Eligible for Non-billed Budget, you must also define the following:

- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the service agreement's current balance to zero when a service agreement of this type is linked to an active, monitored Non-Billed Budget.

If the Special Role is Payment Arrangement and you have not enabled Use Alternate PA Creation Logic, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the payment arrangement service agreement.
- Set **Use Alternate PA Creation Logic** if your payment arrangement SA Types share a debt class with other SA Types. When this is set, the current balance on the transfer adjustment on the payment arrangement SA is set to zero instead of using the below adjustment type to set the current balance to zero. When payment arrangements are in their own debt class, the additional credit adjustment offsets the transfer adjustment. This results in an offsetting credit and debit in the payment arrangement debt class and a single credit on the non-payment arrangement debt class. However, when a single debt class is used, the two credits inaccurately impact the way debt age (arrears) is calculated and presented. Using the alternate PA creation logic ensures that debt age is calculated and displayed accurately when a single debt class is used.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the payment arrangement's current balance to zero after funds have been transferred.

If the Special Role is Write Off, you must also define the following adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the uncollectable service agreements to the write off service agreement.

> **Note**
>
> It may be important to your organization to track the original source of debt that is being written off. The system is delivered with three characteristic types: C1-WODST, C1-WOCHT, and C1-WOCHV that can record the distribution code, characteristic type and characteristic value from the FT GL(s) being written off onto the write off adjustment. To enable this logic, specify these characteristic types as allowable characteristic types on your write off transfer adjustment type.

If the Prepay Option is **Prepaid Smart Meter**, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the prepaid current balance to zero after debt has been transferred.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

The **Stop Option** can be used to automatically stop a service agreement when all other service agreements of an account are stopped. Valid values are: Automatically Stop SA. When all service point related service agreements of an account are stopped then all additional service agreements where the **Stop Option** is set to Automatically Stop SA will also be stopped. This is useful, for example, with charitable contribution service agreements. The charity service agreement should be stopped when all utility related services are stopped.

> **NOT_SUPPORTED**
>
> Refer to The Lifecycle of a Service Agreement for more information on the **Stop Option.**

Turn on **One Time Charge** if this SA type is used for one-time invoices. When a one-time invoice service agreement is created, the system sets the stop date of the SA to be equal to the start date.

Turn on **Sub SA** if this SA type is used to define the business rules for sub service agreements.

> **NOT_SUPPORTED**
>
> Refer to Sub Service Agreements for more information about sub service agreements.

Renewal of SAs of this type may be Optional, Not Allowed or Required depending on your business processes. If renewal is not allowed, the SA expires on the expiration date. Renewal treatment is an important consideration for SAs that require an expiration date, such as non-billed budget SAs.

If renewal is required or optional, specify the **Days Before Expiration for Renewal**. Note that currently this is only used by Non-Billed Budgets to calculate the renewal date based on the expiration date.

If the Special Role is Non-billed Budget, **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

> **NOT_SUPPORTED**
>
> Refer to Credit and Collections and Non-Billed Budgets for more information about monitoring Non-Billed Budgets.

Set **Eligible for Payment Arrangement** to Eligible if this SA type can be included in a payment arrangement.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This is automatically set to Ineligible on SA types with a Special Role of Payment Arrangement.

Where Used

The alert information is used by Control Central to alert a CSR when unusual service agreements exist for an account. Refer to Control Central - Search for more information.

Only SA types designated as being Billable Charge may have billable charges linked to them. Refer to Maintaining Billable Charges for more information.

Only SA types designated as being Cash Deposit are processed by the various deposit-related background processes (e.g., interest calculation, automatic refund, etc.). Refer to The Big Picture Of Deposits for more information.

Only SA types designated as being Interval may define Contract Option Types, Profile Relationship Types and TOU Map Types. Refer to Designing Your SA Interval Billing Options for more information. This role also ensures that a service agreement of this type defines the cutoff time and start day option required by billing. Refer to Start and End Times for Billing for more information.

Only SA types designated as Loan are used to define the loan terms for a loan SA. Refer to **Loans** for more information.

Only SA types designated as Non-billed Budget may be used to set up Non-Billed Budgets. Refer to **Non-Billed Budgets** for more information.

Only SA types designated as being Payment Arrangement may be used on the payment arrangement window group. Refer to Setting Up Payment Arrangements for more information.

Only SA types designated as being Write Off may be specified as the write off SA type on distribution codes. Refer to Setting Up Distribution Codes for more information.

Only service agreements whose SA type is designated as being Write Off appear on the Write Off SAs query. Refer to Write Off - Write Off SAs for more information.

SA Type - Billing

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Billing** page to define how the system manages bill segments for service agreements of a given SA type.

Description of Page

Turn on **Eligible for Billing** if the system should create bill segments for service agreements of this type. This will typically be turned on for all service agreements except for those used to hold write-off amounts or to levy one-off adjustments.

Define the minimum number of days a bill segment (other than the final segment) must span using **Minimum Days for Billing**. This is useful to prevent initial bill segments that span only a few days.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about minimum days, refer to Preventing Short Bill Segments.

Select the **Bill Segment Type** that controls both how bill segments for this SA Type will be created and how the related financial transaction affects the general ledger and the customer's debt.

NOT_SUPPORTED

For more information about bill segment types, refer to Setting Up Bill Segment Types.

Use **Default Description on Bill** to define the verbiage that should print on the customer's bill.

Note

Rates overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a rate. Why? Because the description that appears on the bill segment is defined on the rate schedule's rate version calculation group.

Billable charges overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a billable charge. Why? Because the description that appears on the bill segment is defined on the billable charge.

Use the **Billing Processing Sequence** if you need to control the order in which service agreements linked to this SA type are processed by billing and interval data creation processes.

NOT_SUPPORTED

Refer to Processing Sequence Considerations for more information.

Use **Bill Print Priority** to define the order in which the SA type's bill segments should appear on bills (relative to the other SA types that appear on a bill).

Note

The values for this field are customizable using the Lookup table. This field name is BILL_PRT_PRIO_FLG.

Use **Max Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, an operator truly

Copyright © 2026, Oracle and/or its affiliates.

intends to send the bill out, they should regenerate the bill. Refer to How To Correct A Bill Segment That's In Error for more information.

> **Warning**
>
> The value entered in this field will DEFAULT onto service agreements of this type when they are first created. An operator may change the default value on a service agreement in case a specific customer has unusually high bills that continually error out. It's important to be aware that if you change the value of High Bill Amount on an SA type and there already exist service agreements of this type, the existing service agreements will contain the original value (the new value on the SA type will not be propagated on the existing service agreements).

Use **Graph Unit Of Measure** to define the unit of measure of the graphed consumption on the bill (if any).

Turn on **Allow Estimates** if the system is allowed to generate estimated consumption if meter reading(s) cannot be found at billing time. This value is defaulted onto service agreements and can be overridden on an individual service agreement.

> **NOT_SUPPORTED**
>
> For more information about estimated consumption, refer to The Theory Behind Consumption Estimation.

Turn on **Characteristic Premise Required** if a characteristic premise must be linked to the service agreement when the service agreement is activated. The characteristic premise is used to define the taxing authorities associated with the service agreement's bill segments. It is also used to identify where the service agreement's service is located on various windows.

> **NOT_SUPPORTED**
>
> For more information about how characteristic premise is used, refer to **An Illustration Of A Bill Factor And Its Characteristics**.

Use the **Initial Start Date Option** to control how billing should calculate the consumption period for the very first bill for service agreements of this type. This field is not applicable for sub SA types or SA types with a special role of Billable Charge. Valid values are Include First Day, Add 1 Day Always and Add 1 Day for Back-to-back. Refer to Initial Consumption Period Considerations for more information.

Non-metered service agreements may have the end date of their bill segments defined on a user-maintained bill period schedule. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter). If this SA type should be billed like this, select Use Bill Period in the **Use Calendar Billing** field. When this option is used, you must define the **Bill Period** whose schedule defines the bill segment end dates.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about bill period schedules, refer to Designing Bill Periods. For more information about other bill end date methods, refer to Ways To Control The End Date Of A Bill Segment.

Instead of the Use Bill Period method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16th of some month, the ongoing bill segments will start on roughly the 16th of each month. This option is frequently used to bill for garbage or cable service. If this SA type should be billed like this, select Anniversary Future Billing or Anniversary Past Billing in the **Use Calendar Billing** field. When either option is used, you must define the **Anniversary Bill Frequency**. This frequency defines the amount of time between bill segments.

NOT_SUPPORTED

For more information about anniversary billing, refer to Using The Anniversary Method. For more information about other bill end date methods, refer to Ways To Control The End Date Of A Bill Segment.

Total Bill Amount indicates whether service agreements of this type can use the total amount to bill field on the service agreement page. Valid values are Not Allowed and Required. Only SA types used to bill for deposits or loans should have this field set to Required.

If Required is selected, you must enter the **Total Amount To Bill Label**. The **Total Amount To Bill Label** defines the label that prefixes the total bill amount on the service agreement page for service agreements of this SA type.

NOT_SUPPORTED

For more information about total amount to bill and deposit service agreements, refer to Total Amount To Bill. For more information about total amount to bill and loan service agreements, refer to **Setting Up The System To Enable Loans** .

Recurring Charge indicates whether service agreements of this type can use the recurring charge field on the service agreement window. Valid values are Not Allowed, Optional and Required. If either Optional or Required are used, you must enter:

- **Recurring Chg Amt Label**. This defines the label that prefixes the recurring charge amount on the service agreement window for service agreements of this SA type.
- **Recurring Charge Frequency**. This defines the following:
  - Specifies the frequency at which the Recurring Charge Amount specified on service agreements of the SA Type is to be billed.
  - Serves as the basis for proration of the Recurring Charge Amount.
  - Specifies the frequency at which service agreements of the SA Type without a rate and/or meters will be billed.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about how to use the recurring charge information, refer to Charitable Contribution Segmentation, Merchandise Segmentation - Installment Billing, Deposit Segmentation - Installment Billing, Payment Arrangement Segmentation, Budget Billing Segmentation, The Terms Of A Loan Are Stored On A Service Agreement.

Turn on **Eligible for Budget** if service agreements of this type can participate in budget billing. If this switch is turned on, then you must define the **Adj**ustment **Type (Synch Current)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type when a budget is cancelled. (The Adjustment Type (Synch Current) field is on the main page.)

NOT_SUPPORTED

Refer to Budget Billing for more information about budgets in general. Refer to Budget Billing Segmentation and Designing and Defining Budget Plans for more information.

Set the **Eligible for Non-Billed Budget** flag to Eligible for Non-Billed Budget if you want SAs of this type to be eligible to be covered by a Non-Billed Budget. If this flag is set to Eligible for Non-Billed Budget, you must also define the **Adjustment Type (Current = 0)** field (on SA Type - Detail).

NOT_SUPPORTED

Refer to Current Amount For SAs Covered By A Non-Billed Budget and SA Types for SAs Covered by Non-Billed Budgets for more information.

- Require Total Amount Switch versus Bill Segment Algorithm
- Allow Recurring Charge Switch versus Bill Segment Algorithm

Require Total Amount Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's required total amount switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Require Total Amount Switch: Not allowed	SA Type Require Total Amount Switch: Required

Copyright © 2026, Oracle and/or its affiliates.

Apply Rate	Metered services. Lamp services. Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	N/A
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	N/A	Deposit installment plans.
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices. Pass through charges	N/A
Loan	N/A	Loans.

Allow Recurring Charge Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's allow recurring charge switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	**SA Type Recurring Charge Switch:** Not allowed	**SA Type Recurring Charge Switch:** Optional	**SA Type Recurring Charge Switch:** Required
Apply Rate	Metered services - no budget Lamp services Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	Metered services - budget optional	Metered services - budget required
Recurring Charge With Auto Stop	N/A	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!
Recurring Charge For Amount To Bill	N/A	Deposit installment plans. SEE NOTE!	Deposit installment plans. SEE NOTE!
Recurring Charge	Charitable contributions	N/A	N/A

Copyright © 2026, Oracle and/or its affiliates.

Billable Charge	One time invoices. Pass through charges	N/A	N/A
Loan	N/A	N/A	Loans.

> **Note**
>
> Most recurring charge SA types require a recurring charge amount on their service agreements. However, the above matrix indicates you can have recurring charge SA types where this value is optional. Why? A special algorithm exists in billing that says if the recurring charge amount is 0 (zero) the system will bill the remaining payoff balance or total amount to bill. This algorithm exists so that you can easily bill the amount in one lump sum (i.e., don't bill it in installments).

Where Used

The billing information is used when the system creates a bill segment for service agreements of this type.

SA Type - Rate

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Rate** page to define the rates that may be referenced on service agreements of a given type.

Description of Page

Turn on **Rate Required** if the bill segment creation algorithm for the SA type expects a rate schedule to be referenced on service agreements of this type.

> **NOT_SUPPORTED**
>
> For more information, refer to **Rates** .

Define the date that the system uses when selecting an effective-dated rate (from the service agreement's rate history) using the **Rate Selection Date**. Selecting Bill Start Date causes the system to use the rate effective on the first day of the bill segment's consumption period. Selecting Bill End Date causes the system to use the rate effective on the last day of the bill segment's consumption period. Selecting Accounting Date causes the system to use the rate effective on the accounting date associated with the bill.

When a rate changes within a bill segment's consumption period, and CCB and MDM are integrated, the period may be divided into separate usage periods – one for each active rate schedule during that period. The usage periods and their related consumption (or billable quantities) are then prepared for billing, and the rate schedule calculations are applied to their associated periods.

This feature is possible if the MDM usage subscription type is configured with the base Dynamic Usage Group Determination algorithm, which determines the applicable usage group for each effective rate schedule. This algorithm requires that the CCB rate schedule has usage

Copyright © 2026, Oracle and/or its affiliates.

group extendable look-ups configured for the rate schedule and device configuration type combinations.

A typical use case is when there is a smart meter rollout in the middle of billing period and there are rate schedule changes that coincide with the meter exchange date. The usage group that is tied to the old meter will have rules that calculate scalar consumption, and the usage group that is tied to the new meter will have rules that calculate interval consumption. The end result is that the customer is billed with scalar consumption for the period where old meter was installed, and billed with interval consumption for the period where new meter is installed.

If the Contract Management module is not turned off, which includes umbrella agreement management, indicate the **Rate Source**. Check SA Only indicates that the rate schedule currently in effect for the service agreement should always be used. Check TOS First, then SA indicates that if the service agreement is linked to a terms of service record, the service agreement's rate could be overridden by one linked to the terms of service record.

The information in the **Rate Schedules** collection defines the rates that may be referenced on service agreements of this type. The following fields are required for each SA Type:

Rate Schedule Specify the rate schedule; its description is displayed adjacent.

Use As Default Turn on this switch for the rate to be defaulted on new service agreements.

- Rate Required versus Bill Segment Algorithm

Rate Required versus Bill Segment Algorithm

The following table shows appropriate combinations of the SA type's rate required switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not applicable. Otherwise, we list typical types of service agreements that will use a combination. Be aware that no cross validation exists between the rate required switch and the bill segment creation algorithm when setting up the SA type.

Bill Segment Create Algorithm	SA Type Rate Required Switch: Not allowed	SA Type Rate Required Switch: Rate required on SA
Apply Rate	N/A	Metered services. Lamp services. Misc item services. Company usage.
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	Deposit installment plans.	N/A
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices.	Billable charges that require a rate to add-on extra charges (like taxes) or billable charges where the consumption is interfaced and the system is responsible for calculating the charges.

Copyright © 2026, Oracle and/or its affiliates.

Loan	Loans.	N/A

Where Used

This information is used to default and validate the rate specified on a service agreement. Refer to Service Agreement - Rate Info for more information.

SA Type - SP Type

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **SP Type** page to define the service point types that may be referenced on service agreements of a given type.

Description of Page

Turn on **Service Points Required** if at least one service point should be linked to service agreements of this type in order to properly bill the service agreements.

The information in the **SP Types** collection defines the service point (SP) types that may be referenced on this SA type's service agreements. The following fields are required for each SA Type:

SP Type Specify the SP type; its description is displayed adjacent.

> **NOT_SUPPORTED**
>
> For more information about SP types, refer to Designing SP Types.

Where Used

This information is used to validate the types of service points linked to a service agreement. Refer to Service Ag reement - SA / SP for more information.

SA Type - Adjustment Profiles

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Adj Profile** page to define the adjustment profiles that define adjustment types that may be referenced on service agreements of a given type.

Description of Page

Define the **Adjustment Type Profiles** that, in turn, define adjustment types that may be referenced on service agreements of a given type.

> **NOT_SUPPORTED**
>
> For more information about adjustment type profiles, refer to Setting Up Adjustment Type Profiles.

Copyright © 2026, Oracle and/or its affiliates.

Where Used

This information is used to validate the adjustments linked to the service agreement. Refer to Adjustment - Main Information for more information.

SA Type - C&C

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **C&C** page to maintain attributes that affect how the system severs the service agreement when collection attempts fail.

> **NOT_SUPPORTED**
>
> Refer to Designing Your Severance Procedures for more information.

Description of Page

Select the **Debt Class** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class.

Select the **Write Off Debt Class Code** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class during write-off processing.

> **Note**
>
> **Write Off Debt Class vs. Regular Debt Class.** It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt. Refer to The Big Picture Of Write Off Processing for more information.

The information in the **Severance Criteria** collection defines the SA Type's severance criteria. Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer or premise. For example, you may have a different severance process if the customer has life support equipment.

> **NOT_SUPPORTED**
>
> The following information is not intuitively obvious. Refer to Designing Your Severance Procedures for more information.

The following fields are required for each instance:

Copyright © 2026, Oracle and/or its affiliates.

Priority The priority controls the order in which the system determines if the severance process should be applied (the first severance process whose algorithm applies is used). Higher priorities are checked before lower priorities.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: Collection Class Control, Severance Criteria, Write Off Controland Workflow Process Profiles .

Severance Criteria Algorithm Select the algorithm to be used to check if the severance process should be initiated for service agreements of this type. If a condition is met, a severance process is created using the associated severance process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines if the severance of a service agreement should be processed using the associated **Severance Process Template**.

> **Important**
>
> You must have at least one entry in this collection otherwise the system will not start a severance process when a service agreement of this type needs to be stopped due to non payment. This entry should have the lowest priority code and should reference a **Severance Criteria Algorithm** that references the SV CRIT DFLT algorithm type.

Severance Process Template Specify the severance process template to use to sever the service agreement; its description is displayed adjacent.

Where Used

The debt class has multiple uses:

- The system summarizes an account's debt by debt class on Account - Main Information and Account - Financial Balances.
- Debt class is one component that controls how the system analyzes an account's overdue debt (the others are the account's collection class and currency). Refer to Different Collection Criteria For Different Customers And Different Debt for more information.
- Write off debt class is one component that control how the system writes off an account's stopped service agreements. Refer to Different Write-Off Criteria For Different Customers And Different Debt for more information.

The severance criteria are used when a collection event is activated that indicates that service should be severed.

SA Type - Billable Charge Template

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **BC Template** page to define the billable charge templates that can be used on service agreements of a given type.

> **Note**
>
> **Only billable charges have billable charge templates.** Only service agreements that are defined as Billable Charges (in the Special Role on the Details window) may use the grid on this window.

Description of Page

The information in the **Billable Charge Template** collection defines the SA Type's permissible billable charge templates. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge. The following fields are required for each template:

Billable Charge Template Specify the billable charge template. Its description is displayed adjacent.

Use As Default Turn on this switch for the template to be defaulted on new billable charges linked to service agreements of this type (if any).

> **NOT_SUPPORTED**
>
> For more information about billable charge templates, refer to Setting Up Billable Charge Templates.

Where Used

This information is used to limit the billable charge templates that can be used for a given SA type.

SA Type - Characteristics

To define characteristics common to all service agreements of a given type, open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define a **Characteristic Type**, **Sequence**, and **Characteristic Value** common to all service agreements of this type.

> **Note**
>
> You can only choose characteristic types defined as permissible on a SA Type record. Refer to Setting Up Characteristic Types & Their Values for more information.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Algorithms

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for service agreements of a given type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

> ⚠ **Warning**
>
> These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description

Copyright © 2026, Oracle and/or its affiliates.

Bill Completion	Optional	These algorithms are executed whenever a bill is completed for an account that contains a non-canceled service agreement of this type. The following situations necessitate the definition of a completion algorithm on an SA type: - As explained under Technical Implementation of A/R Transfer and Technical Implementation of Routing Billable Charges To Service Providers, when a bill is completed, the system needs to set up the data necessary to interface any "master" SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate algorithm on the master SA types. - As explained under Billing For SAs Covered By The Non-Billed Budget, when a bill is completed for accounts that have a Non-Billed Budget SA, the system needs to distribute the Non-Billed Budget's credit balance to the covered SAs. The system will only do this if you specify an appropriate algorithm on the NBB SA types. - As explained under Overpayment Segmentation, when a bill is completed, the system may apply an excess credit from a prior overpayment to an account's service agreements. **Note**. Algorithms of this type are called for all non- Canceled service agreements, regardless of whether or not they are billed. If your algorithms should only be processed under certain conditions (for example, only process this algorithm for Active service agreements), then it is the responsibility of the algorithm to check the conditions before continuing.

Copyright © 2026, Oracle and/or its affiliates.

Bill Eligibility	Optional	These algorithms are executed during billing and allow logic to be introduced to check additional criteria to determine if an SA is eligible for billing.
Break NBB SA	Optional	These algorithms are executed when a Non-Billed Budget is manually stopped via the **Non-Billed Budget maintenance page** . Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.
Break Pay Arrangement	Optional	These algorithms are by executed by severance events when the event is created for payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place when a customer breaks a payment arrangement. Refer to Monitoring Payment Arrangements for more information about breaking payment arrangements.
Budget Eligibility	Optional	These algorithms are executed when determining if a service agreement is eligible for budget. Algorithms of this type are only applicable on SA types that are marked as eligible for budget and may be used to override that setting and indicate that the service agreement is not eligible. For example, maybe service agreements in a certain rate are not eligible. Or perhaps service agreements with a given characteristic value are not eligible.
Cut Process Rule	Optional	These algorithms are executed to create a cut process for service agreements of this type. Refer to The Big Picture Of Cut Processes for more information.

Copyright © 2026, Oracle and/or its affiliates.

FT Freeze	Optional	These algorithms are executed whenever a financial transaction is frozen that is linked to a service agreement of this type. The following situations necessitate the definition of an FT freeze algorithm: - As explained under Technical Implementation of Routing Consumption To Service Providers, when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. - As explained under Technical Implementation of Paying The Service Provider, when a financial transaction (FT) is frozen that is associated with a sub SA, the system must check if this FT should trigger the "payment" of a service provider. If so, it has to create an adjustment to increase how much we owe the service provider. The system will only do this if you specify an appropriate FT Freeze Algorithm on the sub SA types.

Copyright © 2026, Oracle and/or its affiliates.

High Bill Amount	Optional	This algorithm type checks for high bill amounts during batch billing. A bill threshold amount can be defined on a service agreement. By default the system compares this threshold amount to the bill segment amount during batch billing. If the bill segment amount exceeds the given threshold value, a bill error is generated. No proration takes place on the threshold amount if the bill segment's consumption period falls outside of the rate frequency's normal period. This algorithm may be used to override the default system behavior. It will prorate the SA's bill threshold amount before comparing it to the batch bill segment amount if the consumption period falls outside of the rate frequency's normal period.
Landlord Reversion	Optional	These algorithms are used to create, update or cancel a service agreement for a landlord when service is started, stopped or updated for a premise that references a landlord agreement. Algorithms of this type are called: - When starting a new SA (start initiation) - When stopping an SA (stop initiation) - When canceling a pending start SA - When changing the stop / start dates of back-to-back service agreements
Loan Interest Charge	Optional	These algorithms are executed whenever the interest charge needs to be calculated for a loan, such as when the loan amortization schedule is created and when a bill segment is created for a loan SA. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.

Copyright © 2026, Oracle and/or its affiliates.

Loan Periods and Amount	Optional	These algorithms are executed whenever a user clicks the Calculate button on **Loan - Main** or on the Start SA Confirmation dialog for a loan SA. It calculates either the number of periodic payments or the payment amount (depending on whether the user specifies the number of payments or the payment amount as input). This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Loan Schedule	Optional	These algorithms are executed whenever the system needs to create a **loan amortization schedule** for a loan, such as when you renegotiate the terms of a loan on **Loan - Main** . This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Override Proration Days	Optional	This algorithm is invoked from rate application, right after base has determined if proration applies. It is used to override base days, normal days and “is within proration window” indicator, which were determined by base logic. Only one algorithm may be plugged-in to this system event. This is available only in the calculation rule based rating engine.

Copyright © 2026, Oracle and/or its affiliates.

Payment Arrangement	Optional	These algorithms are by executed to handle the creation, breaking and canceling of payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place during the lifecycle of a payment arrangement. Refer to Monitoring Payment Arrangements for more information about payment arrangements. Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.
Payment Freeze	Optional	These algorithms are executed whenever a payment is frozen. The following situations necessitate the definition of such an algorithm: - For a loan SA, such an algorithm is required to create a frozen adjustment that transfers any credit balance resulting from an overpayment to the loan's principal balance. Refer to Defining Loan Options for more information.
Pre-Bill Completion	Optional	These algorithms are executed immediately prior to bill completion when a bill contains a bill segment for a service agreement whose SA type has such an algorithm. The following situations necessitate the definition of such an algorithm: - If you want to delete a bill segment that's in error on the last night of a bill cycle when there are other bill segments that aren't in error, use such an algorithm.

Copyright © 2026, Oracle and/or its affiliates.

Process NBB Scheduled Payment	Optional	These algorithms are executed by the NBB Scheduled Payment Processing background process whenever a scheduled payment is due. If the Non-Billed Budget SA is unmonitored, this algorithm is not called. This algorithm should be specified on Non-Billed Budget SA types to create the necessary adjustments for the Non-Billed Budget SA.
Proposal SA Acceptance	Optional	These algorithms are executed when a proposal service agreement is accepted. Refer to Enabling The Creation Of A Real Service Agreement for more information.
Proposal SA Bill Segment Generation	Optional	These algorithms are executed to generate simulated bills segments for a **proposal service agreement** . Refer to **Enabling The Generation Of Simulated Bill Segments** for more information.
Proposal SA Creation	Optional	These algorithms are executed when a **proposal service agreement** is created. Refer to **Enabling The Automatic Generation Of Billing Scenarios** for more information.
SA Activation	Optional	These algorithms are executed when a service agreement status changes from Pending Start to Active. It performs any additional activities that are necessary to activate an SA. The following situations necessitate the definition of such an algorithm: If you want to create a customer contact to indicate that a non-billed budget has been activated, use such an algorithm.

Copyright © 2026, Oracle and/or its affiliates.

SA Cancel	Optional	These algorithms are executed when a service agreement status changes to Canceled. It performs any additional activities that are necessary to cancel an SA. An example of when you may use this algorithm is that perhaps your business rules dictate that the creation of a payment arrangement should create a credit rating history transaction. When a payment arrangement SA is canceled, the credit rating should be updated with an end date.
SA Creation	Optional	These algorithms are executed when a service agreement is created. The following situations necessitate the definition of such an algorithm on an SA type: - If you want to create a To Do entry whenever a new service agreement of a given type is added, specify such an algorithm. - If you want to automatically activate SAs of a given type (instead of waiting for the background SA activation process to run), specify such an algorithm. - If you want to create a Workflow Process when a service agreement of a given type is added, specify such an algorithm.
SA Information	Optional	We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm. Plug an algorithm into this spot to override the "SA information" algorithm on installation options or the system default "SA information" if no such algorithm is defined on installation options.

Copyright © 2026, Oracle and/or its affiliates.

SA Renewal	Optional	These algorithms are executed by the Service Agreement Renewal background process whenever an SA is due for renewal or when the user clicks the **Renew** button (for **Non-Billed Budgets**). It performs any activities that are necessary to renew an SA and returns the new renewal and expiration dates for the SA.
SA Stop	Optional	These algorithms are executed whenever a service agreement's status changes from pending stop to stopped. The following situations necessitate the definition of a SA stop algorithm: - For Non-Billed Budgets to distribute any remaining credit balance from the Non-Billed Budget SA to the covered SAs, you must specify such an algorithm. - For service credit memberships that have a refundable membership fee, an SA Stop algorithm attempts to refund the fee if this is the last SA linked to the membership that is being stopped.

Copyright © 2026, Oracle and/or its affiliates.

SA Stop Initiation	Optional	These algorithms are executed whenever a service agreement's status becomes pending stop. The following situations necessitate the definition of a stop initiation algorithm on an SA type: - As explained under Finalizing Pending Stops, service agreements are normally transitioned from pending stop to stopped by a background process (or manually). For Non-Billed Budget SAs to transition to stopped automatically (without waiting for the background process), you must specify such an algorithm. **When does a SA become pending stop?** Service agreements typically become pending stop when a user initiates a request to stop service on Start Stop - Main. A severance process with an Expire SA severance event causes a service agreement to become pending stop (when the event is executed). Additionally, the Stop Expired Service Agreements background process starts the process to initiate the stop of an SA when the expiration date is on or before the process date.
Start Stop Field Work	Optional	These algorithms are executed to create the field activities necessary to start and stop service. Refer to Starting Service and Field Activities and to Stopping Service and Field Activities for a description of when algorithms of this type are called. The following situations necessitate the definition of a start stop fieldwork creation algorithm: - If a service agreement has field activities created to start and stop service at its service points, its SA type must have an appropriate start stop field work creation algorithm.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Billable Charge Overrides

The BCU2 - Create Billable Charge background process is responsible for creating billable charges for each billable charge upload staging record interfaced into the system. This process will override the values of the various switches referenced on a billable charge upload staging line if the respective service agreement's SA type has an override value for the billable charge upload staging line's billable charge line type.

> **Note**
>
> **This information is optional.** If you don't need to override the values of a **Billable Charge Line Type** you don't need to set up this information.

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **BC Upload Override** page to define override values for a given SA Type / Billable Charge Upload Staging Line Type.

Description of Page

Use the **Billable Charge Overrides** collection to define values to be overridden on billable charge lines uploaded from an external system (refer to the description above for the details). The following switches may be overridden for a given **SA Type** and **Billable Charge Line Type.**

- Use the **Show on Bill** switch to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.
- Use the **Appear in Summary** switch to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.
- Use **Memo Only, No GL** switch to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.
- Use **Distribution Code** to define the value to be defaulted into the Distribution Code on billable charge upload lines that reference this line type.

SA Type - Contract Option Type

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Contract Option Type** page to define the contract option types, which are valid for service agreements of a given type.

> **Note**
>
> **This tab may not appear.** This tab is suppressed if the interval billing Complex Billing module is turned on, or the service agreement type specifies that bill determinants are *required for billing* within the SA Type - Billing tab.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Contract Options are used by the system to define special options under which certain calculations supporting a contract's rate may be overridden or altered occasionally for specific periods of time. Refer to Contract Option Background Topics for more information.

Description of Page

If the SA Type's special role is Interval, you may define the **Contract Option Types** that are valid for contract options linked to a service agreement of this type.

NOT_SUPPORTED

For more information, refer to Setting Up Contract Option Types.

Where Used

This information is used to validate the contract options linked to the service agreement. Refer to Service Agreement - Contract Options for more information.

SA Type - Interval Info

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Interval Info** page to define the interval profile relationship types and TOU map relationship types, which are valid for service agreements of a given type.

Note

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is turned off.

Description of Page

If the SA Type's special role is Interval , you may define the **Interval Profile Relationship Types** that may be linked to service agreements of this type.

NOT_SUPPORTED

For more information about interval profile relationship types, see Designing Interval Profile Relationship Types.

If the SA Type's special role is Interval , you may define the **TOU Map Relationship Types** that may be linked to service agreements of this type.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about TOU map relationship types, refer to Designing TOU Map Relationship Types.

Where Used

The interval profile information is used to validate the interval profile relationship types linked to the service agreement. Refer to Service Agreement - Interval Info for more information.

The TOU map information is used to validate TOU map relationship types linked to a service agreement. Refer to Service Agreement - Interval Info for more information.

SA Type - NBB Recommendation Rule

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **NBB Rec'n Rule** page to define the recommendation rules that are valid for Non-Billed Budget SAs of this type.

Description of Page

If the SA Type's special role is Non-Billed Budget, you may define the **Recommendation Rules** that are valid on non-billed budget SAs of this type. Check the **Use As Default** box to indicate the default recommendation rule for service agreements of this type.

NOT_SUPPORTED

For more information about Non-Billed Budgets, refer to **Defining Non-Billed Budget Options** .

Where Used

The Non-Billed Budget recommendation rules are used to recommend the payment amount and payment schedule for Non-Billed Budget service agreements. Refer to **Maintaining Non-Billed Budgets** for more information.

Setting Up Start Options

Start options save users time and prevent data entry errors because they default many values on a service agreement (e.g., the rate schedule, recurring charge amount, contract riders, contract terms, characteristics, terms and conditions, etc. can all be defaulted onto a service agreement from a start option).

A SA type may have zero or more start options.

- A SA type without start options is usually one that has a very limited number of options. For example, if a SA type has a single valid rate and no customer-specific contract values, you don't need to setup a start option (the SA's default rate can default based on the information defined when you setup the SA type).

Copyright © 2026, Oracle and/or its affiliates.

- A SA type with multiple start options is one where many different permutations are possible. For example, a SA type that can have multiple rates and each rate can have multiple riders is a good candidate for start options (where each start option will default, for example, a specific rate and set of contract riders).

When the Start/Stop transaction is used to start service AND the service being started uses a SA type with start options, the user is asked to select one of the start options. The service agreement that's created is populated with fields from the start option.

When the Order transaction is used to start service, the user selects start options, but only indirectly. It works like this:

- A user selects a "package" of services to start service for a customer.
- A "package" contains one or more start options.
- When a user selects a package, the system creates a service agreement for each start option on the package (and defaults the information on each service agreement from the respective start option).

A start option's default values may change over time (i.e., the information on a start option is effective-dated). The start service logic uses the version of the start option that is effective on the day service starts.

Start options can cause a great deal of information to be populated on a service agreement. There are several ways to change this default information:

- A user may override this information using the Service Agreement transaction.
- If the service agreement is in the pending start state, you can use the Start/Stop - Pending SAs page to change the service agreement's SA type and/or start option.
- If the service agreement is in active or pending stop states, a button appears on Service Agreement - Main called **Apply New Start Option**. When pressed, the user is allowed to define a start option and the date its terms become effective on the service agreement. Refer to Changing A Start Option for the details of this functionality.

The topics in this section describe how to setup start options.

> **Note**
>
> **The merge transaction can save setup time.** The Start Options Merge transaction can be used to construct a start option by copying pieces from other start options.

- Start Option - Terms and Conditions

Start Option Considerations - Rate-Oriented SA Types

To understand the following discussion, you should be familiar with the following concepts:

- SA types that use rates have one or more valid rate schedules. Only these rate schedules may be defined on service agreements of a given type.
- One of a SA type's rate schedules may be designated as the "default" rate. The system assigns the "default" rate to new service agreements when a CSR doesn't choose a start option.
- Start options may be used by customer service reps when a service is started for a customer. A start option causes the customer's new service agreement to be populated with a specific rate and contract terms (e.g., contract riders, contract values). The use of start options is not allowed if the service's SA type does not require a start option. The use of start options is required if the service's SA type requires a start option.

Whether or not a SA Type has start options is dependent on the following factors:

- If a SA Type has only one valid rate and the rate doesn't use customer-specific contract terms (e.g., contract riders, contract values), the SA Type does not need any start options. Why? Because the system default's the SA type's default rate on new service agreement when no start option is used at start time.
- If a SA Type has only one valid rate, but under unusual circumstances, it uses customer-specific contract terms, you'll want an option for every situation (both the standard one and the unusual ones).
- If a SA Type has a single rate with a variety of contract terms (which, by definition, are different for each customer), then you'd want a start option for each permissible combination of contract terms. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).
- If a SA type has multiple valid rates and a variety of contract terms (a combination of the previous two points), you'd need a start option for each permissible combination. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).

Start Option Considerations - SA Types That Use Recurring Charges

To understand the following discussion, you should be familiar with the following concepts:

- Many SA types use the recurring charge algorithms to generate the bill segments. For example, if you let a customer pay for a $900 heat pump in 3 installments of $300, you'd have an SA type called CA/MERCH-I and indicate it uses the recurring charge algorithm.
- When a CSR creates an SA type that uses recurring charge algorithms, they can enter the recurring charge amounts on Start/Stop Service - Start Confirmation window OR they can specify a start option on this window and let the system populate the recurring charge amount. For example, if you let a customer pay for a $900 heat pump in 3 installments of $300, you can set up a start option called HP 3PAY with an installment amount of $300.

Copyright © 2026, Oracle and/or its affiliates.

- Depending on the type of service being started, you might also need to generate an adjustment when service is started in order to initialize the total debt. For example, when a customer buys a heat pump we'll need an adjustment issued to realize the entire $900 of revenue.

The following table provides examples of recurring charge SA types with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments
CA/CHARITY	DONATE $5		5	This causes a charitable contribution to be created with an installment amount of $5.
CA/CHARITY	DONATE $10		10	This causes a charitable contribution to be created with an installment amount of $10.
CA/PA-REGU	PAY $10 PM		10	This causes a payment arrangement to be created with an installment amount of $10.
CA/PA-REGU	PAY $20 PM		20	This causes a payment arrangement to be created with an installment amount of $20.
CA/PA-UNRE	PAY $10 PM		10	This causes a payment arrangement to be created with an installment amount of $10.
CA/PA-UNRE	PAY $20 PM		20	This causes a payment arrangement to be created with an installment amount of $20.
CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of $300. It also causes an adjustment to be issued to realize the $900 of revenue.

Copyright © 2026, Oracle and/or its affiliates.

CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of $250. It also causes an adjustment to be issued to realize the $750 of revenue.
CA/DEP-I	PAY $40 PM		40	This causes a deposit service agreement to be created with an installment amount of $40. The CSR would be required to define the total deposit amount to be billed over the life of the service agreement on the secondary SA window on the Start Account window.

Start Option Considerations - Initial Adjustment SA Types

To understand the following discussion, you should be familiar with the following concepts:

- Some SA types depend on an adjustment to book their initial debt. For example, the CA/MERCH-I SA type requires an initial adjustment to book the payoff amount for the entire cost of the merchandise. Another example would be a loan service agreement (refer to Booking The Principal Amount Using An Adjustment for the details).
- When a CSR starts an SA type that requires an initial adjustment, they can create the adjustment immediately after starting service OR then can specify a start option when they start service and let the system generate the adjustment. You could let the system create the adjustment to book the $900 associated with the heat pump as shown in the previous section.

The following table provides examples of SA types that use adjustments with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments

Copyright © 2026, Oracle and/or its affiliates.

CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of $300. It also causes an adjustment to be issued to realize the $900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of $250. It also causes an adjustment to be issued to realize the $750 of revenue.
CA/CONNECT	CONNECT	CONNECT		This causes an adjustment to be issued to realize the connection charge.

Start Option Considerations - Interval SA Types

Refer to Designing Your SA Interval Billing Options for information about setting up start options for interval service agreements.

Start Option - Main

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Add** to define a SA type's start options.

Description of Page

Every start option is uniquely identified by the following fields:

CIS Division & SA Type Enter the Division and SA type to which the start option is linked.

Start Option Enter the unique identifier of the option. Pick something easy to recognize as this will be used by CSRs to pick an option when they start service.

Effective Date Enter the earliest effective date. It should be the same as the earliest effective date of the start option's rate (although it doesn't hurt for it to be earlier). The date defaults to the current date. (The status, below, should be Active.)

The remaining fields further describe a start option.

Enter a **Description** for the start option.

Copyright © 2026, Oracle and/or its affiliates.

Indicate its **Status**. For new start options, the status should be Active. When it's no longer applicable, change it to Inactive.

Enter the primary **Rate Schedule** that should be defaulted onto service agreements created using this option. Refer to Start Option Considerations For SA Types That Use Rates for more information.

> **NOT_SUPPORTED**
>
> For more information about a service agreement's rates, refer to Service Agreement - Rate Info.

Enter the **Adjustment Type** that should be generated, if any, when service is started using this option. Refer to Start Option Considerations For SA Types That Use Initial Adjustments for more information.

Enter the **Recurring Charge Amount** that should be defaulted onto service agreements created using this option. This field is only visible when the SA type allows recurring charges. In addition, the prompt for this field is defined on the SA type table on the billing window (e.g., it could appear as Payment Amount, Budget Amount, or Installment Amount). Refer to Start Option Considerations For SA Types That Use Recurring Charges for more information.

Enter the **Currency Code** in which monetary amounts are denominated.

> **Note**
>
> The currency code defaults from the installation record.

Enter the **Total Amount to Bill** that should be defaulted onto service agreements created using this option. This is useful to initiate either a loan or a deposit. The prompt for this field is defined on the SA type table on the billing window (e.g., it could be Deposit Amount or Loan Amount).

Use **Number of Periods** to default the number of payment periods of service agreements created using this option. This field is only allowed for SA types with special role of Loan. Refer to The Terms Of A Loan Are Stored On A Service Agreement for more information.

If your SA Type has a special role of Interval, then you must enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements created using this option. For start day option, you may choose Current Day or Previous Day. Refer to Start and End Times for Billing for more information about how these fields are used.

If your SA Type has a special role of Billing Determinants Required, you may enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements that are created using this option. For start day option, you may choose **Current Day** or **Previous Day**.

If your SA Type has a special role of Billable Charge, then you can setup the start option to automatically create a billable charge when a service agreement is created using this start option. For example, you might have a start option that automatically creates a "one-time invoice" service agreement along with a "tree trimming" billable charge. To use this feature you should turn on the **Create Billable Charge** switch and specify the **Billable Charge Template** that will be used to create the billable charge. These fields are only allowed for SA types with special role of Billable Charge.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Setting Up Billable Charge Templates for more information about templates. Refer to An Easier Way To Create One Time Charges for an example of how you can setup a campaign with packages that use this type of start option.

Note

The duplicate action in the page actions toolbar enables you to copy another start option. Refer to Duplicate Button in the system wide standards document for more information.

Start Option - Rate Info

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Rate Info** page to define the start option's default values for contract riders and contract values.

Description of Page

The information in the **Contract Riders** collection defines the contract riders to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Bill Factor The bill factor defines the type of rider. You may only reference bill factors designated as being applicable for contract riders.

Number of Days The number of days the rider should be in effect. This value is used by the system to set the stop date on the service agreement's contract rider. If the rider has no expiration, set this field to 0. Default note: this field will be set to 0 if left blank.

NOT_SUPPORTED

For more information about a rate's contract riders, refer to **Defining General Bill Factor Information** . For more information about a service agreement's contract riders, refer to Service Agreement - Contract Riders.

The information in the **Contract Values** collection defines the contract values to be defaulted onto service agreements created using this start option. The following fields are required for each event:

Bill Factor The bill factor defines the type of value. You may only reference bill factors designated as allowing values in contract terms.

Number of Days The number of days the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Value The amount of the contract value.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about a rate's contract values, refer to **Defining General Bill Factor Information** . For more information about a service agreement's contract values, refer to Service Agreement - Contract Values.

Start Option - Characteristics & Qty

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Characteristics & Qty** page to define the start option's default values for characteristics and contract quantities.

Description of Page

The information in the **Characteristics** collection defines the characteristics to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Characteristic Type This defines the type of characteristic. Note: you may only define characteristics valid on service agreements.

Characteristic Value This defines the characteristic value that will be defaulted.

NOT_SUPPORTED

For more information about a service agreement's characteristics, refer to Service Agreement - Characteristics.

The information in the **Contract Quantity** collection defines the contract quantities to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Contract Quantity Type This defines the type of contract quantity.

Contract Quantity The amount of the contract quantity.

NOT_SUPPORTED

For more information about a service agreement's contract quantities, refer to Service Agreement - Contract Quantity.

Start Option - Contract Option

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Designing Your SA Interval Billing Options for information about setting up start options for interval service agreements.

Note

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is turned off.

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Contract Option** page to define the start option's contract option default values.

Description of Page

The collection of contract option types will be used to link contract options to a service agreement that will be created with this start option. If the contract option to create for the service agreement will be SA Specific, simply indicate the **Contract Option Type**. This will cause a new contract option to be created with this contract option type and the new contract option will be linked to the new SA at start time. If the contract option to create for the service agreement will be Shared, indicate the contract option type and the **Contract Option ID**. This will cause the specified contract option to be linked to the new SA at start time.

NOT_SUPPORTED

For more information about contract option types, see Designing Your Contract Option Types.

Start Option - Interval Info

NOT_SUPPORTED

Refer to Designing Your SA Interval Billing Options for information about setting up start options for interval service agreements.

Note

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is turned off.

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Interval Info** page to define the start option's interval profile and TOU map default values.

Description of Page

The collection of interval profile information will be used to link interval profiles to a service agreement that will be created with this start option. The **Interval Profile Relationship Type** indicates the value that will be linked to each new SA Profile record. For each interval profile relationship type, define either an **Interval Profile Type** or an **Interval Profile ID** depending on whether the Profile to be linked to the new service agreement should be SA Specific or Shared. For SA Specific, indicate an interval profile type. This will cause a new interval profile to be created with this interval profile type and the new interval profile will be linked to the new SA at start time. For Shared profiles, indicate the Interval Profile ID. This will cause the specified Profile to be linked to the new SA at start time.

If a **Derivation Algorithm** is linked to the interval profile type, then the algorithm and its **Creation Priority** are displayed.

NOT_SUPPORTED

For more information about interval profile relationship types, see Designing Interval Profile Relationship Types. For more information about Shared profiles vs. SA Specific profiles, see **Common Profiles vs. SA Owned Profiles** .

The collection of TOU map information will be used to link TOU Maps to a service agreement that will be created with this start option. The **TOU Relationship Type** indicates the value that will be linked to each new SA TOU Map record. For each TOU relationship type, define either a **TOU Map Type** or a **TOU Map ID** depending on whether the map to be linked to the new service agreement should be SA Specific or Shared. For SA Specific, indicate a TOU map type. This will cause a new TOU map to be created with this TOU map type and the new TOU map will be linked to the new SA at start time. For Shared map, indicate the TOU map id. This will cause the specified map to be linked to the new SA at start time.

If a TOU map creation algorithm is linked to the TOU Map type, then the **Derivation Algorithm** and its **Creation Priority** are displayed.

NOT_SUPPORTED

For more information about TOU map relationship types, see Designing Your TOU Map Relationship Types.

Start Option - TOU Contract Value

NOT_SUPPORTED

Refer to Designing Your SA Interval Billing Options for information about setting up start options for interval service agreements.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **This tab may not appear.** This tab is suppressed if the interval billing Complex Billing module is turned off.

Open **Admin** , and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **TOU Contract Value** page to define the start option's default TOU contract values.

Description of Page

The **TOU Contract Value** scroll contains information to define when you would like TOU contract values to be defaulted onto service agreements created using this start option

Indicate the **Bill Factor** associated with the TOU contract values. You may only reference bill factors designated as "TOU" bill factor types and where the value may be in contract terms.

Indicate the **TOU Group**, which contains the appropriate collection of TOU codes for service agreements created using this start option.

Indicate the **Number of Days** the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Use the Time of Use collection to indicate the TOU **Value** associated with each **Time of Use** codes for the TOU Group.

> **NOT_SUPPORTED**
>
> For more information about TOU contract values, refer to Customer Specific TOU Values.

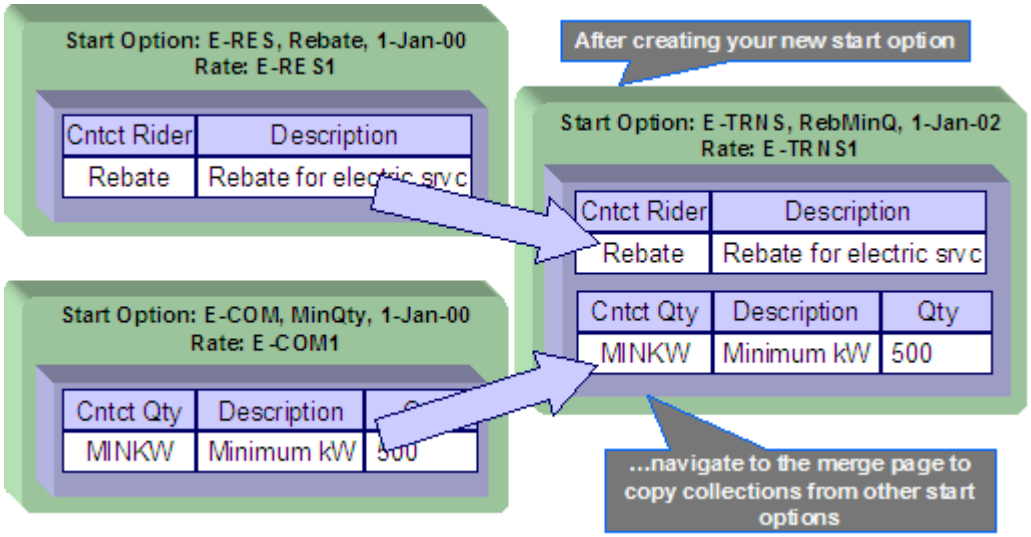
Start Option - Terms and Conditions

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Terms and Conditions** page to define the start option's default terms and conditions.

Description of Page

The information in the grid defines the terms and conditions to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Terms and Conditions This is the code that identifies a term and condition (T&C).



Number of Days The number of days the T&C should be in effect. This value is used by the system to set the end date on the service agreement's T&C. If the T&C has no expiration, set this field to 0. Default note: this field is set to 0 if left blank.

Start Option Merge

Copyright © 2026, Oracle and/or its affiliates.

Use this page to modify an existing start option by copying information from other start options. This page may be used to copy records from the contract rider, contract value, contract quantity, characteristic, interval profile, TOU map, contract option and TOU contract value collections from one or more existing start options to another.

> **Note**
>
> The target start option must exist prior to using this page. If you are creating a new start option, you must first go to the Start Option page to add the new start option and then navigate to the merge page to copy collection information.

> **Note**
>
> **Duplicate versus Merge**. The **Start Option** page has Duplication capability. You would duplicate a start option if you want to a) create a new start option AND b) populate it with all the information from an existing start option. You would use the start option merge page if you want to build a start option using pieces of one or more start options.

- Start Option Merge - Main
- Removing A Row From A Grid
- Adding A New Row To A Start Option
- Removing An Uncommitted Row From A Start Option
- Start Option Merge - Characteristics and Quantities
- Start Option Merge - Contract Option
- Start Option Merge - Interval Info
- Start Option Merge - Terms and Conditions

Copyright © 2026, Oracle and/or its affiliates.

Start Option Merge - Main

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge.**

Description of Page

Select the **Original Start Option**, which is the target for merging the start option collection information.

Select the **Merge From Start Option**, which is your template start option to copy the collections from.

> **Note**
>
> You may only copy information from one Merge From start option at a time. If you wish to copy information from more than one start option, select the first Merge From start option, copy the desired records, Save, then select the next Merge From start option.

The left portion of the page will display any existing records in the collections for the original start option. The right portion of the page will display the existing records in the collections for the Merge From start option.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From start option to the Original start option. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **Contract Riders** collection initially displays existing contract riders linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **Number of Days** for each contract rider is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Values** collection initially displays existing contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor**, **Number of Days** and **Value** for each contract value is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The topics, which follow, describe how to perform common maintenance tasks:

Removing A Row From A Grid

If you wish to remove a record linked to the Original start option, click the "-" button to the left of the record.

Adding A New Row To A Start Option

You may move any of the records from the Merge From start option to the original start option by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear

Copyright © 2026, Oracle and/or its affiliates.

from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing An Uncommitted Row From A Start Option

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Start Option Merge - Characteristics and Quantities

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Characteristics and Quantities** page to copy rows in the characteristic and contract quantity collections.

Description of Page

The left portion of the **Characteristics** collection initially displays existing characteristics linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Characteristic Type** and **Characteristic Value** for each characteristic are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Quantity** collection initially displays existing contract quantities linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Quantity Type** and **Contract Quantity** for each contract quantity are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

NOT_SUPPORTED

Refer to Start Option Merge - Main for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Contract Option

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Contract Option** page to copy rows in the contract options collection.

Note

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is turned off.

Description of Page

The left portion of the **Contract Option** collection initially displays existing contract option information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Option Type**, **Contract Option ID** and **Description** of

Copyright © 2026, Oracle and/or its affiliates.

the contract option for each contract option row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

NOT_SUPPORTED

Refer to Start Option Merge - Main for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Interval Info

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Interval Info** page to copy rows in the interval profile, and TOU map and TOU contract quantity collections.

Note

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is turned off.

Description of Page

The left portion of the **Interval Profiles** collection initially displays existing interval profile information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Interval Profile Rel**ationship **Type**, **Interval Profile Type** and **Interval Profile ID** for each interval profile row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **TOU Maps** collection initially displays existing TOU map information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **TOU Map Relationship Type**, **TOU Map Type** and **TOU Map ID** for each TOU map row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **TOU Contract Values** collection initially displays existing TOU contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **TOU Group** for each TOU contract value are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

NOT_SUPPORTED

Refer to Start Option Merge - Main for more information about how to perform common maintenance tasks for the grids displayed on this tab page.

Start Option Merge - Terms and Conditions

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Terms and Conditions** page to copy terms and conditions (T&Cs).

Description of Page

The left side of the **Terms and Conditions** grid initially displays the T&Cs linked to the original start option. On the right side, the T&Cs linked to the merge from start option are displayed initially.

NOT_SUPPORTED

Refer to Start Option Merge - Main for a description of how to perform common maintenance tasks for the grids displayed on this page.

Defining SA Relationship Options

We use the term "SA Relationship" to describe functionality that supports the following situations:

- When companies other than your own provide a service to your customers AND you have some type of interaction with these companies. For example, in a deregulated market, customers deal with both distribution and energy supply companies. These companies typically exchange a great deal of information about their joint customers.
- When multiple rates are associated with a service (where each rate corresponds with a sub-category of service). For example, most water companies charge for both water and wastewater service using separate rates for each. While it is possible to set up water and wastewater as separate service agreements, the SA relationship functionality allows you to set up a single "master" service agreement (for the water service) and associate with it a "sub" service agreement (for the wastewater service).
- When a party representing a group of customers negotiates a contract that is applied over and above those of the individual service agreements. For example, the head office of a national chain may negotiate for additional discounts that should be calculated together or individually. The SA relationship functionality may be used to track the covered service agreements and to calculate and transfer discounts to the head office's service agreement. Refer to the special discounts section.

Warning

Setting up the SA relationship control tables is as challenging as your organization's business rules. If you don't have requirements similar to those described above, you don't have to set up anything. If you have these types of requirements, your setup process will be taxing as you must design and set up control tables that manage the financial and consumption interactions that take place between you, your customers, and the various service providers.

Copyright © 2026, Oracle and/or its affiliates.

The topics in this section describe tables that control your SA relationship functionality. Refer to Defining Workflow and Notification Options for a description of the tables that control how your organization communicates with the service providers who provide service to your customers.

- The Big Picture of SA Relationships and Service Providers
- Designing Your SA Relationship Types and Service Providers
- Setting Up SA Relationship Information
- Negotiated Terms

The Big Picture of SA Relationships and Service Providers

You must set up service providers if companies other than your own provide a service to your customers AND you have some type of interaction with these companies. You will have one service provider for each such company. For example, if you are a distribution company in a deregulated market, you will have a service provider for each company that provides any of the following services:

- Energy (commonly referred to as Energy Supply Companies, Energy Service Providers, Retailers, and Suppliers)
- Meter service (commonly referred to as Meter Service Providers and Meter Agents)
- Meter reading (commonly referred to as Meter Data Management Agencies and Meter Reading Service Providers)
- Billing (commonly referred to as Billing Agents)

The topics in this section provide background information about service providers.

- Persons and Service Providers
- Service Providers Are Linked To Service Agreements
- Service Providers May Change Over Time
- How To Set Up SA Relationships On A Customer's Service Agreement

Copyright © 2026, Oracle and/or its affiliates.

Persons and Service Providers

A great deal of information about your service providers is defined using a person. For example, a service provider's name, address, phone numbers, electronic ID's, etc. are all defined on the person object.

In addition, every service provider must have a service provider object created for it. The service provider object contains information about a provider's relationships with the customer and your organization, for example:

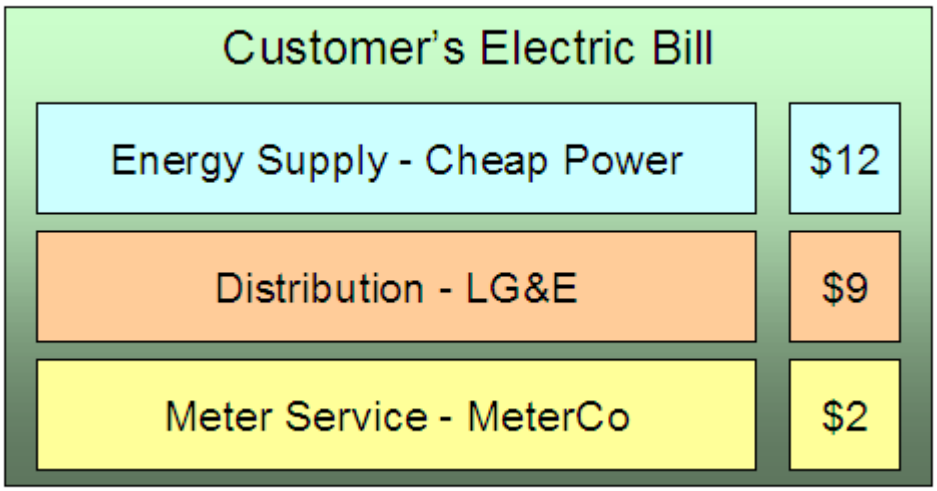
- Do you calculate bills for the service provider? If so, do you have their rates or do they interface their charges to you? Refer to Billing Relationships for more information.
- Do you send the customers' consumption to the service provider? Do they send it to you? Refer to Consumption Relationships for more information.
- How are financial settlements between your organization and the service provider implemented (do you pay them when you get paid?, do you purchase the receivable for them?, etc.). Refer to Service Providers Have Service Agreements Too for more information.
- Etc.

NOT_SUPPORTED

Refer to Designing Your SA Relationship Types and Service Providers for more information.

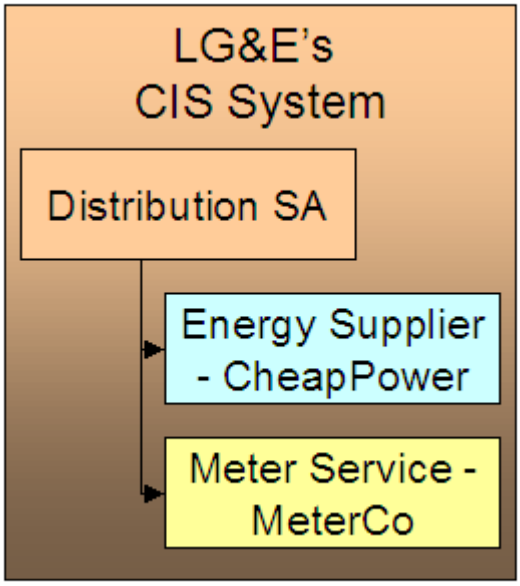
Note

In some situations, you will need to set up a service provider for your own company. Refer to When Your Company Is A Service Provider for the details.



Service Providers Are Linked To Service Agreements

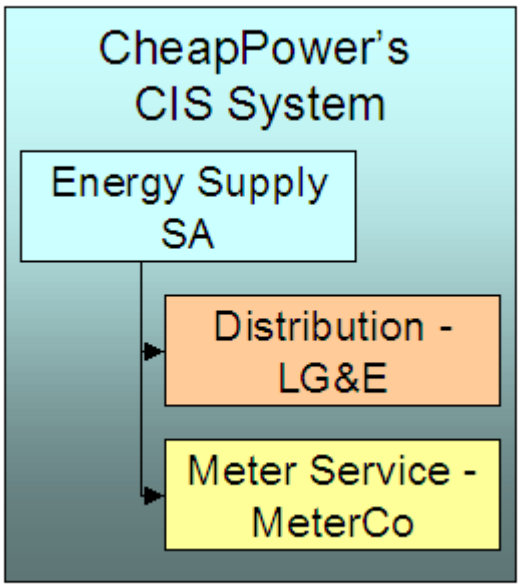
The following diagram illustrates a customer's bill for electric service in a deregulated market. Notice that there are separate sections for energy, distribution and meter service.



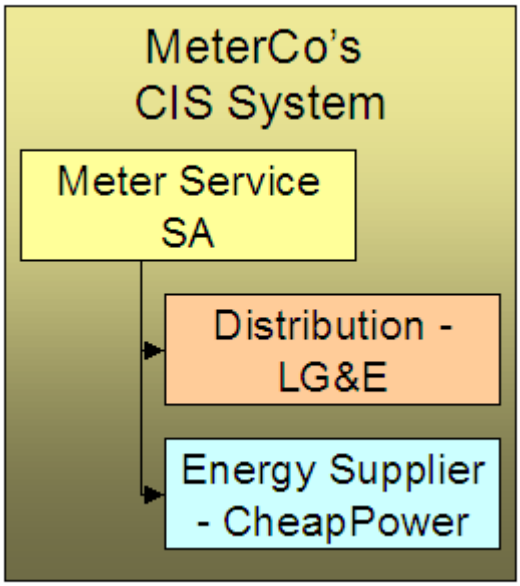
Note

Consolidated billing. The following is an example of a bill that consolidates charges from many service providers. Rather than receive a consolidated bill, it is possible for the customer to receive 3 separate bills, one from each service provider (we refer to this as Dual billing).

Copyright © 2026, Oracle and/or its affiliates.



If we were to look at this customer's service agreement in the distribution company's CIS system, we'd find a service agreement for distribution charges, and linked to it would be information about the meter service and energy service providers:



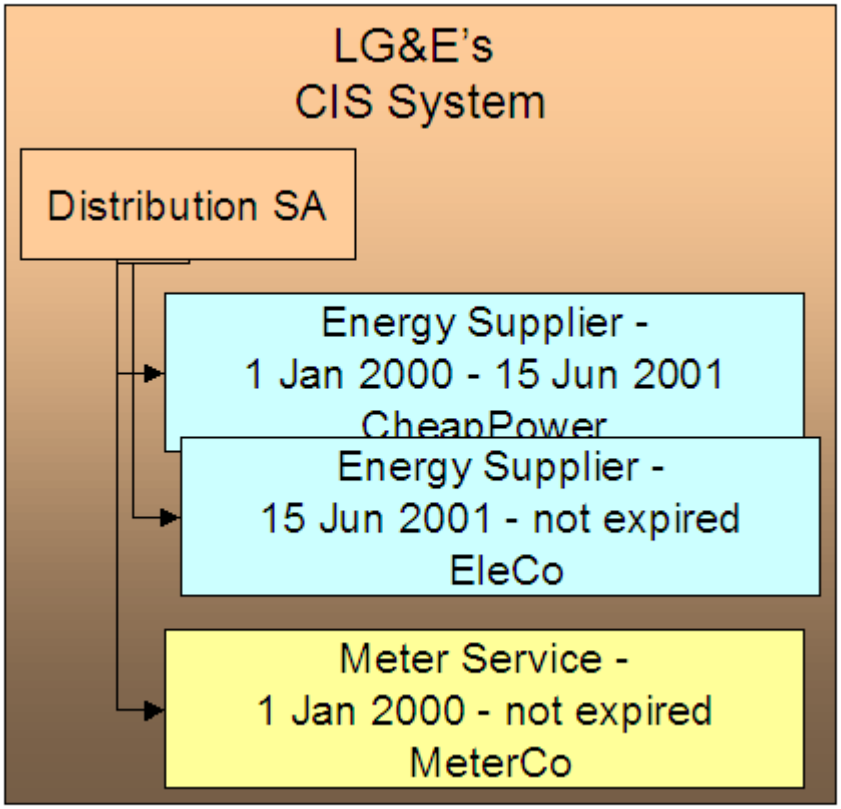
If we look at this customer's service agreement in the energy supply company's CIS system, we'd find a service agreement for energy charges, and linked to it would be information about the distribution and meter service providers:

Copyright © 2026, Oracle and/or its affiliates.

And finally, if we look at this customer's service agreement in the meter service company's CIS system, we'd find a service agreement for meter service charges, and linked to it would be information about the distribution and energy providers:

> **Note**
>
> **Bottom line.** A customer's service providers keep track of the customer and each other in their respective CIS systems. A customer will have a service agreement (or the equivalent) in each service provider's CIS system. A customer's service agreement defines the service providers who supply each type of service.

Copyright © 2026, Oracle and/or its affiliates.



NOT_SUPPORTED

Because information about customers and their services needs to be kept up-to-date in many different CIS systems, there is a need for automated communications between service providers. Refer to Service Providers Have To Communicate About Customers for more information.

Service Providers May Change Over Time

A customer typically has a choice of service providers. Over time, their choice may change. The system keeps track of a customer's service providers throughout time so that it can accurately cancel / rebill historical bills. This means that the service provider relationship is *effective-dated*.

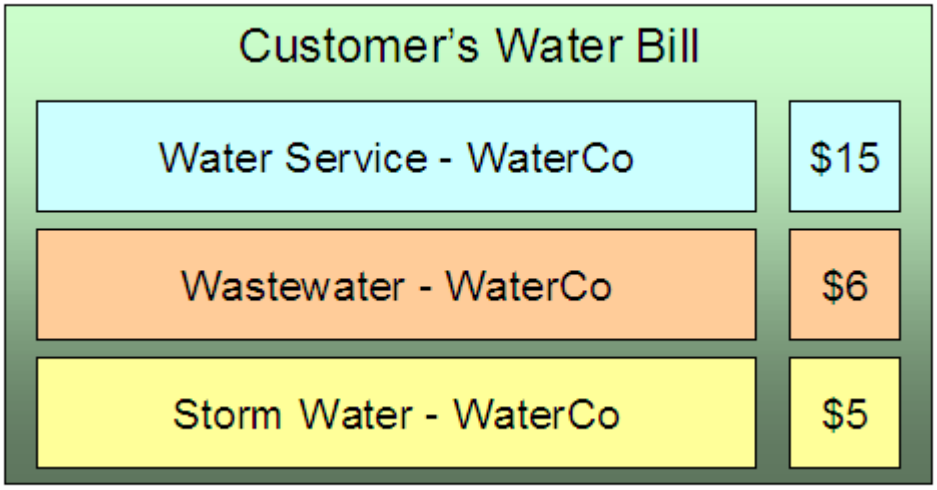
The following diagram illustrates how a distribution company's system keeps track of a customer's service providers (notice the customer changed energy suppliers):

How To Set Up SA Relationships On A Customer's Service Agreement

There are three ways to set up a customer's service providers:

- **Manually.** An operator can manually change a service agreement's SA relationships. The manual method is NOT recommended as changing service providers typically involves many events (e.g., you have to notify the current service provider that they will be

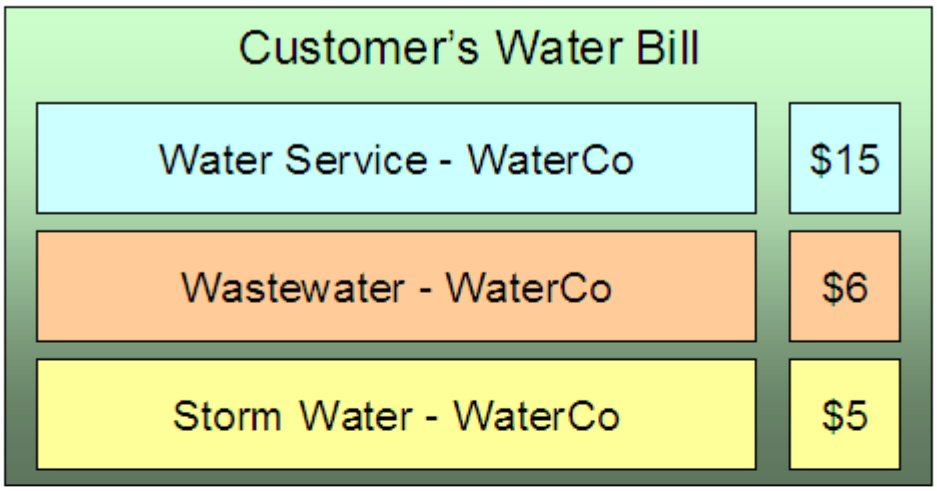
Copyright © 2026, Oracle and/or its affiliates.



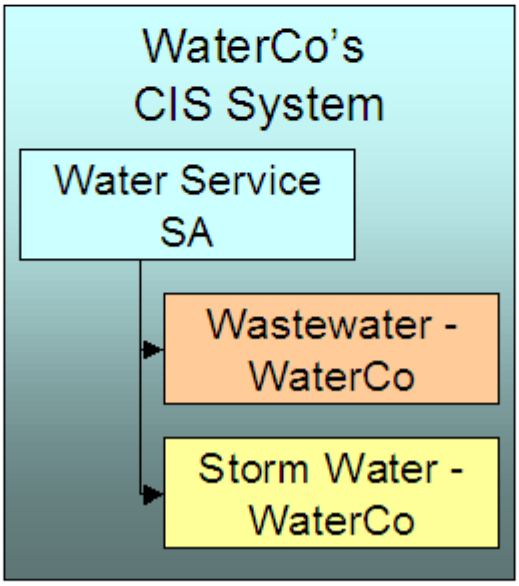
dropped). We strongly recommend having an operator kick off a workflow process and let the workflow process notify the service providers and make the desired changes. Refer to Defining Workflow and Notification Options for more information.

- **Use Default Service Providers.** The system will default a service provider on a required SA relationship when a service agreement is activated. Refer to Defaulting Relationship Types And Defaulting Service Providers for more information.
- **Workflow Processing.** A workflow process may contain workflow events that change a service agreement's SA relationships.Refer to Defining Workflow and Notification Options for more information.

When Your Company Is A Service Provider



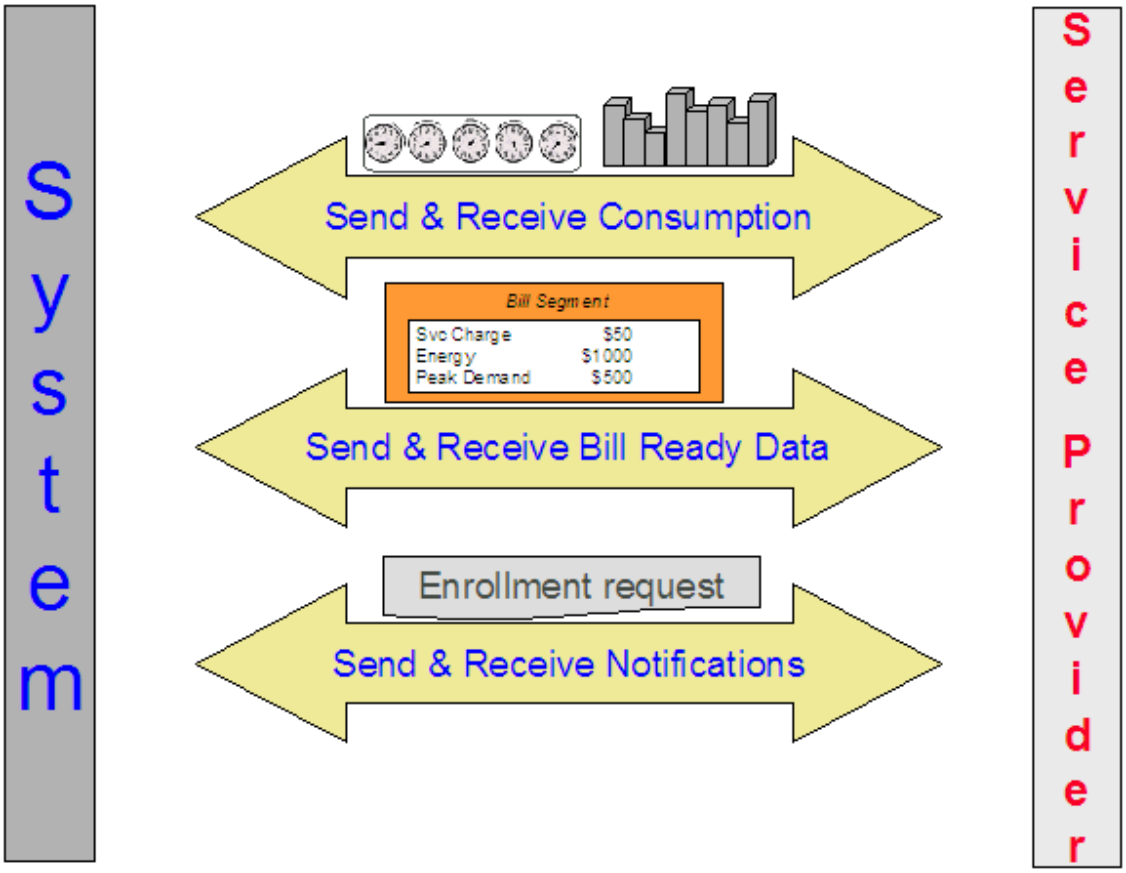
Besides setting up service providers for other companies that provide services to your customer, you may have to set up a service provider for your own company. You have to do this when:



- **Your organization can supply one of the services.** Refer to the illustration in Service Providers Are Linked To Service Agreements. If you are LG&E and you supply energy in addition to distribution, you would need to set up a service provider for your own organization. Why? Because whenever you have a subcategory of service (e.g., energy supply), you must indicate the service provider who provides this service; even when it's you.
- **You decide to break up a service into subcategories** (and have a separate service agreement for each category). For example, a water company may choose to break up service charges into water, wastewater and storm water (they may do this because there are different rates for each category of service). The following is an example of the segregated charges associated with this water company's service charges.

This water company system may benefit by creating a single service (for water) and indicating there are subcategories of service (for wastewater and storm water). Whenever you have a subcategory of service, you must indicate the service provider who provides this service. And, in this example, the water company would be the sole service provider for each subcategory of service.

Copyright © 2026, Oracle and/or its affiliates.



Note

Refer to We Bill For Them - Rate Ready Bill Segments Are Special for restrictions in respect of using subcategories of service.

Service Providers Have To Communicate About Customers

The providers of service typically have to communicate with each other in respect of the customer's service. The following diagram illustrates the major interfaces of information between your system and your service providers.

Copyright © 2026, Oracle and/or its affiliates.

Depending on where your organization fits in the service provider hierarchy, you may:

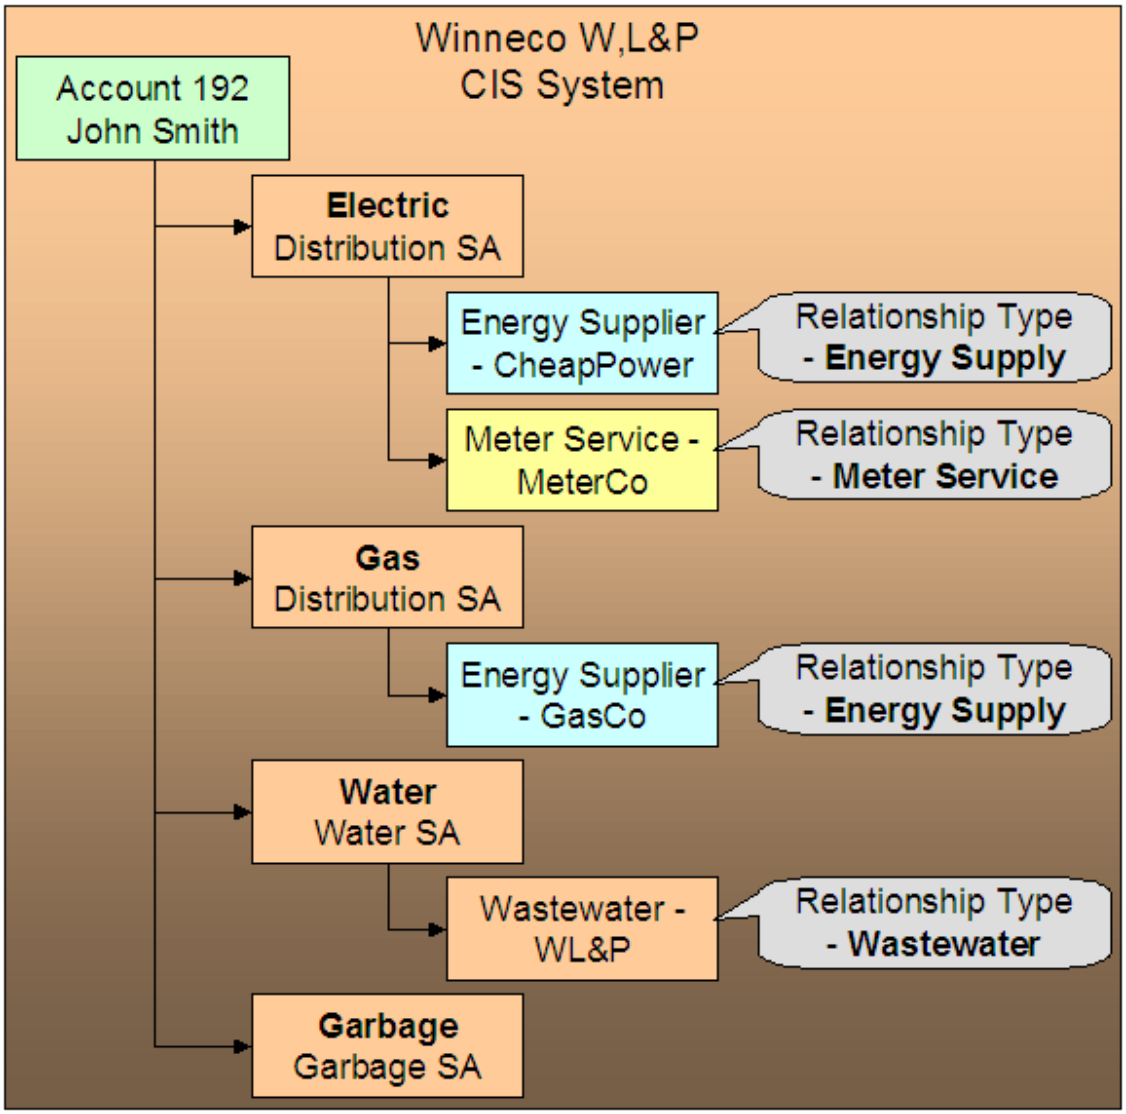
- Bill for other service providers (or they may bill for you). Refer to Billing Relationships for more information about billing communications.
- Send the customer's consumption to service providers (or they may send it to you). Refer to Consumption Relationships for more information about consumption communications.
- Apprise service providers of the changes to the customers' service (or they may apprise you). Refer to How Do You Communicate With Service Providers? for more information about communications between service providers.

Relationships Between Service Providers

Service providers may arrange contractual relationships with other service providers to provide additional services, e.g., an energy service provider may work with a specific meter data management agency to gather and report interval meter read data.

The system does nothing special to enforce or record these inter-relationships. Why? Because most service provider switches are received by notification records. Notification records indicate all the associated service providers. There is no need for the system to maintain the inter-service provider associations.

A Service Agreement Can Have Many Types Of Relationships



Copyright © 2026, Oracle and/or its affiliates.

As described in the previous sections, a given service can be subdivided into subcategories. Each type of service can have zero, one or more subcategories. We call each subcategory a **SA Relationship Type**. The topics in this section provide information about SA relationship types.

- An Example
- Valid Relationship Types and Service Providers Are Defined On SA Types
- Defaulting Relationship Types And Defaulting Service Providers
- Required Relationship Types and Billing
- Relationship Types Do Not Impact Start/Stop

An Example

We'll use the following example of a customer in a municipal utility's CIS system to explain SA Relationship types:

Note the following:

Copyright © 2026, Oracle and/or its affiliates.

- Electric service has 2 SA relationship types: energy supply and meter service.
- Gas service has 1 SA relationship type: energy supply.
- Water service has 1 SA relationship type: waste water.
- Garbage service has no SA relationship types.

> **Note**
>
> **Bottom line.** Service providers are related to the customer via "your" service agreement. Each service provider linked to a service agreement is defined in respect of a SA Relationship Type. This relationship is effective-dated because we care about how it changes over time.
>
> **Your relationship type is implied.** The SA relationship type of "your" service agreement is implied, e.g., if you are a distribution company, "your" service agreement's implied SA relationship type is "distribution".

Valid Relationship Types and Service Providers Are Defined On SA Types

You control which services have SA relationships (and which don't) when you set up your SA types. Each SA type can have zero, one or more SA relationship types. Each relationship type, in turn, can have one or more valid service providers.

> **NOT_SUPPORTED**
>
> Refer to Setting Up SA Relationships For SA Types for the page used to define the service providers and SA relationship types for each SA type.

Defaulting Relationship Types And Defaulting Service Providers

Please be aware of the following:

- A SA relationship type for a given SA type can be marked as being **Required**.
- A service provider for a given SA relationship type / SA type can be marked as being the **Default**.

If, at activation time, the customer's master SA is missing a **Required** SA relationship that has a **Default** service provider, the activation process automatically creates the SA relationship type and links to it the **Default** service provider. If a master service agreement doesn't have all **Required** SA relationships, the service agreement cannot be activated. This is handy when your organization is the default service provider for a relationship type.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Automatic Creation of Sub SAs for information about how the system will automatically create sub service agreements for the defaulted SA relationship / service provider if your organization provides billing services for the service provider. Refer to Setting Up SA Relationships For SA Types for the page used to define the service providers and SA relationship types for each SA type.

Required Relationship Types and Billing

When the system attempts to create a bill segment for a service agreement whose SA type has **Required** relationship types, it checks if all such relationships are defined for the service agreement. If not, a bill segment error will be generated.

The reason this restriction exists is to handle the situation when your required relationship types change over time. For example, assume on your first day of production you only need energy suppliers defined on electric service agreements. After several months, gas deregulates. When this happens, you will need to change your control tables to indicate that your gas SA types require an energy supplier. If you don't write a default program to update your existing gas service agreements, billing will complain.

Relationship Types Do Not Impact Start/Stop

Customer service representatives (CSR's) are typically not involved with the customer's choice of service providers. Most organizations hear about a customer's service providers from the service providers or from a central body. This means that the start/stop dialog is not impacted by SA relationships. This also means that CSR's are not impacted by SA relationships (unless something goes wrong). If something goes wrong, the CSR's may need to manually correct SA relationships. Refer to How To Set Up Service Providers On A Customer's Service Agreement for more information.

Billing Relationships

When you set up a service provider, you must define your organization's billing relationship with the service provider. The following points provide examples of the billing relationships supported in the system,

- If you are an energy supply company, you may provide billing services for the distribution company. This means that your bill contains both your charges and the distribution company's charges. We refer to this as the **We Bill For Them** billing relationship.
- Alternatively, the distribution company may provide billing services for you. This means that the distribution company's bill contains your charges and their charges. We refer to this as the **They Bill For Us** billing relationship.
- Alternatively, you may both send bills to the customer. We refer to this as the **Dual Billing** relationship.
- Alternatively, if you subcategorize your services OR if your company provides one of the services that is provided by your service providers, then the system will create a separate

Copyright © 2026, Oracle and/or its affiliates.

bill segment for the subcategory of service. We refer to this as the **It's Us** billing relationship.

If you provide billing services for another service provider (i.e., you bill for them), there are two ways to determine the service provider's charges:

- You can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.
- You can let the service provider calculate their own charges and interface them to you. We call this the **Bill Ready** calculation method.

If a service provider provides billing services for you (i.e., they bill for you):

- If the service provider has a suitable CIS system, they can load your rates in their system and calculate your charges for you. We call this the **Rate Ready** calculation method.
- You can calculate your charges and interface them to them. We call this the **Bill Ready** calculation method.

If you don't have a billing relationship with a service provider, you still need a service provider record to define such. Why? Because the system needs to know that it doesn't have to worry about a particular service provider in respect of billing. In addition, you may have other interactions with a service provider that have nothing to do with billing, e.g., you may send or receive consumption.

The topics in this section provide a wealth of information about the various billing relationships and the ramifications of each.

- Sub Service Agreements
- We Bill For Them
- Service Providers Have Service Agreements Too
- They Bill For Us
- Combinations Of Service Provider Billing Methods
- Different Service Providers Can Bill Different Services
- If You Deal With TBFU Service Providers, You Cannot Reopen Bills

Sub Service Agreements

If you provide billing services for another service provider OR if you subcategorize your own charges, there will be a separate service agreement (SA) linked to the customer's account that holds these unique charges. We refer to this new service agreement as a **Sub SA**. We use the term "sub" because this service agreement is subservient to the "master" service agreement. By subservient we mean:

- A sub SA's start and stop dates are the same as the master SA. This statement may seem odd, but it's true – all sub SAs linked to a master service agreement have the same start and stop dates as the master.
- A sub SA's status (i.e., *pending start*, *active*, *pending stop*, *stopped*, etc.) is controlled by its master service agreement. As a rule, the master SA transitions its status first and the sub SA(s) follow.

Copyright © 2026, Oracle and/or its affiliates.

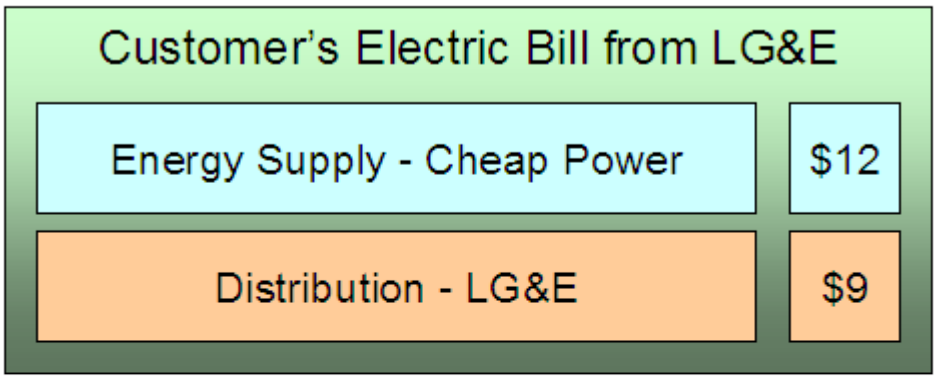
> **Note**
>
> There are situations where the master service agreement transitions its status and the sub service agreement(s) does not. One example of this is when both the master and sub SAs are closed and a payment cancellation occurs that only affects the master SA. In this scenario, the master SA becomes reactivated and the sub SA remains closed. Another example is when a straggling billable charge posts to a sub SA; the master SA is not affected.

- Refer to The Rate Ready Calculation Method for additional examples of subservience.

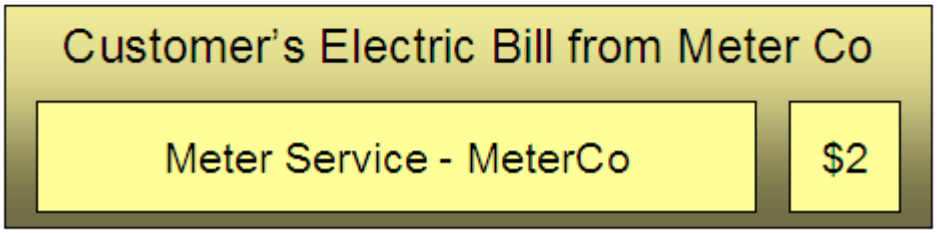
> **Note**
>
> You may find it helpful to keep in mind that sub SAs are only used for service providers with a billing relationship of It's Us and We Bill For Them. This is because these are the only relationships that have implicit billing responsibilities.

The topics in this section provide additional information about sub SAs.

- Only Some Service Providers Have Sub SAs
- Automatic Creation of Sub SAs
- Sub SA State Transition

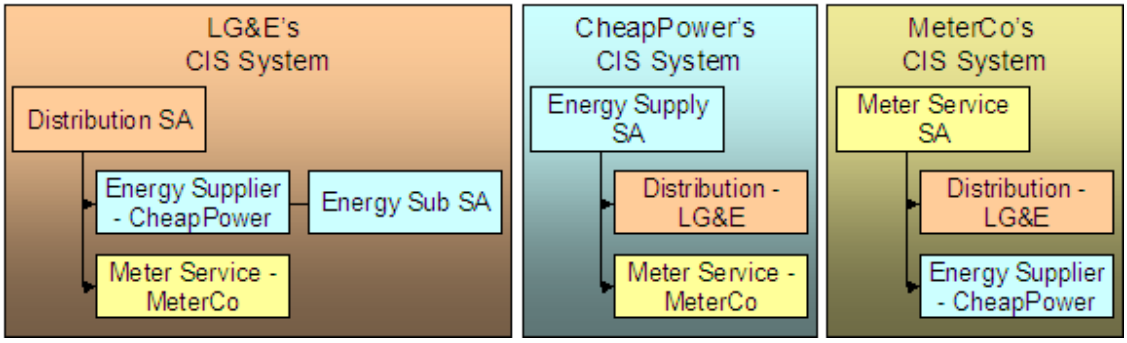


Only Some Service Providers Have Sub SAs



If you do not provide billing services for a service provider, there will be no sub SAs associated with the service provider's SA relationships. Let's use an example to make the point; assume:

- Service is divided into distribution, energy and meter service charges.
- You are the distribution company and you provide billing services for the energy supply company.
- The meter service company bills the customer independently.



In this situation, the customer will receive two bills: one from you (LG&E), the other from MeterCo. Notice that your bill (LG&E) contains your distribution charges AND CheapPower's energy charges:

Copyright © 2026, Oracle and/or its affiliates.

If we were to look at the customer information in the three service providers' respective CIS systems, we'd find the following service agreements and SA relationships for the customer:

Notice the following:

- The customer has a service agreement in each supplier's CIS system.
- Because LG&E (the distribution company) bills for CheapPower, all customers who have their energy supplied by CheapPower will have a sub SA in LG&E's system. This sub SA maintains the charges (and receivable balance) associated with CheapPower's energy charges.
- Notice that neither CheapPower's nor MeterCo's CIS systems use sub SAs. This is because neither company bills for other service providers.

> **Note**
>
> **Sub SAs are needed if you subcategorize your charges.** The above example shows sub SAs being used when a company provides billing service for another company. Sub SAs are also used when you subcategorize your charges - each sub SA contains the rate associated with each subcategory.

Copyright © 2026, Oracle and/or its affiliates.

Automatic Creation of Sub SAs

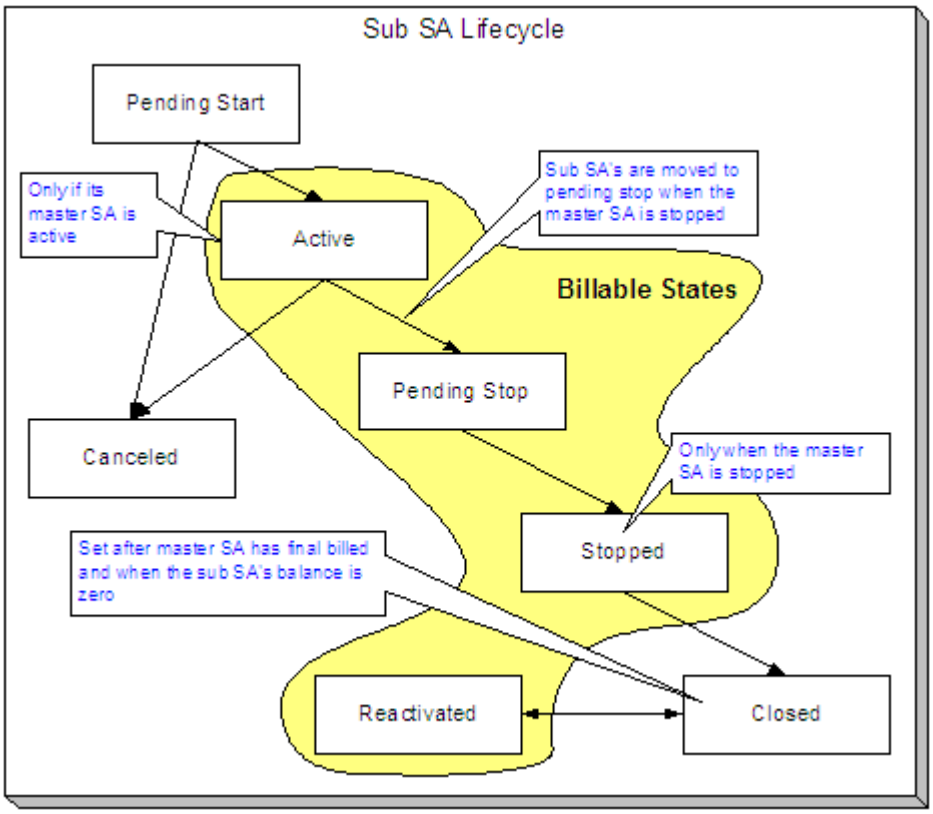
The system creates sub SAs for customers choosing service providers where the billing option is It's Us or We Bill For Them. The system creates sub SAs via the following mechanisms:

- The analyze SA relationships background process (ANLYZSAR) monitors newly activated SA relationships. If the respective service provider is It's Us or We Bill For Them, this process creates the sub SA(s) using the information defined on SA Type SA Relationship Type. Refer to Setting Up SA Relationships For SA Types for more details.

> **Note**
>
> The analyze SA relationships background process also activates and stops sub SAs. Refer to Sub SA State Transition for the details.

- A button exists on the SA Relationships page. This button, when pressed, creates sub SAs real-time. This button would only be used if the operator couldn't wait for the background process to run.

The SA type associated with the new sub SAs is defined when you set up each SA Type / SA Relationship Type. Refer to Setting Up SA Relationships For SA Types for more information.



If the SA type uses start options, the start option contains additional values (e.g., rates, contract riders) that are used to populate the newly created sub SAs. Note: start options are typically not used for We Bill For Them - Bill Ready service provider because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs. Refer to Setting Up SA Relationships For SA Types for more information.

> **Note**
>
> **Manually created sub SAs.** In very unusual situations, an operator may create a sub SA manually. An operator would do this using the SA Relationship transaction.

Sub SA State Transition

Sub SAs follow normal SA state transition rules, but have a few additional rules about when the transitions can take place.

Copyright © 2026, Oracle and/or its affiliates.

The following points highlight the additional state transition rules:

- A sub SA can only become Active if its master SA is Active. Most sub SAs are activated by the analyze SA relationships background process. However, a user can manually activate a sub SA using the activate button on the SA maintenance page.
- Sub SAs become Pending Stop when their master becomes Stopped . This typically occurs when the SA activation background process stops the master SA. However, this can happen real time if a user manually stops a master SA using the stop button on the SA maintenance page.
- A sub SA can only become Stopped if its master SA is Stopped . Most sub SAs are stopped by the analyze SA relationships background process. However, a user can manually activate a sub SA using the stop button on the SA maintenance page.
- A sub SA becomes Closed if its master has been final billed and it has a balance of zero. Most sub SAs are closed when their balance becomes zero after the master SA is final billed. However, a user can manually close a sub SA using the close button on the SA maintenance page. Note, if additional billable charges are interfaced after the master has been closed, the sub SA will be Reactivated.

We Bill For Them

If you provide billing services for another service provider, then you have a We Bill For Them billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

- Sub SAs Are Used When We Bill For Them
- The Rate Ready Calculation Method

Copyright © 2026, Oracle and/or its affiliates.

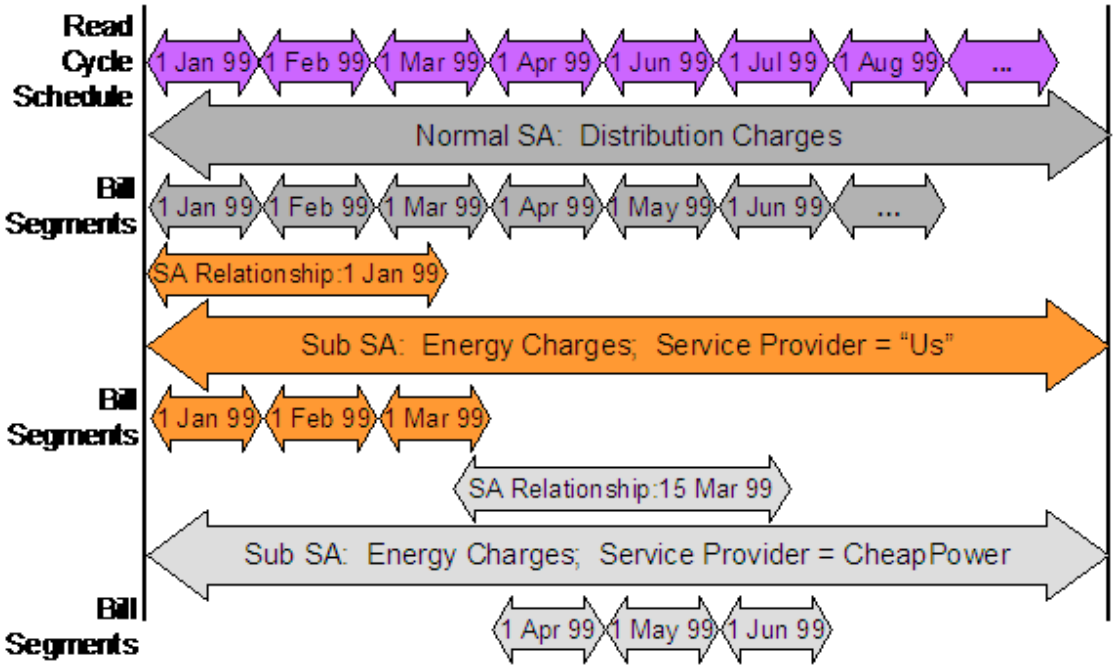
- The Bill Ready Calculation Method
- Pay at Bill Time Versus Pay at Pay Time
- Paying The Service Provider - Technical Implementation

Sub SAs Are Used When We Bill For Them

As described under Sub Service Agreements, sub SAs are used for We Bill For Them service providers. The sub SAs hold the service providers charges. It's important to note that the system allows more than one sub SA to be created for a given service provider.

The Rate Ready Calculation Method

If you provide billing services for a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.



> **Note**
>
> It's Us **can be Rate Ready.** The prior paragraph indicated that the Rate Ready billing option was used for We Bill For Them service providers. If you subcategorize your services and use rates to calculate each subcategory's charges, the service provider(s) set up for your own organization will also be subject to the Rate Ready rules described below.

If a customer uses a We Bill For Them - Rate Ready service provider, the system will create a separate bill segment for the service provider's charges. Keep in mind the following in respect of these types of bill segments:

- The consumption is copied from the "master" service agreement (note: we copy item details and read details after pre-processing calculation groups, if any exist, have been applied). This means that the bill period on the sub SA's bill segment is identical to that on the normal SA. This also means that if the "master" SA is in error, bill segments for the sub SA will not be created.
- The rate defined on the sub SA is applied against this consumption. All pre-processing calculation groups defined on the service provider's rate will be used to manipulate this consumption. If you have pre-processing calculation group on your master SA's rate to apply a line loss or convert a cubic foot to a therm, you don't have to have these pre-processing calculation group on the sub SA's rate (because we copy the consumption from the master to the sub after pre-processing calculation group, if any exist, have been applied).

The following illustration should help:

Copyright © 2026, Oracle and/or its affiliates.

Be aware of the following:

- This example is from a distribution company's perspective.
- From 1 Jan 99 through 15 Mar 99, the distribution company distributes power AND supplies energy (i.e., the distribution company is the service provider of energy).
- On 15 Mar 99, CheapPower becomes the energy supplier. However, the next bill period ends on 30 Mar 99. This means that CheapPower will only start supplying energy on 1 Apr 99. See the following note for why the effective date of the supplier switch is not the true effective date from billing's perspective.

> **Note**
>
> **Service Provider Changes Take Effect On The Next Bill.** If the service provider is changed within a customer's billing period, the system assumes that the service provider in effect at the START of the period is effective the entire billing period. This means that a change of service providers will only take effect on the bill whose start date follows the change date.

Please be aware of the following characteristics of Rate Ready bill segments:

- You cannot cancel a Rate Ready bill segment independently from the master bill segment. If you need to cancel / rebill the sub SA's bill segment, you must cancel / rebill the master SA's bill segment.
- You cannot delete a Rate Ready bill segment independently from the master bill segment. If you need to delete the sub SA's bill segment, you must delete the master SA's bill segment.
- Similarly, if you cancel / rebill the normal SA's bill segment, all Rate Ready bill segments will be cancelled / rebilled.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** Creating, freezing, deleting, and canceling a "master" bill segment does the same with all Rate Ready bill segments. You cannot create, freeze, delete or cancel a Rate Ready bill segment independent of its master bill segment.

The Bill Ready Calculation Method

If a customer uses a We Bill For Them - Bill Ready service provider, the service provider calculates their own charges and interfaces them to the system. We then present their charges on our bill; we don't actually calculate anything (sometimes this is referred to as "pass through" billing).

The sub SA linked to a We Bill For Them - Bill Ready must be a billable charge SA. Why? Because billable charge SAs exist to hold bill lines until such time as a bill is created for the customer's account. Refer to Setting Up Billable Charge Templates for more information.

Please be aware of the following characteristics of Bill Ready bill segments:

- Unlike Rate Ready bill segments, Bill Ready bill segments can span different time periods than the master SA. This is because you cannot predict when a service provider will interface their billable charges to you. In fact, a given bill could contain billable charges that span different periods and these charges could have been interfaced from historic and existing service providers.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be created and deleted independently from the master bill segment.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be cancelled independently from the master bill segment.

Sending Consumption And Waiting For The Charges

Uploading Consumption (Rather Than Uploading Calculated Charges)

Calculating Taxes On Uploaded Charges

Sending Consumption And Waiting For The Charges

If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service provider to calculate their charges, you need to be aware of the following:

- We do NOT recommend sending raw meter reads to service providers. Rather, we recommend sending these service providers the same consumption that you use on your bill segments. Remember, the system maintains a snapshot of billed consumption on bill segments associated with service agreements that are linked to service points.
- But to implement our recommendation (of only interfacing billed consumption to service providers), we need to create a bill segment for the master SA and then wait until the service provider returns the billable charge before sending out the bill. The following points describe how this works:
  - Early in the bill cycle, the system creates a bill segment for the master SA (remember, the system maintains a snapshot of billed consumption on bill segments linked to service points). When the master bill segment is frozen, the system interfaces the snapshot consumption to all service providers associated with the master service

Copyright © 2026, Oracle and/or its affiliates.

agreement who need consumption (this is defined on the service provider). Refer to We Can Send Billed Consumption To Any Service Provider for more information about interfacing consumption to service providers.

- The bill associated with the bill segment will not be completed. Why? Because the bill segments associated with the We Bill For Them - Bill Ready service providers will be in Error. This only happens if you use the Billable Charge bill segment creation algorithm (this algorithm is plugged in on the sub SA's SA type). On the algorithm, make sure to specify a value of Y for the parameter **Wait For The Last Day Of The Bill Cycle**. By doing this, a bill segment in the Error state will exist for the sub SA until the last night of the bill cycle's window.
- On the last night of the bill cycle window, when the system attempts to create a bill segment for the billable charge SA associated with the We Bill For Them - Bill Ready, it will either find recently interfaced billable charges or it won't. If it finds unbilled, billable charges, a bill segment will be created for the sub SA and the billable charges will be swept onto it. If it doesn't find unbilled billable charges, the bill will be completed (i.e., sent out) without the service provider's charges.

> **Note**
>
> **Bottom line.** If a customer's account uses We Bill For Them - Bill Ready service providers, the bill will not be completed (i.e., sent out) until the last night of the bill cycle (if you use the appropriate algorithm). Why? Because we wait until the last night of the bill cycle before trying to sweep on recently interfaced billable charges. If no billable charges have been interfaced from the service provider by the last night of the bill cycle, the bill will be sent out without the service provider's charges.
>
> **Batch versus Online Bill Creation.** If you create a bill online, the system will NOT create an Error bill segment for the We Bill For Them - Bill Ready service provider. Why? Because if you want to create an online bill, either the service provider has interfaced their charges or they haven't. If they have, they should be swept on the bill (via the creation of a bill segment). If they haven't, it shouldn't prevent you from completing the bill.

Top of the Page

Uploading Consumption (Rather Than Uploading Calculated Charges)

We understand this is confusing, but it is quite possible to set up the system so that the We Bill For Them - Bill Ready service provider passes in CONSUMPTION rather than the calculated bill lines. They would only do this if they are not able to calculate the charges in their system and have therefore provided you with their rates. To do this, you would set up everything as described above. In addition, when you upload the billable charges, you must specify the consumption to be rated in the billable charge's service quantity (SQ) collection.

Top of the Page

Calculating Taxes On Uploaded Charges

It is possible to set up the system to calculate taxes for billable charges. You would do this if the service providers are passing through the charges and want you to calculate the taxes.

If you want taxes calculated on top of billable charges:

- Create a service quantity (SQ) on the billable charge that contains the total monetary amount that taxes will be calculated on. Note, you would not have to do this if you have a

Copyright © 2026, Oracle and/or its affiliates.

pre-processing calculation group in your rate that calculates the total monetary amount to which taxes should be applied.

- Specify a rate on the billable charge service agreement. This rate will contain calculation rules that calculate taxes. Note, the calculation rules will be simple SQ calculation rules that apply a percentage to the value of the SQ that represents the monetary amount on which taxes should be calculated.

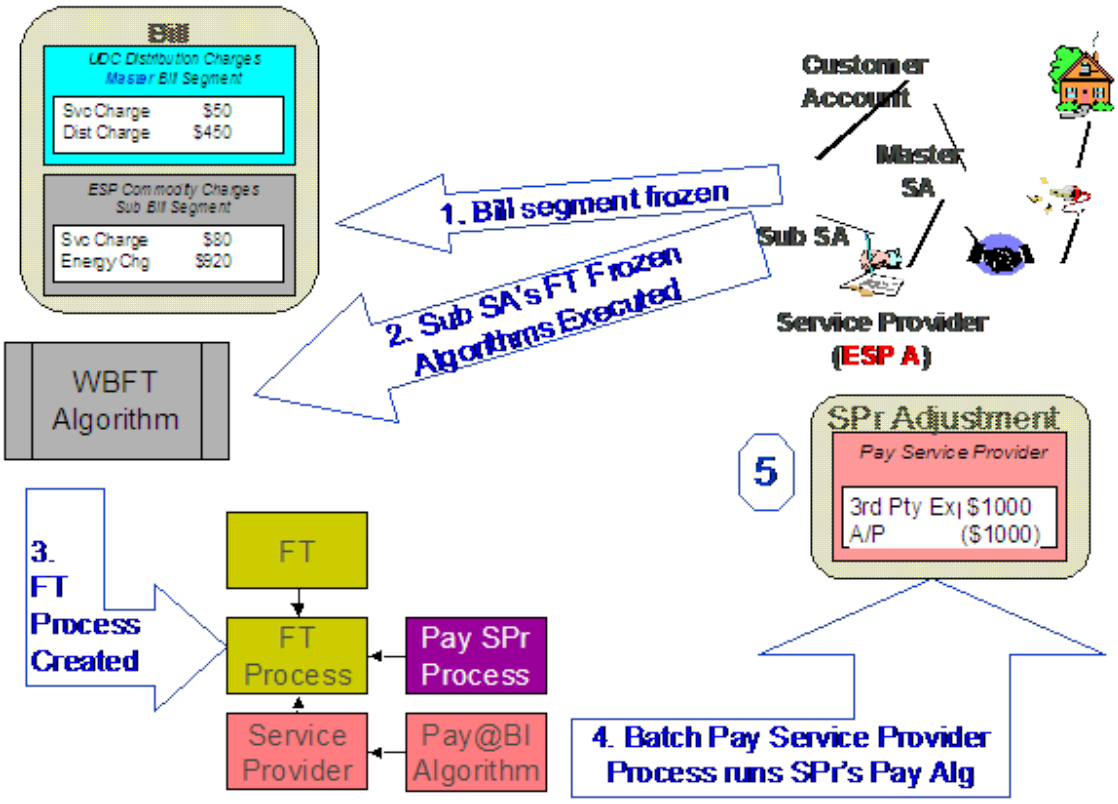
When the system creates the bill segment for the billable charge, it will call the rate and the rate will calculate the taxes and add additional lines (actually, bill calculation headers) to the bill segment.

Pay at Bill Time Versus Pay at Pay Time

If you provide billing services for another service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will owe them money because you will be receiving money from their customers for their service. You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you freeze the customer's bill segment. Some people refer to this method as "purchasing the receivable from the service provider". We call this the **Pay At Bill Time** method.
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer. We call this the **Pay At Pay Time** method.

The method used for a service provider is defined on the service provider's record.



> **NOT_SUPPORTED**
>
> Refer to When We Bill For Them, We Owe Them Money for more information.

Paying The Service Provider - Technical Implementation

> **Warning**
>
> This section describes, technically, how we increase the amount we owe a We Bill For Them service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with increasing how much we owe a We Bill For Them service provider.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the sub SA's SA type), one of these algorithms will determine if there is a WBFT service provider associated with the sub SA. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that looks at new FT's and determines if a related "payable" adjustment should be created for the We Bill For Them service provider. This batch process uses the service provider's Payment Relationship and Pay Service Provider algorithm to determine when and how to create these "payable" adjustments.

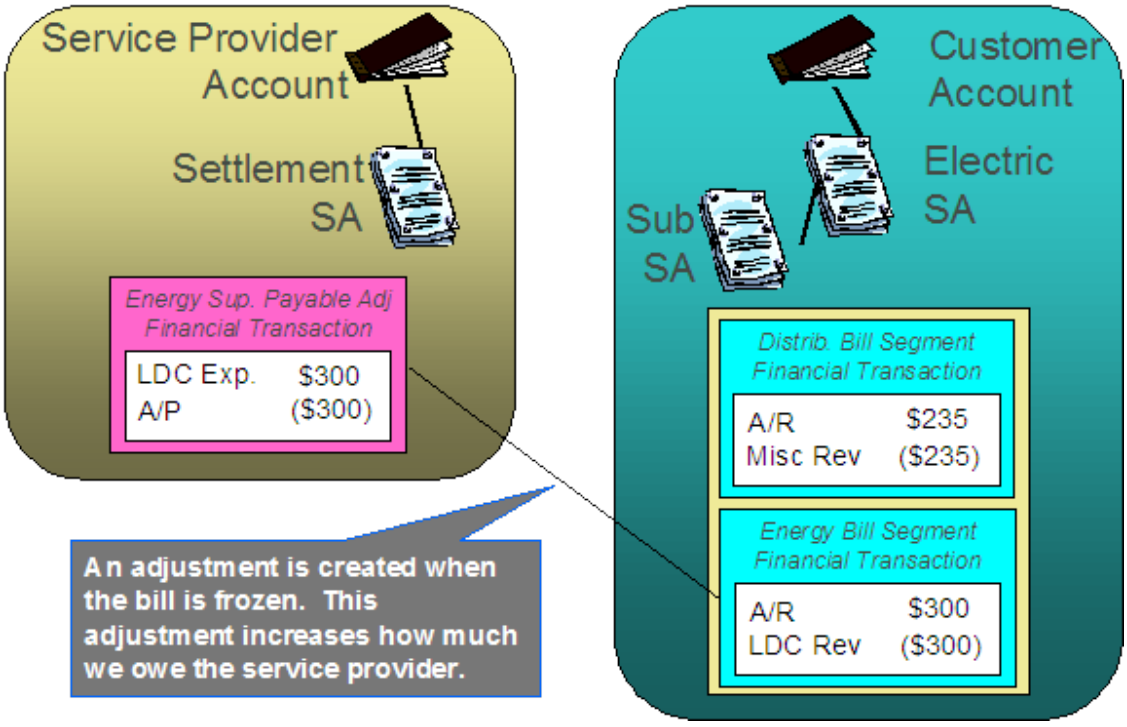
Service Providers Have Service Agreements Too

Most service providers need service agreements as explained in the following topics.

- When We Bill For Them, We Owe Them Money
- Adjustments and We Bill For Them Service Providers
- When They Bill For Us, They Owe Us Money

When We Bill For Them, We Owe Them Money

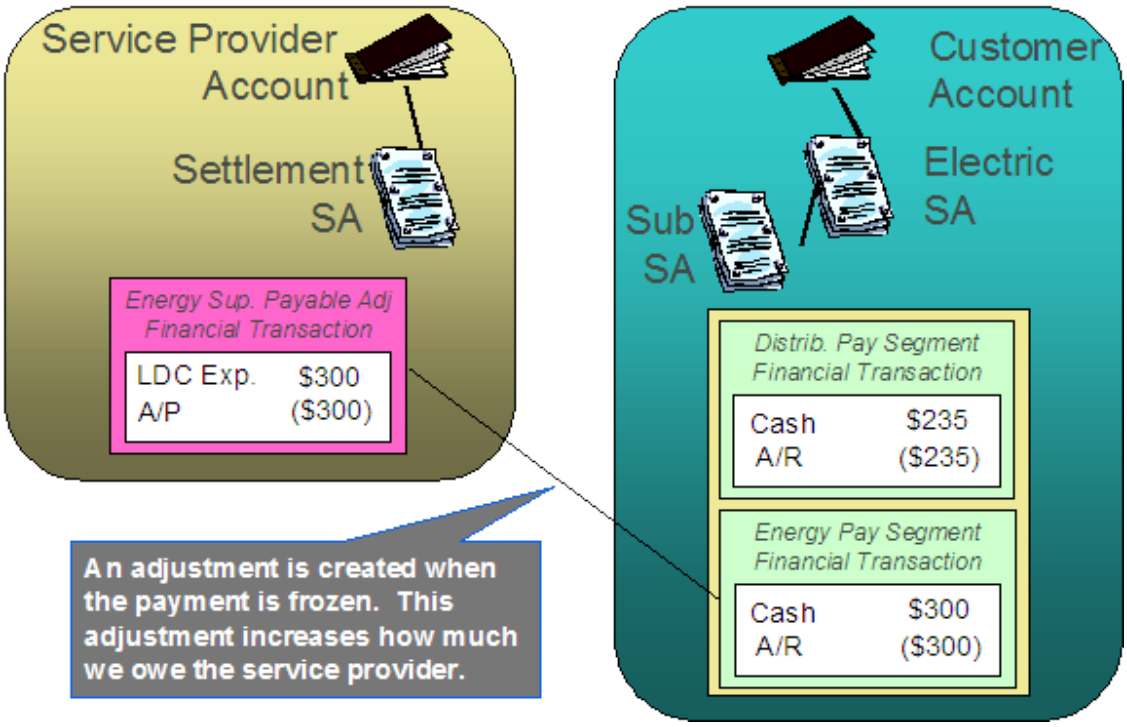
When you bill on behalf of a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will eventually owe them money (because the customer pays you



Copyright © 2026, Oracle and/or its affiliates.

for the service provider's service). You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you create the customer's bill. Some people refer to this method as "purchasing the receivable from the service provider".
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer.



The system keeps track of how much you owe a service provider on a service agreement linked to the service provider's account. The system creates adjustments against this service agreement to increase how much you owe them.

If you "purchase the receivable" (i.e., you owe them when you bill the customer), an adjustment is created when the customer is billed. If you owe them only when you are paid by the customer, an adjustment is created when the customer pays. The following example illustrates an adjustment being created when the bill is frozen (illustrating the "purchase the receivable" scenario):

If you only pay the service provider when you are paid, the example would look as follows:

Copyright © 2026, Oracle and/or its affiliates.

Adjustments and We Bill For Them Service Providers

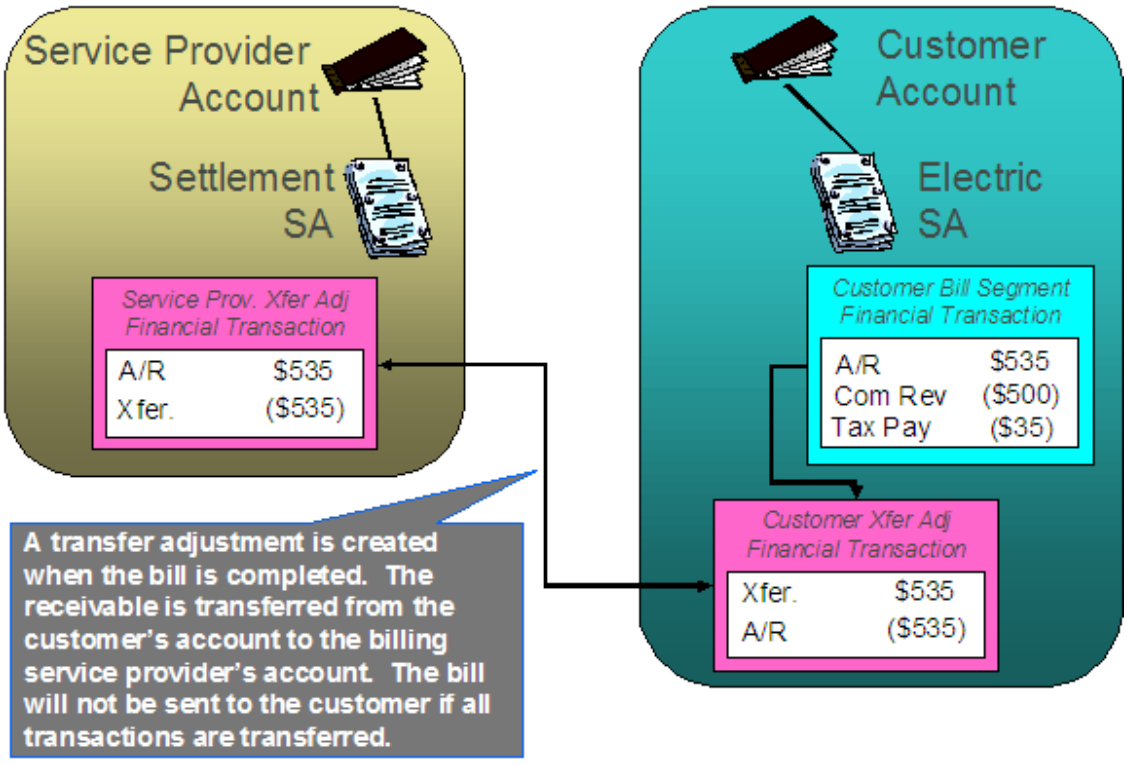
NOT_SUPPORTED

It's important that you are comfortable with the information described under When We Bill For Them, We Owe Them Money before reading this section.

Adjustments associated with We Bill For Them sub service agreements are tricky. The following points describe how the system "pays" the related service provider when adjustments are issued against the customer's sub service agreement:

- For Pay At Bill Time service providers, most adjustments are treated just like bill segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. The reason "most" is underlined in the previous sentence is because A/P adjustments (i.e., adjustments used to interface check requests to your A/P system) are excluded. Why? Because A/P adjustments are used to refund overpayments to the customer. Overpayments are purely between the customer and your company (you never transferred the overpayment to the service provider because it's associated with a Pay At Bill Time service provider).
- For Pay At Pay Time service providers, A/P adjustments are treated just like payment segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. All other types of adjustments are ignored. Why? Because A/P adjustments are used to refund overpayments to the customer. Think of it like this - when the customer originally overpaid, you transferred this overpayment to the Pay At Pay Time service provider; therefore, when you refund the overpayment, you get to take the money back from the service provider.

Copyright © 2026, Oracle and/or its affiliates.



When They Bill For Us, They Owe Us Money

When a service provider bills on behalf of your organization, they will eventually owe you money (because the customer pays them for your service).

The system keeps track of how much a service provider owes you on a service agreement linked to the service provider's account. The question is, How does the system determine how much you are owed when you don't produce a bill? Well, you do produce a bill, it just doesn't get sent to the customer. We understand this is a little confusing, but think about it like this:

- The service provider is presenting your charges on their bill.
- You still have to calculate how much the customer owes your organization otherwise you'll never know how much you are owed by the service provider.

As illustrated below, when a bill is completed, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these, it transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.

> **Note**
>
> **Bottom line.** We always generate a bill for "us", even though we don't send it to the customer.

Copyright © 2026, Oracle and/or its affiliates.

They Bill For Us

If a service provider provides billing services for you, then you have a They Bill For Us billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

- The Customer Still Needs A Service Agreement
- They Bill For Us - Bill Ready
- They Bill For Us - Rate Ready
- A/R Transfer - Technical Implementation
- Routing Billable Charges To Service Providers - Technical Implementation
- Bill Routings Are Changed

The Customer Still Needs A Service Agreement

If a service provider bills for you, you still need a service agreement for the customer. Why? Because:

- As explained under Service Providers Are Linked To Service Agreements, service providers are defined in respect of a customer's service agreement (therefore the customer must have a service agreement).
- As explained under When They Bill For Us, They Owe Us Money, you still have to calculate bills for the customer.

> **Note**
>
> **A customer's bill history still exists.** Be aware that even when a service provider bills for us, you will still be able to see the customer's billing history. It's just that the customer won't owe you anything because the receivable balance will be transferred to the service provider's account.

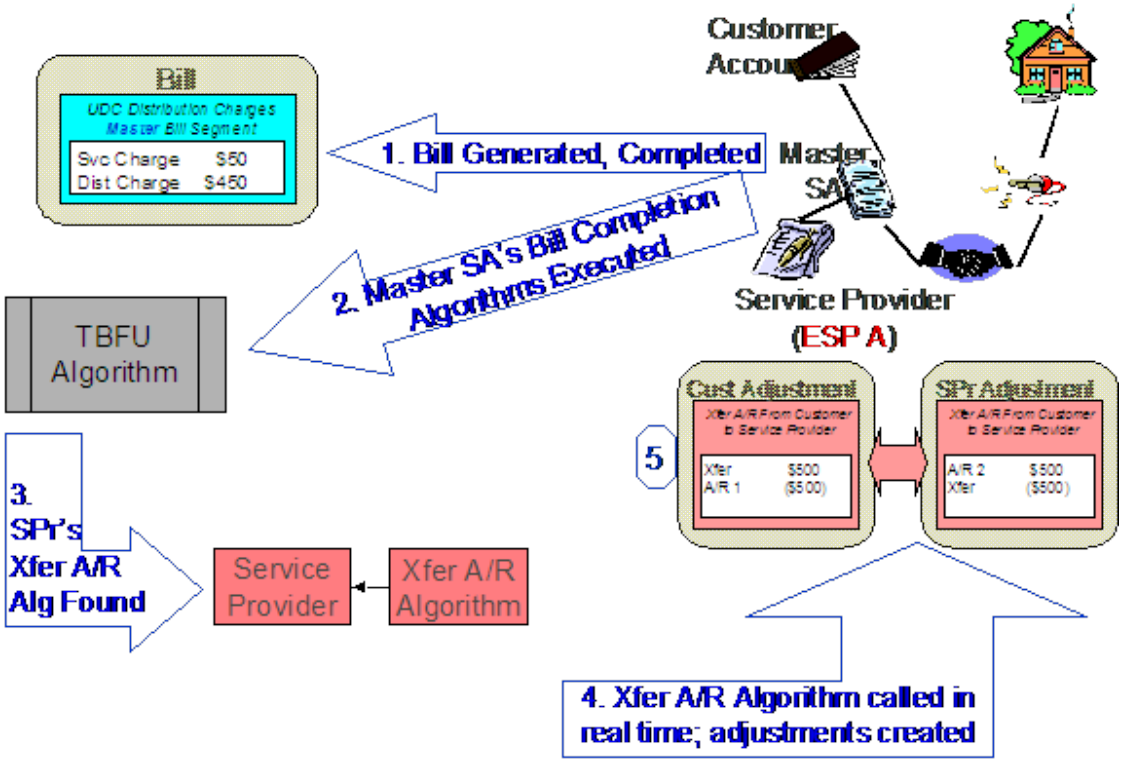
They Bill For Us - Bill Ready

At bill completion time, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these,

- It transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.
- Note that payments and A/P adjustments are not transferred. Why? Because payments and A/P adjustments are purely between the customer and your company.
- Each bill segment and adjustment is marked to be interfaced to the service provider (via a separate background process).

Copyright © 2026, Oracle and/or its affiliates.

They Bill For Us - Rate Ready



The They Bill For Us - Rate Ready option is not a recommended option. Why? Because you really have to compute how much the customer owes as explained above. If you go to the trouble of figuring out how much the customer owes, then it makes sense to interface this to the billing service provider.

The only difference between this option and They Bill For Us - Bill Ready is that the system will not interface the bill segments and adjustments to the billing service provider.

A/R Transfer - Technical Implementation

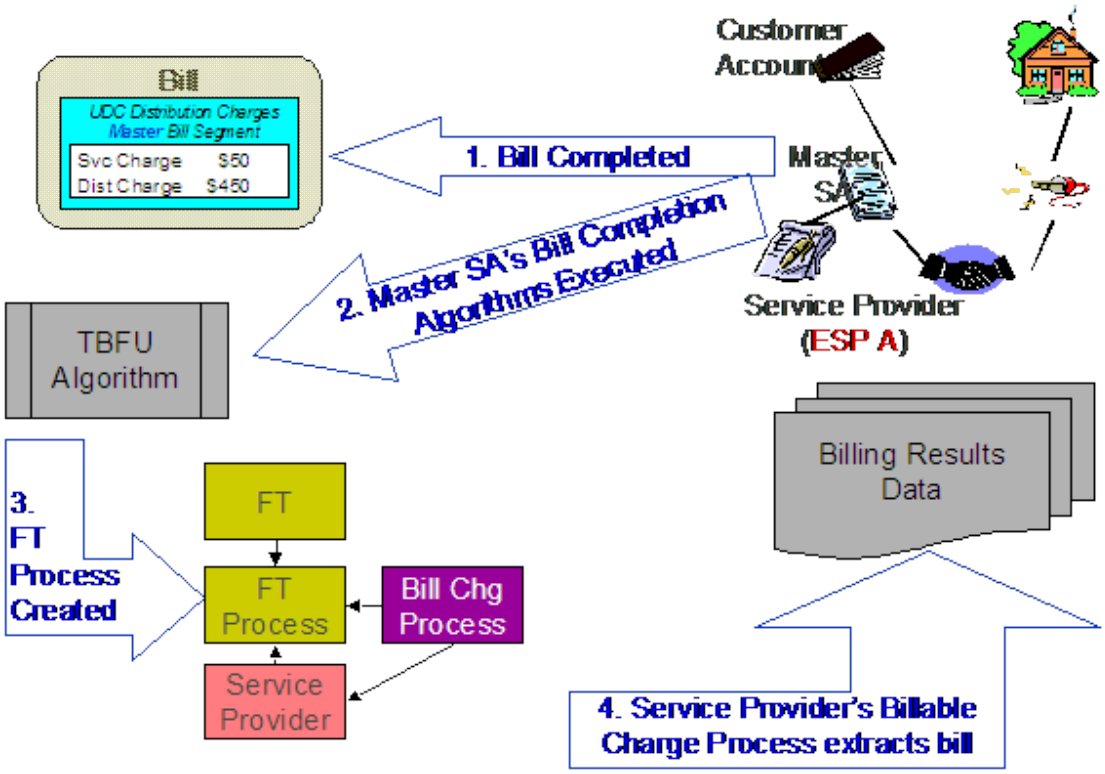
> **Warning**
>
> This section describes, technically, how a customer's A/R balance is transferred to a They Bill For Us service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with the transference of a customer's A/R balance to a They Bill For Us service provider.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.

Copyright © 2026, Oracle and/or its affiliates.



- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will execute the Transfer A/R algorithm defined on the service provider's record. This algorithm causes a transfer adjustment to be created (transferring the financial transaction's affect on the customer's balance from the customer to the service provider).

> **Note**
>
> If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be transferred to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Routing Billable Charges To Service Providers - Technical Implementation

> **Warning**
>
> This section describes, technically, how we send billable charges to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending billable charges to service providers.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

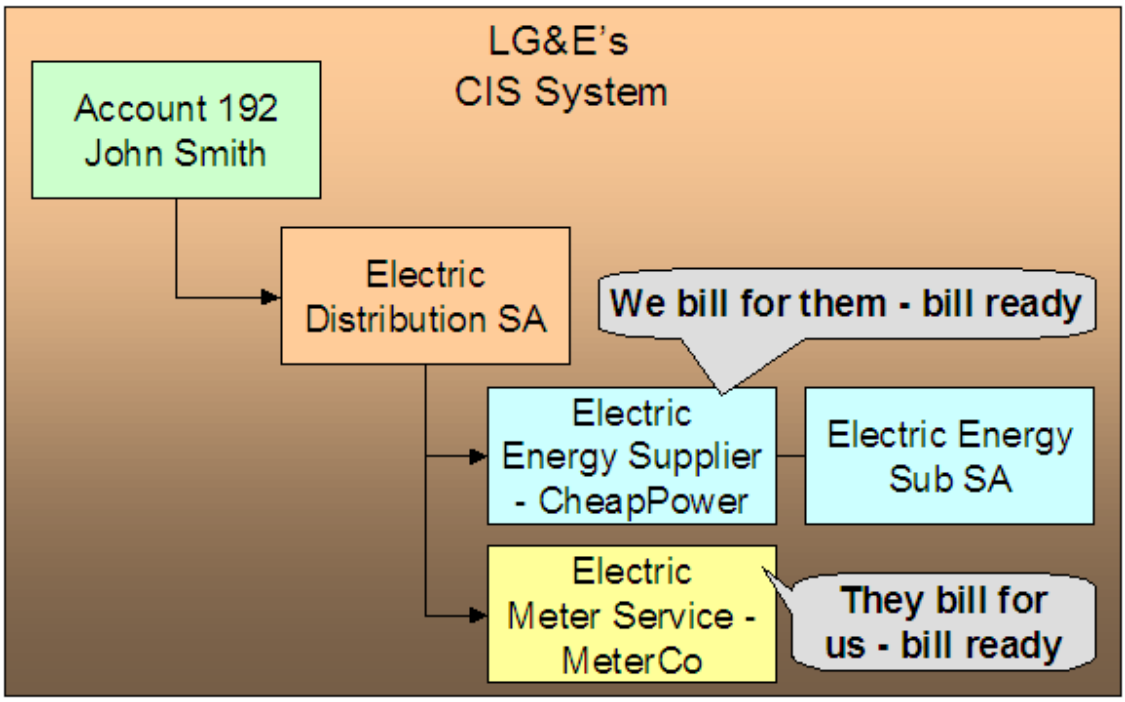
- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable charges to the service provider. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Billable Charge Download Process.

> **Note**
>
> If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be routed to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Bill Routings Are Changed

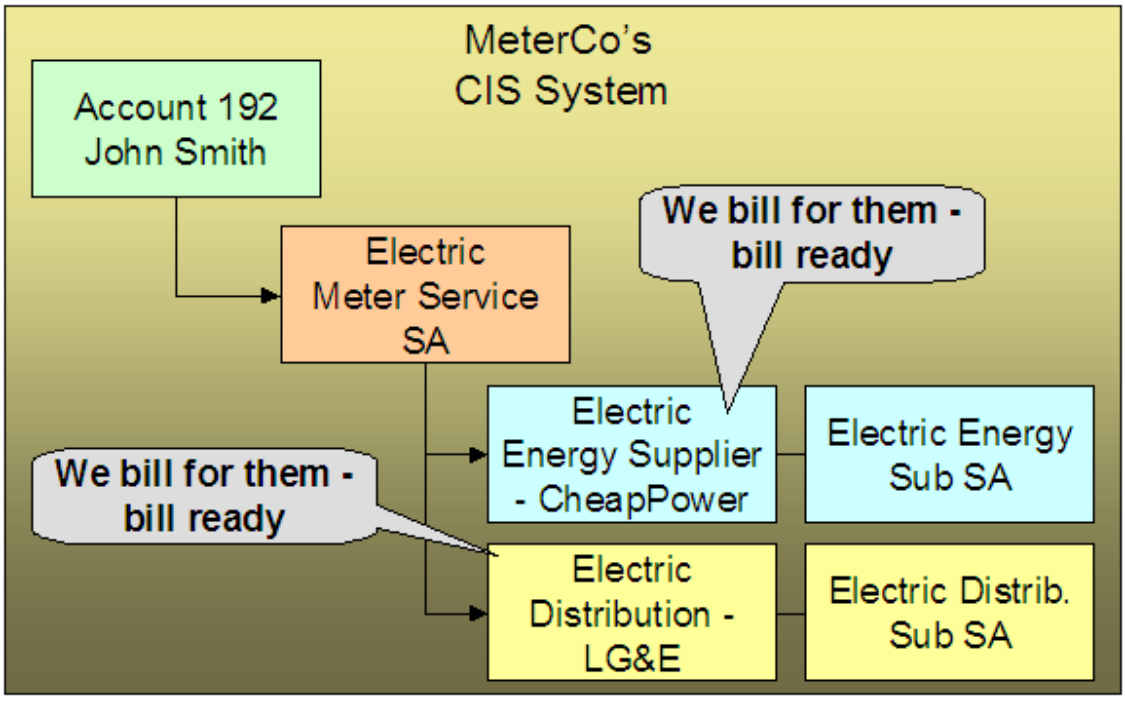
If all of an account's "master" SAs have a SA relationship with a service provider who bills for us (i.e., the service provider's billing relationship is They Bill For Us), then we have nothing to send to the customer. The system still creates bill routings, but with a couple of differences:

- The Batch Process Id and Run Number are reset.
- The Customer's Name is prefixed with the text from a bill message code 6, 10103. This message code's text is *** Bill not sent.



This way, the operators can easily see that that the bill was not routed and why.

> **NOT_SUPPORTED**
>
> Refer to Different Service Providers Can Bill Different Services for information about how the various services under an account could be billed by different service providers.

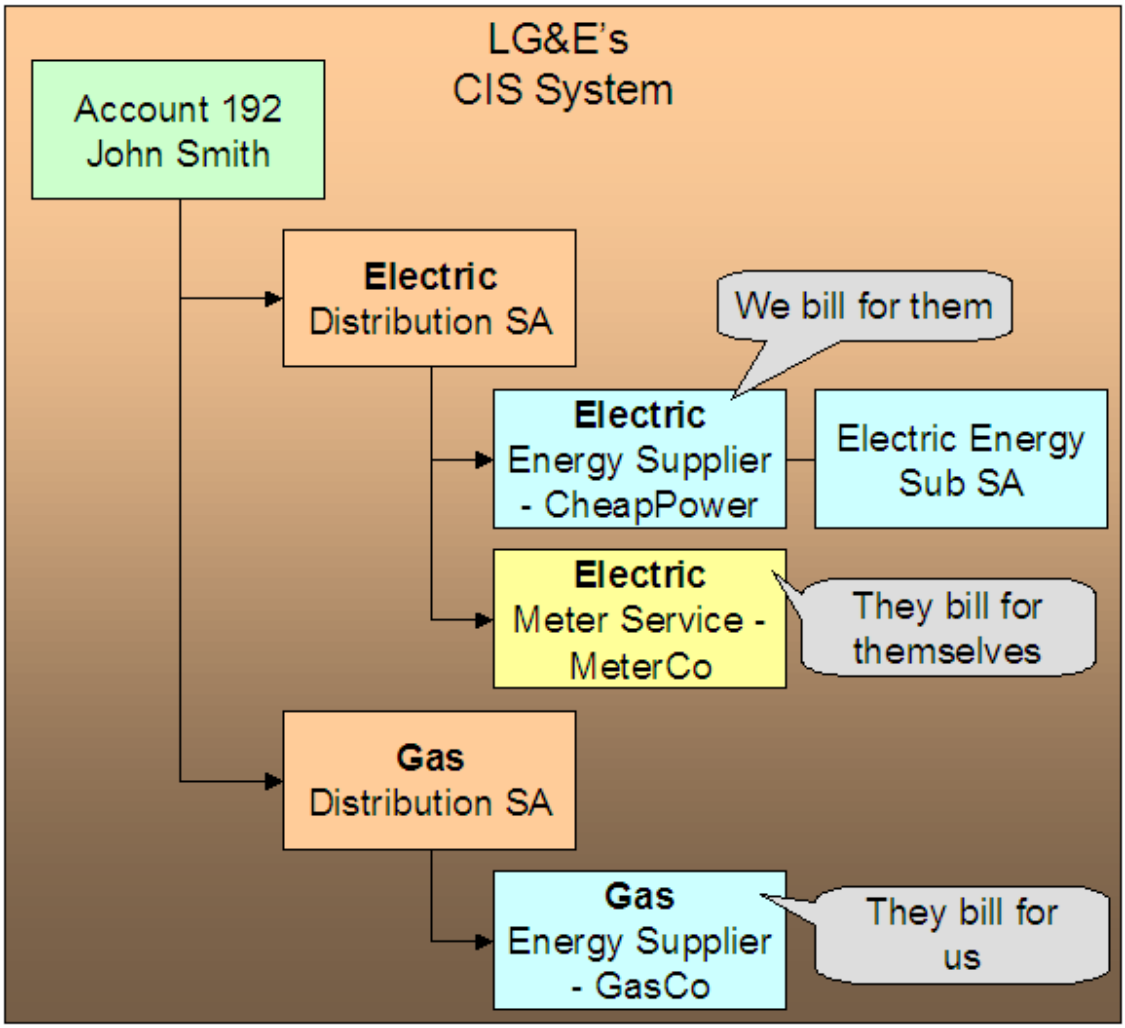


Combinations Of Service Provider Billing Methods

Consider the following situation:

Copyright © 2026, Oracle and/or its affiliates.

In the above example, we are billing for the energy service provider and the meter service provider is billing for us. This means that we will calculate the charges for ourselves, interface charges from CheapPower, and then interface our charges and CheapPower's charges to MeterCo. MeterCo will then produce a bill for the customer that contains our distribution charges, CheapPower's energy charges, and MeterCo's service charges. To help solidify this point, let's look at how this customer would look in MeterCo's CIS system.



There are some restrictions in respect of permissible combinations of service providers that may supply service to a customer as described in the following points:

Copyright © 2026, Oracle and/or its affiliates.

- If the system encounters a customer with a We Bill For Them (WBFT) - Bill Ready service provider and another service provider that is They Bill For Us (TBFU) - Rate Ready, a billing error will be produced. Why? Because TBFU - Rate Ready means they have everything they need to calculate our bills and therefore we do not interface bill lines to them. If we don't interface our bill lines to them, then we can't interface the charges that were interfaced from the WBFT - Bill Ready service provider. You may wonder why we don't prohibit WBFT - Rate Ready and TBFU - Rate Ready, because it's conceivable for the TBFU service provider to have our rate and the WBFT service provider's rate.
- If the system encounters a WBFT - Pay At Pay Time service provider and another service provider that is TBFU, a billing error will be produced. Why? Because when the system detects a TBFU service provider, it transfers the receivable from the customer to the service provider (and therefore the customer's account will never be paid).

Different Service Providers Can Bill Different Services

Be aware that the system determines billing relationships at the service agreement level, NOT at the account level. To make the point, check out the following customer in a distribution company's system:

Be aware of the following in respect of the above illustration:

Copyright © 2026, Oracle and/or its affiliates.

- The distribution company (LG&E) distributes both electricity and gas.
- The customer has a choice of energy service providers for both gas and electricity.
- This customer - John Smith - purchases electricity from CheapPower, and purchases gas from GasCo.
- LG&E provides billing services for CheapPower.
- GasCo provides billing service for LG&E.

In this situation, LG&E will send bills to the customer that contain both electric distribution and energy charges (but no gas distribution charges). GasCo will also send bills to the customer; these will contain both LG&E's gas distribution charges as well as their own energy charges.

If You Deal With TBFU Service Providers, You Cannot Reopen Bills

NOT_SUPPORTED

Refer to Bill Lifecycle for information about reopening previously completed bills.

If your organization deals with They Bill For Us (TBFU) service providers, a great deal happens when a bill is completed (e.g., the receivable is transferred from the customer to the service provider, we may mark the bill segments and adjustments for routing to the service provider, etc.). These things cannot be undone and therefore the system will not let you reopen bills when these things have occurred.

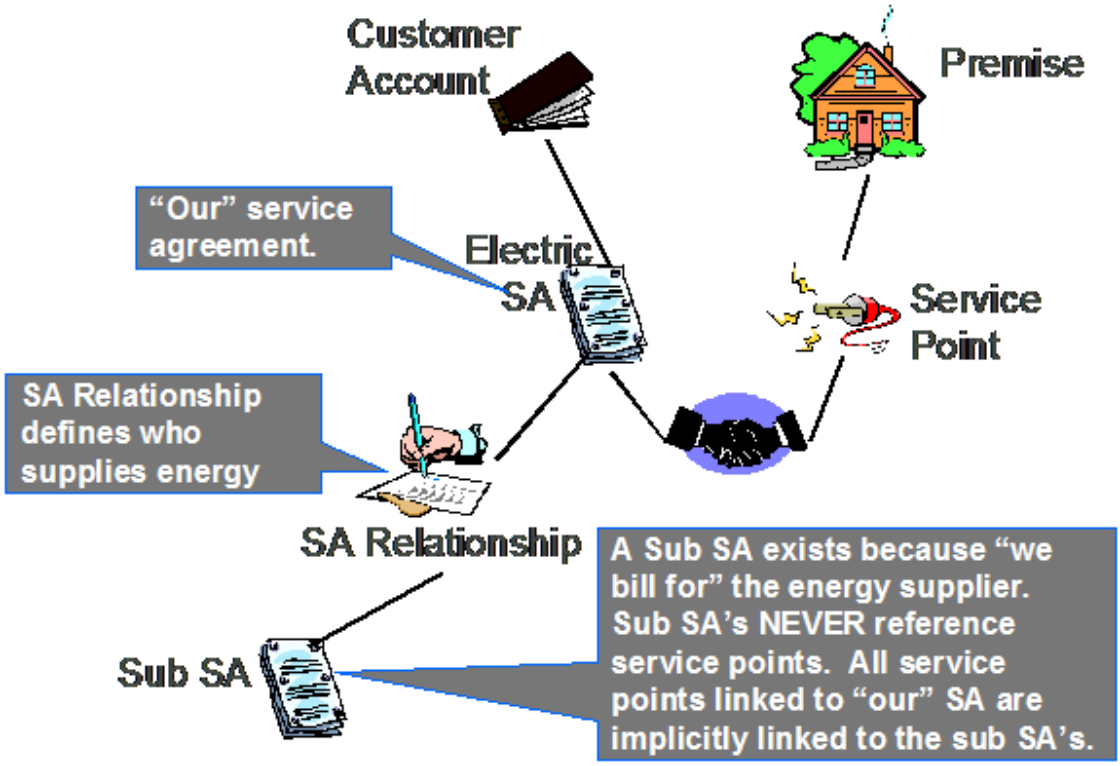
Note

Technical rule. The specific rule that prevents the reopening of bills is as follows: if a bill contains a service agreement whose SA type has one or more bill completion algorithms, the system will not allow the bill to be reopened. Refer to SA Type - Algorithms for more information about bill completion algorithms.

Consumption Relationships

When you set up a service provider, you must define your organization's consumption relationship with the service provider - a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

The topics in this section provide a wealth of information about the various consumption relationships and the ramifications of each.



- Only The Master SA Is Linked To Service Points
- We Can Send Billed Consumption To Any Service Provider
- Routing Consumption To Service Providers - Technical Implementation
- We Can Receive Consumption From Service Providers

Copyright © 2026, Oracle and/or its affiliates.

- MDMAs And Service Cycles

Only The Master SA Is Linked To Service Points

The following diagram makes the point that service points cannot be linked to sub SAs (i.e., service agreements that exist to hold charges associated with We Bill For Them service providers). This is because all service points associated with our "master" SA are implicitly linked to all sub SAs.

It's important to understand why the system does not allow sub SAs to reference service points:

- The consumption associated with all service providers should be the same, otherwise the customer will receive inconsistent bills from different service providers.
- The easiest way to ensure consumption is the same for all service providers is to make sure that they all have the same service points (which they must if sub SAs "inherit" their service points from their master).

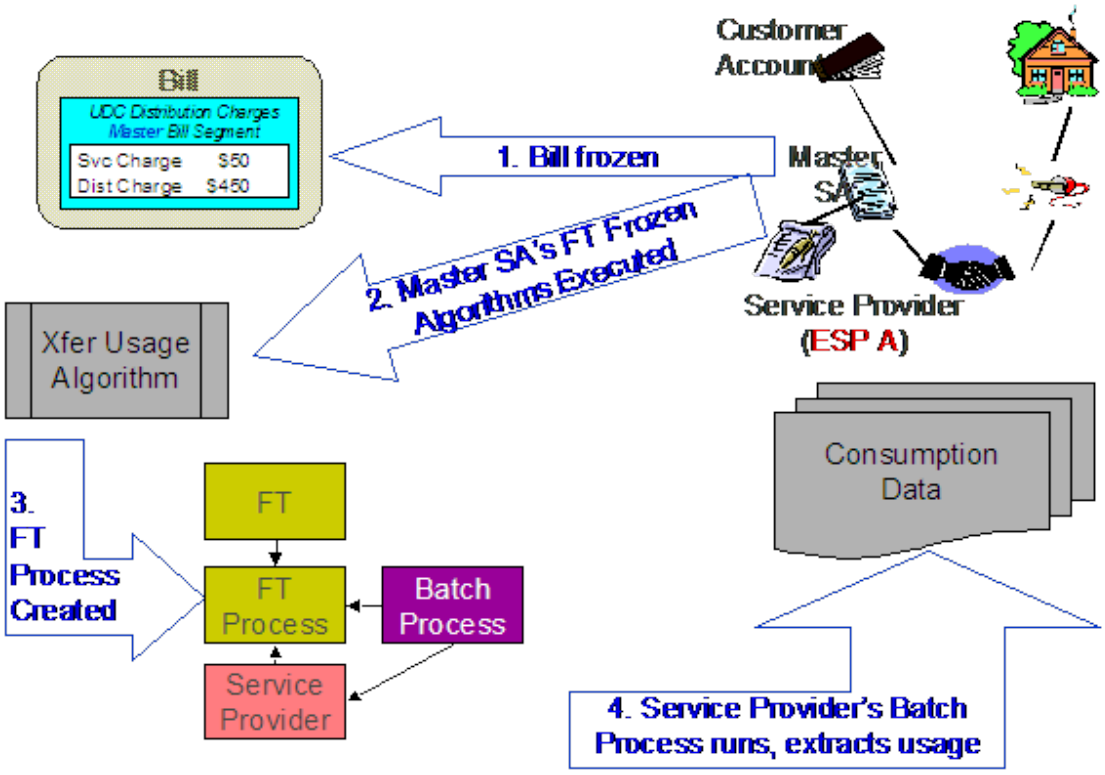
We Can Send Billed Consumption To Any Service Provider

You can send consumption to any service provider. It doesn't matter what their billing relationship is. Information on the service provider object tells the system if AND how to send consumption to a service provider.

Rather than send raw reads to service providers, we download consumption that has been calculated and snapshot onto the "master" bill segment. We send this billed consumption because:

Copyright © 2026, Oracle and/or its affiliates.

- It is clean and validated
- Register indexes have been subtracted
- Multiple registers have been summed



> **Note**
>
> We only send consumption after a bill segment is Frozen. If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service providers to calculate their charges, please refer to The Bill Ready Calculation Method for an explanation of how the system waits a given amount of time for the recipient of the consumption to interface their charges back to the system before sending the bill to the customer. In other words, the bill sent to the customer should contain the bill segment that triggered the consumption download as well as bill segments containing uploaded billable charges.

Routing Consumption To Service Providers - Technical Implementation

> **Warning**
>
> This section describes, technically, how we send consumption to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending consumption to service providers.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the master SA's SA type), one of these algorithms will determine if there are service providers associated with the master SA who need consumption. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable consumption to the service provider. If multiple service providers need consumption, multiple rows will be inserted. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Consumption Download Process.

We Can Receive Consumption From Service Providers

We can receive consumption from any source. The system can receive consumption from service providers. Each customer must have:

- A premise
- A service point
- A device with measuring components sufficient to hold the interfaced consumption

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **You don't have to perfectly model the service points and meters.** If you are not the distribution company, you may be worried about how to keep devices and service point information up-to-date. Be aware that you don't have to model the SPs and devices perfectly. Why? Because you just need to set up enough information so that consumption can be received accurately.

MDMAs And Service Cycles

> **Warning**
>
> This section uses terminology and concepts described in The Cyclical Meter Read Process.

A Meter Data Management Agency (MDMA) is a service provider who reads meters. In some locales, a meter can be read by a variety of MDMAs, in other locales there is no MDMA as the meter is read by the distribution company. If your organization has MDMAs, then you need to be aware of the following:

- MDMAs must be linked to service agreements as a service provider. Like all service providers, they can change over time.
- When an MDMA is reading a service agreement's meters, the MDMA may override the customer's service cycle (and schedule) with their own cycle. If they do this, the customer's service cycle in the MDMA's system is defined on the service agreement's SA relationship information for the MDMA. Note: whether or not a service provider can override a service cycle is controlled by a switch on the service provider's record. Refer to Setting Up Service Providers for more details.
- A service provider's service cycle schedules are maintained using the system's normal service cycle schedule. The ID of the service provider associated with each schedule is defined on the service cycle; in other words, if a service provider reads meters and they can override the customer's service cycle, the service provider's service cycles must be defined in the system. Refer to Designing Service Cycles, Routes, And Schedules for more information.
- At billing time, the system determines if a service agreement is covered by an MDMA. If so, it uses the service cycle defined on the service agreement's MDMA SA relationship record.
- If your organization ever reads the customers' meters, your regular read cycle should be maintained on your service points. You can think of the service cycle that is defined on a service agreement's MDMA SA relationship record as an override of your service points normal service cycle.
- If the meter read download process detects that a service point is linked to a service agreement with an active MDMA, it still creates a meter read download staging record; however, it marks it as Do Not Need To Read. This means that when a service point is no longer read by an MDMA, the meter read will be downloaded normally.

Copyright © 2026, Oracle and/or its affiliates.

- Refer to We Can Receive Consumption From Service Providers for a description of how a service provider interfaces consumption into the system.

Deposits Issues

> **Warning**
>
> This section uses terminology and concepts described in The Big Picture Of Deposits.

Deposits should be held using normal deposit service agreements (SAs). You should NOT use the Sub Service Agreements (sub SA) functionality to hold or bill for deposits because deposit service agreements do not have the same state transition as do master SAs (e.g., you can activate or stop a deposit independent from its master).

However sub SAs can be covered by a deposit. If so, their SA type must reference a deposit class. To make the point, let's examine a few scenarios:

- Assume you have a sub SA for your own charges (this can happen when we use sub SAs to unbundle charges from the Master SA). In this case, it is likely that the sub SA and master SA will be in the same deposit class. This means that a single deposit SA would cover both the master and the sub SA.
- Assume They Bill For Us (Bill or Rate Ready). In this situation, we still have a master SA for our charges and we transfer the charges to the service provider who does the billing. In this case, it is likely that we would be holding the deposit for the service provider, not on the end-use customer. If we are in a situation where 1) we cannot hold a deposit against the service provider, and/or 2) we are not assured of the service provider paying us when the customer doesn't pay them, then we might want to put the master SA in a deposit class and hold a deposit against the customer's account using a normal deposit SA. We would not expect the service provider to bill the customer for the deposit, so we don't need a sub SA. We bill the customer directly for the deposit using our normal deposit SA.
- Assume We Bill For Them (Bill or Rate Ready). In this situation, we could hold a normal deposit SA for the customer's master SA. For sub SAs, we have two scenarios:
  - **We pay at billing time.** Since we purchase the receivable, we would want to increase our normal deposit to cover the Sub SA. To do this, the sub SA's SA type's deposit class should be the same as our master SA's deposit class.
  - **We pay at payment time.** It seems unlikely that we would want to hold a deposit on behalf of a service provider when we don't purchase the receivable. However, it is possible to do so by putting the sub SA into its own deposit class. If you did this, the system will require a separate deposit SA for the service provider's deposit. The system would calculate and refund such deposits using the algorithms defined on the new deposit SA's SA type's deposit class. It's important to be aware that the deposit is not held with respect to the specific service provider. Rather, it is just held in the system as separate deposit that could be used for any service agreement that belongs to its deposit class.

Credit and Collection Issues

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> This section uses terminology and concepts described in The Big Picture Of Credit & Collections (C&C).

C&C is only tricky if you deal with We Bill For Them service providers. We'll run through the service provider billing relationships to explain why:

- If we have a Dual relationship with a service provider, we don't have their debt, so we only have a responsibility to tell them when we cut a customer (via a Notification). We don't have to worry about collecting their debt.
- If we have a They Bill For Us relationship with a service provider, there is no debt on the customer's SA because it gets transferred to the service provider (and the service provider's SA will fall into arrears if they don't pay us).
- If we have a We Bill For Them or It's Us relationship with a service provider, the customer's debt associated with the service provider's service is maintained on a sub SA (i.e., it is segregated from our debt). This segregation of debt is both a powerful feature and a cause of administrative difficulties. The topics in this section provide more information about this issues.
- Debt Class Recommendations
- Severing Service

Debt Class Recommendations

A service agreement's debt class is an important element in determining how a customer's debt is collected. In general, we recommend the following:

- If the service provider has a billing relationship of It's Us, we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Billing Time), we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you don't buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Pay Time), you may want to use a different debt class on the sub SA. Why? Because you may collect the service provider's debt differently.

> **Note**
>
> **Bottom line.** If both the "master" and the sub SAs fall into arrears, you will have 1 or 2 collection processes, it all depends on the debt class assigned to each SA type.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Automating Your C&C Activities for information describing how debt class plays a part in this processing.

Severing Service

Sub SAs and severance is tricky. Why?

- Because it's possible for the master SA to be in arrears when the sub SA isn't (for all the standard reasons - directed payments, cancel / rebills, etc.).
- Because it's possible for the sub SA to be on one collection process and the master to be on another (due to different debt classes or different time lines).

Both of these situations could result in severance starting for only one of the service agreements in the master / sub relationship. However, YOU CAN'T CUT SERVICE FOR ONE WITHOUT CUTTING THE OTHER because there is only one service point.

Before we describe how to deal with this conundrum, we'd like to remind you that the system starts a unique severance process for each SA (sub or normal) to be severed. It only creates a severance process for those service agreements linked to a collection process when the collection process' Start Severance event is activated. The type of severance process that is created is controlled by each service agreement's SA Type's severance criteria. Please keep in mind the following when designing these severance processes:

- Only The "Master" Service Agreement Is Linked To Service Points. This means only master SAs should have a "cut for non payment" severance event. Note: typically, such a severance process will expire the "master SA" several days after the cut event if funds are NOT received.
- As described under Sub SA State Transition, a sub SA becomes Pending Stop (and eventually Stopped) when its "master" is stopped. This means the sub SAs will be finaled when the master is finaled.
- If you start severance on a sub SA when the master isn't being severed, you have a problem because you can't cut the sub SA independent from the master SA.

We'll use an example to illustrate how you should design your severance processes to deal with the above challenge. Assume you have a master and a sub SA where both are being managed under the same collection process. Also assume that the Start Severance event kicks off on 18-Dec-1999. In this situation, we'd recommend the following severance processes to be kicked off.

Master SA Severance Process

Trigger Dt.	Event Type	Status
18-Dec-99	Set door hanger	Pending
Pending	Cut for non pay	Pending
Pending	Expire SA	Pending

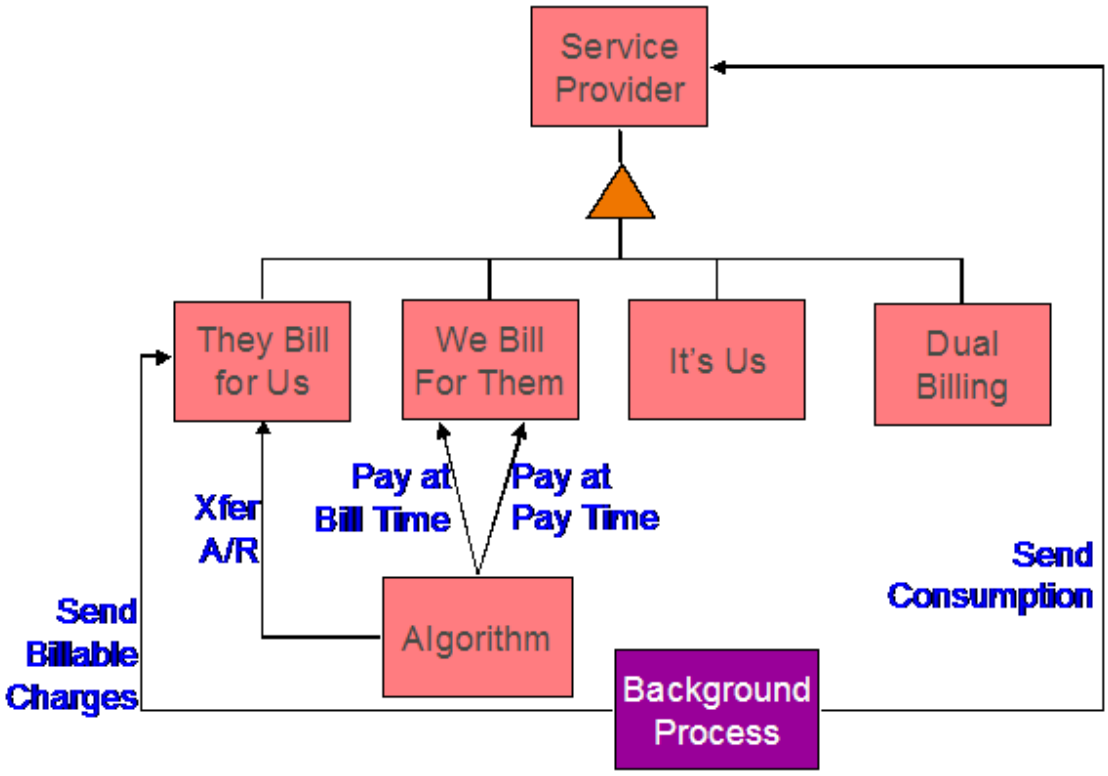
Sub SA Severance Process

Trigger Dt.	Event Type	Status
3-Jan-00	Create To Do Entry	Pending

Copyright © 2026, Oracle and/or its affiliates.

Notice that the sub SA's severance process contains a single event that generates a To Do Entry on a date in the future of the Expire SA event on the Master SA. This entry should be something like "sub being severed independent of its master". This event will only be triggered if the master SA is paid off and the sub SA isn't. Why? Because if the master SA's Expire SA event is executed, the Sub SA will be Stopped and stopping a SA cancels outstanding severance processes. If the sub gets paid, the system will cancel the sub's severance process.

Let's change the example and assume that the master starts severance and the sub doesn't. In this situation, the master SA will eventually hit the Expire SA event and the sub SA will also stop. There's no alternative.



And let's change the example again and assume the sub starts severance and the master doesn't. In this situation, the To Do Entry will only be created X days after the start of severance. If you can't stand this date being X days in the future of the creation of the severance process, create an "Severance Criteria Algorithm" that checks if the master is not being severed or collected and generates a different severance process (with a different start date). Refer to Designing Your Severance Procedures for more information about Severance Criteria Algorithms.

An Object-Oriented Perspective Of Service Providers

> **Warning**
>
> Skip this section if you are not technically inclined.

The following object diagram illustrates in a concise format the various types of service providers and the plug in algorithms and processes available for each.

Copyright © 2026, Oracle and/or its affiliates.

How Do You Communicate With Service Providers?

You communicate with service providers (and they communicate with you) using the following mechanisms:

- You can use traditional interface techniques. For example, if you send consumption to service providers every month (so they can compute their charges), you could use the Consumption Download interface.
- You can use "notifications" to communicate with service providers. Notifications are electronic transactions that service providers exchange to communicate information about a customer. For example, you could use a notification to send a message to an energy supplier when a customer stops service. Note: the term "Direct Access Service Request" (DASR) is synonymous with Notification.

The difference between notifications and traditional interfaces is subtle. Think of notifications as a generic interface that can be used to communicate many different things (e.g., you can use notifications to advise stops, meter exchanges, supplier switches). Traditional interfaces communicate only one thing (and you need one traditional interface for each "thing"). For example, one interface is devoted to downloading consumption, another is responsible for uploading pass through charges, etc.

NOT_SUPPORTED

Refer to The Big Picture Of Notification Processing for more information about notification.

Copyright © 2026, Oracle and/or its affiliates.

Off Cycle Switch

If the customer care and billing application integrates with meter data management (mdm) system, it may be set up to generate sub-bill segments for each and every service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, that is effective in the billing period. This requires that the meter data management system can calculate the consumption for each effective SA relationship period.

If the switch is from or to a service provider having **They Bill for Us** billing relationship, separate bills have to be generated manually for each relationship effective in the billing period. This restriction is due to requirement for CCB application to generate a bill for a **They Bill for Us** relationship, so that the customer's charges are calculated and eventually transferred to the service provider. The generated bill for **They Bill for Us** billing relationship is not sent to the customer.

- Billing Master Configuration
- Rate Schedule
- Sub-SA Type
- Usage Request
- Sending Consumption to Service Providers

Billing Master Configuration

To enable Off Cycle Switch, navigate to **Admin**, and then **General**, and then **Master Configuration** and add a new entry for Billing Master Configuration.

Specify the values for **Off Cycle Switch Option**, **Implementation Date** and **Off Cycle Switch Option for Old Bill**. Refer to the embedded help on billing master configuration portal for details.

Rate Schedule

Rate schedules assigned to the sub-SA of service provider, having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, must be configured with an SQ rule (for component-based engine) or a pre-processing calculation rule (for rule-base engine) that will obtain the sub-usage's consumption and load it into the bill segment SQ collection during rate application.

For more information, refer to the base package algorithm types provided for this purpose: US (component based engine) and C1-ACRSUBUSG (rule based engine).

Sub-SA Type

When implementing this feature, sub-SA types of service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship must be configured as non-bill determinant.

Usage Request

Usage request is sent to the Oracle Utilities Meter Data Management (MDM) system, to obtain the calculated consumption for the billing period - this is used to calculate master bill segment's charges.

Copyright © 2026, Oracle and/or its affiliates.

In addition, sub-usage request is sent to the mdm system, for each relationship that is effective during the billing period. Calculated consumption on these sub-usage requests is used to calculate sub-bill segment charges.

Sending Consumption to Service Providers

Calculated consumption on these sub-usage requests also serves as the source for consumption download process if consumption is required to be sent to the service provider. A base package algorithm type - C1-STGCNSMP, stages the download by creating an entry in the general process table, capturing the sub-usage id, batch control for consumption download and the batch number.

> **Note**
>
> It is implementation responsibility to build the consumption download batch process that will extract the consumption for sub-usage request as required.

Designing Your SA Relationship Types and Service Providers

As explain in A Service Agreement Can Have Many Types Of Relationships, SA relationship types and service providers are only required when you subcategorize your service agreements.

The topics in this section describe how to design your SA relationship types.

- Designing SA Relationship Types
- Designing Service Providers
- Designing Your SA Types And Start Options For Sub SAs
- Reference Send Consumption Algorithm On Master SA Types
- Reference TBFU Algorithm On Master SA Types
- Designing SA Types For Service Provider Financial Settlements

Designing SA Relationship Types

The easiest way to design SA relationship types is to start with the matrix of SA types designed in SA Types And The Financial Design. For each SA type in the matrix, determine if either of the following questions is true:

- Can companies other than your own provide some subcategory of the service (and do you have some type of interaction with these companies)? For example, this would be true if you are an energy supply company because a different company is responsible for distributing the power to the customer (and you probably exchange consumption and financial transactions with this company).
- Does your organization use different rates for subcategories of the service? For example, this would be true if you use separate rates for water and wastewater service (even though both are based on the customer's water consumption).

Copyright © 2026, Oracle and/or its affiliates.

If either of the above is true, you will need a SA relationship type for each subcategory of service.

We'll use an example to help make the point. Using the SA types we designed earlier (see SA Types And The Financial Design), we'll assume the following:

- We are designing the system for an electric, gas, water, waste water, and cable utility.
- Residential electric customers have a choice of energy supplier.
- Commercial and industrial electric customers can choose an energy supplier and a meter service provider.
- Commercial and industrial gas customers have a choice of energy supplier.

> **Note**
>
> We are not showing most of the SA types that we designed earlier because they do not have subcategories of service.

CIS BU/ SA Type	SA Relationship Type
G/COM	Energy supply
G/IND	Energy supply
E/RES	Energy supply
E/COM	Energy supply
	Meter service
E/IND	Energy supply
	Meter service

> **Note**
>
> Notice that we did not design a SA relationship type for our own distribution service. This is because our relationship type is implied (e.g., if you are a distribution company, you do not have to set up a SA relationship type for distribution service because the customer's "master" service agreement is implicitly associated with distribution service).

Designing Service Providers

After you design your SA relationship types, you need to list every potential service provider for each SA relationship type.

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas

Copyright © 2026, Oracle and/or its affiliates.

		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power
		Us
E/COM	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us
E/IND	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us

Next, list each unique service provider identified above:

Service Provider
AmeriGas
TransGas
Green Power
Cheap Power
Us
ElectriCorp
TeniCorp
MeterCorp

You will have at least one service provider for each entry in the above list. However, you may have to set up more than one service provider in the system for a given company. The topics below explain how this happens.

- Billing Relationship Segmentation
- We Bill For Them - Payment Relationship Segmentation
- Consumption Relationship Segmentation
- Other Segmentations
- Geographic Area Segmentation

Billing Relationship Segmentation

Copyright © 2026, Oracle and/or its affiliates.

As described under Billing Relationships, a service provider may bill for you, you may bill for them, or you may each send a separate bill to the customer. In the table below, we have shown the assumed billing relationships for each service provider.

Service Provider	Billing Relationship
AmeriGas	We Bill For Them - Bill Ready
TransGas	We Bill For Them - Bill Ready
Green Power	We Bill For Them - Rate Ready
Cheap Power - Res	We Bill For Them - Rate Ready
Cheap Power - Com/Ind	Dual Billing
Us - Billable	It's Us
Us - Non billable	None
ElectriCorp	They Bill For Us - Bill Ready
TeniCorp	We Bill For Them - Bill Ready
MeterCorp	Dual Billing

Notice that we had to introduce additional service providers:

- Cheap Power has two service providers - one for residential customers, the other for commercial/industrial customers. This is necessary because we provide billing service for them for residential customers (We Bill For Them - Rate Ready), but for commercial and industrial customers they bill for themselves (Dual Billing).
- Our own service provider (the service provider known as "Us") has two service providers - one for energy supply because we bill for the energy we supply (It's Us), and another for meter service because we don't create bills for meter service (None).

We Bill For Them - Payment Relationship Segmentation

As described under Pay At Bill Time vs. Pay At Pay Time when you provide billing service for a service provider you have to define if you pay the service provider when you bill the customer OR only later, when the customer pays you.

In the table below, we have shown the payment relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Com/Ind	Dual Billing	N/A
Us - Billable	It's Us	N/A
Us - Non billable	None	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time
MeterCorp	Dual Billing	N/A

Copyright © 2026, Oracle and/or its affiliates.

Notice that we had to introduce an additional service provider for TeniCorp because for commercial customer we purchase the receivable (Pay At Bill Time), but for industrial customers we only pay them when we're paid by the customer (Pay At Pay Time).

Consumption Relationship Segmentation

As described under Consumption Relationships a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

In the table below, we have shown the consumption relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Notice that we didn't have to proliferate service providers due to consumption relationships.

Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of service providers. However, many obscure factors could cause the introduction of more service providers. In this section we explain these more obscure factors.

- Payment Method
- Transfer Receivable Method
- Billable Charge Download Process
- Consumption Download Process
- Notification Upload Processing

Copyright © 2026, Oracle and/or its affiliates.

- Notification Download Processing
- Financial Settlement Service Agreement

Payment Method

As described under Pay At Bill Time vs. Pay At Pay Time, when you provide billing service for a service provider you have to pay the service provider at some point in time. The algorithm that defines the amount to pay (and how the related adjustment is generated) is defined on the service provider record. If a service provider has different payment algorithms for different customer segments, you must split the service provider accordingly.

Transfer Receivable Method

As described under When They Bill For Us, They Owe Us Money, a service provider will owe you money if they provide billing service for you. The algorithm that defines how to transfer the customer's receivable to the service provider is defined on the service provider record. If a service provider has different transfer A/R algorithms for different customer segments, you must split the service provider accordingly.

Billable Charge Download Process

As described under They Bill For Us - Bill Ready, billable charges are interfaced to service providers who provide billing service for you. The background process that performs the interface of billable charges is defined on the service provider record. If a service provider has different billable charge interfaces for different customer segments, you must split the service provider accordingly.

Consumption Download Process

As described under We Can Send Billed Consumption To Any Service Provider, consumption can be sent to any service provider. The background process that performs the interface of consumption is defined on the service provider record. If a service provider has different consumption interfaces, you must split the service provider accordingly.

Notification Upload Processing

A service provider can send you notifications. Whenever a notification is uploaded, the system creates a workflow process to process each such notification. The type of workflow process that's created is controlled by the service provider's workflow process profile. If a service provider requires a different workflow process for a given type of notification (for whatever reason), you must split the service provider accordingly. For details, see Designing Notification Upload & Workflow Procedures.

Notification Download Processing

Copyright © 2026, Oracle and/or its affiliates.

The system will send notifications to service providers when something noteworthy happens and when information is needed from a service provider. The type of notification that is sent to a service provider and the background process that interfaces the notification to the service provider is defined on the service provider's notification download profile. If a service provider requires a different type of notification to be sent or they have different interface protocols for a given type of notification, you must split the service provider accordingly. For details, see Designing Notification Downloads.

Financial Settlement Service Agreement

As described under Service Providers Have Service Agreements Too, service providers have service agreements. These service agreements contain how much you owe the service provider (if you bill for them) and how much they owe you (if they bill for you). If you want to have separate service agreements for financial settlements associated with distinct customer segments, you must split the service provider accordingly.

Geographic Area Segmentation

The following table reflects the new service providers that were added since we started Designing Service Providers.

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas
		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power - Res
		Us - Billable
E/COM	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
		TeniCorp - Com
	Meter service	MeterCorp
		Us - Non billable
E/IND	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
		TeniCorp - Ind
	Meter service	MeterCorp
		Us - Non billable

Next, determine the postal code ranges in which a service provider is allowed to provide service.

Copyright © 2026, Oracle and/or its affiliates.

CIS BU/ SA Type	SA Relationship Type	Service Provider	Postal Range
G/COM	Energy supply	AmeriGas	94000 - 95999
		TransGas	94000 - 95999
		Green Power	94000 - 95999
G/IND	Energy supply	AmeriGas	94000 - 95999
		TransGas	94000 - 95999
		Green Power	94000 - 95999
E/RES	Energy supply	Green Power	94000 - 95999
			93000 - 93999
		Cheap Power - Res	94000 - 95999
		Us - Billable	94000 - 95999
E/COM	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Com	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999
E/IND	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Ind	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999

Next, we need to strip off the SA types because the postal ranges are defined for combinations of service provider and SA relationship type. Notice the problem - we have a service provider - Green Power has different postal ranges for the same SA relationship type. You have two ways to fix this problem, you can split your service provider (have one for the gas and another for the electric), or you can split the SA relationship type (have one for the gas and another for the electric). We've chosen the former in our example.

SA Relationship Type	Service Provider	Postal Range
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	Green Power - Electric	94000 - 95999
		93000 - 93999
	Cheap Power - Res	94000 - 95999
	Us - Billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999

Copyright © 2026, Oracle and/or its affiliates.

	Cheap Power - Com/Ind	94000 - 95999
	TeniCorp - Com	94000 - 95999
Meter service	MeterCorp	94000 - 95999
	Us - Non billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999
	Cheap Power - Com/Ind	94000 - 95999
	TeniCorp - Ind	94000 - 95999
Meter service	MeterCorp	94000 - 95999
	Us - Non billable	94000 - 95999

In the table below, we have shown the final list of service providers.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power - Electric	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Green Power - Gas	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Designing Your SA Types And Start Options For Sub SAs

When you were Designing Service Providers, you defined the service providers that were valid for every combination of SA type and SA relationship type. If you provide billing services for another service provider or if you subcategorize your own services, you another task - you have to design the SA types for your sub SAs.

As described earlier, there will be a separate Sub Service Agreement for every SA relationship for which we calculate a bill segment. Every sub SA must reference an SA type. The following table shows sample SA types (notice that they are only used for We Bill For Them and It's Us service providers).

Copyright © 2026, Oracle and/or its affiliates.

CIS BU/ SA Type	SA Relationship Type	Service Provider	SA Type(s) for Sub SAs
G/COM	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GC1
G/IND	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GI1
E/RES	Energy supply	Green Power - Electric	GP-ER1
		Cheap Power - Res	CP-ER1
		Us - Billable	US-ER1
E/COM	Energy supply	ElectriCorp	Not applicable - they bill for us
		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Com	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing
E/IND	Energy supply	ElectriCorp	Not applicable - they bill for us
		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Ind	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing

The design steps required to set up these SA types are similar to those described under Designing SA Types For Service Agreements With Service Points. The following points provide a few suggestions that will help you design your SA types for sub SAs:

- The business unit should be the same as defined for the master service agreement.
- Service type should be set up as per Service Segmentation.
- Distribution code should be set up as per Receivable Segmentation.
- Obviously, the sub SA switch should be turned on.
- Start options:
  - If the SA type is used for a We Bill For Them - Rate Ready service provider or for yourself, the start options should be Required because rates, contract riders and/or contract values will be populated on the sub SA from a start option. Refer to Automatic Creation of Sub SAs for more information.
  - If the SA type is used for a We Bill For Them - Bill Ready service provider, the start options should be not allowed because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs.

Copyright © 2026, Oracle and/or its affiliates.

- The payment distribution and late payment information should be set up as for any SA type. Refer to Cash Distribution Segmentation and Late Payment Charge Segmentation for more information.
- If the SA type is used for We Bill For Them - Bill Ready service provider, the special role should be Billable Charge, otherwise it should not be used. Remember, you should not use sub SAs for Cash Deposits.
- Deposit class should be used if the sub SA is covered by a deposit. Refer to Deposits Issues for more information.
- The one time charge switch should be off.
- Bill segment type:
  - If the SA type is used for a We Bill For Them - Bill Ready service provider, the bill segment type should reference a bill segment creation algorithm that creates bill segments from billable charges (and generates bill segment errors until the last night of the bill cycle). Refer to The Bill Ready Calculation Method for more information.
  - If the SA type is used for a We Bill For Them - Rate Ready service provider, the bill segment type should reference a get consumption algorithm that gets consumption from the master SA, and a bill segment creation algorithm that applies a rate.
- Specify a characteristic premise is required if the sub SA is associated with premise-oriented service.
- The calendar billing options should not be used.
- The recurring charge information should not be used.
- Sub SAs used for We Bill For Them - Rate Ready service providers should NOT be eligible for budgets and therefore the eligible for budget switch should be off. This admonition is given because budget billing causes current amount due to be out-of-sync with payoff amount due and we don't want this to happen for sub SAs. Why? Because we use the bill segments associated with these sub SAs to determine how much we owe the service provider.
- If the SA type is used for a We Bill For Them - Rate Ready service provider or for your own company, rates need to be set up; otherwise they should not be used.
- Sub SAs never reference service points. Refer to Only The "Master" Service Agreement Is Linked To Service Points for more information.
- Adjustment types profiles should be set up accordingly.
- Refer to Credit and Collection Issues for recommendations in respect of the debt class, write off debt class, and severance criteria associated with these SA types.
- Billable charge templates should not be used.
- Completion algorithms cannot be used for sub SAs.
- If the SA type is used for a We Bill For Them service provider, you should link to the SA type the FT freeze algorithm that controls how we pay the service provider. Refer to Pay At Bill Time vs. Pay At Pay Time for how this algorithm is used.
- The creation of bill segments for the sub SAs occurs after the bill segment for the related master SA is created. If you populate a billing processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other.

Refer to Setting Up SA Types for how to set up these new SA types in the system.

Copyright © 2026, Oracle and/or its affiliates.

Reference Send Consumption Algorithm On Master SA Types

As explained under We Can Send Billed Consumption To Any Service Provider, when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. Refer to SA Type - Algorithm (FT Freeze Algorithm) for more information.

Reference TBFU Algorithm On Master SA Types

As explained under They Bill For Us, when a bill is completed, the system needs to check if there are any service providers who bill for us associated with the bills "master" SAs. If so, it sets up the data necessary to interface the master SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate FT Completion Algorithm on the master SA types. Refer to SA Type - Algorithm (Bill Completion Algorithm) for more information.

> **Note**
>
> If there are multiple master SAs on a bill, the financial transactions associated with each respective master SA could be routed to different service providers (e.g., one service provider could bill for gas and another could bill for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Designing SA Types For Service Provider Financial Settlements

As explained in Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us service providers require a service agreement. You must create SA types for these types of service agreements. The following points provide a few suggestions that will help you design these financial settlement SA types:

- Service type should probably be a non-service oriented service type.
- Distribution code for We Bill For Them settlement SAs should be a payable account (or treat it as a "contra" receivable. Refer to Receivable Segmentation for more information.
- The sub SA switch should be turned off.
- Start options are not allowed.
- The payment distribution and late payment information should be set up as for any SA type. Refer to Cash Distribution Segmentation and Late Payment Charge Segmentation for more information.
- Special role should not be used.
- Deposit class should be used if the settlement service agreement is covered by a deposit. This would probably only be used for They Bill For Us service providers (because they will owe us money).

Copyright © 2026, Oracle and/or its affiliates.

- The one time charge switch should be off.
- These service agreements are not billable and therefore none of the billing information should be specified.
- The characteristic premise switch should be off.
- Rates should not be used.
- Service points should not be used.
- Adjustment types profiles should be set up accordingly.
- Debt class, write off debt class, and severance criteria should be set up accordingly.
- Billable charge templates should not be used.
- Completion algorithms should not be used.
- Freeze algorithms should not be used.

Refer to Setting Up SA Types for how to set up these new SA types in the system.

Setting Up SA Relationship Information

In the previous section, Designing Your SA Relationship Types and Service Providers, we presented a case study that illustrated a mythical organization's SA relationship information. In this section we explain how to set up this information.

- Setting Up SA Relationship Types
- Setting Up Service Providers
- Setting Up SA Types and Start Options For Sub SAs
- Setting Up SA Types For Financial Settlements
- Update Master SA Types With FT Freeze and Bill Completion Algorithms
- Setting Up SA Relationships For SA Types
- Setting Up Market SA Relationship Options

Setting Up SA Relationship Types

Open **Admin**, and then **Open Market**, and then **SA Relationship Type** to define your SA relationship types. Refer to Designing SA Relationship Types for more information.

Description of Page

Enter an **SA Relationship Type** code, **Description** and **Service Provider Model** for every relationship type.

Specify the **Market Service ProviderService Provider Model** if the SA relationships of the type reference a Service Provider Market Option — i.e. Market, Provider Configuration Option and Market Relationship Service Provider are specified in addition to SA Relationship Type and Service Provider.

Otherwise, specify the **Service ProviderService Provider Model** .

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Service Providers

This portal is used to maintain Service Providers.

Refer to The Big Picture of SA Relationships and Service Providers for more information.

You can access the portal from **Admin**, and then **Open Market**, and then **Service Provider**. You are brought to a query portal with options for searching for a specific service provider. Once a service provider is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Service Provider** zone shows the details of the service provider. Refer to the zone's embedded help for more information.

Setting Up SA Types and Start Options For Sub SAs

The SA types and start options described under Designing Your SA Types And Start Options For Sub SAs must be set up. Refer to Setting Up SA Types for how to do this.

Setting Up SA Types For Financial Settlements

The SA types described under Designing SA Types For Service Provider Financial Settlements must be set up. Refer to Setting Up SA Types for how to do this.

Update Master SA Types With FT Freeze and Bill Completion Algorithms

Refer to SA Type - Algorithm for more information.

Setting Up SA Relationships For SA Types

This portal is used to maintain SA Type SA Relationship Types.

Refer to Designing Your SA Relationship Types and Service Providers for more information.

You can access the portal from **Admin**, and then **Open Market**, and then **SA Type SA Relationship Type**. You are brought to a query portal with options for searching for a specific SA Type SA Relationship Type. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **SA Type SA Relationship Type** zone shows the details of the SA Type SA Relationship Type. Refer to the zone's embedded help for more information.

Setting Up Market SA Relationship Options

The following sections describe how to set up Provider Configuration Options, Market Provider Configuration Options and Service Provider Market Options.

Copyright © 2026, Oracle and/or its affiliates.

- Setting Up Provider Configuration Options
- Setting Up Market Provider Configuration Options

Setting Up Provider Configuration Options

This portal is used to maintain Provider Configuration Options.

You can access the portal from **Admin**, and then **Open Market**, and then **Provider Configuration Option**.

The following zones may appear as part of the portal's **Main** page:

- **Provider Configuration Option List** zone lists all Provider Configuration Option records. Broadcast a record to display the details of the selected record.
- **Provider Configuration Option** zone provides information about the selected Provider Configuration Option.
- **Market Provider Configuration Options** zone lists the existing Market Provider Configurations for the selected Provider Configuration Option. Maintenance actions are available on this zone.

Setting Up Market Provider Configuration Options

This portal is used to maintain Market Provider Configuration Options.

You can access the portal from **Admin**, and then **Open Market**, and then **Market Provider Configuration Option**. You are brought to a query portal with options for searching for a specific Market Provider Configuration Option. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** page:

- **Market Provider Configuration Option** zone shows the details of the Market Provider Configuration Option.
- **Service Provider Market Options** zone shows the service providers with their start dates, end dates (if applicable) and statuses. Maintenance actions are provided. A broadcast icon appears if the Service Provider Market Option has sub-SA(s) and/or entries in the Status History log. Clicking on the broadcast icon displays the following zones:
  - **Service Agreements** zone shows the Service Provider Market Option’s sub-SAs.
  - **Status History** zone shows the history of changes to the Service Provider Market Option, which can include changes to Start Date, End Date and/or Status.

Negotiated Terms

The topics in this section describe the use of SA relationship functionality for applying certain types of negotiated terms. It assumes that you are familiar with SA relationship functionality in general.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Negotiated terms are optional.** The functionality described in this section is only relevant if your organization offers this functionality.
>
> **Umbrella agreements**. If the Contract Management module is not turned off, you may also choose to use umbrella agreements to manage the functionality described here.

Imagine that the head office for a multi-site organization negotiates special terms that cover a number of its sites, each of whom have their own account and service agreement. The negotiated terms typically involve discounts. These discounts may be realized

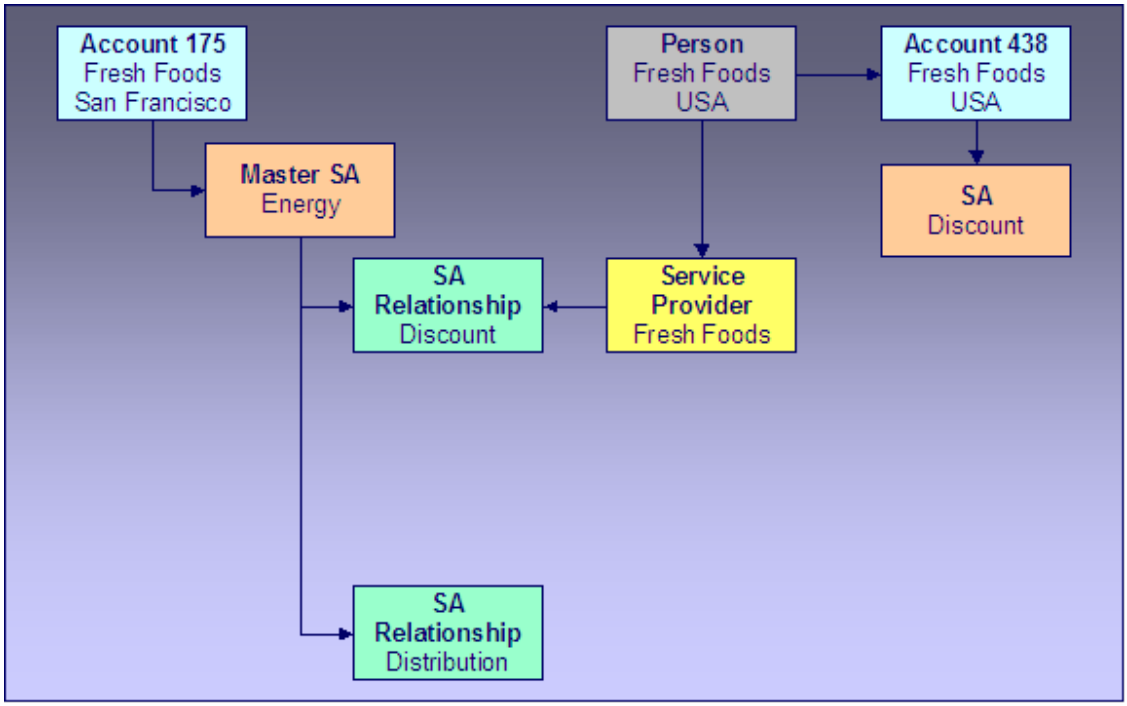
- Under a single service agreement, separate and distinct from the service agreements that are covered, or
- Individually, for each covered service agreement. In this case, two sub-scenarios exist:
  - The discounts may be reflected on the bill segment of each service agreement, or
  - The discounts may be transferred to another service agreement (the group's service agreement). The discount does NOT appear on the individual bill segment for the service agreements that are covered by the negotiated terms.

SA relationships track and manage complex business relationships between a customer and a service provider. You can define the above relationships using service agreement relationship functionality. This is a special type of SA relationship in which the head office is the service provider.

- Examples Of Special Discounts
- Setting Up The System To Enable Negotiated Terms

Examples Of Special Discounts

The following topics illustrate examples of how your organization may configure the system to handle this business functionality.



- Example Using Aggregated Consumption
- Example Using Site-by-site Discount

Example Using Aggregated Consumption

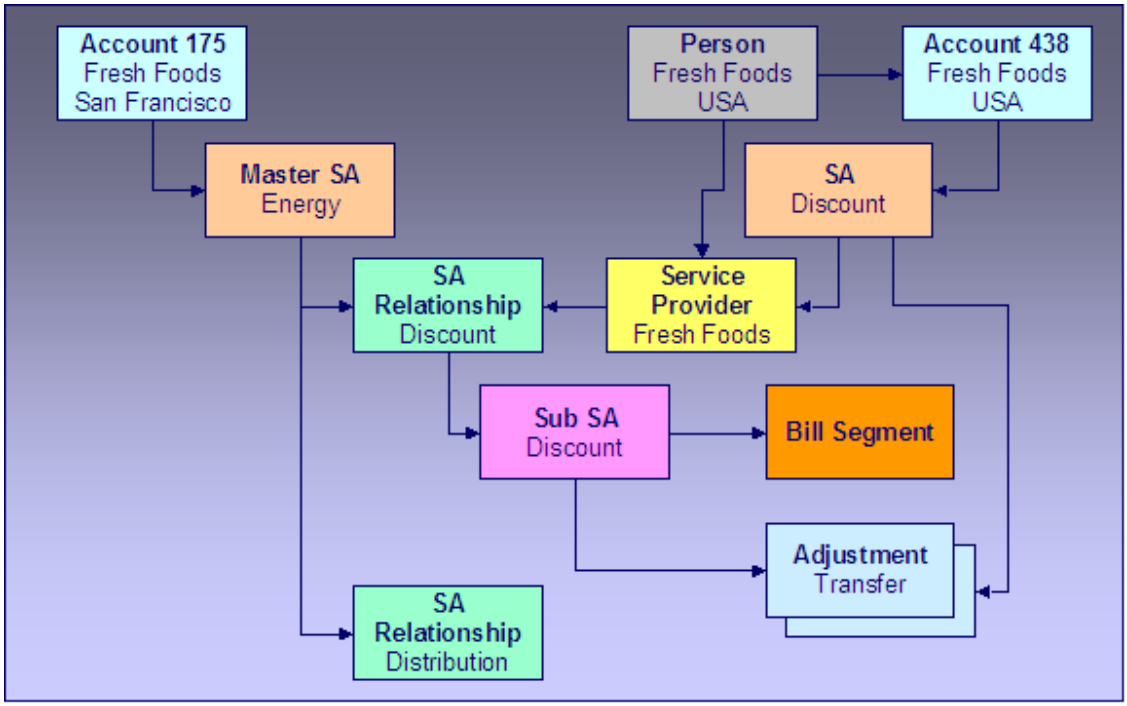
A customer, Fresh Foods has 10 stores each with its own account and electric service agreement, i.e., each store is billed separately. Fresh Food's head office decides to negotiate a group discount that applies to one or more of the individual stores.

In the following diagram, one store's account is shown.

Copyright © 2026, Oracle and/or its affiliates.

Example Using Aggregated Consumption

Note the following:



- An SA relationship is created for the energy SA covered by the negotiated terms.
- The service provider in the relationship is the head office.
- This relationship does not have a sub-SA because no additional billing services are provided for each individual covered service agreement.
- Discounts are calculated using the head office discount service agreement and affect only this service agreement and therefore only the head office's account.
- The master SA may have other deregulated relationships, such as the distribution relationship shown.

> **Note**
>
> **Aggregated consumption algorithm.** In this scenario, the service provider's service agreement amalgamates the group's consumption and applies a rate to calculate the discount. This algorithm is not provided - you get to write this algorithm to meet your needs.

Example Using Site-by-site Discount

In this scenario, the discount is calculated on a site-by-site basis.

Copyright © 2026, Oracle and/or its affiliates.

Example Using Site By Site Discount

Note the following differences between this example and the one where consumption is aggregated:

- Each service agreement participating in the discount has an SA relationship with a sub SA.
- Discounts are calculated on a site-by-site basis by the sub SA for each service agreement covered by the discount agreement.
- The discounts may be transferred to the head office service agreement using transfer adjustments. In this case, you may choose to not show the discount on the individual site's bills.

Setting Up The System To Enable Negotiated Terms

The above topics provided background information about how special negotiated terms could be supported in the system. The following discussion summarizes the various setup tasks alluded to above. These notes highlight the setup required in addition to that detailed in Setting Up SA Relationships Information.

- Algorithm
- SA Relationship Type
- Service Provider
- SA Type SA Relationship Type
- SA Type

Algorithm

Copyright © 2026, Oracle and/or its affiliates.

If you use sub SAs to calculate charges / discounts for each covered service agreement individually and you want to transfer the charges / discounts to the service provider's service agreement at bill completion, you will need to set up a bill completion algorithm to do this.

Refer to the algorithm type BCMP-TR for more information.

SA Relationship Type

You will need an SA relationship type that will be used for each type of negotiated term or discount.

Service Provider

Set up a service provider using the principal party of the negotiated discount. For example, if a head office negotiates a special agreement for its sites, you should set up a new service provider representing the head office.

- **Billing Relationship** will depend on the type of negotiated terms you choose to set up. For terms where debits / credits are calculated for each covered service agreement individually, select We Bill For Them, Rate Ready. We are effectively billing on behalf of the principal party. For terms where the discount is calculated on an amalgamated SA there is no billing relationship because no additional billing services are provided for each covered service agreement.
- Select a **Payment Relationship** of Pay SPR Not Applicable if debits / credits to the sub-SA should not be transferred to the service provider. If you want to transfer charges at bill completion time using a bill completion algorithm, you should also select Pay SPR Not Applicable because you will not be creating adjustments to pay the principal party service at payment time or at billing time.
- Enter a **Transfer A/R Algorithm** to transfer the debit / credit from the sub-SA to the principal party's service agreement. If you do not want to transfer the debit / credit to the principally party's service agreement, you do not need to specify a transfer algorithm.

SA Type SA Relationship Type

Associate the SA relationship type setup for negotiated terms with the SA type(s) of the service agreements that are covered by the terms. The following are suggested values for the SA type SA relationship type:

- **Required**. Relationships of this type should not be required for the SA type because the negotiated terms will only cover selected service agreements with that SA type.
- **Gaps in SA Relationship** are Allowed if service agreements of this type do not have to have an SA relationship of this type with a service provider throughout the effective period of the SA.
- Add the service provider set up above to the list of valid service providers for this SA type and SA relationship type combination.

Copyright © 2026, Oracle and/or its affiliates.

SA Type

Set up an SA type for the sub SAs that will be used to calculate discounts. This SA type should use the BCMP-TR bill completion algorithm if you want to transfer the discounts to the head office.

> **Note**
>
> **TBFU Deregulated Relationship with WBFT Negotiated Terms Relationship**. If you have the unusual situation where a master service agreement has a relationship with a TBFU service provider as well as a negotiated term "relationship" with a WBFT service provider, and you transfer charges / discounts from the discount agreement sub SA to the WBFT service provider, you will not be able to use the algorithms provided to transfer receivables to the service providers. This is because bill completion algorithms associated with the SA type of a master service agreement are executed before any bill completion algorithms associated with the SA types of sub service agreements. Consequently the TBFU XFER algorithm associated with the master service agreement will transfer all receivables from related sub SAs to the TBFU service provider before the BCMP-TR algorithm can transfer the discount agreement receivables. You will need to modify the TBFU XFER bill completion algorithm that transfers receivables from the customer to the TBFU service provider to exclude the discount agreement receivables.

Defining Service Credit Options

Some companies allow their customers to participate in a special rewards program. The term "service credits" is used to describe a program that rewards customers for their business. The topics in this section provide details to help you set up the control tables required to support any service credit program that your company supports.

> **Note**
>
> **Penalty Points**. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

- The Big Picture Of Service Credits
- Designing Your Service Credit Options
- Setting Up Service Credit Options
- Service Credit Examples

Copyright © 2026, Oracle and/or its affiliates.

The Big Picture Of Service Credits

The topics in this section provide background information about service credit functionality.

- Service Credit Membership

Service Credit Membership

Let's look at some examples of special programs that may use service credits functionality:

- Capital credits - When customers receive their utility service from a cooperative, they are considered "members" of the cooperative and may over time receive capital credit allocations from the cooperative based on their service history and the cooperative's profits allocated during that time period.
- Frequent flier miles - Perhaps your company has made an agreement with one or more airlines to allow customers to accumulate frequent flier miles for every x amount spent on service.
- Free pay-per-view movies - Maybe your cable service offers free pay-per-view movies under certain conditions. Using service credits, you can set up your system to accumulate the free pay-per-view movies and use the free movies to offset actual movies viewed by the customer.
- Any other type of loyalty program where the customer earns credits that may later be redeemed in some way.

To participate in a program such as those described above, the customer is linked to a service credit membership. The membership record provides the following functionality:

- It defines the accounts that are linked to the membership.

> **NOT_SUPPORTED**
>
> Refer to Who are the Members? for information about linking persons and accounts to a membership.

- It defines a membership type, which controls certain behavior about the membership.
- It may define an external ID if the membership is associated with an external program, such as a frequent flier mile program.
- It may define a service agreement to use for miscellaneous financial transactions that may get created.
- It may define characteristics used to capture miscellaneous information about the membership.
- Over time, service credit events are created for a membership. The events indicate an amount that either adds or subtracts credit units (i.e., points, miles, movies, dollars, etc) for the membership.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture of Service Credit Membership for more information about functionality related to a membership.

- How Are Service Credits Earned?
- How Are Service Credits Redeemed?
- Service Agreements For a Membership

How Are Service Credits Earned?

Service credits may be monetary rewards for service or they may be non-monetary rewards such as free movies or frequent flier miles. In any case, how the membership earns the points or rewards depends on the business rules for the program you are offering.

A typical scenario is that the service credits are earned for a membership as a result of other services linked to the membership's accounts. For example:

- Perhaps free pay-per-view movies are earned when signing up for cable service. In this case, the pay-per-view movie membership is related to the membership account's cable service agreement. Refer to Service Credits Earned When Starting Service for more information.
- Perhaps one frequent flier mile is earned for every $10 spent on electricity. In this case, the frequent flier membership is related to the membership account's electricity service agreements (for example, electricity distribution, electricity retail and lamp service). Refer to service credits earned through billing for more information.
- For a capital credits membership, capital credit allocations are calculated based on the amount spent by the customer for standard service, for example electricity and/or gas service. In this case, the capital credit membership is related to the membership account's electricity and/or gas service agreements. For capital credits, a background process is used to calculate the allocated amounts. Refer to Allocating Capital Credit for more information.

It is also possible to earn service credits irrespective of other service for the membership's accounts. (Again, it depends on the business rules for the program you are offering.) For example, perhaps you offer 500 frequent flier miles for signing up for service with your company, regardless of the type of service chosen. In addition, assume that no additional miles are earned for ongoing service. In this example, there is no need to link the membership to any service agreements.

NOT_SUPPORTED

Refer to Service Agreements Contribute to a Membership for more information.

Each earned service credit amount is linked to the membership via a service credit event.

Copyright © 2026, Oracle and/or its affiliates.

How Are Service Credits Redeemed?

Once service credits have been earned for a membership, how may a customer redeem these credits? The method by which the credits are redeemed depends on the business rules for the program you are offering. Here are some examples of how a service credit may be redeemed:

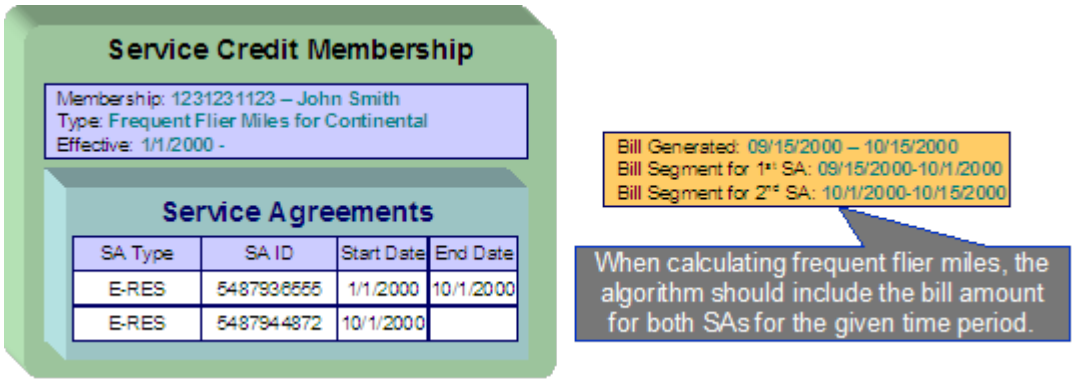
- For free pay-per-view movies, perhaps your customer's monthly cable bill is credited for any pay-per-view movies until all free movies are used. Refer to Service Credits Redeemed Through Billing for more information.
- For frequent flier miles, the information about the earned miles is exported to the appropriate airline. The miles are actually redeemed by the customer through the airline, not through your company. Refer to Interface Membership Information to a Third Party for more information.
- For a capital credit membership, the company periodically (maybe once a year) decides if credits should be redeemed (referred to as "retired") and if so, how much. The company runs a background process to calculate the "retirement" amount. When an amount is retired, the membership balance is reduced by the retirement amount and the amount is transferred to service agreements related to the membership. Refer to Capital Credit Retirement for more information.

> **Note**
>
> **Tracking Membership Balances**. If service credits are redeemed via the system, your membership should probably be configured to keep track of a balance. Refer to Event Amounts May Contribute to a Balance for more information.

Each service credit amount redeemed through the system is linked to the membership via a service credit event.

Service Agreements For a Membership

There are three types of service agreements that may be associated with a service credit membership. The following sections describe these types.



- SAs Contribute to the Membership
- SA Used for Miscellaneous Transactions
- Membership Fee SAs

SAs Contribute to the Membership

As described in how are service credits earned , many memberships are related to specific service agreements for the membership's accounts. We refer to these service agreements as the SAs that contribute to the membership because often the service credit amounts earned for the membership are based on amounts spent by the customer for these services.

Copyright © 2026, Oracle and/or its affiliates.

During the lifetime of a membership, service agreements that contribute to a membership may be stopped and other service agreements started. For example, perhaps you have a frequent flier membership that is related to electric service. Imagine that the customer starts out with a certain rate for electric service, but later decides to opt for a different type of rate that requires expiring the old service agreement and creating a new one. How does this affect your frequent flier mile calculation? It depends on how you design the algorithm that creates the frequent flier events. Essentially, the algorithm must cater for this situation. The following diagram illustrates the scenario.

The service agreements that contribute to a membership are not linked directly to the membership record. This would cause a maintenance burden, requiring links to be updated when service is stopped or started for applicable service agreements. Rather, this link is indirect. The list of service agreement types is defined for the membership type. The system can determine which service agreements are "linked" to the membership by looking at the SA types for the membership type.

NOT_SUPPORTED

Refer to Determine The Types of Service Agreements That Contribute to the Membership for more information on designing your membership type to include appropriate SA types.

SA Used for Miscellaneous Transactions

For some memberships, you may need to define a special service agreement to use for miscellaneous transactions. For example:

If events created for a membership cause an adjustment to be created to affect the general ledger, rather than allowing the system to arbitrarily pick a service agreement to use for this adjustment, the SA to use should be indicated on the membership. Refer to An Event May Cause Other Actions to Occur for more information.

Membership Fee SAs

For some memberships, a membership fee may be applicable. A special service agreement is used to hold the fee. This service agreement is not linked directly to the membership, but is simply a service agreement linked to one of the membership's accounts.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Some fees may be refundable.** The refunding of a fee must be handled by an algorithm. Refer to SAST-RF for information about the algorithm type provided with the base product.

Designing Your Service Credit Options

This section helps you to determine how to design your service credit membership types and service credit event types.

- Designing Your Membership Types
- Designing Your Service Credit Event Types
- How Are Service Credit Events Created?

Designing Your Membership Types

This section discusses the options to consider when designing your service credit membership types.

First consider the type of unit that your membership's service credit events represent.

- Is it related to a currency? If so, ensure that your currency is correctly defined on the currency page.
- Is it a non-currency unit, such as movies, points or miles? If so, you need to define the unit on the credit unit page.

Next, consider other behavior that your membership may exhibit.

- Should your membership calculate an overall balance ?
- Will miscellaneous financial transactions be created for you membership over its lifetime? If so you may need to link a service agreement to your membership.
- Should events linked to your membership reference a fiscal year ?

The table below illustrates three types of memberships: one for capital credits, one for frequent flier miles and one for free pay-per-view movies.

Membership Type	Description	Unit Type / Currency or Credit Unit	Has Balance?	Require SA?	Fiscal Year?
STDCAPCR	Standard capital credit membership	Currency / $	Yes	Yes	Yes
FFDELTA	Delta frequent flier miles	Credit Unit / Miles	No	No	No
FREEPPV	Free pay-per-view movies	Credit Unit / Movies	Yes	No	No

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the settings for each membership above:

- The capital credit membership uses a currency of US dollars for its units. Over time, capital credits are allocated and retired. The overall balance of the credits and debits should be calculated and displayed for information purposes. It is common for the allocation and retirement of capital credits to affect the GL, and as a result, a membership SA is required for posting these financial effects. Finally, in a capital credit situation, the allocation is typically related to a specific fiscal year. When calculating and displaying balances, the balance for each fiscal year must also be available. As a result, the fiscal year must be set to required.
- For the frequent flier membership type, a separate membership type must be created for each different airline. This is because a separate membership must exist for each separate airline in order to keep track of the accumulated miles correctly. The membership type does not have a balance because the accumulated miles are interfaced to the airline and the airline keeps track of the balance. In this example, no SA is required because an assumption is being made that the creation of frequent flier miles does not affect the GL. (Accumulating miles is no liability or expense for the company. The miles are simply accumulated on behalf of a third party.) Finally, the frequent flier miles do not need to indicate a fiscal year.
- For the free pay-per-view movies membership, we assume that the credits are redeemed from within the system. For example, perhaps a calculation rule calculation algorithm or pre-processing calculation rule redeems the free pay-per-view movies over time as customers are billed for the movies. As a result, the membership should have a balance. In this example, no SA is required because an assumption is being made that any affect on the GL is posted at the time the free movies are redeemed (i.e., when calculating a bill). (This is just an example. It's possible that you may want to post to the GL when free movies are accumulated to mark a payable for the company.) Finally, free pay-per-view movies do not need to indicate a fiscal year.

More options must be considered for each membership type.

- Consider Whether the Membership Should Indicate Subcategories
- Determine the Types of Service Agreements Linked to the Membership
- Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership
- Determine Whether The Membership Requires Additional Information

Consider Whether the Membership Should Indicate Subcategories

For some types of memberships, the amount of each service credit event is further grouped by a subcategory. Refer to Events May Indicate a Subcategory for more information.

Use subcategories if multiple subtypes of credits may be accumulated and redeemed and if balances need to be tracked for each subcategory.

For our sample membership types, only the capital credits type should indicate subcategories.

Membership Type	Description	Subcategories
STDCAPCR	Standard capital credit membership	Distribution Transportation
FFDELTA	Delta frequent flier miles	
FREEPPV	Free pay-per-view movies	

Copyright © 2026, Oracle and/or its affiliates.

Determine the Types of Service Agreements Linked to the Membership

Memberships typically exist to reward customers for participating in standard service with the company. Refer to How Are Service Credits Earned? for more information. If memberships of this type are related to standard service for your company, determine the SA types for these service agreements.

> **Note**
>
> **Standard Service SA Types**. These service agreement types are probably different from the type of service agreement you may link as the membership SA. The membership SA is used for miscellaneous charges like general ledger posting. These SA types are related to electricity service, gas service, etc.

For our three examples, assume that the company provides electric service and cable. The capital credits are related only to electric service, frequent flier miles are accumulated for a combination of services, and free pay-per-view movies are related only to cable service.

Membership Type	Description	SA Types
STDCAPCR	Standard capital credit membership	E-RES (Electric Residential) AL-RES (Area Lighting)
FFDELTA	Delta frequent flier miles	E-RES (Electric Residential) AL-RES (Area Lighting) CABLE - RES (Cable Residential)
FREEPPV	Free pay-per-view movies	CABLE-RES (Cable Residential)

Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership

Should a letter or bill message be generated when a membership is created or activated? Should anything happen when a membership is inactivated? If so, you may need to define one or more algorithms to be plugged in on the membership type.

For our examples, let's say that a bill message is generated when a frequent flier or free pay-per-view membership is created. Let's say that a letter is generated when a capital credits membership is activated. We also assume that when a capital credits membership becomes inactive, any outstanding balance is redeemed. For the frequent flier miles and pay-per-view memberships, we assume nothing special occurs when the membership becomes inactive.

> **NOT_SUPPORTED**
>
> Refer to Lifecycle of a Membership for more information about the various status values for a membership.

Copyright © 2026, Oracle and/or its affiliates.

Membership Type	Description	Algorithm System Event	Algorithm
STDCAPCR	Standard capital credit membership	Membership Activation	Send Letter
		Membership Inactivation	Redeem Balances
FFDELTA	Delta frequent flier miles	Membership Creation	Generate Bill Message
FREEPPV	Free pay-per-view movies	Membership Creation	Generate Bill Message

> **Note**
>
> **Sample Algorithms**. The base package does not provide sample algorithms for all the above examples. Refer to Service Credit Membership Type - Algorithm for more information about the algorithms provided with the system.

Determine Whether The Membership Requires Additional Information

Is there any information about your membership that you need to capture that is not already provided by the base system logic? If the answer is yes, you may need to define characteristics for your membership. Use the characteristic collection on the membership type to define the types of characteristics allowed for memberships of this type. You may also define default values for you membership's characteristics.

Designing Your Service Credit Event Types

Now that you have designed your membership types, you need to design the types of service credit events that may be created for your membership.

In many cases, a credit event should cause additional functionality to occur. Algorithms are executed when an event is completed and when an event is canceled and are used to perform additional functionality. The following points illustrate possible algorithms that may be needed when a credit event is completed.

- Validate the event as compared to other events. For example, perhaps a new event should never cause the overall membership balance to fall below zero. You could use an algorithm on the service credit event type to check this condition.
- Create an adjustment that posts to the general ledger. Your credit event may not affect the customer's balance when created, but perhaps it should have an effect on the general ledger. For these types of credit events, you may need to create an adjustment to post to the GL.
- Create adjustments to affect the customer's balance. When "redeeming" a credit, you may need to transfer a monetary amount to one or more of the customer's service agreements.

Copyright © 2026, Oracle and/or its affiliates.

- Create a bill message. Perhaps when a credit is accumulated, you want to inform the customer via a message on the bill indicating the credit amount. A temporary bill message is added to one of the membership's accounts.

> **Note**
>
> **One Account Message of the Same Message Type**. The temporary bill message collection on the account allows only one bill message of the same bill message type. If it's possible for multiple types of events to be generated for the same account, consider creating a different bill message type for each event type.

- Stamp a batch code and batch run number onto the event. This would be used when your event information needs to be interfaced to an external system.

The following points illustrate possible algorithms that may be needed when a credit event is canceled.

- Validate the event as compared to other events. For example, perhaps canceling an event should never cause the overall membership balance to fall below zero.
- Cancel adjustments that may have been created when the event was completed.

To illustrate examples of when to use some of the algorithms above, we'll design event types for the membership types designed above.

- Designing Capital Credit Event Types
- Designing Frequent Flier Event Types
- Designing Pay-per-view Event Types

Designing Capital Credit Event Types

The following event types illustrate typical events for a capital credits membership.

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ALLOCATECCR	Capital credit allocation	STDCAPCR	Event Creation	Create Simple Adjustment
			Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments
RETIRECCR	Retire capital credit (apply to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Adjustments to Affect Customer's Balance
			Event Cancellation	Cancel Related Adjustments

Copyright © 2026, Oracle and/or its affiliates.

FORFEITCCR	Forfeit capital credit (retirement not applied to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Simple Adjustment (affect GL only)
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments

These event types assume the following:

- When credit events are allocated, the customer is notified via a bill message, the general ledger is affected so a simple GL only adjustment is created. If an event of this type is canceled, any adjustments that were created should be canceled. The event amount should always be positive, so checking that the membership balance does not fall below zero is only checked for event cancellation.
- When capital credits are retired, it's possible that the full membership balance is not applied to the customer's balance. For the portion of the retirement that does affect the customer's balance, you need an algorithm that applies the credits to the customer's service agreements via adjustments. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.
- For the portion of the retirement that is not applied to the customer's balance, the event amount should simply affect the GL so a GL only adjustment is created. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.

> **Note**
>
> **Service credit event types are independent of subcategories.** A capital credits membership typically uses subcategories. When events are created for different subcategories, the same service credit event type may be used. As a result, all subcategories use the same event completion and event cancellation algorithms.

Designing Frequent Flier Event Types

The following event types illustrate typical events for a frequent flier membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDMILES	Add miles to the membership	FFDELTA	Event Creation	Generate Bill Message
			Event Creation	Populate Batch Information

Copyright © 2026, Oracle and/or its affiliates.

	Event Cancellation	Event may not be canceled.

This event type assume the following:

- A new event should generate a bill message.
- Information about the event amount should be interfaced to an external system so batch information should be populated when the event is completed.
- Events of this type may not be canceled because the information is interfaced to an external system. Rather, to reverse an event, simply create a new event whose amount is a credit. This credit amount is also interfaced to an external system.

> **Note**
>
> **Sample Algorithm.** The system does not provide a sample cancellation algorithm that prevents the event from being canceled.

- There is no validation to ensure that the balance does not fall below zero. Recall that this membership was defined as not requiring a balance.

Notice that only one type of event has been defined for this membership. That is because the credits for this membership are not redeemed via this system. Rather they are accumulated on behalf of an external system.

Designing Pay-per-view Event Types

The following event types illustrate typical events for a free pay-per-view movies membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDPPV	Free pay-per-view movies	FREEPPV	Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
REDEEMPPV	Redeem pay-per-view movies	FREEPPV	Event Creation	Validate Balance Not < Zero
			Event Creation	Generate Bill Message

These event types assume the following:

- Any type of new event should generate a bill message.
- For adding free movies, it is assumed that the quantity is positive so when the event is cancelled, the algorithm verifies that the balance does not become negative.
- For redeeming free movies, it is assumed that the quantity is negative so when the event is completed, the algorithm verifies that the balance does not become negative.
- These events do not affect the general ledger and they do not directly affect the customer's balance so no adjustment algorithm is needed.

Copyright © 2026, Oracle and/or its affiliates.

How Are Service Credit Events Created?

Now that you have designed the behavior of your service credit events, an important issue is to determine how these events are created. Consider your business practice for each type of membership.

Let's use our sample memberships to work through different ways that you may create service credits.

- Service Credits for Capital Credit Memberships
- Service Credits for Frequent Flier Memberships
- Service Credits for Free Movies Memberships

Service Credits for Capital Credit Memberships

For a capital credit membership, capital credit allocations are calculated once a year based on billing history and the cost of service. To accomplish this, a background process calculates the amount and creates the service credits. Refer to allocating capital credits for a sample process provided with the base package.

Credits are redeemed via the retirement process. The company determines when to retire capital credits based on analysis of their financial situation. This retirement process is also handled by a background process. Refer to capital credit retirement for a process provided with the base package.

For capital credits memberships, special functionality is required when a member dies. The capital credits are considered part of the person's estate and may need to be retired and applied to a beneficiary's account. This process depends on the company's business practice. However, typically, the membership status would change to inactive so that new capital credit allocations are not created for the membership. The system provides a sample inactivation algorithm called SCMI-RB that transfers part or all of the outstanding credit balance to the member's service agreements. From there, a user can cut a check to the beneficiary.

> **Note**
>
> **Some Credits Are Never Retired**. For many cooperatives, some types of allocated credits are never retired. Refer to Partial Retirement for more information.

Service Credits for Frequent Flier Memberships

In our example, frequent flier miles were related to both the electricity and phone service. Let's assume that frequent flier miles are accumulated every $x spent on electricity and phone service. In this example, a bill completion algorithm creates service credits based on the bill segment amounts for these service agreements. Refer to Service Credits Earned Through Billing for more information.

Copyright © 2026, Oracle and/or its affiliates.

As mentioned before, the frequent flier miles are not redeemed using this system, but are interfaced to a third party for redemption.

Service Credits for Free Movies Memberships

> **Note**
>
> **Sample Algorithms**. No base package algorithm types are provided to support the logic described in this example.

In this scenario, let's suppose that a customer receives three free pay-per-view movies when signing up for new service. To handle this, perhaps an SA creation algorithm creates the membership and the service credits when the service is started. Or perhaps you want to wait until the first bill is generated and a bill completion algorithm is used to generate the first credit. It depends on your business practice.

For redeeming the free pay-per-view movies, it is assumed that the movies are credited during billing after it is determined that the customer has been billed for a movie. The number of movies used for the membership is reduced until all the free movies are used.

> **NOT_SUPPORTED**
>
> Refer to Service Credits Redeemed Through Billing for more information.

Setting Up Service Credit Options

- Setting Up Credit Units
- Setting Up SC Membership Inactive Reasons
- Setting Up Service Credit Membership Types
- Setting Up Service Credit Event Types

Setting Up Credit Units

Credit unit is used for service credit membership types whose events record non-monetary units. Open **Admin**, and then **Service Credit**, and then **Credit Unit** to set up credit units.

Description of Page

The following fields display for each credit unit:

Credit Unit The unique identifier of the credit unit.

Copyright © 2026, Oracle and/or its affiliates.

Description The description of the unit. This also acts as a label for the unit when displaying information about a service credit event.

Symbol / Label Position Indicates whether or not the label for this credit unit appears as a Prefix or as a Suffix to the service credit event amount.

Decimal Positions Indicates the number of decimal positions used for this credit unit. This information should be used by any algorithm or background process that creates a service credit event to determine how to store the event amount. It is also use to correctly display the service credit amounts.

Setting Up SC Membership Inactive Reasons

The service credit membership inactive reason must be specified when the status of a service credit membership changes to inactive. Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Inactive Reason** to set up service credit inactive reasons.

Description of Page

The following fields display for each inactive reason:

Inactive Reason The unique identifier of the service credit membership inactive reason.

Description The description of the inactive reason.

Setting Up Service Credit Membership Types

- SC Membership Type - Main
- SC Membership Type - Algorithm
- SC Membership Type - Characteristics

SC Membership Type - Main

Service credit memberships have a membership type. Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Add** to define the membership type.

Description of Page

Enter a unique **Service Credit Membership Type** and **Description** for each membership type.

Use the **SA Requirement** flag to indicate whether a miscellaneous SA must be linked to memberships of this type. The possible values are SA Required and SA Not Allowed .

> **Note**
>
> The value defaults to SA Required.

Copyright © 2026, Oracle and/or its affiliates.

Use the **Fiscal Year Requirement** flag to indicate whether events linked to memberships of this type should indicate a fiscal year. The possible values are Fiscal Year Required and Fiscal Year Not Allowed.

> **Note**
>
> **Default Note**. The value defaults to Fiscal Year Not Allowed.

Use the **SCM Event Balance** flag to indicate whether or not a balance of service credit events linked to memberships of this type should be calculated and displayed. The possible values are Has a Balance and No Balance.

> **Note**
>
> **Default Note**. The value defaults to Has a Balance.

Use the **SC Membership Type Unit** flag to indicate whether or not the unit for the event amounts for events linked to memberships of this type is Currency or Credit Unit. When the unit is currency, indicate the **Currency Code**. When the unit is credit unit, indicate the **Credit Unit**.

If events linked to memberships of this type must indicate a subcategory, enter a valid **Subcategory Name** and **Description** for each subcategory applicable to this membership.

> **NOT_SUPPORTED**
>
> Refer to Events May Indicate a Subcategory for more information.

Use the **SA Types** grid to indicate the types of service agreements that contribute to memberships of this type. Indicate the **CIS Division** and **SA Type** for each type of service agreement that is related to a membership of this type.

SC Membership Type - Algorithm

Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Search** and navigate to the **Algorithm** page to define any algorithms that are associated with a membership type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

Copyright © 2026, Oracle and/or its affiliates.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Membership Creation	Optional	Use this system event for algorithms that are executed when a membership is created.

Copyright © 2026, Oracle and/or its affiliates.

Membership Activation	Optional	Use this system event for algorithms that are executed when a membership becomes active.

> **Note**
>
> **Creating Memberships In Active Status**. A membership may be created in either pending status or in active status, based on your business practice. For memberships created in active status, the system executes the

Copyright © 2026, Oracle and/or its affiliates.

		membership creation algorithms and the membership activation algorithms.
Membership Inactivation	Optional	Use a system event of Membership Inactivation for algorithms that are executed when a membership becomes inactive .

SC Membership Type - Characteristics

To define characteristics that can be defined for service credit memberships of a given type, open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define characteristics that can be defined for service credit memberships of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on service credit memberships of a given type. Turn on the **Default** switch to default the **Characteristic Type** when service credit memberships of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Service Credit Event Types

Service credit events created for a service credit membership have an event type. Open **Admin**, and then **Service Credit Event Type**, and then **Add** to set up service credit event types.

Description of Page

Enter a unique **Service Credit Event Type** and **Description** for each event type.

Indicate the **Service Credit Membership Type** to which this event type belongs.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Event Completion	Optional	Use a system event of Event Completion for algorithms that are executed when an event is completed. Refer to An Event May Cause Other Actions to Occur for more information.
Event Cancellation	Optional	Use this system event for algorithms that are executed when an event is canceled.

Service Credit Examples

In this section, we provide examples of how to define your control tables to support functionality related to different types of service credit memberships. While your company may not define your environment exactly the same way, this section should help solidify your understanding of how to set up your company's service credit options.

- Defining Control Tables for a Refundable Fee
- Defining Control Tables for a Nonrefundable Fee
- Defining an SA Type for Miscellaneous Transactions
- Using Campaigns/Packages to Set Up Membership
- Defining Another Person for Your Account
- Service Credits Earned When Starting Service
- Service Credits Earned Through Billing
- Service Credits Redeemed Through Billing
- Designing Your Rate Options for Capital Credits
- Partial Retirement
- Interface Membership Information to a Third Party

Defining Control Tables for a Refundable Fee

If your membership requires payment of a fee that is refundable, you must define an SA type to use for the refundable fee.

- Adjustment Type for Refundable Fee

Copyright © 2026, Oracle and/or its affiliates.

- SA Type for Refundable Fee
- Start Option for Refundable Fee
- Algorithm for Refunding the Fee

Adjustment Type for Refundable Fee

This example assumes that the fee is set up similarly to a deposit. The adjustment used to charge the fee would affect the current balance, but not the payoff balance or the general ledger because the fee is not considered a "receivable", rather it is an amount collected and held for the customer.

Create an adjustment type for levying the fee. Indicate the fee amount and indicate the ADJT-CA adjustment FT creation algorithm, which affects the current balance, but not the payoff balance or the general ledger.

> **Note**
>
> **Adjustment Type Profiles**. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Refundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which should cause the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Refundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

> **NOT_SUPPORTED**
>
> Refer to Including The Membership Fee on campaigns and packages for more information about levying the fee via the order transaction.

Algorithm for Refunding the Fee

Copyright © 2026, Oracle and/or its affiliates.

The base product provides an algorithm type SAST-RF that refunds a fee when service agreements that contribute to the membership are stopped. You must create an algorithm for this algorithm type and enter the SA type created above as an input parameter.

This SA stop algorithm must be plugged in on all SA types that you defined for the membership type.

Defining Control Tables for a Nonrefundable Fee

If your membership requires payment of a fee that is not refundable, you can set this up in two ways:

- You can create a special SA type to handle charging the fee. For this SA type, define a start option that causes an adjustment to be levied as part of the start service process. This adjustment contains your fee. You may use this option if the membership is related to multiple types of services and not all services need to be present in order to create the membership.
- You can levy an adjustment on one of the other service agreements that is being started. To do this, you would use a start option to define an adjustment to be levied as part of the start service process. You may use this option if the membership is related to a single service (for example, free pay-per-view movies).

For our example, we will set up the SA for the nonrefundable fee with a separate 'fee' SA type.

- Adjustment Type for Nonrefundable Fee
- SA Type for Nonrefundable Fee
- Start Option for Nonrefundable Fee

Adjustment Type for Nonrefundable Fee

Create an adjustment type for levying the fee. Indicate the fee amount and indicate the ADJT-NM adjustment FT creation algorithm, which affects the current balance and payoff balance by the adjustment amount, and affects the general ledger.

> **Note**
>
> **Adjustment Type Profiles**. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Nonrefundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the

Copyright © 2026, Oracle and/or its affiliates.

payment amount, which causes the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Nonrefundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

> **NOT_SUPPORTED**
>
> Refer to Including The Membership Fee on campaigns and packages for more information about levying the fee via the order transaction.

Defining an SA Type for Miscellaneous Transactions

Does your membership require a service agreement to support miscellaneous transactions? If so, you need to consider the SA type to use for this service agreement. This SA type should be marked as not billable.

If you choose to use the order transaction to set up the membership, this SA type must be defined on the algorithm that creates the membership.

It is possible that you may require a start option for this SA type, for example if you want to define a characteristic for service agreements of this type.

Using Campaigns/Packages to Set Up Membership

If enrollment in a membership is a common occurrence for your customers when starting service, you should consider using the order page to start service for the customer and to create the membership as well.

> **Note**
>
> This section only makes sense if you are familiar with the Sales and Marketing chapter.

The recommendation is to use a question/miscellaneous field to ask the customer service representative to indicate the appropriate membership type. Algorithms validate this membership type and use it to create a membership of that type.

This section walks you through how to set up the campaign / package required to support this.

- Column Reference for Membership Type
- Algorithms to Create Membership via Order
- Define a Campaign for Creating a Membership When Starting Service

Copyright © 2026, Oracle and/or its affiliates.

- Including the Membership Fee

Column Reference for Membership Type

In order to ask the customer service representative to define an appropriate service credit membership type, you must define a column reference for the membership type.

Add a new column reference with the following information:

- Column Reference: SCM-TYPE
- Description: SC Membership Type
- FK Reference: SCM TYPE
- Long Description: Service Credit membership type to use when creating a service credit membership at start time.

> **Note**
>
> **Column Reference Algorithms**. This column reference indicates a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information.

Algorithms to Create Membership via Order

The base product provides two algorithm types to support the creation of a membership record via the order page: a validation algorithm type and a posting algorithm type.

Validate Membership Information

This algorithm is a column reference validation algorithm that checks that an input membership type is valid. Refer to CRVL-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: VAL MEM TYPE
- Description: Validate SC Membership Type
- Algorithm Type: CRVL-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE

Post Membership Information

This algorithm is a column reference posting algorithm that creates a membership using the membership type indicated by the user. Refer to CRPS-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: CREATE MEMBRSHP
- Description: Validate SC Membership Type
- Algorithm Type: CRPS-ME

Copyright © 2026, Oracle and/or its affiliates.

- Parameter1: (Column Reference for Membership Type): SCM-TYPE
- Parameter2: (Service Credit Membership Status): 10 -Pending or 20 -Active. Refer to Lifecycle of a Membership for more information.
- Parameters3-5: (Division, SA Type, Start Option): Indicate the information needed to create an SA for miscellaneous transactions.

> **Note**
>
> This algorithm first looks for an existing service agreement of this division / SA type linked to the membership's accounts. If one exists, it uses that SA to link to the membership. If an SA does not exist, it creates one with the input division, SA and (optional) start option.
>
> **Update the Column Reference.** Now that you have defined the validation and posting algorithms, return to your column reference for membership type and define the algorithms there.

Although your company may support multiple types of memberships, this column reference and its algorithms have been designed such that only one column reference for membership type would be needed to set up any type of membership. Although the posting algorithm for the membership type column reference indicates an SA type to use for miscellaneous transactions, a service agreement is only created and linked if your membership type indicates that an SA is required. As a result, you may use the same column reference for both memberships that require an SA and those that don't require an SA. However, if you have different membership types that require an SA and each uses a different SA type or a different start option for the membership SA, you need to define more than one posting algorithm and, as a result, more than one column reference.

Define a Campaign for Creating a Membership When Starting Service

Many factors must be considered when designing your campaigns and packages. The possible creation of a membership when using the order page is simply another factor to consider.

If you plan to define a question/miscellaneous field to capture a service credit membership type, the available packages linked to the campaign should be ones that are related to memberships. For example, if your membership is related to electric service, it doesn't make sense to create a membership for a campaign designed to generate a one-time charge.

When defining a question/miscellaneous field, you must indicate its applicability. Consider whether a membership type is required, optional or only applicable for certain packages. This helps ensure that your users capture this information when appropriate.

Including the Membership Fee

You must determine the best way to setup your campaign/package to handle the levying of your membership fee, if applicable. Consider some of the following questions.

- If the membership has a fee, is it a refundable fee or a non-refundable fee?

Copyright © 2026, Oracle and/or its affiliates.

- Is the fee always applicable for the membership? Or is it waived under certain conditions? For example, maybe the fee is applicable if a customer signs up for a single service, but the fee is waived if the customer signs up for two or more services.

The SCM type column reference and question/miscellaneous field are set up to ask the user what type of membership to create. Because the applicability of the fee may differ for each membership type, you should carefully consider the campaign / package setup to levy the fee correctly.

- If a fee is always applicable for a membership, you may consider creating a membership creation algorithm that creates a fee SA with a start option to levy the fee when the membership is created.

> **Note**
>
> **Sample Algorithm**. The base product does not provide a membership creation algorithm to do this.

- If the fee is not always applicable for a membership, you must determine when the fee is applicable. The recommendation is to include the fee SA type in the SAs-to-create collection for the appropriate package. For example,
  - If the fee is applicable when the customer signs up for a single service, you should define a package for each single service that includes one SA to create for the single service and the fee SA as another SA to create.
  - If the fee is waived when the customer signs up for two or more services, you should define a package for each combination of the multiple services. These packages do not include the fee SA in the SAs to create.
- If the customer signing up for service is a former customer who has returned, perhaps the fee was paid earlier when the customer originally had service. In this case, maybe your business practice is to waive the fee at this time. To do this, you should set up a question/ miscellaneous field for the user to mark that this is a returning customer. Based on the answer to this question, perhaps only packages that do not levy any fee are eligible for selection.

Defining Another Person for Your Account

It is common for a capital credit membership to define more than one person for the account being turned on and linked to a membership. A typical example is a married couple. Both spouses are indicated on the account and financially responsible persons and as a result, both are considered members.

Column reference algorithms have been provided by the base product to enable linking a second person to your account via the order page.

This section walks you through how to set up the column reference and campaign to support this.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Linking A Second Person to the Account.** This logic is not restricted to service credit functionality. Any campaign may be designed to include the ability to link a second person to the account being started.

- Column References for Additional Person
- Algorithms to Link Additional Person via Order
- Design a Campaign to Include Linking an Additional Person

Column References for Additional Person

In order to ask the customer service representative to link an additional person for the account, you must define several column references to use as questions/miscellaneous fields.

- We should assume that the person may already exist in the database. As a result, a question to record the person ID is needed.
- If the person does not already exist, the user should capture the person's name, an ID type and an ID number. Questions for these three fields are needed. The system uses this information to create a new person.
- Whether we are using an existing person or creating a new one, the person's link to the account must include an account relationship type. A question to record the account relationship type is needed.

Add a new column reference for person ID:

- Column Reference: PERSON-ID
- Description: Person ID
- FK Reference: PER
- Long Description: Person ID of the additional person to link to the order's account.

Add a new column reference for person name:

- Column Reference: PERSON-NAME
- Description: Person Name
- FK Reference: not applicable
- Long Description: Name of a new person to create.

Add a new column reference for identifier type:

- Column Reference: PER-ID-TYPE
- Description: Person Identifier Type
- FK Reference: ID TYPE
- Long Description: Person Identifier type for the primary ID of the additional person to link to the order's account.

Add a new column reference for identifier number:

- Column Reference: PER-ID-NUM

Copyright © 2026, Oracle and/or its affiliates.

- Description: Person ID Number
- FK Reference: not applicable
- Long Description: Identifier number for the primary ID of the additional person to link to the order's account.

Add a new column reference for account relationship type:

- Column Reference: ACCT-REL-TYPE
- Description: Account Relationship Type
- FK Reference: ACCT REL
- Long Description: Relationship type to use for the link between the additional person and the order's account.

> **Note**
>
> **Column Reference Algorithms**. One of the column references above must indicate a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information. We recommend using the account relationship type record because that is used for all additional persons.

Algorithms to Link Additional Person via Order

The base product has provided two algorithm types to support the linking of an additional person to the account via the order page: a validation algorithm type and a posting algorithm type.

Validate Addition Person Information

This algorithm is a column reference validation algorithm which checks that either a person id or person name, a valid ID type and ID number are provided and that a valid account relationship type is provided. Refer to CRVL-PE for more information. You must define an appropriate algorithm for this algorithm type and on that algorithm you must define the column reference used for the five fields required for this validation. For example:

- Algorithm: VAL ADD PER
- Description: Validate Additional Person Info
- Algorithm Type: CRVL-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

Post Addition Person

This algorithm is a column reference posting algorithm that may link an existing person to the order's account or create a new person and link that person to the order's account. Refer to CRPS-PE for more information. You must define an appropriate algorithm for this algorithm

Copyright © 2026, Oracle and/or its affiliates.

type, and on that algorithm you must define the column reference used for the five fields required for this logic. For example:

- Algorithm: LINK ADDNTL PER
- Description: Link additional person to order's account
- Algorithm Type: CRPS-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

> **Note**
>
> **Update the Column Reference.** Now that you have defined the validation and posting algorithms, return to your column reference for account relationship type and define the algorithms there.

Design a Campaign to Include Linking an Additional Person

Any campaign related to a specific account may include the questions and miscellaneous fields defined here to create/link an additional person to the account.

Simply create entries in the questions and miscellaneous fields collection to prompt the user to ask for the required information. A question should exist for each column reference created above. The following table illustrates a possible setup.

Seq	Description	Prompt on Order	Column Reference	Dependency
10	Account relationship type for additional person.	If you would like to link another person to this account, please enter an account relationship type.	ACCT-REL-TYPE	Must have account
20	Person ID for additional person	If the additional person already exists in the database, enter the person id.	PERSON-ID	Must have account
30	Person name for additional person	If you would like to create a new person, please enter the person name.	PERSON-NAME	Must have account
40	ID type for additional person	Please enter the ID type of the new person.	PER-ID-TYPE	Must have account

Copyright © 2026, Oracle and/or its affiliates.

50	ID Number for additional person	Please enter the ID number of the additional person.	PER-ID-NUM	Must have account

Service Credits Earned When Starting Service

For some memberships, you may want to add service credits when starting the program. For example, the customer gets three free pay-per-view movies when signing on for cable service. Or a customer receives 500 frequent flier miles for signing up for a combination of gas and electric service.

There are various ways that you can accomplish this. You should work with your implementers to consider the various options to determine the method that best suits your business practice.

- You could use an SA activation algorithm to create a membership and an event for the initial points. Use this method if the points are related to a single type of service agreement and the points are earned automatically when starting service (i.e., without any human decision to be made).
- You could use a membership creation or membership activation algorithm to generate a service credit event automatically. This method assumes that the decision to create the membership has been made and that the free initial points are always earned for this type of membership (i.e., regardless of the type of service created).
- You could use questions and miscellaneous fields for a campaign/package to determine a customer's eligibility for participation in the membership and for the initial free points. A column reference posting algorithm could create the membership and/or the service credit event for the free points based on the answers to the questions.
- Perhaps the initial free points are only earned after the first bill is generated. Use a bill completion algorithm to generate the initial points.

You may think of other plug-in spots that could be used to generate free initial points based on your business needs.

Service Credits Earned Through Billing

For some memberships, you may accumulate points as a result of billed amounts for other services. For example, perhaps your customers earn one frequent flier mile for every $10 spent on the combined electricity, gas and water bills each month.

To accomplish this, you must design an algorithm to be executed at billing time. There are various plug-in spots executed at billing time that you may use, but the recommended plug-in is a post completion algorithm on the customer class. This plug-in is executed after all bill segments are frozen and most of the completion logic has occurred.

Your algorithm should determine the service agreements that contribute to the membership and calculate the service credit amount for those service agreements bill segments.

This algorithm should also consider what to do when bill segments that contributed to the event are canceled. The algorithm provide with the base product CBCM-SC checks to see if any canceled bill segments are referenced on any previous events. If so, it includes the canceled amount on the new event. This may cause the new event to be a negative amount. The assumption is that over time, earned credits will compensate for the negative event amount.

Copyright © 2026, Oracle and/or its affiliates.

For a membership that interfaces information to a third party, it is assumed that the negative event amount is also interfaced.

Service Credits Redeemed Through Billing

For some memberships, your customer may redeem their earned points by receiving a discount on their bill. For example, if your cable customer has earned one free pay-per-view movie, you can give them a credit the next time they get billed for a pay-per-view movie.

The base product has not provided any algorithms to credit a bill based on earned service credits. This section will identify considerations your implementers should follow when designing algorithms to redeem service credits through billing.

The recommendation is to credit the customer's bill by generating an adjustment using a pre-bill completion algorithm. This algorithm's responsibilities are as follows:

- Determine if the appropriate bill segment(s) contain the charges that need to be credited. For example, if the service credit is for a free pay-per-view movie, determine if the customer has been billed for a pay-per-view movie.
- Determine if the customer's current service credit balance for this program. For example, how many free pay-per-view movie credits are left?
- Create an adjustment to credit the appropriate service agreement by the eligible credit amount.
- Update the service credit membership balance by creating a new SC event with a credit for the number of points redeemed. Link the adjustment to the event as a contributed to FT.
- Consider cancel/rebill situations. If a cancel/rebill has occurred, determine if there is a change to the redeemed credits. For example, if the original bill had one pay-per-view movie that was credited and the new bill also has one pay-per-view movie, no change is needed to the service credit balance. If the original bill had more pay-per-view movies than the new bill, perhaps one or more redeemed service credit points should be reinstated. If the original bill had fewer pay-per-view movies than the new bill, perhaps more points should be redeemed.

You may wonder why we don't recommend crediting the customer's bill while generating the bill segment. For example, use pre-processing calculation rule to determine if any points should be redeemed and use a calculation rule to generate a bill calculation line with the credit amount.

The reason for this is that cancel/rebill logic is not straightforward. Algorithms executed during rate application should NOT perform any updates, such as updating the service credit membership balance. The balance should be updated using a bill segment freeze algorithm or a bill completion algorithm.

When a cancellation occurs, the service credit balance should be updated to reinstate the redeemed points. Again, this should occur when the cancellation is frozen or at bill completion time. If you perform a cancel/rebill, the calculation of the rebill segment does not have the up-to-date information about the service credit balance because the reinstatement of the points by the canceled segment has not occurred yet.

Designing Your Rate Options for Capital Credits

The capital credit allocation background process relies on certain data configuration in order to function correctly. This section identifies the required data setup.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Allocating Capital Credits for more information.

- Identifying SQ and Sales Information for Historical Bill Segments
- Designing Bill Factors for Credit Allocation

Identifying SQ and Sales Information for Historical Bill Segments

To allocate capital credits, the background process retrieves billing history for each SA that contributes to the membership for the given fiscal year. The process needs to calculate the service quantity (SQ) amount billed and the sales amount billed for the SA in that year.

Note

Sales Amount. The sales amount refers to the monetary amount billed. For a capital credit allocation, this amount would generally exclude taxes and may exclude other line item amounts from the bill.

In order to calculate the amounts correctly, the background process must determine which bill calculation lines for each bill segment contain the SQ and/or sales information. Characteristics on the bill calculation lines identify which bill lines should be used.

The rest of this section uses examples to illustrate how you may configure your rate options to support this.

- Define Characteristics for SQ and Sales
- Define Calculation Rules
- Define Batch Control Parameters

Define Characteristics for SQ and Sales

Char Type for identifying bill lines that hold **SQ information**

- Char Type: CCA-SQ
- Description: Capital credit allocation usage
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Char Type for identifying bill lines that hold **sales information**

- Char Type: CCA-SALES
- Description: Capital credit allocation sales
- Type of Char: Pre-defined

Copyright © 2026, Oracle and/or its affiliates.

- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Define Calculation Rules

Identify each rate schedule that may be linked to a service agreement that contributes to a capital credit membership.

For each of these rate schedules, identify the calculation rules whose resulting bill calculation line will contain a billable service quantity that should be included in the SQ calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SQ char type (defined above) and a char value of Y.

For each rate schedule, identify the calculation rules whose resulting bill calculation line amount should be included in the sales calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SALES char type (defined above) and a char value of Y.

> **Note**
>
> **Characteristic Information**. The system automatically copies characteristic info from a calculation rule to its resulting bill calculation line if the char type entities include both calculation rule and bill calc line.

Define Batch Control Parameters

The background process to allocate capital credits CPCRALOC receives the char type and char value to identify the bill calculation lines that contain the SQ and sales amounts. Once you have your characteristics defined, update your batch control to include these values as default parameter values.

Designing Bill Factors for Credit Allocation

The capital credit allocation process uses an allocation factor in its calculation. A typical capital credit membership may define multiple subcategories, meaning that allocation amounts are calculated each year for the multiple subcategories. The calculation is the same for each subcategory, but the allocation factor differs.

The process has been designed to calculate the allocation for a single subcategory. If your organization requires allocations calculated for multiple subcategories, the process must be run for each subcategory. The allocation process receives a bill factor as an input parameter. As a result, a different bill factor should be set up to define the allocation factor for each subcategory.

For each subcategory, the allocation factor may differ further for the type of customer. For example, the allocation for a commercial customer may differ from the allocation factor for a residential customer. The allocation background process expects the bill factor for each subcategory to define a characteristic type of revenue class. The process determines each service agreement's revenue class by looking at the value defined on its SA type.

Copyright © 2026, Oracle and/or its affiliates.

Following is an example of bill factors set up for a capital credit membership with two subcategories: transportation and generation.

- Characteristic Type for Allocation Bill Factor
- Bill Factor for Transportation
- Bill Factor for Generation

Characteristic Type for Allocation Bill Factor

Char Type: REV-CLASS

Description: Revenue Class

Type of Char: Pre-defined

Values: (define all the valid revenue class values)

Char Entity: Bill Factor

Bill Factor for Transportation

Bill Factor Id: CCAF-TRANS

Description: Transportation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new transportation allocation factor for each revenue class must be defined)

Bill Factor for Generation

Bill Factor Id: CCAF-GEN

Description: Generation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new generation allocation factor for each revenue class must be defined)

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The characteristic source is characteristic collection.** It is the responsibility of the background process to determine the SA's revenue class and to pass this value into the bill factor routines to retrieve the correct bill factor value.
>
> **Estimating Allocation Factors**. Often the company needs to estimate the allocation factors for the new fiscal year and may adjust the values several times until the calculated allocation amounts are satisfactory. Refer to Allocating Capital Credit for more information.

Partial Retirement

In the cooperative business, it is common to never retire certain capital credit allocation amounts. The amounts that do not retire should be assigned their own subcategory.

When executing the retirement background process, the subcategory to retire may be input to the process. If you have certain subcategories that you do not retire, you would simply run the background process for the subcategories that do retire.

Cooperatives typically retire amounts and transfer the amounts to a beneficiary when a member dies. This is known as "estate retirement". Refer to Service Credits for Capital Credit Memberships for more information. If your business practice designates that certain subcategories of allocated amounts do not get retired, this probably holds true for estate retirement as well. If that is the case, your membership inactivation algorithm should be designed to only retire the appropriate amounts by subcategory.

Interface Membership Information to a Third Party

For some memberships, you may accumulate points for a third party, for example accumulating frequent flier miles for an airline. For these types of memberships, you must interface the event information to the third party.

To interface information to a third party, you may choose one of the following options:

- Design an extract program to interface the information
- Use workflow and notification to interface the information via the XAI tool
- Interface Via an Extract Program
- Use Workflow & Notification to Interface Info
- Other Considerations For Interfacing Info to a Third Party

Interface Via an Extract Program

The service credit event may indicate a batch code and batch run number. Design a program to extract event information to a third party. This extract program would select service credit events marked with its batch code and the current run number.

Copyright © 2026, Oracle and/or its affiliates.

Your service credit event must define a completion algorithm that stamps the appropriate batch code and run number. The base product provides an algorithm type to perform this logic. Refer to SCEC-BT for more information.

Use Workflow & Notification to Interface Info

Workflow and notification allows you to send information to a third party via an extract program or via XAI. The service credit event has its own logic for interfacing via an extract program, so you would use workflow and notification only if you need to interface to the third party via XAI.

> **NOT_SUPPORTED**
>
> Refer to Designing Notification Downloads for more information.

Other Considerations For Interfacing Info to a Third Party

Because event information is extracted to a third party, you must consider how to handle adjustments to the event amount. For example, if your event is generated based on the creation of a bill segment, what should happen if that bill segment is cancelled?

You may want to prevent these types of events from getting canceled. Validation like this may be added via a user exit or using an event cancellation algorithm.

> **Note**
>
> **Sample Algorithms**. The product does not provide any base algorithms to prevent an event from being canceled.

You should allow negative event amounts to be created so that this information may also be sent to the third party's system.

Defining Loan Options

The topics in this section describe how to set up the system to enable loan functionality.

> **Note**
>
> **Loans are optional.** The system configuration requirements described in this section are only relevant if your organization loans money to customers.

- The Terms Of A Loan Are Stored On A Service Agreement

Copyright © 2026, Oracle and/or its affiliates.

- Payoff Balance and Current Balance for Loans
- Booking The Principal Amount Using An Adjustment
- Loan Amortization Schedule Calculation
- Billing For Loans And Interest Calculation
- Paying What Is Owed
- Overpayments On Loans
- Adjusting Loan Amounts
- Writing Off Loans
- Distribution Codes for Loans
- Setting Up The System To Enable Loans

The Terms Of A Loan Are Stored On A Service Agreement

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA Type) contains the loan's terms:

- The **loan amount** is held in the service agreement's Total Amount to Bill.
- The **customer's periodic payment amount** is held in the service agreement's Recurring Charge Amount.
- The **number of amortization periods** (e.g., 36 months, 240 months, etc.) is held in the service agreement's Number of Payment Periods.
- If the **interest rate** is the same for all customers with this type of loan service agreement, the interest rate is defined on the service agreement's SA type (using a bill factor). A specific interest rate can be defaulted from a start option contract value. If a specific interest rate applies to the customer, the SA type's interest rate can be overridden by specifying a bill factor value on the customer's service agreement (where the bill factor value contains the specific interest rate for the customer).
- The SA type controls the **periodicity of the bills** (e.g., monthly or bi-weekly).

Because a loan is defined using a service agreement, the typical functionality that is controlled by the service agreement's SA type is supported, including:

- How and when it is billed.
- How payments are booked in the GL (and the payment priority relative to other service agreements).
- How its debt is monitored by credit and collections.
- How late payment charges are calculated.

Loan service agreements are created using Start/Stop just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Automatic calculation of periodic payment amount / number of periods.** The system calculates a loan's periodic payment amount or number of payments (whichever is left blank). You can have the system do this on Start/Stop Maintenance (using the **Calculate** button that appears on the start service confirmation window), and on Loan - Main (by clicking the **Calculate** button). Regardless of where you do this, the calculation is performed by an algorithm on the loan's SA type. Refer to the LPDA-SI algorithm type for more information about the base package algorithm.

Payoff Balance and Current Balance for Loans

As described under Current Amount versus Payoff Amount, a loan service agreement's current balance and payoff balance differ during the lifetime of the loan. Current balance contains how much the customer owes to remain current (typically their periodic payment amount), and payoff balance contains the amount the customer would have to pay to payoff the loan (typically the principal balance plus any accrued interest charges).

Unlike other SAs, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). The current balance for a loan is always the amount of the short-term receivables. The payoff balance for a loan is always the net of the short-term receivables and the long-term receivables.

If the SA has a special role of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. For example, when a bill segment is generated for the loan SA, the amount of the periodic payment is transferred from the long-term receivables to the short-term receivables. Don't worry, the examples in the following sections show exactly what these transactions look like.

An operator can see the how the bills, payments and adjustments have affected the GL, current balance and payoff balance using SA Financial History.

The following sections provide examples of how adjustments, bills and payments are recorded in the GL and the subsequent effect on the current and payoff balances. When reading the examples, remember that the payoff balance is always the net of the short-term receivable and the long-term receivable balances.

Booking The Principal Amount Using An Adjustment

When a loan service agreement is activated (i.e., when its status changes from pending start to active), an adjustment is created to book the principal amount. If the customer takes out a loan of 10,000, the adjustment's financial transaction looks as follows:

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance

Copyright © 2026, Oracle and/or its affiliates.

Loan service agreement is activated (and an adjustment is created to book the principal)	Long Term Loan Receivable 10,000 Cash <10,000>	0	10,000	0	10,000

This adjustment is issued if:

- The service agreement's SA type indicates a special role of Loan.
- The loan service agreement's Total Amount to Bill contains an amount (i.e., the loan amount).
- The loan service agreement was created using a start option on Start/Stop Maintenance AND the start option references an adjustment type and this adjustment type has been set up as follows:
  - The adjustment type's distribution code should reference the GL account to credit (e.g., Cash).
  - The adjustment type's FT algorithm reference Payoff Amt = Adj Amt / Current Amt = 0 (booking principal only impacts a customer's payoff balance).

Note that because this financial transaction doesn't have a current amount (the customer doesn't actually owe a current amount yet), there is no need to book anything to the short-term receivables distribution code.

Loan Amortization Schedule Calculation

The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

A loan's amortization schedule is calculated when an operator clicks the **Calculate** button on Loan - Main . Please be aware that when this button is clicked, an algorithm plugged in on the loan SA type actually calculates the amortization schedule (refer to the algorithm type LSCH-SI for more information).

Billing For Loans And Interest Calculation

A bill segment is produced for a loan when its service agreement's account is next billed.

Factors on a loan's SA type controls when a bill segment is produced for a loan. Typically SA types for loan service agreements are set up to use anniversary calendar billing. For this configuration:

- You must indicate the type of anniversary billing in the calendar billing option. Currently, we only support the Anniversary Future Billing (meaning that loans are billed in advance just like a classic home loan is). Refer to Using The Anniversary Method for more information about how this billing method controls the end date of the loan bill segment.
- You must reference an anniversary billing frequency consistent with the recurring charge frequency (e.g., monthly, quarterly, etc.).

Copyright © 2026, Oracle and/or its affiliates.

To set up for a loan that is billed on a monthly basis, you would define the following fields in SA Type - Billing:

- **Use Calendar Billing**: Anniversary Future Billing
- **Anniversary Bill Frequency**: Monthly
- **Total Bill Amount**: Required
- **Recurring Charge**: Required
- **Recurring Charge Frequency**: Monthly
- **Total Amount To Bill Label**: Loan Amount
- **Recurring Chg Amt Label**: Payment Amount

If your type of loan must be billed on an exact date (for example, always on the 15th of the month) or with an exact number of days between each bill (for example, every 14 days), then your loan should be set up to use the calendar billing option of Use Bill Period. In order for your loan bills to be created on specific dates, the system makes the following assumptions:

- Your bill cycle schedule for the loan's account is defined with the dates that you want the loan to bill and is defined with the window start date equal to the window end date.
- You define a bill period schedule corresponding to your bill cycle schedule. Each bill period schedule's bill date should match your bill cycle window start date and each bill period schedule's bill segment end date should be set to the loan period end date.
- Considerations for the first bill. If the loan SA Type's Initial Start Date Option indicates that the first day of the service agreement should be billed, then the loan SA's start date should match the window start date of the next bill cycle schedule for the account. If the loan SA Type's Initial Start Date Option indicates that first day of the service agreement should not be included, then the loan SA's start date should be one day prior to the window start date of the next bill cycle schedule for the account.
- Define your recurring charge frequency to match the frequency of your bill periods.

How the bill segment affects the customer's balance, and how it affects the general ledger are controlled by several algorithms defined on the loan service agreement's SA type and bill segment type:

- The SA type's loan schedule algorithm controls how the loan amortization schedule is calculated.
- The SA type's loan interest charge algorithm controls how interest is calculated.
- The bill segment type's create algorithm controls how the bill lines are constructed.
- The bill segment type's financial algorithm controls how the general ledger is affected by the bill.

The second entry in the following table contains an example of the financial transaction produced by the base package algorithms (note, the first financial transaction in the table was described under Booking The Principal Amount Using An Adjustment).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000

Copyright © 2026, Oracle and/or its affiliates.

First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95

Several important points are illustrated above:

- When a bill segment is produced for a loan service agreement, the following takes place (if you use a bill segment creation algorithm of Create Bill Segment for Loans):
  - The loan SA type's bill segment creation algorithm calls the SA type's loan interest charge algorithm.
  - The base package loan interest charge algorithm calculates simple interest based on: 1) unbilled principal (i.e., the service agreement's payoff balance minus the current balance), 2) the number of billing periods covered by the bill, and 3) the interest rate. Refer to the algorithm type LINT-SI for more information about the base package interest calculation algorithm.

> **Note**
>
> **No interest on interest and no interest on past due amounts.** Just like a classic home loan, the base package algorithms do not calculate interest on interest, nor do they calculate interest on past due amounts. If you want to levy a late payment charge, use the SA type's late payment processing. If your organization calculates interest differently, you must develop your own algorithm(s).

- The SA type's bill segment creation algorithm uses the calculated interest to format the bill segment's bill lines. It creates one bill line to show the amount of interest in the payment, and another bill line to show the amount of principal. The principal amount is equal to the service agreement's periodic payment amount minus the amount of calculated interest.
- The financial transaction illustrated above is created if you use a bill segment financial algorithm of Payoff Amt = Interest / Current Amt = Bill Amount on the loan's bill segment type. The following explains how this algorithm works:
  - The SA's current balance increases by the amount of the loan's periodic payment amount (i.e., its recurring charge amount). In other words, the amount the customer thinks they owe increases by 438.71.

Copyright © 2026, Oracle and/or its affiliates.

- The SA's payoff balance increases by the amount of interest. In other words, if the customer wanted to payoff the loan, they'd owe 10,041.66.
- The *Interest* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of interest and debits it to the SA type's receivable distribution code (long-term receivables) and credits it to the distribution code defined on the interest rate's bill factor (typically interest revenue).
- The *Transfer* portion of the GL accounting transfers moneys from long-term receivables (i.e., the unbilled principal) to short term receivables (the billed portion of the debt). The amount transferred is equal to the FT's effect on the service agreement's current balance, allowing the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Remember that the payoff balance is the net of the short-term and long-term receivables.

Paying What Is Owed

When a payment is made for a loan:

- The service agreement's payoff amount is reduced by the payment amount.
- The service agreement's current amount is reduced by the payment amount.

The events that happen when a customer makes a payment against a loan is controlled by the FT algorithm plugged in on the loan service agreement's payment segment type. We'll use an example to help explain how this algorithm works. The 3 rd entry in the following table illustrates the financial transaction produced when a payment is made (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000

Copyright © 2026, Oracle and/or its affiliates.

First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95
Payment is made	Affect Cash Cash 438.71 Long Term Loan Receivable <438.71> Transfer Long Term To Short Term: Long Term Loan Receivable 438.71 Short Term Loan Receivable <438.71>	-438.71	-438.71	0	9,602.95 short-term: 0 long-term: 9,602.95

The financial transaction illustrated above is created if you use a payment segment FT creation algorithm of Payoff Amt = Current Amt = Pay Amt on the loan's payment segment type. The following explains how this algorithm works:

- The SA's current balance decreases by the amount of the payment amount. In other words, the customer thinks they owe 0 after the payment. Note refer to Overpayments for information about how an overpayment affects the SA's balances and the general ledger.
- The SA's payoff balance decreases by the amount of the payment. In other words, if the customer wanted to payoff their loan, they'd owe 9,602.95.
- The *Cash* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of the payment and debits it to the payment segment type's distribution code (typically cash) and credits it to the SA type's receivable distribution code (long-term receivable).
- The *Transfer* portion of the GL accounting effectively reduces short-term receivables by the FT's effect on the customer's current balance. This reduction is handled by an offsetting increase to long-term receivables (to make up for reduction made when the cash was applied). Again, this differentiation between short-term and long-term receivables allows

Copyright © 2026, Oracle and/or its affiliates.

the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term).

Overpayments On Loans

You can determine whether you want to accept loan overpayments. Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan.

When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Any customer classes for which you want to allow loan overpayments should use an overpayment distribution algorithm that keeps the overpayment on the loan SA.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to zero out the current balance and transfer the amount of the credit from the SA's short-term receivable to long-term receivable. The adjustment may appear on the customer's next bill to show the additional amount paid against the principal.

The algorithm that controls this adjustment to remove the credit on current balance is plugged in on the loan service agreement's SA type and is applied on the SA Type - Payment Freeze system event.

The third and fourth entries in the following table illustrate an overpayment (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000
First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95

Copyright © 2026, Oracle and/or its affiliates.

Payment is made (with an overpayment of 200.00)	Affect Cash Cash 638.71 Long Term Loan Receivable <638.71> Transfer Long Term To Short Term: Long Term Loan Receivable 638.71 Short Term Loan Receivable <638.71>	-638.71	-638.71	-200.00	9,402.95 short-term: <200.00> long-term: 9,602.95
Create adjustment to remove SA's credit.	Transfer Short Term Credit to Long Term: Short Term Loan Receivable 200.00 Long Term Loan Receivable <200.00>	200.00	0	0	9,402.95 short-term: 0 long-term: 9,402.95

In the third financial transaction illustrated above, the billed amount of the payment works essentially the same as that illustrated under Paying What Is Owed. If the Keep Overpayment on Loan SA algorithm is plugged in on the overpayment distribution event on the customer class, the overpayment amount is applied to the loan SA, creating a credit on the SA's current balance. The following explains how this algorithm works:

- If the account has an loan SA and there is an excess credit, the credit is applied to the loan SA (as long as this does not cause the loan SA to have a credit payoff balance).
- If there is not a loan SA to which the credit can be applied, the algorithm checks to see if there is an open excess credit SA for the account.
  - If so, the excess credit amount is applied to the excess credit SA.
  - If not, the algorithm creates an excess credit SA and applies the amount to this SA.

The fourth financial transaction illustrated above is created if the Create Adjustment to Remove SA's Credit algorithm is plugged in on the loan's SA type's payment freeze event. The following explains how this algorithm works:

- If the SA's current balance is less than zero, the algorithm creates a frozen adjustment that removes the credit by transferring the credit from the short-term receivable to the long-term receivable. This adjustment ID is captured on the pay segment so the adjustment can be canceled if the payment is later canceled. Note that the adjustment cancel reason used by the system in this case is specified on the Financial Transaction Options Feature Configuration using the Adjustment Cancel Reason For Payment Linked To Adjustment option type.

Copyright © 2026, Oracle and/or its affiliates.

- The SA's current balance increases by the amount of the credit transfer. In other words, the customer thinks they owe 0 after the transfer.
- The SA's payoff balance doesn't change because the payoff balance is always the net of the short-term and long-term receivables. In other words, if the customer wanted to payoff their loan, they'd still owe 9,402.95.

> **Note**
>
> **Overpayments and interest.** The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

Adjusting Loan Amounts

You would issue ad hoc adjustments if you need to change a loan's payoff and/or current balance outside of the normal billing / payment functions.

An adjustment can:

- Reduce a loan's payoff balance.
- Reduce a loan's current balance (i.e., how much the customer thinks they currently owe).
- Reduce both the loan's payoff and current balance.

For adjustments that affect payoff amount only:

- These adjustments are used to change the principal owed, e.g., if an additional amount is loaned.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = 0 FT algorithm.
- GL lines will be generated to reflect the change to principal.

For adjustments that reduce current amount only:

- These adjustments can be used to change the amount that the customer must pay as part of the next bill.
- The adjustment's adjustment type should reference the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) FT algorithm.
- Typically, GL lines are not generated for FTs that only affect the customer's current balance. However, moneys must be transferred from long to short in the amount of the adjustment (as described above under Payoff Balance and Current Balance for Loans).

For adjustments that reduce both payoff and current amount:

- These adjustment types can be used to levy additional charges, such as late fees, or to correct interest calculations.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = Adj FT algorithm.

Copyright © 2026, Oracle and/or its affiliates.

- GL lines are generated to reflect the change to principal. In addition, GL lines must be generated to transfer money from long to short in the amount of the adjustment (as described above under Payoff Balance and Current Balance for Loans).

> **Note**
>
> Adjustments that affect the principal balance (payoff balance - current balance) affect the term of the loan because interest is based on the principal balance.
>
> **Adjustments can cause credit balances to exist.** If you credit the loan SA, it is possible for the current balance to become negative. You may need to create additional adjustments that affect the current amount, depending on whether the customer needs to pay this amount as part of the next payment.

Writing Off Loans

Loans are written off using the standard write-off processing.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture Of Write Off Processing for background information.

We illustrate the classic financial transactions that transpire to financially write-off a loan to help illustrate important points (these are the fourth and fifth entries in the following table):

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 1000 Cash <1000>	0	10,000	0	10,000 long-term: 10,000

The only unusual portion of the last two financial transactions is the impact on short and long term receivables. Please see the examples above under Billing For Loans And Interest Calculation and Paying What Is Owed to understand how any impact to a loan's current balance causes this type of financial transfer to occur.

Distribution Codes for Loans

As explained above under Payoff Balance and Current Balance for Loans, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the

Copyright © 2026, Oracle and/or its affiliates.

general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Both receivables distribution codes are defined on the loan SA type.

In addition, loans have a distribution code used to book interest revenue. The interest revenue distribution code is defined on the loan's bill factor value for a revenue class (defined on the loan's SA type). For example, on the bill factor you can use one distribution code to book interest revenue from the residential revenue class and another distribution code to book interest revenue from the commercial revenue class. In this example, you create two loan SA types, one for residential revenue and the other for commercial revenue.

Loans may also have a bad loan debt (expense) distribution code that is used when writing off a loan. The bad loan debt distribution code is defined on the loan's write-off service agreement type. Refer to Defining Credit & Collections Options for more information.

Setting Up The System To Enable Loans

The above topics provided background information about how loans are supported in the system. The following discussion summarizes the various setup tasks alluded to above.

- Distribution Code
- Adjustment Types
- Adjustment Type Profile
- Algorithms
- Bill Factor
- Customer Class
- Bill Segment Type
- Frequency
- Bill Period
- Bill Cycle Schedule
- Collection, Severance and Write Off Processes
- SA Type
- Start Options

Distribution Code

You must set up the following distribution codes:

- Long term receivables
- Short term receivables
- Interest revenue
- Bad loan debt

Copyright © 2026, Oracle and/or its affiliates.

Adjustment Types

The following adjustment types are needed:

- Activate a loan. This should reference a distribution code associated with cash or the cash equivalent and an FT algorithm of Payoff Amt = Adj / Current Amt = 0.

> **Note**
>
> **Creating Checks for Loan Amounts.** If you want the system to initiate a check to the customer for the loan amount, the loan activation adjustment type should indicate an **A/P Request Type Code**. Refer to Controls The Interface To A/P & 1099 Reporting for more information.

- Remove Credit (Overpayment). This adjustment should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Even though this algorithm indicates that there is no effect on the GL, there is a special exception built in for loan SAs. The special exception creates GL details to transfer the current balance (short-term receivable) to the long-term receivable. Refer to Overpayments for more information.

> **Note**
>
> **Printing Overpayments on Bills**. If you want the overpayment adjustment to appear on customers' bills, turn on **Print by Default** and enter a **Description on Bill** (e.g. "Additional Principal"). For more information, refer to Controls Information Printed On The Bill.

- Adjustment types to perform any of the adjustments described under Adjusting Loan Amounts.

Adjustment Type Profile

Create an adjustment type profile that references the adjustment types used on a loan. Besides the above adjustment types, it should also reference adjustment types to levy late payment charges (if applicable), levy non-sufficient funds charges (if applicable), refund overpayments (if applicable), sync current balance with payoff balance at write-off time, transfer balances to a write-off service agreement, and write-down small balances.

Algorithms

Add the following algorithms:

- Overpayment Distribution. This algorithm is later plugged in on the customer class for the Overpayment Distribution system event. Refer to the algorithm type OVPY-LO-CSA for more information about the base package algorithm.

Copyright © 2026, Oracle and/or its affiliates.

- Bill Segment Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBS-LO for more information about the base package algorithm.
- Bill Segment Financial Transaction Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBF-LO for more information about the base package algorithm.
- Amortization Schedule. This algorithm is later plugged in on the SA type for the Loan Schedule system event. Refer to the algorithm type LSCH-SI for more information about the base package algorithm.
- Interest Calculation. This algorithm is later plugged in on the SA type for the Loan Interest Charge system event. Refer to the LINT-SI algorithm type for more information about the base package algorithm.
- Payment Periods/Payment Amount Calculation. This algorithm is later plugged in on the SA type for the Loan Periods and Amount system event. Refer to the algorithm type LPDA-SI for more information about the base package algorithm.
- Loan SA Payment Freeze. This algorithm has a parameter that must reference the Remove Credit adjustment type defined above. This algorithm is later plugged in on the SA type for the Payment Freeze system event. Refer to the algorithm type STPZ-RMVCR for more information about the base package algorithm.

Bill Factor

You must set up a bill factor that defines the interest rate. If you have different interest rates for different types of loans, you can create a separate bill factor for each or you can use start options to override the interest rate.

On the bill factor's bill factor value, make sure to reference the GL distribution code used to book interest revenue for the revenue class specified on the loan's SA type.

Customer Class

Any customer class on which you want to allow overpayments for a loan must use the overpayment distribution algorithm defined above. The overpayment distribution algorithm keeps the overpayment on the loan SA rather than transferring it to an excess credit SA, allowing a subsequent adjustment to apply the overpayment to the principal balance.

Bill Segment Type

Create a bill segment type that references the bill segment creation algorithm defined above and the FT creation algorithm defined above.

Frequency

Copyright © 2026, Oracle and/or its affiliates.

Create frequency codes to correspond to the frequency of your loans. When setting up your SA types, you must indicate a recurring charge frequency and, if you use the Anniversary Billing Option, you must indicate an anniversary frequency.

Bill Period

If you use the Use Bill Period option, set up a bill period with an appropriate schedule of dates for billing your loan.

Bill Cycle Schedule

If you use the Use Bill Period option, the bill cycle schedule for these types of loans should be defined with an appropriate schedule of dates for billing your loan.

Collection, Severance and Write Off Processes

You should set up the appropriate credit and collections information. Refer to Defining Credit & Collections Options for more information.

SA Type

You must set up a SA type for your loan service agreements (you may need multiple SA types if you have different business rules for different types of loans). The following points describe the minimal requirements for a loan SA type.

- SA Type - Main
- SA Type - Detail
- SA Type - Billing
- SA Type - Rate
- SA Type - SP Type
- SA Type - Adjustment Profile
- SA Type - Credit and Collections
- SA Type - Algorithms

SA Type - Main

Define the following options:

- **Distribution Code** should be a long-term receivable code.
- **Service Type** should references something like "Miscellaneous Service".
- Specify the **Revenue Class** that, together with the interest bill factor, determines the distribution code used to book the loan interest revenue.

Copyright © 2026, Oracle and/or its affiliates.

- **Start Option** should be turned on.
- The Payment Segment Type should reference the Normal Payment. The base package payment segment financial algorithm (Payoff Amt = Current Amt = Pay Amt) used for Normal Payment pay segment types creates the additional GL details to transfer the credit from long-term receivables to short-term receivables if the SA's special role is Loan.
- Turn on **Late Payment Charge** if applicable.
- Define an appropriate **Adj**ustment **Type (Synch Current)** that will cause current balance to be synchronized with payoff balance (if the loan is written off).

SA Type - Detail

Define the following options:

- **Special Role** is Loan.
- Specify the **Interest Bill Factor** set up above. You can use start options to override.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the short-term receivable account defined above as the **Loan A/R Distribution Code**. If you do not want the system to differentiate between short-term receivables and long-term receivables, make the loan A/R distribution code the same as the distribution code (above).

SA Type - Billing

> **NOT_SUPPORTED**
>
> For an overview of some of these options, be sure to refer to Billing For Loans And Interest Calculation for more information.

Define the following options:

- The Bill Segment Type should reference the value created above.
- **Characteristic Premise Req**uired should not be checked. (A loan SA is not a premise-based service. SA types that have this box checked are filtered out of the SA type search when the start method is Start a SA, so users will never be able to start a loan SA that requires a characteristic premise.)
- **Use Calendar Billing** must equal Anniversary Future Billing or Use Bill Period.
- **Bill Period** is required for the Use Bill Period option.
- **Anniversary Billing Frequency** is required for the Anniversary Future Billing option and must equal the periodicity of the bills (monthly, weekly, etc.).
- **Total Bill Amount** is required (it holds the principal).
- **Total Amount To Bill Label** should reference something like "Loan Amount".

Copyright © 2026, Oracle and/or its affiliates.

- **Recurring Charge** is required (it holds the periodic payment amount).
- **Recurring Chg Amt Label** should reference something like "Payment Amount".
- **Recurring Charge Frequency** is required (it defines the periodicity associated with the recurring charge amount) and must be the same as the bill period frequency or the anniversary billing frequency (based on your **Use Calendar Billing** option).

SA Type - Rate

Turn off the **Rate Required** switch as loans do not use rates.

SA Type - SP Type

Turn off the **Service Points Required** switch as loans do not have service points.

SA Type - Adjustment Profile

Adjustment Type Profile should reference the profile set up above.

SA Type - Credit and Collections

The credit and collections information should reference a **Severance Process Template** that simply expires the loan. The **Debt Class** and **Write Off Debt Class** should reference an appropriate value consistent with your credit and collections rules. Refer to Defining Credit & Collections Options for more information.

SA Type - Algorithms

The Loan Schedule, Loan Interest Charge, Loan Periods, and Amounts and Payment Freeze algorithms defined above must be set up.

Start Options

Loans require a start option to define the adjustment type that is used to create the adjustment to book the initial principal amount when the loan is activated. Loan start options can also specify default values for loan amount, payment amount, and number of periods.

Create at least one start option for each loan SA type. The following information should be defined:

- **Adjustment Type** should reference the adjustment type defined above to book principal.
- **Recurring Charge Amount** (Payment Amount) should only be defined if you have standard loan payments.

Copyright © 2026, Oracle and/or its affiliates.

- **Total Amount To Bill** (Loan Amount) should only be defined if you have standard loan amounts.
- **Number of Payment Periods** should be the number of payment periods in the loan (if you have a standard loan period).
- If you want to define a set of standard APRs for a loan SA Type, set up a **Contract Value** on the Rate Info page. The **Bill Factor** should match the interest bill factor specified on the SA Type.

Defining Non-Billed Budget Options

A Non-Billed Budget (NBB) is a payment plan that allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Non-Billed Budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. As the name suggests, bills are not created for the Non-Billed Budget's scheduled payments; customers must remember to make their payments at the scheduled intervals. The topics in this section describe how to design and set up non-billed budgets.

> **Note**
>
> **Non-Billed Budgets are optional.** The system configuration requirements described in this section are only relevant if your organization offers Non-Billed Budgets.

- What Is A Non-Billed Budget?
- The Financial Impact Of Non-Billed Budgets
- Financial Transactions For Unmonitored Non-Billed Budgets
- Designing Non-Billed Budgets
- Non-Billed Budget Recommendation Rule
- Setting Up The System To Enable Non-Billed Budgets

What Is A Non-Billed Budget?

A Non-Billed Budget is a special type of budget or payment plan that encompasses three major elements:

- A set of scheduled payments
- The business rules used to recommend and potentially renew the payment schedule
- The business rules that govern the financial impact on the current and payoff balances of the SAs covered by the payment schedule

Non-Billed Budgets are managed via a service agreement whose SA type has a special role of Non-Billed Budget. If an SA type has a special role of Non-Billed Budget it must have one or more recommendation rules, and SAs of that type are allowed to have payment schedules.

Copyright © 2026, Oracle and/or its affiliates.

The Financial Impact Of Non-Billed Budgets

When you set up the Non-Billed Budget SA type, you can indicate whether the Non-Billed Budget is monitored by the account debt monitor process. The following sections contain examples of financial transactions for Non-Billed Budgets that are monitored by the account debt monitor.

> **Note**
>
> **Unmonitored Non-Billed Budgets.** SAs that are covered by unmonitored Non-Billed Budgets are subject to different financial treatment than those that are monitored. The financial transactions relevant for unmonitored Non-Billed Budgets are discussed later.

- Current Amount For SAs Covered By A Non-Billed Budget
- Scheduled And Actual Payments On The Non-Billed Budget
- Overpayments for Non-Billed Budgets
- Underpayments For Non-Billed Budgets
- Billing For SAs Covered By The Non-Billed Budget
- Distributing Non-Billed Budget Credit
- Stopping an SA Covered By a Non-Billed Budget

Current Amount For SAs Covered By A Non-Billed Budget

As described under Current Amount versus Payoff Amount , the values of the current balance and payoff balance are the same for most financial transactions. One exception is for SAs that are covered by a Non-Billed Budget in which case the current balance is always zero and the payoff balance is always the amount the customer really owes.

When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget, the system creates adjustments for all affected SAs to set the current amount equal to zero. The adjustment type that references the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) algorithm is taken from the SA's SA type.

> **Note**
>
> **Non-Billed Budgets and Open Item Accounts.** If the Non-Billed Budget is for an open item account, no match event is created for the financial transaction that reduces the current amount to zero. This FT must be manually matched if required.

The following example shows the effect of activating a Non-Billed Budget that covers an electric SA with a current balance of 25. The transactions for the electric SA are illustrated on the right and the transactions for the non-billed budget SA are illustrated on the left.

Copyright © 2026, Oracle and/or its affiliates.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				

By setting the current balance for the covered SAs to zero, the SAs are insulated from the regular debt monitoring process. Depending on the Non-Billed Budget recommendation algorithm , the payoff balance can be ignored, divided evenly between the scheduled payments or added to the first scheduled payment.

Activating a Non-Billed Budget has no affect on its own current or payoff balances.

Scheduled And Actual Payments On The Non-Billed Budget

When a scheduled payment is due, an adjustment is created to increase the Non-Billed Budget's current balance by the expected amount. The current balance on the SA can be monitored to ensure that payments are being made on time.

When the payment is made, the Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment. This accumulated credit is transferred to the covered SAs when the next bill for the account is completed.

The following example illustrates scheduled and actual payments for the Non-Billed Budget in the previous example. The amount of the scheduled Non-Billed Budget payments is 10. Note that the first two transactions were described above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10

An algorithm (Process NBB Scheduled Payment) plugged in on the Non-Billed Budget SA type creates the appropriate financial transactions when the scheduled payment is due. The

Copyright © 2026, Oracle and/or its affiliates.

algorithm is called by the Non-Billed Budget Scheduled Payment Processing (NBBPS) background process.

The normal payment processing handles the adjustments created when the payment is made.

> **Note**
>
> **Non-Billed Budget Payment Cancellation.** If a payment is canceled, the financial transaction is reversed.
>
> **Automatic Payments And Non-Billed Budgets.** Users may set up a Non-Billed Budget to use automatic payments by setting up the account's auto pay options. Users may also exclude the Non-Billed Budget from automatic payment if the account is set up for automatic payment. The NBB Scheduled Payment Automatic Payment Create background process calls the Auto Pay Creation algorithm to create the auto payment for a Non-Billed Budget.

Overpayments for Non-Billed Budgets

Typically, payments in excess of the Non-Billed Budget's current balance are credited to an overpayment (excess credit) SA. When the next adjustment is created for a scheduled payment, the credit on the overpayment SA is used to relieve the non-billed budget current balance.

> **Note**
>
> **Overpayment Distribution Algorithm.** The overpayment distribution is a function of the overpayment distribution algorithm plugged in on the account's customer class. We strongly recommend that the Non-Billed Budget SA type be set up so that overpayment is not allowed. Any excess payments should go to an overpayment SA. For more information about overpayment distribution, refer to Overpayment Segmentation.

In the example below, the customer pays 20 for a scheduled payment instead of 10. The non-billed budget SA is illustrated on the right and the overpayment SA is illustrated on the left. The electric SA is not illustrated in the example below because scheduled payments, payments and overpayments have no effect on covered SAs. The first four transactions were illustrated above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Non-Billed Budget SA				Overpayment SA			
Starting balance								
Non-Billed Budget is activated								

Copyright © 2026, Oracle and/or its affiliates.

First scheduled payment is due	10	0	10	0				
Payment	-10	-10	0	-10				
Second scheduled payment is due	10	0	10	-10				
Over-payment	-10	-10	0	-20	-10	-10	-10	-10
Third scheduled payment is due	10	0	10	-20				
Transfer Adjustment	-10	-10	0	-30	10	10	0	0

After the Process NBB Scheduled Payment algorithm creates the next scheduled payment, it looks for a credit amount on the overpayment SA and creates an adjustment to transfer the credit balance (or the amount of the payment if the credit is more than the scheduled payment amount) from the overpayment SA to the non-billed budget SA. The overpayment transfer adjustment type and the overpayment SA type are specified as parameters to the algorithm.

Underpayments For Non-Billed Budgets

An insufficient payment or a canceled payment leaves a current balance on the Non-Billed Budget SA.

In the example below, the customer makes a payment of 7 for the fourth scheduled payment. The example below does not show the overpayment SA (illustrated above). The first eight transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0

Copyright © 2026, Oracle and/or its affiliates.

Payment	-10	-10	0	-10
Second scheduled payment is due	10	0	10	-10
Over-payment	-10	-10	0	-20
Third scheduled payment is due	10	0	10	-20
Transfer Adjustment	-10	-10	0	-30
Fourth scheduled payment	10	0	10	-30
Underpayment	-7	-7	3	-37

The Process NBB Scheduled Payment algorithm creates a trigger to ensure that the current balance is monitored by the account debt monitor. Refer to Credit And Collections And Non-Billed Budgets for more information.

Billing For SAs Covered By The Non-Billed Budget

When the next bill for the account is completed, the credit on the Non-Billed Budget is transferred to the covered SAs. The credit is prorated over the covered SAs according to the relative payoff balances on each SA.

In the example below, the electric SA's bill is 33. The first ten transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0

Copyright © 2026, Oracle and/or its affiliates.

Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over-payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				
Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0

When a bill segment financial transaction is created, the current amount is set to zero for SAs that are covered by the Non-Billed Budget (if you use a bill segment FT algorithm of Payoff Amt = Bill Amt / Current Amt = Amt Due). Though not evident by the name, the Payoff Amt = Bill Amt / Current Amt = Amt Due algorithm does set the current amount to zero for monitored Non-Billed Budgets. (For SAs with other roles, the current amount is equal to the amount due or the recurring charge.)

A bill completion algorithm transfers money from the Non-Billed Budget to the covered SAs (if you plug in the NBB Credit Transfer bill completion algorithm on the Non-Billed Budget SA type). The algorithm type supplied with the base package distributes the credit using the method described in Distributing Non-Billed Budget Credit.

> **Note**
>
> **Canceled Bill Segments.** No new processing occurs when a bill segment is canceled; any credit balance remains on the covered SA.

Distributing Non-Billed Budget Credit

Copyright © 2026, Oracle and/or its affiliates.

Both the NBB Credit Transfer bill completion algorithm type and the Non-Billed Budget SA stop algorithm type supplied with the base package use the same method of distributing a credit from a Non-Billed Budget SA to the covered SAs. The following points describe how the credit is distributed:

- Covered SAs that are already in credit (due to some other circumstance, such as a cancellation and rebill) are excluded from the distribution.
- The distribution to each covered SA will not exceed its total payoff to ensure that none of the covered SAs have a credit balance.
- The credit is prorated over the covered SAs according to the relative payoff balances on each SA.
- The calculation of the payoff balance is adjusted to exclude the current balance to ensure that the credit is prorated over the debt covered by the budget, not any ad-hoc debt for the SA.

> **Note**
>
> The current balance on covered SAs should always be zero. The only exception occurs if an adjustment has been added that directly affected the SA balance. In this case, the distribution assumes that the balance is outside the non-billed budget and needs to be paid separately.

- Any excess credit remains on the Non-Billed Budget SA until the next distribution takes place or until the Non-Billed Budget SA is stopped.
- The type of adjustments created is determined by the **Adjustment Type (Xfer)** specified on the Non-Billed Budget SA type.

The examples in the table below illustrate the points above.

NBB SA Credit	SA 1 Payoff	SA 1 Current	SA 2 Payoff	SA 2 Current	SA 1 Credit Xfer	SA 2 Credit Xfer
-100.00	-100.00	0.00	-200.00	0.00	0.00	0.00
-100.00	150.00	0.00	-50.00	0.00	-100.00	0.00
-300.00	150.00	0.00	50.00	0.00	-150.00	-50.00
-100.00	150.00	0.00	250.00	0.00	-37.50	-62.50
-100.00	150.00	0.00	250.00	50.00	-42.86	-57.14

The first example above shows that covered SAs with a credit balance are excluded from the distribution. Any excess credit remains on the Non-Billed Budget.

The second example shows that one covered SA has a credit balance, so the entire credit is distributed to the remaining SA.

The third example shows the amount distributed to a covered SA does not exceed its payoff balance. Again, any excess credit remains on the Non-Billed Budget SA.

The fourth example illustrates how the credit is prorated based on the payoff balance. The fifth example illustrates the same prorating but with a current balance on one of the SAs (SA 2). (Remember that the prorating excludes any current balance.)

Copyright © 2026, Oracle and/or its affiliates.

The prorated amount is calculated by subtracting the current balance from the payoff balance then multiplying the result by the distribution amount and dividing by the total payoff owing of all covered SAs.

Stopping an SA Covered By a Non-Billed Budget

If a service agreement covered by a Non-Billed Budget is stopped, the system must bring the current balance and payoff balance of the covered SA back in synch. The system creates an adjustment using the Synch Current adjustment type from the SA's SA type.

In the example below, the electric SA's payoff balance is 21. The first twelve transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over-payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				

Copyright © 2026, Oracle and/or its affiliates.

Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0
SA is stopped	21	0	21	21				

> **Note**
>
> In addition to synching the current and payoff balance, the SA being stopped is removed from the covered SAs collection. When the last covered SA is removed from the collection, the Non-Billed Budget is also stopped.

Financial Transactions For Unmonitored Non-Billed Budgets

Some companies have the concept of non-billed budgets where the payments made by the customer are optional. This functionality is implemented as an unmonitored Non-Billed Budget. Unmonitored Non-Billed Budgets allow a customer to make optional prepayments towards a bill.

As explained previously, unmonitored Non-Billed Budgets receive different financial treatment than monitored Non-Billed Budgets. The financial transaction algorithms use the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type to create the appropriate financial transactions. The following table describes the differences in the financial treatment of monitored and unmonitored Non-Billed Budgets.

System Event	Monitored Non-Billed Budgets	Unmonitored Non-Billed Budgets
When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget...	The system creates adjustments for all affected SAs to set the current balance equal to zero.	The current balances for covered SAs are not zeroed. The activate SA and Non-Billed Budget maintenance processing do not create any adjustments if the Non-Billed Budget is unmonitored.
When a scheduled payment is due...	An adjustment is created to increase the Non-Billed Budget's current balance by the expected amount.	There is no change to the Non-Billed Budget's current balance; it is always zero. The scheduled payment processing background process does not execute the NBB process scheduled payment algorithm.
When the payment is made...	The Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment.	Typically the payments are distributed to an excess credit (overpayment) SA. Refer to Distributing Payments for Unmonitored Non-Billed Budgets for more information.

Copyright © 2026, Oracle and/or its affiliates.

When a bill segment financial transaction is created...	The current amount is set to zero for SAs that are covered by the Non-Billed Budget.	The covered SAs' current amounts are equal to their payoff amounts.
At bill completion...	Money from the Non-Billed Budget is transferred to the covered SAs. Customers may receive a bill for information purposes, but they are not required to pay it.	Money from the overpayment SA is transferred to the account's SAs. The customer is still liable to pay the outstanding balance.
When the Non-Billed Budget is stopped or an SA is removed from a Non-Billed Budget...	The system creates adjustments for all affected SAs to synchronize their current balances with their payoff balances, thus removing the zero current balance and replacing it with the actual current balance.	There is no change to the current balances for covered SAs as the balances already reflect the actual current balance.

Unmonitored Non-Billed Budgets also receive different credit and collections treatment. Refer to Credit and Collections and Unmonitored Non-billed Budgets for more information.

- Distributing Payments for Unmonitored Non-Billed Budgets
- Transferring Credit from Unmonitored Non-Billed Budgets

Distributing Payments for Unmonitored Non-Billed Budgets

For Non-Billed Budgets, payments are distributed according to the payment and overpayment algorithms on the customer class. The base package payment distribution algorithm applies a payment first towards any SAs that have overdue or current balances (refer to Distributing A Payment for more information). Since the unmonitored Non-Billed Budget SA doesn't have a current balance, it is not considered by the payment distribution algorithm. If there aren't any SAs with a current balance, the overpayment distribution algorithm handles the remaining credit. You can elect to:

- Apply the overpayment to an excess credit SA. This is the method that we strongly recommend because all financial transactions are then a function of the normal payment, overpayment and billing processes.
- Apply the overpayment to the highest priority SA that is eligible for overpayment (as specified on the SA type). You can use this method to apply the overpayment to the unmonitored Non-Billed Budget SA. If you use this method, you must also set up the system to transfer the credit from the unmonitored Non-Billed Budget.

> **Note**
>
> **Use An Excess Credit SA.** We strongly recommend that payments for unmonitored Non-Billed Budgets are distributed to an excess credit SA. In this case, the Non-Billed Budget is just a shell to hold the covered SAs and recommend a payment schedule; all financial transactions are a function of the normal payment, overpayment and billing processes.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Overpayment Segmentation for a detailed discussion of overpayment distribution options.

Transferring Credit from Unmonitored Non-Billed Budgets

If you distribute an overpayment to an unmonitored Non-Billed Budget SA (i.e. the unmonitored non-billed budget maintains a credit balance instead of an overpayment SA), you must plug-in a bill completion algorithm on the SA type to transfer the credit balance to the covered SAs at bill completion time. The bill completion algorithm type (BCMP-NB) supplied with the base package transfers the credit balance to the covered service agreements when the bill is completed. Additionally, the **Adjustment Type (Xfer)** on unmonitored Non-Billed Budget SA types should reference a FT algorithm of Payoff Amt = Adj / Current Amt = Adj to ensure that the credit is removed from both the current and payoff balances.

Warning

You must create your own SA stop algorithm type for correctly stopping an unmonitored non-billed budget that maintains a credit balance. The SA stop algorithm that is supplied with the base package does NOT transfer remaining credit from the unmonitored Non-Billed Budget SA. (The base package SA stop algorithm transfers the remaining credit using the overpayment distribution algorithm on the customer type, which you have set up to transfer to back to the unmonitored non-billed budget.)

Designing Non-Billed Budgets

The topics in this section describe functionality that you must consider when designing non-billed budgets.

- Making SAs Eligible For Non-Billed Budgets
- Designing Recommendation Rules

Making SAs Eligible For Non-Billed Budgets

A billable SA may be covered by a Non-Billed Budget when its SA type is flagged as Eligible for Non-Billed Budget.

All SAs that are eligible for non-billed budgets should reference a bill segment type that uses the Payoff Amt = Bill Amt / Current Amt = Amt Due bill segment FT algorithm. This algorithm sets the SA's current amount to zero if it is covered by a monitored Non-Billed Budget.

A list of the SAs covered by a Non-Billed Budget is maintained with the non-billed budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Copyright © 2026, Oracle and/or its affiliates.

Designing Recommendation Rules

Users (and the renewal process) ask the system to recommend the scheduled payments for a Non-Billed Budget. In general, this recommendation process must establish:

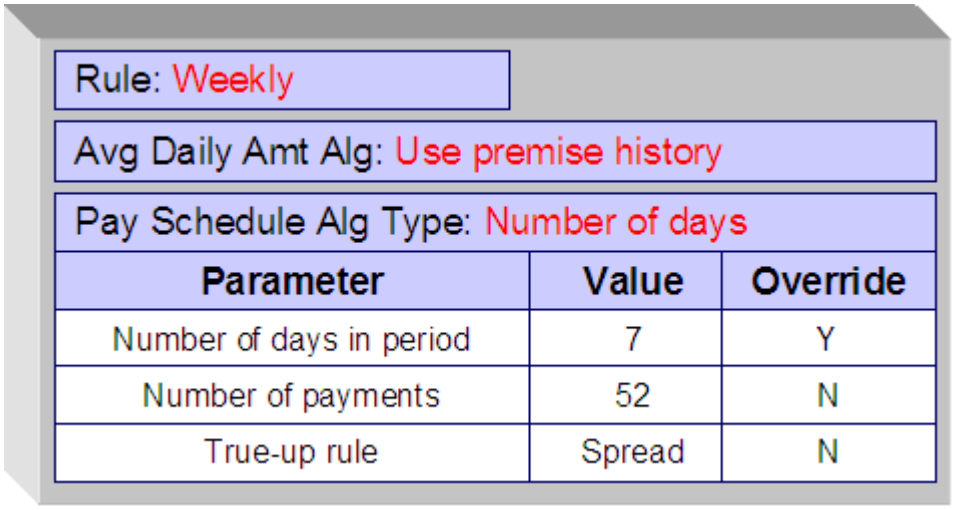
- The amount to be paid
- The dates on which the payments are due

We envision many different types of recommendation rules. For example:

- Recommend 26 scheduled payments to be made on a fortnightly basis that are due on Tuesdays.
- Recommend monthly payments that are due on the nearest workday after the 10th of the month.
- Recommend scheduled payments where the customer pays their annual charges in 10 out of 12 months where the payments are not due in November and December.
- Recommend bi-monthly payments where the payments are due on the first workday following the 5th and 20th of the month.

Additionally, the recommendation rules must determine how to handle any outstanding payoff balances for covered SAs. The true-up rule provided with the base package payment schedule algorithm type can ignore the payoff balance, divide the payoff balance evenly between the scheduled payments, or add the payoff balance to the first scheduled payment.

A recommendation rule comprises three elements:



- An algorithm to calculate an average daily amount (the NBDA-DA algorithm type provided with the base package uses premise billing history)

> **Note**
>
> **Calculating an Amount for Non-utility SAs.** The algorithm type supplied with the base package only handles service-point oriented SAs. For example, the average daily amount algorithm calculates an average daily amount. For non-utility SAs, you must develop the appropriate algorithm types.

- Two algorithm types are provided with the base package to calculate a schedule of payments. NBPS-MON calculates a monthly schedule and NBPS-PS calculates a scheduled based on a specified number of days.
- A collection of default parameter values for the payment schedule algorithm type

A recommendation rule (based on the algorithm types provided with the base package) is illustrated below.

Copyright © 2026, Oracle and/or its affiliates.

Rule: Weekly

Avg Daily Amt Alg: Use premise history

Pay Schedule Alg Type: Number of days

Parameter	Value	Override
Number of days in period	7	Y
Number of payments	52	N
True-up rule	Spread	N

Weekly Payments Recommendation Rule

> **Note**
>
> **Additional Parameters.** Not all of the parameters associated with the weekly payment schedule algorithm type are illustrated. Refer to the NBPS-PS algorithm type for a detail description of the parameters.

The default parameter values for the payment schedule algorithm type may change over time, so the collection contains an effective date. If default values are changed, these changes do not affect Non-Billed Budgets already in effect. Existing Non-Billed Budgets keep the parameter values that were used when the Non-Billed Budget was started.

A user may override the default parameter values for the payment schedule algorithm type to customize the schedule if an override is allowed for a parameter. Additionally, a user may edit the payment schedule details at any time (provided the payment has not yet been processed).

The parameter values used for the recommendation rule are kept with the Non-Billed Budget SA, so that any customized parameter changes can be re-applied to a renewed Non-Billed Budget. For example, the parameter that determines the payment due day may default to the first of the month. To customize the schedule, this value may be changed to the fifth of the month. This amended value is kept with the Non-Billed Budget SA to ensure that the renewed budget follows the same monthly schedule.

> **Note**
>
> Normally parameter values for an algorithm type are kept with the algorithm. Because the parameters may vary for each Non-Billed Budget, the parameter values are kept with the SA in the case of Non-Billed Budgets.

Refer to Non-billed Budgets Recommendation Rule - Main for information on creating recommendation rules.

- Example Recommendation Rules
- Activating Non-Billed Budgets

Copyright © 2026, Oracle and/or its affiliates.

- Renewing Non-Billed Budgets
- Expiring Non-Billed Budgets
- Stopping Non-Billed Budgets
- Automatic Payment and Non-Billed Budgets

- Non-Billed Budget Status
- Alerts For Non-Billed Budgets

Example Recommendation Rules

The following examples may be helpful in designing and implementing your recommendation rules.

> **Note**
>
> **Developing Your Own Payment Schedule Algorithms.** The base package comes supplied with a monthly payment schedule algorithm type. You can use this algorithm as an example when creating payment schedule algorithm types for your implementation.

- Fortnightly Payments Recommendation Rule Example
- Monthly Payments Recommendation Rule Example
- Ten Out of Twelve Months Recommendation Rule Example

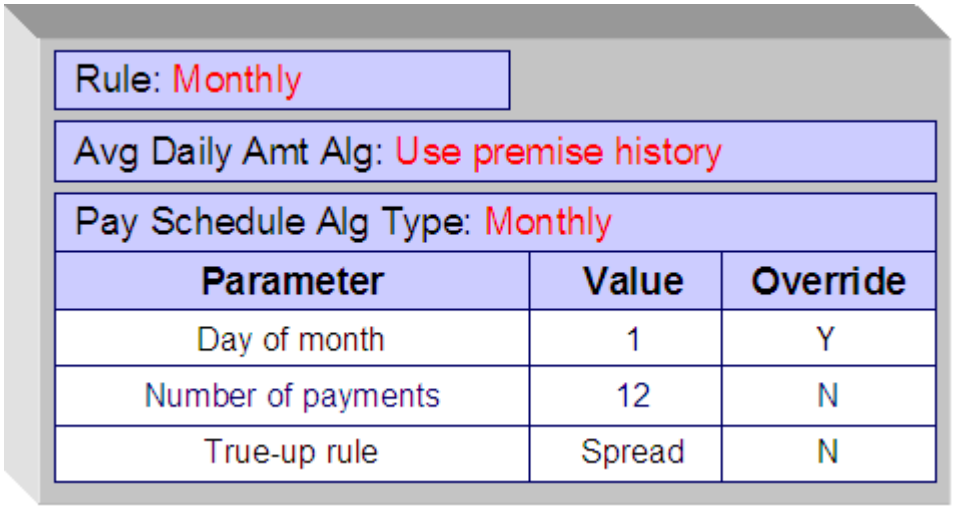
Fortnightly Payments Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay every two weeks. The current balance for any covered SAs is added to the first payment.

Rule: Fortnightly

Avg Daily Amt Alg: Use premise history

Pay Schedule Alg Type: Number of days

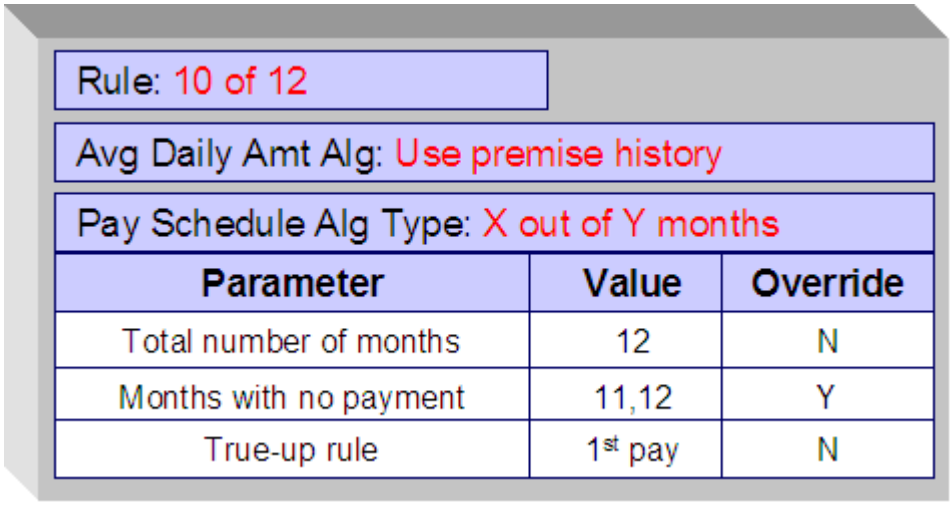


Parameter	Value	Override
Number of days in period	14	Y
Number of payments	26	N
True-up rule	Spread	N

Copyright © 2026, Oracle and/or its affiliates.

Fortnightly Payments Recommendation Rule

Monthly Payments Recommendation Rule Example



The following diagram illustrates a recommendation rule where the customers pay twice monthly on the first of the month. The current balance for any covered SAs is spread out over the scheduled payments.

Monthly Payments Recommendation Rule

Ten Out of Twelve Months Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay one a month except for months during a holiday season (November and December). The current balance for any covered SAs is added to the first payment.

Ten Out of Twelve Months Recommendation Rule

Copyright © 2026, Oracle and/or its affiliates.

Activating Non-Billed Budgets

You can plug in an algorithm (of type SACR-AT) on the SA Creation system event on the Non-Billed Budget SA type to automatically activate the Non-Billed Budget (i.e. transition it from pending start to active status). If you don't use a SA Creation algorithm to activate the Non-Billed Budget, it is activated the next time the SA activation background process runs.

When a Non-Billed Budget is activated, you can perform special processing using an algorithm plugged in on the SA Activation system event on the Non-Billed Budget SA type. The special processing can be developed to do anything that you would like, for example you could:

- Create a customer contact that with an appropriate letter template can generate a letter to inform the customer of their payment amount and payment schedule.
- Initiate the creation of a payment coupon book for a customer.

The system comes supplied with a sample algorithm type (called SAAT-CC) that simply creates a customer contact to indicate that the Non-Billed Budget is activated.

Renewing Non-Billed Budgets

A Non-Billed Budget can be renewed either manually or via a background process. When the Non-Billed Budget SA is created, the expiration date, renewal date and the recommendation rule used to create the initial budget are kept with the SA. A renewal flag on the Non-Billed Budget SA type controls if a renewal is required, optional or not allowed. If renewal is required, a user must specify a renewal date when creating the service agreement. The renewal date is defaulted on to an SA based on the valued of the **Days Before Expiration for Renewal** field on the SA type.

An algorithm on the SA type can customize the processing required to renew an SA.

The SA renewal background process:

- Executes the SA renewal algorithm (specified on the SA type) when the renewal date is reached (i.e., it is on or before the process date). The base package comes with an algorithm type (SARN-NB) that determines the current recommendation rule for a non-billed budget and executes the associated payment schedule algorithm using the Non-Billed Budget SA-specific parameter values to generate a new schedule. It returns new expiration and renewal dates.
- If the renewal algorithm is successful, the renewal and expiration date fields on the SA are updated with the new values.
- If the renewal process is not successful, a To Do list entry (of type TD-SARN) is created for the account and SA.

The new payment schedule that is returned from the renewal process for a Non-Billed Budget is appended to the current schedule.

A user can manually launch the renewal process for a Non-Billed Budget SA by clicking the **Renew NBB** button on the Non-Billed Budget maintenance page .

Expiring Non-Billed Budgets

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budget service agreements may specify an expiration date. The SA expiration background process initiates the stop process for all pending start or active SAs where the expiration date is reached (before or on the process date).

Stopping Non-Billed Budgets

When a Non-Billed Budget stop is initiated, either on request or because it has expired and is not being renewed, the Non-Billed Budget is transitioned to pending stop status. You can plug in an algorithm (of type SAIS-ST) on the SA Stop Initiation system event on the Non-Billed Budget SA type to automatically finalize and stop the SA (i.e. transition it to stopped status). If you don't use a SA Stop Initiation algorithm, the Non-Billed Budget is stopped the next time the SA activation background process runs.

To finalize a pending stop SA, the system first calls the stop SA algorithm plugged-in on the SA Stop system event on the SA type. The stop SA algorithm type (SAST-NB) supplied with the base package:

- Distributes any credit on the Non-Billed Budget to the covered SAs (using the method described in Distributing Non-Billed Budget Credit)
- Distributes any excess credit remaining on the non-billed budget using the overpayment distribution algorithm for the account's customer class and the overpayment transfer adjustment type (specified as a parameter to the algorithm)
- Creates a trigger to cause the account to be reviewed by the account debt monitor
- Creates a customer contact (if the customer contact class and customer contact type parameters are populated)

> **Warning**
>
> If you do not plug in an SA stop algorithm that transfers the credit balance from the non-billed budget to its covered SAs (or an excess credit SA), the stopped Non-Billed Budget may have a credit balance. You must then manually distribute this credit.

After the SA stop algorithm is finished, the SA stop processing performs the following steps if the SA type has a special role of Non-Billed Budget:

- If the Non-Billed Budget is monitored, create adjustments to synchronize the current and payoff balance of covered SAs using the **Adj. Type (Synch Current)** adjustment type from the covered SAs' SA types
- Remove the covered SAs from the Non-Billed Budget
- Remove all the scheduled payments from the non-billed budget
- Create an adjustment to synchronize current and payoff on the Non-Billed Budget SA using the **Adj. Type (Synch Current)** adjustment type from the Non-Billed Budget's SA type

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Synchronizing current and payoff effectively sets the current amount to zero on the Non-Billed Budget SA, as the payoff amount should have been reduced to zero by the distribution and overpayment processing in the algorithm for SA Stop.

> **NOT_SUPPORTED**
>
> Refer to The Lifecycle Of A Service Agreement for more information about how a pending stop SA is stopped and closed.

Automatic Payment and Non-Billed Budgets

If a customer wants to pay their non-billed budget scheduled payments automatically, the account must be set up for automatic payment. In addition, the Non-Billed Budget must indicate that automatic payment is being used.

> **NOT_SUPPORTED**
>
> Refer to How To Set Up Automatic Payment For A Non-Billed Budget for more information.

When this is done, a background process referred to as NBBAPAY creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

> **Note**
>
> You must ensure that your auto pay creation algorithm supports Non-Billed Budget scheduled payments. The APAY-CREATE algorithm type supplied with the base package supports non-billed budget scheduled payments.

Credit and Collections and Non-Billed Budgets

Unless the Non-Billed Budget is unmonitored, the account debt monitor (ADM) monitors a Non-Billed Budget SA's current amount just as it does for any other SA. The scheduled payment algorithm creates a trigger to ensure that the account debt monitor reviews the account the next time it runs. The review date on the trigger record is set to the process business date.

A separate debt class is needed for Non-Billed Budget SA types, thus allowing you to define collection class controls, debt criteria and collection process templates specifically for Non-Billed Budgets. The debt criteria should be set up to trigger a collection process when the arrears amount exceeds $0.01 for more than n payment periods plus the number of grace days that you want to allow.

Copyright © 2026, Oracle and/or its affiliates.

The collection process template can perform any of the events in standard collection processes, such as sending letters to customers and creating severance processes. At a minimum, the collection process template should be set up to start a severance process for all service agreements in the debt class. (Since the debt class is specifically for Non-Billed Budgets, the Non-Billed Budget is the only SA that will be subject to a severance process.)

The Non-Billed Budget severance process template should include the following event types:

- Populate a characteristic on the SA to indicate that the SA is broken. The base package comes supplied with a severance event algorithm type (SVEV-NB) that sets an SA characteristic to indicate that it was "severed".
- Expire Severance Agreement to move the SA to the pending stop state.

When the system subsequently stops the Non-Billed Budget, the system removes the covered SAs from the Non-Billed Budget and synchronizes their current balances with their payoff balances. Since the SAs have current balances again, they are subject to the account debt monitor, which can start subsequent collection processes for any of the SAs that meet the debt criteria for their debt class.

NOT_SUPPORTED

Refer to Stopping Non-billed Budgets for a complete description of the events that occur when a Non-Billed Budget is stopped.

Customers can catch up on their payments and avoid having their Non-Billed Budget broken as long as their current balance doesn't violate the debt criteria for the Non-Billed Budget's collection process.

Credit and Collections and Unmonitored Non-Billed Budgets

If the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type is set to Unmonitored, the NBB Scheduled Payment Processing background process does not create a trigger for the account debt monitor. Additionally, the Non-Billed Budget's current amount is always equal to zero, so it never violates any debt collection criteria. We recommend using a debt class that has the **Eligible for Collection** flag turned off, such as the N/A debt class.

For unmonitored Non-Billed Budgets, the current balance is kept on the covered SAs so they are subject to the account debt monitor and any debt criteria for their SA types' debt classes. For more information, refer to Financial Transactions for Unmonitored Non-Billed Budgets.

Non-Billed Budget Status

A Non-Billed Budget SA's status is just like any other SA's status. In addition, you can use a characteristic to keep an explicit status relevant to the Non-Billed Budget:

- A base package severance event algorithm type (SVEV-NB) creates a characteristic value to indicate if a Non-Billed Budget is "broken" (i.e. stopped as a result of a severance process).
- A base package break Non-Billed Budget algorithm type (NBBR-BRK) creates a characteristic value to indicate if a Non-Billed Budget is "canceled" (i.e. manually stopped by a user).

Copyright © 2026, Oracle and/or its affiliates.

An active Non-Billed Budget implicitly has a "kept" status (i.e. all scheduled payments have been made).

Alerts For Non-Billed Budgets

The system provides alerts to highlight the existence of Non-Billed Budgets. These alerts are important to assist the customer service representatives:

- An alert is displayed if the account has a Non-Billed Budget that is not stopped (e.g., pending start, active or pending stop).
- When a user denies a Non-Billed Budget (for whatever reason), the user should create a customer contact with a given customer contact type. This type of alert prevents the customer from shopping around. An existing alert algorithm type (CC BY TYPCL) can highlight these customer contacts.
- For customers who are permanently forbidden from having a Non-Billed Budget, the user should put a permanent alert on the account.
- Use an algorithm to highlight cancelled or severed non-billed budgets with an entry in the alert zone. The algorithm type to do this is not provided. Use PP BY STATUS and CCAL-WF as examples of how to create this type of algorithm.

NOT_SUPPORTED

For more information about introducing alert conditions on Control Central, refer to Installation Options - Algorithms.

Non-Billed Budget Recommendation Rule

Recommendation rules are used to recommend scheduled payments for Non-Billed Budgets. For information about designing recommendation rules, refer to Designing Recommendation Rules.

To define recommendation rules, navigate to **Admin**, and then **Financial**, and then **NBB Recommendation Rule**, and then **Add.**

Description of Page

Enter an easily recognizable **Recommendation Rule** code and **Description** for each recommendation rule.

Specify the **Average Daily Amount Algorithm** used to calculate the average daily amount for this recommendation rule.

Specify the **Payment Schedule Algorithm Type** used to create the recommended payment scheduled for Non-Billed Budgets that use this recommendation rule. The Payment Schedule Algorithm Type cannot be modified if a Non-Billed Budget SA that is not stopped or cancelled is using this recommendation rule.

Payment Schedule Parameters enables you to define collections of default parameter values for the payment schedule algorithm type that are effective dated. For each collection:

Copyright © 2026, Oracle and/or its affiliates.

- **Effective Date** defines the date on which the collection of parameter values becomes effective.
- **NBB Rule Parameter Value** specifies the default value of each parameter supplied to the algorithm. Note that the payment schedule algorithm type controls the number and type of parameters.
- **Override** indicates whether the user can override the default value for the parameter.

Setting Up The System To Enable Non-Billed Budgets

The above topics provided background information about how Non-Billed Budgets are supported in the system. The topics in this section describe how to set up the system to enable Non-Billed Budget functionality.

> **Note**
>
> **Example Setup.** This section describes typical non-billed budget configurations. Your set up and configuration may differ depending on your business needs. This section is provided for guidance only. Read the descriptions of Non-Billed Budget functionality above to understand the implications of the described setup.

- NBB Distribution Codes

- NBB Adjustment Type Profiles
- NBB Characteristic Types
- NBB Customer Contact Class And Types
- NBB Algorithms
- NBB Debt Class And Collection Process
- SA Types for SAs Covered by NBBs
- NBB Recommendation Rules
- Non-Billed Budget SA Types
- NBB Background Processes

NBB Distribution Codes

You must set up a Non-Billed Budget Clearance distribution code that is used on the Non-Billed Budget SA type to credit non-billed payments.

NBB Adjustment Types

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Non-Billed Budget Financial Transaction Algorithms.** The Non-Billed Budget adjustment types use the standard FT algorithm types that are provided with the base package. If you have not yet defined algorithms for these types in your system, do so before creating the Non-Billed Budget adjustment types.

The following adjustment types are needed:

- Add SA To Non-Billed Budget. This adjustment type should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on **Adjustment Type (Current=0)** on SA types that are eligible for Non-Billed Budgets. Note that this adjustment type is never used if the SA is added to an unmonitored Non-Billed Budget.
- Bill Complete for Monitored Non-Billed Budget. This adjustment type should reference a distribution code used for balance transfer clearing. It should reference a FT algorithm of Payoff Amt = Adj / Current Amt = 0. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are monitored Non-Billed Budgets.
- Synch Balance for Non-Billed Budget. This adjustment type should be set up for **Sync. Current Amount** and should reference a FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). This adjustment type is referenced on the **Adj. Type (Synch Current)** on Non-Billed Budget SA types. It is used when a Non-Billed Budget SA is stopped to synch the current balance with the payoff balance.
- Scheduled Payment. This adjustment type should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on the Non-Billed Budget process scheduled payment algorithm.
- Overpayment Transfer. This adjustment type should reference a transfer distribution code and a FT algorithm of Payoff Amt = Adj / Current Amt = Adj. This adjustment is referenced on the non-billed budget process scheduled payment algorithm and the stop non-billed budget algorithm. Note that if there is already a transfer adjustment type created in your system, you do not need to create a new one.

If you are setting up an unmonitored Non-Billed Budget that maintains a credit balance (as opposed to maintaining the credit balance on an overpayment SA), you need to create an adjustment type for Bill Complete for Unmonitored Non-Billed Budget. (Refer to Transferring Credit from Unmonitored Non-billed Budgets for more information.) The adjustment type should reference a transfer distribution code and a FT algorithm of Payoff Amt = Adj / Current Amt = Adj. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are unmonitored Non-Billed Budgets.

NBB Adjustment Type Profiles

Create an adjustment type profile for Non-Billed Budgets that references the following adjustment types:

- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)
- Synch balance for Non-Billed Budget

Copyright © 2026, Oracle and/or its affiliates.

- Scheduled payment
- Overpayment transfer

Create an adjustment type profile for eligible SAs that references the following adjustment types:

- Add SAs to monitored Non-Billed Budgets
- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)

> **Note**
>
> **Bill Complete Adjustment Types.** Because the bill complete adjustment types transfer amounts between two SAs, they must be in profiles for both Non-Billed Budget and eligible SA types.
>
> **Overpayment Transfer Adjustment Type.** The overpayment transfer adjustment type created above is used to transfer funds from an excess credit SA to a Non-Billed Budget when the scheduled payment is processed. It is also used to transfer excess funds from a Non-Billed Budget that is being closed to an excess credit SA. The transfer adjustment should therefore be added to an adjustment type profile that is referenced on the excess credit SA type.

NBB Characteristic Types

Create a Non-Billed Budget status characteristic type that specifies Service Agreement as its characteristic entity. The characteristic type should include the following predefined values:

- Non-Billed Budget Canceled
- Non-Billed Budget Severed

NBB Customer Contact Class And Types

Create a Non-Billed Budget customer contact class. The contact class may include the following customer contact types:

- Non-Billed Budget Activate
- Non-Billed Budget Renewal
- Non-Billed Budget Stop

> **Note**
>
> **Customer Contact Letters.** If you want to send letters to your customers when a contact of any of these types is created, you must create an appropriate letter template and attach it to the contact type.

Copyright © 2026, Oracle and/or its affiliates.

NBB Algorithms

You must define the following algorithms:

- On NBB recommendation rule, the Non-Billed Budget Daily Amount Calculation. Refer to the NBDA-DA algorithm type for more information about the base package algorithm.
- On SA type:
  - Non-Billed Budget Process Scheduled Payment. This algorithm has parameters that must reference the Scheduled Payment and Overpayment Transfer adjustment types defined above. Another parameter references an overpayment SA type (that you may need to create if there is not already one in your system). Refer to the NBPA-PS algorithm type for more information about the base package algorithm.
  - Non-Billed Budget SA Renewal. Refer to the SARN-NB algorithm type for more information about the base package algorithm.
  - Break Non-Billed Budget SA. Refer to the NBBR-BRK algorithm type for more information about the base package algorithm.
  - SA Activation - automatically activate SA (if you want to automatically activated Non-Billed Budgets when they are created). Refer to the SACR-AT algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
  - SA Activation - create customer contact (if you want the system to create a customer contact when NBB SAs are activated). Refer to the SAAT-CC algorithm type for more information about the base package algorithm.
  - SA Stop - automatically stop SA (if you want to automatically transition Non-Billed Budgets from pending stop to stop when their stop is initiated). Refer to the SAIS-ST algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
  - SA Stop - Stop Non-Billed Budget. Refer to the SAST-NB algorithm type for more information about the base package algorithm.
  - Bill Completion - Non-Billed Budget Credit Transfer. Refer to the BCMP-NB algorithm type for more information about the base package algorithm.
- On bill segment type, the Bill FT Algorithm (for all SAs that are eligible for NBB). Refer to the BSBF-BA algorithm type for more information about the base package algorithm. Note this is the standard bill FT algorithm type used for common bill transactions. It supports bill FT for non-billed budgets and other SA types. You only need to create it if it doesn't already exist in your system.
- On severance event type, an algorithm for Non-billed Budget Severance. Refer to the SVEV-NB algorithm type for more information about the base package algorithm.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Payment Schedule Algorithm Types.** For Non-Billed Budget payment schedule algorithm types, you need to define the algorithm types (if you add your own algorithm types). You do not need to define algorithms because the parameter values for the algorithm are defaulted on the recommendation rule and stored with the Non-Billed Budget SA. (Normally the algorithm holds the parameter values.) Refer to the NBPS-MON algorithm type for more information about the base package payment schedule algorithm.

NBB Debt Class And Collection Process

Set up a separate debt class, collection class control, collection process template and severance process template for Non-Billed Budgets according to the information in Credit and Collections and Non-Billed Budgets.

SA Types for SAs Covered by NBBs

You must modify the SA type for any SAs that you want to allow to be covered by a Non-Billed Budget.

- Verify that the specified **Bill Segment Type** (on the Billing page) references a financial transaction algorithm to set the current amount to zero for monitored Non-Billed Budgets. The FT creation algorithm type BSBF-BA (i.e., Payoff Amt = Bill Amt / Current Amt = Amt Due) supplied with the base package sets the current amount to zero for SAs that are covered by monitored non-billed budgets, though this is not evident by the name. (For SAs that are not covered by a Non-Billed Budget, the current amount is equal to the amount due or the recurring charge.) Refer to Billing For SAs Covered By The Non-Billed Budget for more information.
- Set the **Eligible for Non Billed Budget** flag (on the Billing page) to Eligible for Non-Billed Budget .
- Populate the **Adjustment Type (Current = 0)** (on the Detail page) to indicate the adjustment to be used to zero out the current amount on the covered SAs when the Non-Billed Budget SA is activated. Use the Add SA To Non-Billed Budget adjustment created above. This adjustment type is only called for SAs that are covered by a monitored Non-Billed Budget.
- Reference an **Adjustment Type Profile** (on the Adjustment Profile page) that includes the Add SA To Non-Billed Budget adjustment type referenced in the **Adjustment Type (Current = 0)** field above.
- If not already specified (for write off), an **Adj. Type (Synch Current)** (on the Main page) is also required. It is used to synchronize (make equal) the current amount with the payoff amount when the SA is removed from (i.e. no longer covered by) a Non-Billed Budget.

NBB Recommendation Rules

Copyright © 2026, Oracle and/or its affiliates.

Set up any NBB Recommendation Rules that you want to be available for your Non-Billed Budget SAs. Use any Non-Billed Budget Daily Amount Calculation algorithms defined above. Also use the Non-billed Budget Monthly Payment Schedule (NBPS-MON) algorithm types and specify the default parameters.

Non-Billed Budget SA Types

You must set up a SA types for your Non-Billed Budget service agreements. You may need multiple Non-Billed Budget SA types if you have different business rules for different types of Non-Billed Budgets, for example, if you have both monitored and unmonitored Non-Billed Budgets or if you support Non-Billed Budgets with different renewal requirements. The following points provide guidelines for creating a non-billed budget SA type.

- SA Type - Main (NBB)
- SA Type - Detail (NBB)
- SA Type - Billing (NBB)
- SA Type - Rate (NBB)
- SA Type - SP Type (NBB)
- SA Type - Adjustment Profile (NBB)
- SA Type - Credit and Collections (NBB)
- SA Type - Algorithms (NBB)
- SA Type - NBB Recommendation Rule (NBB)

SA Type - Main (NBB)

Service Type should reference something like "Miscellaneous Service".

Distribution Code should be the one you set up to book credits for Non-Billed Budgets.

Revenue Class should be set to N/A. (Revenue classes are not applicable because Non-Billed Budgets do not apply a rate and revenue classes are only relevant for SA types that use a rate.)

The **Payment Segment Type** should reference the Normal Payment.

Do Not Overpay should be on. Any excess payments should go to the overpayment SA, not the Non-Billed Budget SA.

Late Payment Charge is not applicable and should not be turned on because Non-Billed Budgets are not billed.

Adj. Type (Synch Current) should reference the Synch Balance for Non-Billed Budget adjustment type created above.

SA Type - Detail (NBB)

- **Special Role** is Non-Billed Budget.

Copyright © 2026, Oracle and/or its affiliates.

- **Adjustment Type (Xfer)** must be populated to indicate the adjustment to be used for transferring accumulated credit from the Non-Billed Budget SA to the covered SAs. This field is not used for unmonitored Non-Billed Budgets.
- **Renewal** may be optional, not allowed, or required depending on your business processes.
- If Renewal is required, specify the **Days Before Expiration for Renewal**.
- **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

SA Type - Billing (NBB)

Non-Billed Budget SAs do not get billed, so the **Eligible for Billing** flag should be off.

Additionally, the **Characteristic Premise Required** should not be checked for Non-Billed Budgets.

SA Type - Rate (NBB)

Non-Billed Budget SAs do not use rates, so the **Rate Required** flag should be off.

SA Type - SP Type (NBB)

Non-Billed Budget SAs do not have service points, so the **Service Points Required** flag should be off.

SA Type - Adjustment Profile (NBB)

Adjustment Type Profile should reference the adjustment type profile for Non-Billed Budgets (set up above).

SA Type - Credit and Collections (NBB)

The credit and collections information should reference a **Severance Process Template** that calls the Non-Billed Budget Severance algorithm created above and expires the Non-Billed Budget SA. The **Debt Class** should reference an appropriate value consistent with your credit and collections rules. Typically, monitored Non-Billed Budgets should be in their own debt class. Unmonitored Non-Billed Budgets should have a **Debt Class** that is not Eligible for Collection.

The **Write Off Debt Class** is not applicable because the Non-Billed Budget contains no debt to be written off. Reference a debt class such as N/A. Refer to Defining Credit & Collections Options for more information.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Algorithms (NBB)

The SA type algorithms defined above must be set up:

- The Non-Billed Budget Credit Transfer algorithm created above should be specified for the Bill Completion system event (not used on unmonitored Non-Billed Budgets).
- The Break Non-Billed Budget SA algorithm created above should be specified for the Break NBB SA system event.
- The Non-Billed Budget Process Scheduled Payment algorithm created above should be specified for the Process NBB Scheduled Payment system event (not used on unmonitored non-billed budgets).
- The Non-Billed Budget SA Renewal algorithm created above should be specified for the SA Renewal system event.
- If you created the Automatic SA Activation algorithm above, it should be specified for the SA Creation system event.
- The Non-Billed Budget SA Activation algorithm created above should be specified for the SA Activation system event.
- If you created the Automatic SA Stop algorithm above, it should be specified for the SA Stop Initiation system event.
- The Stop Non-Billed Budget algorithm created above should be specified for the SA Stop system event.

SA Type - NBB Recommendation Rule (NBB)

Add the recommendation rules defined above that are valid for SAs of this type. Also, indicate which recommendation rule should be used as the default.

NBB Background Processes

Ensure that the following background processes are scheduled:

- Non-Billed Budget Scheduled Payment Processing (NBBPS)
- Non-Billed Budget Scheduled Payment Automatic Payment Create (NBBAPAY)
- Service Agreement Renewal (SARENEW)
- Stop Expired Service Agreements (SAEXPIRE)

Defining Quotation Options

This section describes tables that must be set up before quotations can be created.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, refer to The Big Picture of Quotations.

- Setting Up SA Types For Quotes
- Setting Up Quote Route Types
- Setting Up Terms and Conditions
- Setting Up Decline Reasons
- Setting Up Customer Classes For Quotes

Setting Up SA Types For Quotes

The topics in this section describe additional setup responsibilities required on SA types that can have proposal service agreements.

Note

Assumption. We have assumed that you've already designed your SA types for the services that you sell. If you haven't done this, refer to Defining Service Agreement Types .

- Enabling The Automatic Generation Of Billing Scenarios
- Enabling The Generation Of Simulated Bill Segments
- Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

Enabling The Automatic Generation Of Billing Scenarios

As described under Proposal SAs Contain Billing Scenarios And Template Consumption, a proposal SA requires billing scenarios before a quote detail can be generated. The system will automatically create billing scenarios when a proposal SA is created if you plug-in the appropriate Proposal SA Creation algorithm on each such SA type. Refer to PSAC-CBS for an example algorithm (note, this algorithm can be used to create billing scenarios for both interval and non-interval service agreements).

Enabling The Generation Of Simulated Bill Segments

As described under Creating Quotes And Quote Details, in order for the system to generate simulated bill segments for a proposal SA, you must plug-in a Proposal SA Bill Segment Generation algorithm on the proposal SA's SA type. Refer to CBSP-AR for an example algorithm that creates a simulated bill segments for each billing scenario linked to the proposal SA by calling rate application.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Interval pricing service agreements.** If you have proposal SAs that require the derivation of interval profiles from other interval profiles, you must also plug-in another Proposal SA Bill Segment Generation on the interval SA type. Refer to CBSP-IDDRV for an example algorithm that performs derivation. When you plug-in this type of algorithm, don't forget to use a sequence number less than the one that generates the simulated bill segments (see above); otherwise, the derived interval profiles won't exist when rate application is called.

Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

As described under Accepting / Declining Quote Details, in order for the system to create a real SA when a proposal SA is accepted, you must plug-in a Proposal SA Acceptance algorithm on the proposal SA's SA type. Refer to PSAA-PS for an example algorithm that creates a real SA by copying the proposal SA.

> **Note**
>
> **Interval pricing service agreements.** If the service agreement has SA-specific interval profiles, time-of-use maps, or contract options, it's important that you setup your Proposal SA Acceptance algorithm to create fresh interval profiles, time-of-use maps and contract options when the real SA is created (there's a parameter on PSAA-PS that will do this). Refer to Proposal SAs And Interval Consumption for more information.

Setting Up Quote Route Types

Quote route types control how quotes are routed to customers and prospects. To define a quote route type, open **Admin**, and then **Sales & Marketing**, and then **Quote Route Type.**

> **NOT_SUPPORTED**
>
> Refer to Printing Quotes for more information about how quotes are routed to customers and prospects.

Description of Page

Enter a unique **Quote Route Type** and **Description** for every quote route type.

Quote Routing Method controls the type of information that may be defined when the respective **Quote Route Type** is selected on Account - Person Information. The following options are available:

- Postal: Use this method if the routing is via the postal service.

Copyright © 2026, Oracle and/or its affiliates.

- Fax: Use this method if the routing is via fax.
- Email: Use this method if the routing is via email.

> **Note**
>
> The values for **Quote Routing Method** are customizable using the Lookup table. This field name is QTE_RTG_METH_FLG .

- The next two fields control how quotes that are routed using this method are printed (both in batch and online).
  - Use **Batch Control** to define the process that creates the flat file that is passed to your quote printing software. Refer to Tec hnical Implementation of Printing Quotes In Batch for more information about these processes.
  - Use **Extract Algorithm** to define the plug-in that constructs the "flat file records" that contain the information merged onto quotes routed using this method. Refer to Printing Quotes for more information.

Setting Up Terms and Conditions

As described under Legal Terms and Conditions May Be Specified On SAs , your SA type start options can reference terms and conditions (T&C's) that should be defaulted onto new service agreements (both real and proposal). Each T&C is identified with a terms and condition code. To define a terms and conditions code, open **Admin**, and then **Sales & Marketing**, and then **Terms and Conditions**, and then **Add.**

> **Note**
>
> **T&C print order.** The value of the T&C code controls the order in which the T&C appears on the printed quote. This means you should assign these codes in some type of structured format (e.g., 01...) if you would like them to appear in a certain order.

Description of Page

Enter a unique **Terms and Condition** code and **Description**. Use **Text** to describe the exact terms.

Setting Up Decline Reasons

A proposal SA decline reason must be supplied when a proposal SA is declined. Open **Admin**, and then **Sales & Marketing**, and then **Proposal SA Decline Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Decline Reason** and **Description** for each proposal SA decline reason.

Copyright © 2026, Oracle and/or its affiliates.

Where Used

Decline reasons are used when a quote detail is declined.

Setting Up Customer Classes For Quotes

An optional plug-in spot exists on customer class where you can introduce additional logic to be executed when a quote is completed for an account that belongs to this customer class. The base package comes supplied with a sample algorithm that creates a workflow process when a quote is completed (refer to the algorithm QTEC-WP for more information).

Defining Case Management Options

Case management functionality is a highly configurable tool your organization can use to manage many situations, including (but certainly not limited to) the following:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- an application for new service,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change service providers on a future date,
- the processing of a market message in a deregulated environment,
- ... (the list is only limited by your time and imagination)

Obviously the steps involved in the resolution of the above cases are very different. The topics in this section describe how to configure the system to manage your cases as per your organization's desires.

> **Note**
>
> **Separate module.** The Case Management functionality is associated with a separate module. If the Case Management module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

> **NOT_SUPPORTED**
>
> Refer to Case Management for a description of how end-users use cases.

- The Big Picture Of Cases

Copyright © 2026, Oracle and/or its affiliates.

- Setting Up Case Management Options

The Big Picture Of Cases

The topics in this section provide background information about how to configure the system to support your case management requirements.

- Case Type Controls Everything
- Scripts and Cases
- To Do's and Cases
- Examples of Case Types

Case Type Controls Everything

Whenever a user creates a case, they must specify the type of case (e.g., high-bill complaint, literature request, etc.). The case type controls how the case is handled.

Case types hold the business rules that control cases. Since these business rules can sometimes be quite complicated, setting up case types requires planning and foresight. The topics in this section describe the type of business rules that can be configured on your case types.

- Person / Account / Premise Applicability
- Contact Information Applicability
- Business Object Association
- Additional Information
- Access Rights
- Lifecycle
- Status-Specific Business Rules
- Responsible User Applicability

Person / Account / Premise Applicability

Some types of cases may be person-oriented, others may be premise-oriented, and still others may be account-oriented. For example:

- Cases used to keep track of a literature request would reference the person who requested the literature.
- Cases used to keep track of the inspection of a property would reference the premise being inspected.
- Cases used to keep track of a high-bill complaint would reference the account associated with this bill(s) being disputed.

When you set up a case type, you define if its cases must reference a person, account, and/or premise. Note, any combination of these objects is permitted on a case.

Copyright © 2026, Oracle and/or its affiliates.

Contact Information Applicability

When a case is created, you may want to keep track of how to contact its originator. For example, you may want to record the originator's email address or phone number. When you set up a case type, you define if contact information is required, optional or not allowed on its cases.

Business Object Association

A case type may reference a Business Object, which serves as a link between cases of that type and the options that are associated with the business object.

Additional Information

Some of your cases may require additional information (in the form of characteristics). For example, a high-bill complaint may require at least one bill. When you set up a case type, you can define the additional fields that are required. In addition, you can define default values for these fields.

The case functionality also allows you to require characteristics when a case enters a given state. Refer to Required Fields Before A Case Enters A State for the details.

> **Note**
>
> **Requiring supporting documents.** Because any type of characteristic can be referenced on a case, you can require references to supporting documents by requiring a file location characteristic.

Access Rights

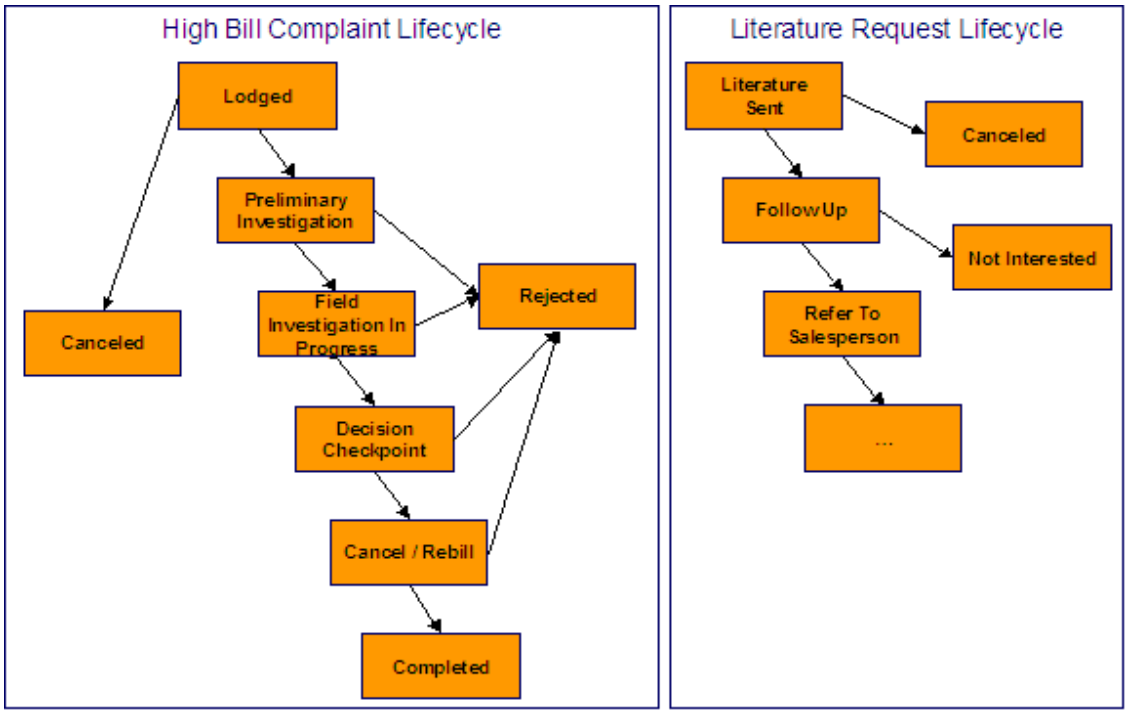
You can take advantage of the system's security to restrict cases of a given type to certain users. For example, you can restrict high-bill complaints to specific user groups.

The following points describe how to implement this type of security:

- Create an application service for each type of case you need to secure
- Define the access modes Add, Inquire and Change for each application service
- Define the applicable application service on each case type
- Link the appropriate user groups to each application service
  - For user groups that are allowed to add cases of a given type, define Add as a valid access mode.
  - For user groups that are allowed to view cases of a given type, define Inquire as a valid access mode

Copyright © 2026, Oracle and/or its affiliates.

– For user groups that are allowed to change cases of a given type, define Change as a valid access mode



If you restrict access to a case type's cases, you can further restrict which users can work on cases given the status of the case. Refer to Which Users Can Transition A Case for more information.

> **Note**
>
> **Restricting access to cases is optional.** If you don't specify an application service on a case type, all users (who have access to the case transaction) may access its cases.

Lifecycle

Many objects in the system have predefined lifecycles whose rules are governed by the base-package and cannot be changed. For example, a service agreement starts out in the Pending Start state and eventually becomes Closed when it's been final billed (and paid). You can't change the system to allow a service agreement to starts its life in the Closed state.

The lifecycle of cases is not governed by the base package. Rather, you define the lifecycle of your cases when you set up their case types. Examine the following diagrams; the one on the left shows the potential lifecycle of a case that manages a high-bill complaint, the one on the right shows the potential lifecycle of a case that manages a customer's literature request.

Potential Lifecycles Of Two Types Of Cases

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Just examples.** The above lifecycles are just examples. When you set up your case types, you must define the valid states for your case type.

The topics that follow describe important concepts that are illustrated in the above diagrams.

- Valid States versus State Transition Rules
- Transitory States
- One Initial State and Multiple Final States
- Allowing A Case To Be Reopened
- Make Sure To Have A Canceled State
- Buttons Are Used To Transition A Case From Status To Status
- State Transitions Are Audited
- Reports and Analytics Highlight Productivity

Valid States versus State Transition Rules

The orange boxes in the above diagram show the potential valid states a given case can have. The lines between the boxes indicate the state transition rules. These rules govern the states a case can move to while it's in a given state. For example, the above diagram indicates a high bill complaint that's in the Lodged state can be either Canceled or moved into the Preliminary Investigation state.

When you set up a case type, you define both its valid states and the state transition rules.

Transitory States

You can define a state in a case type as **Transitory** if you do not wish the case to exist in a particular state. For example, let's assume that an algorithm is associated with the Decision Checkpoint state (Enter Processing) that would automatically determine the next state for the case (i.e. Cancel/Rebill or Reject) and also contains logic to transition the case accordingly. In this scenario, you may not ever want the case to exist in the Decision Checkpoint state, so that a user won't ever see a high bill complaint in that state. If the other states were marked as non-transitory, and an error were to occur during the transition from Decision Checkpoint to Cancel/Rebill, the case would roll back any changes to data made in the Cancel/Rebill (Enter Processing) state along with the changes made in the Decision Checkpoint state, and would end up in the Field Investigation In Progress state - the last non-transitory state prior to Decision Checkpoint.

One Initial State and Multiple Final States

When you set up a case type's states, you must pick one as the initial state. The initial state is the state assigned to new cases of a given type. For example, high-bill complaint cases have an initial state of Lodged, whereas literature request cases have an initial state of Literature Sent.

Copyright © 2026, Oracle and/or its affiliates.

You must also define which statuses are considered to be "final". When a case enters a "final" state, it is complete and no further action is necessary. You might want to think of the "final" states as the potential outcomes of a case. For example, a high-bill complaint has potential outcomes of Completed, Rejected, and Canceled.

The "final" states are used by the system to differentiate between open and closed cases. For example, an alert highlights when the person / account / premise in context has open cases (this alert only exists if you've plugged-in the appropriate installation alert).

Allowing A Case To Be Reopened

You can set up your state transition rules to allow a case to be reopened (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure a case type accordingly.

Make Sure To Have A Canceled State

The system does not allow you to delete a case. Therefore, if you want to support logical deletion, you should have a status of Canceled early in a case type's lifecycle. Doing this allows a user to cancel (i.e., logically delete) a case.

> **Note**
>
> **Cancel reason.** You might want to consider setting up your case types to require a cancel reason (in the form of a predefined value characteristic) when a user cancels a case. Refer to Required Fields Before A Case Enters A State for more information.

Buttons Are Used To Transition A Case From Status To Status

When a case is displayed on Case - Main, a separate button is shown for each state into which the case can be transitioned. For example, a high-bill complaint case that is in the Lodged state would show two buttons: **Start Investigation** and **Cancel**. If the user presses the **Start Investigation** button, the case is transitioned to the Preliminary Investigation state. If the user presses the **Cancel** button, the case is moved to the Canceled state.

You may define the text displayed on the button differently for each state transition. This allows the action description to be varied according to the previous status. For example, the button to transition from New to Active may be labeled **Activate**, but the button to change from Closed to Active may be labeled **Reactivate**.

Refer to Which Users Can Transition A Case for instructions describing how to restrict users to specific actions.

State Transitions Are Audited

The system maintains an audit trail whenever a case transitions from one state to another. This audit is shown in the case's log.

Copyright © 2026, Oracle and/or its affiliates.

Reports and Analytics Highlight Productivity

When you set up a case type's lifecycle, keep in mind that several reports and analytics highlight how long it took cases to transition into a state. For example, you can use a report to see how long it took high-bill complaints to be completed (or initially actioned or ...). Refer to the Reports chapter for the details of case reports.

Status-Specific Business Rules

As described in Lifecycle, when you set up a case type, you define the possible states its cases can pass through. The following topics describe business rules that can be configured for each state.

- A Script That Helps A User Work Through A Case
- Required Fields Before A Case Enters A State
- Validation Before A Case Enters A State
- Additional Processing When Entering A State
- Validation Before A Case Exits A State
- Additional Processing When Exiting A State
- Automatic Transition Rules
- Script Launching Option
- Which Users Can Transition A Case Into A State

A Script That Helps A User Work Through A Case

You can define a Business Process Assistant script that helps a user work a case while it's in a given state. For example, when you set up the Preliminary Investigation state for the high-bill complaint case type, you can define a script. A user can then easily launch this script to help them work through a case in this state.

Please keep the following in mind when you're designing how to integrate BPA scripts with your cases:

- You can have a different script for each state. For example, you could develop a script to help a user work on a case while it's in the Preliminary Investigation state and a different script to help them work in a case while it's in the Decision Checkpoint state.
- Rather than make a user launch a script by pressing a hyperlink on the case page, you can have the system automatically launch the script while the case is in a given state. Refer to Script Launching Option for more information.
- You can also have the system automatically launch a script when a user selects a To Do entry. Refer to Launching Scripts When To Do Entries Are Selected for more information.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Scripts and Cases for more information about how to streamline your case processing with scripts.

Required Fields Before A Case Enters A State

You can define additional fields (i.e., characteristics) that are required before a case can enter a given state. For example,

- You can indicate a high-bill complaint must reference at least one bill before it enters the Preliminary Investigation state.
- You can indicate a case must reference a cancel reason before it enters the Canceled state.

You do this by indicating that characteristics (that were optional when the case was added) are required when a case enters a given state.

Validation Before A Case Enters A State

You can define validation that executes before a case can enter a given state. For example, you can indicate the case must have been assigned a responsible user before it can enter the Preliminary Investigation state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Entering A State

You can define additional processing that should happen when a case enters a given state. For example, you can have a letter created when a high-bill complaint case is Rejected. Similarly, you can have a To Do entry created when a high bill complaint enters the Preliminary Investigation state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

You can also incorporate state transitioning logic within routines that are executed when a case enters a state, so that you do not need to rely upon CASETRAN to transition your cases. For example, when the state entry routines of the Preliminary Investigation status for a high-bill complaint are executed, they may be designed to transition the case into either the Rejected or Field Investigation In Progress state without waiting. Note that your Exit Validation and Exit Processing logic, if configured for the case state, will still be executed as part of the state transition. Auto-Transition logic for this state will be ignored during this transition.

Validation Before A Case Exits A State

You can define validation that executes before a case can exit a given state. For example, you might want to check the account's balance is less than a given value before a case can exit a given state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Copyright © 2026, Oracle and/or its affiliates.

Additional Processing When Exiting A State

You can define additional processing that should happen when a case exits a given state. For example, you can have a To Do entry automatically completed when a high bill complaint leaves the Decision Checkpoint state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

Automatic Transition Rules

You can define rules that automatically transition a case into a different state. For example, you can indicate a literature request should be transitioned to the Follow Up state 1 week after the literature is sent. Similarly, you can indicate a high-bill complaint should transition to the Decision Checkpoint state after the fieldwork is complete. These rules are held in algorithms that are plugged in on the case type and therefore you can define any type of automatic transition rules.

Cases in a state with automatic transition rules are monitored by the CASETRAN background process. Each time this program runs, the respective automatic transition plug-in is called for each such case and it transitions the case if the condition applies.

> **Note**
>
> **When to execute CASETRAN.** Because your automatic transition rules will be dependent on your business requirements, you need to think carefully about when you run the CASETRAN background process. For example, if you have automatic transition rules that transition a case to a new state when a related field activity is completed, you would want to schedule this job to run after field activities are uploaded. If you have rules to transition a case after a customer pays a deposit, you'd want to schedule this job to run after payments are uploaded. Bottom line - your business rules will dictate the frequency of execution.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. In other words, you don't need to wait for the auto-transition background process to be executed. An indication that the case was auto-transitioned online is displayed right below the action buttons section.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Auto-Transition Errors.** Online auto-transition is performed recursively committing each successful state transition to the database. It is performed up to 100 times or until an error is encountered during the process. If this happens, auto-transition stops at the last **non-transitory** state into which a successful transition had occurred. Two case log entries will be generated automatically - one containing the message that a transition error has occurred, and a second containing the actual error message. A To Do entry will also be generated automatically upon rollback. The type of this To Do entry will be taken from 1) the Case Transition Exception To Do Type **option** for the **Business Object** associated with the case type, and if this is not populated, 2) the Exception To Do Type indicated on the Case Options Feature Configuration. All of the above error handling is true for both batch and online processing of cases.

> **Note**
>
> **Triggering Auto-Transition.** If you have a customized process that affects the state of a case and you want the case to be auto-transitioned right away, i.e. not wait for the next scheduled CASETRAN background process to execute, you can customize that process to trigger auto-transition for the specific case, or you can put the state transition logic into the routines that execute at state entry time.

Script Launching Option

You can define whether the script associated with a given state is to be automatically launched while the case is in that state. The system supports the following options:

- Launch the script only if no script is currently active.
- Always launch the script unless this specific script is currently active.

> **Warning**
>
> With this option, if a script is currently open in the page's BPA script area then it will be automatically closed and the case script will open.

- Do not automatically launch the script.

You do this by plugging-in a Script Launching algorithm for the given state. If no such plug-in is provided the script is not automatically launched.

Which Users Can Transition A Case Into A State

If you have restricted access to a case type, you can further restrict which user groups are allowed to transition a case into specific states. For example, you can control which user group can transition a high bill complaint into the Preliminary Investigation state. The following points describe how this is done:

Copyright © 2026, Oracle and/or its affiliates.

- Define actions on the application service defined on the case type. You must define an action for each status that you need to secure.
- Define each status's corresponding action. Note, you only need to link a status to an action if it's secured. Any user with access to the case type can perform statuses that aren't linked to actions.
- Define the transition role for each status's valid next status. You can assign valid next statuses to be reachable via system (only), or system and user.
- Define which user groups have access to the actions (i.e., statuses). In addition, these user groups should have access to the Change action.

Responsible User Applicability

Some of your cases may require a "responsible user". This is the user who has overall responsibility for the case. When you set up a case type, you define if a responsible user is required, optional or not allowed on its cases.

The following points describe how to set up the system if a responsible user is not required when a case is first created, but is later in its lifecycle:

- Indicate that a responsible user is optional on the case type
- Plug-in either an exit validation or entry validation algorithm on one of the case type's states to require a responsible user at some point in a case's lifecycle

> **Note**
>
> **Address To Do entries to the responsible user.** If you use the base-package algorithm to create a To Do entry when a case enters a given state, you can indicate that the To Do entry should be addressed to the responsible user on the case.

Scripts and Cases

There are three ways Business Process Assistant scripts can be used to manage cases:

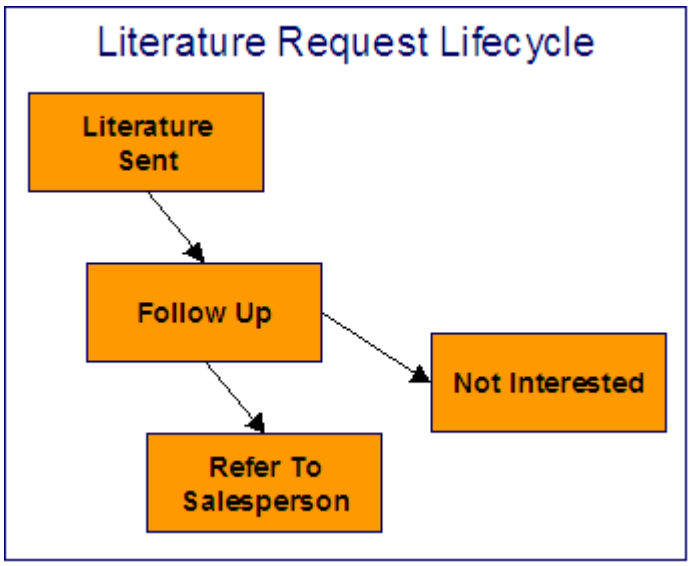
- You can create a BPA script to help users create a case. For example, a script can help a user create a new high-bill complaint.
- Using a script to create a case can save a user a lot of time (and training efforts). This is because the script can automatically populate many fields on the case based on answers to questions.

Refer to Initiating Scripts for a description of how end-users initiate scripts.

- You can create a script to help users work on a case when it's in a given state. Refer to A Script That Helps A User Work A Case for more information.
- You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these ToDo entries without assistance. However, you can set up the system to automatically launch a script when a user selects a ToDo entry. For example, consider a ToDo entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this ToDo entry. This script might guide the user through the

Copyright © 2026, Oracle and/or its affiliates.

investigation process (and help them update the case). Refer to Executing A Script When A To Do Entry Is Selected for more information.



To Do's and Cases

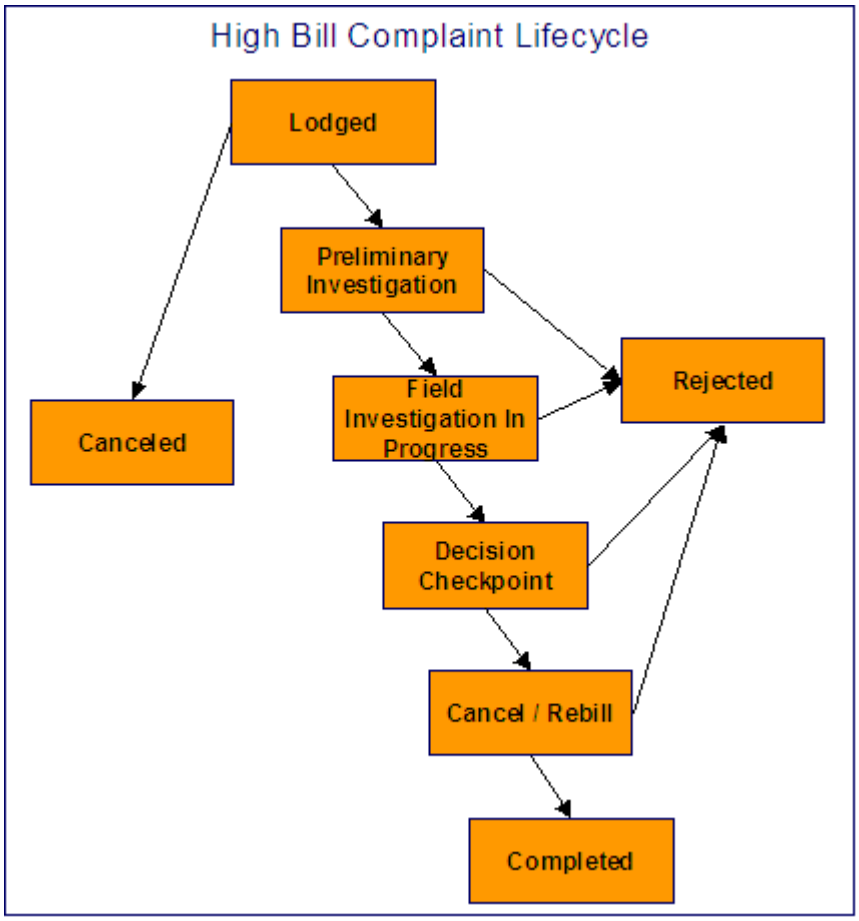
The topics in this section provide background information about how to facilitate case management with To Do entries.

- Creating and Completing To Do Entries
- Launching Scripts When To Do Entries Are Selected
- All To Do Entries Are Visible

Creating and Completing To Do Entries

You can configure your case types to create and complete To Do entries when a case enters or exits a state. Let's use the following lifecycle diagram to illustrate a potential use of To Do's:

Let's assume the following:



- You want a To Do entry created when a literature request case enters the Follow Up state. You want this To Do automatically completed when the case enters either the Refer To Salesperson or Not Interested states. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when a case enters the Refer To Salesperson state. You do not want the system to automatically complete this entry (the sales person must manually do this). Note, we refer to this as the "second" To Do entry below.

To implement the above, you would set up a case type as follows:

- Plug-in an entry processing algorithm on the Follow Up status to create the first To Do entry.
- Plug-in an exit processing algorithm on the Follow Up status to complete the first To Do entry.
- Plug-in an entry processing algorithm on the Refer To Salesperson status to create the second To Do entry.

Copyright © 2026, Oracle and/or its affiliates.

While the case type illustrated above had a single To Do entry "active" at any point in time, you can easily configure a case type to have multiple To Do entries active at any point in time. Let's use the following lifecycle diagram to illustrate this point:

Let's assume the following:

- You want a To Do entry created when a high bill complaint is created and you want it completed when the case reaches the Canceled, Rejected or Approved states. This To Do entry could be used by a supervisor to monitor the number of high-bill complaints logged. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when the case enters the Preliminary Investigation state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "second" To Do entry below.
- You want a different To Do entry created when the case enters the Decision Checkpoint state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "third" To Do entry below.

To implement the above, you would set up the case type as follows:

- Plug-in an entry processing algorithm on the Lodged status to create the first To Do entry. Plug-in an entry processing algorithm on the Canceled, Rejected and Completed statuses to complete this entry.
- Plug-in an entry processing algorithm on the Preliminary Investigation status to create the second To Do entry. Plug-in an exit processing algorithm on the Preliminary Investigation status to complete this entry. We elected to use an exit processing algorithm because we only have to plug it in on one status. If we'd used an entry processing algorithm, we would

Copyright © 2026, Oracle and/or its affiliates.

need to plug it in on the 2 statuses into which a Preliminary Investigation status can transition.

- Plug-in an entry processing algorithm on the Decision Checkpoint status to create the third To Do entry. Plug-in an exit processing algorithm on the Decision Checkpoint status to complete this entry.

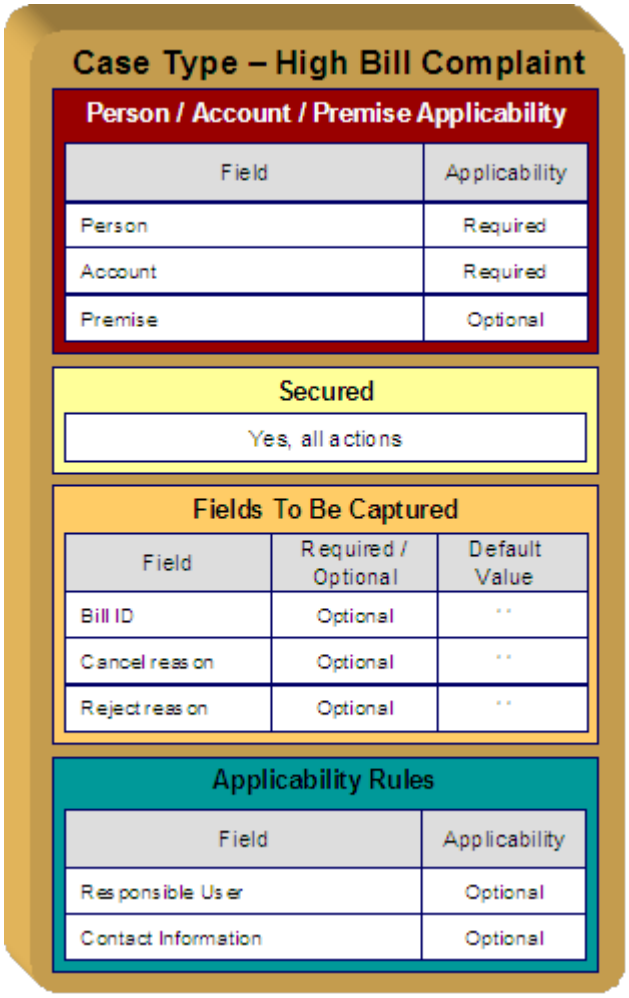
Launching Scripts When To Do Entries Are Selected

You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these To Do entries without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this type of To Do entry. This script might guide the user through the investigation process. Refer to Executing A Script When A To Do Entry Is Selected for more information.

All To Do Entries Are Visible

When a case is displayed on Case Maintenance, the system summarizes the number of To Do entries associated with the case (if you've set up your To Do types appropriately).

Examples of Case Types



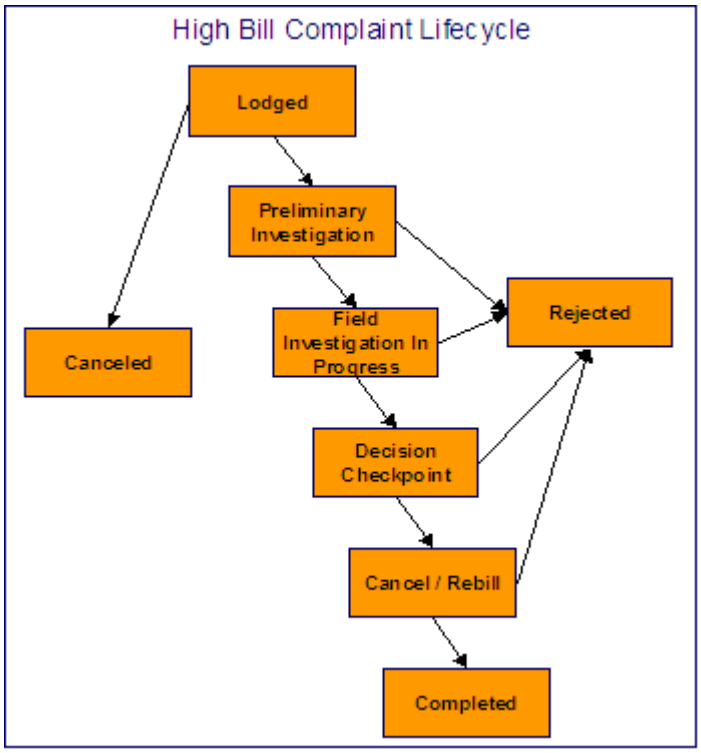
The topics that follow provide examples of case types related to several business processes. Use the information in this section to form an intuitive understanding of case types. After attaining this understanding, you'll be ready to design your own case types.

- High Bill Complaint

High Bill Complaint

Some organizations will set up a case to manage a high-bill complaint. The following diagram illustrates how such a case type might look:

Copyright © 2026, Oracle and/or its affiliates.



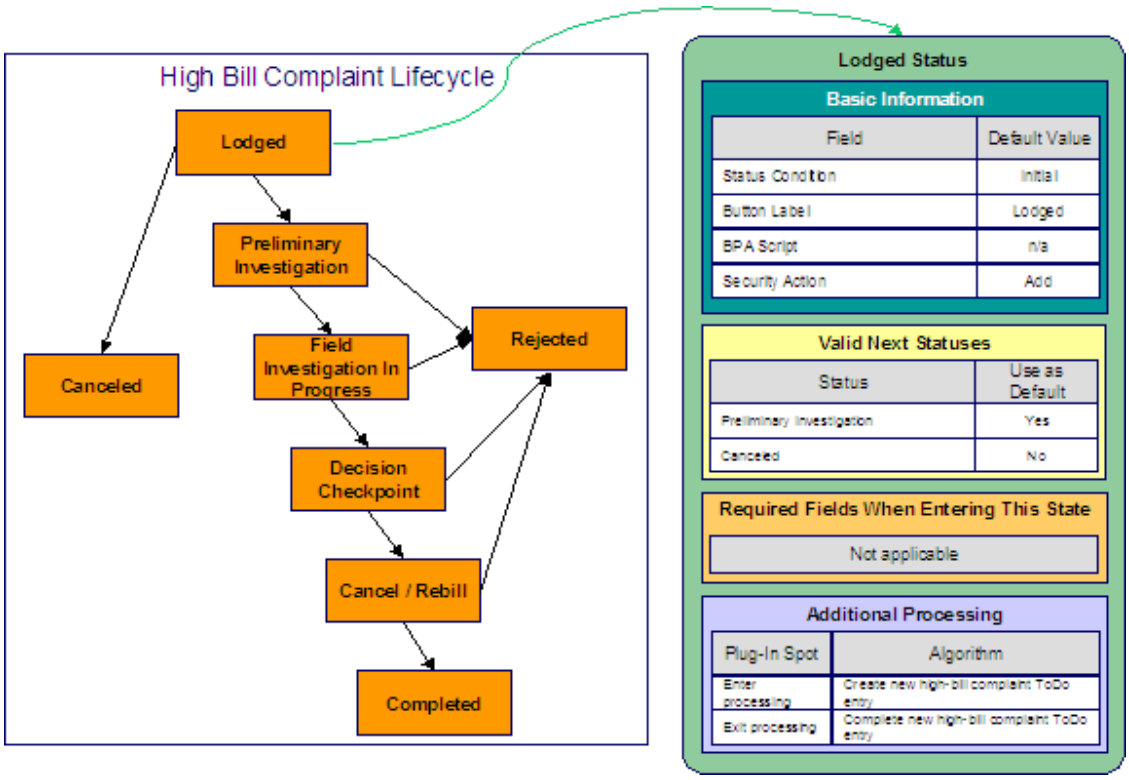
Note the following about the High Bill Complaint case type:

- Notice that we set up the case type to require a person and an account, but premise is optional. This is because a bill can span multiple premises and knowing the premise isn't so important on cases of this type.
- We need to restrict high-bill complaints to specific user groups. This means we need to set up a specific application service for this case type (that has a separate "action" for each status).
- Cases of this type have 3 additional fields over their lifetime. Notice the following:
  - The **Bill ID** characteristic is set up to be optional. This is because we've assumed that sometimes a high-bill complaint case can be lodged when you can't find the bill in question and you still want to log the case.
  - Later in this section, you'll see that we've configured the Preliminary Investigation status to require a **Bill ID** before a case can enter this state.
  - Both the **High Bill Complaint Cancel Reason** and **Reject Reason** are optional. Later in this section, you'll see that we've configured the Canceled and Rejected statuses to require these fields, respectively.
- Cases of this type do not need a **Responsible User** when first created. Later in this section, you'll see how we've configured the Preliminary Investigation status to require a **Responsible User** before a case can enter this state.

Copyright © 2026, Oracle and/or its affiliates.

- Cases of this type do not need **Contact Information**. This was a subjective decision and depends on your organization's philosophy.

The topics that follow describe each of the statuses in a high-bill complaint's lifecycle. We have assumed the following state transition rules:

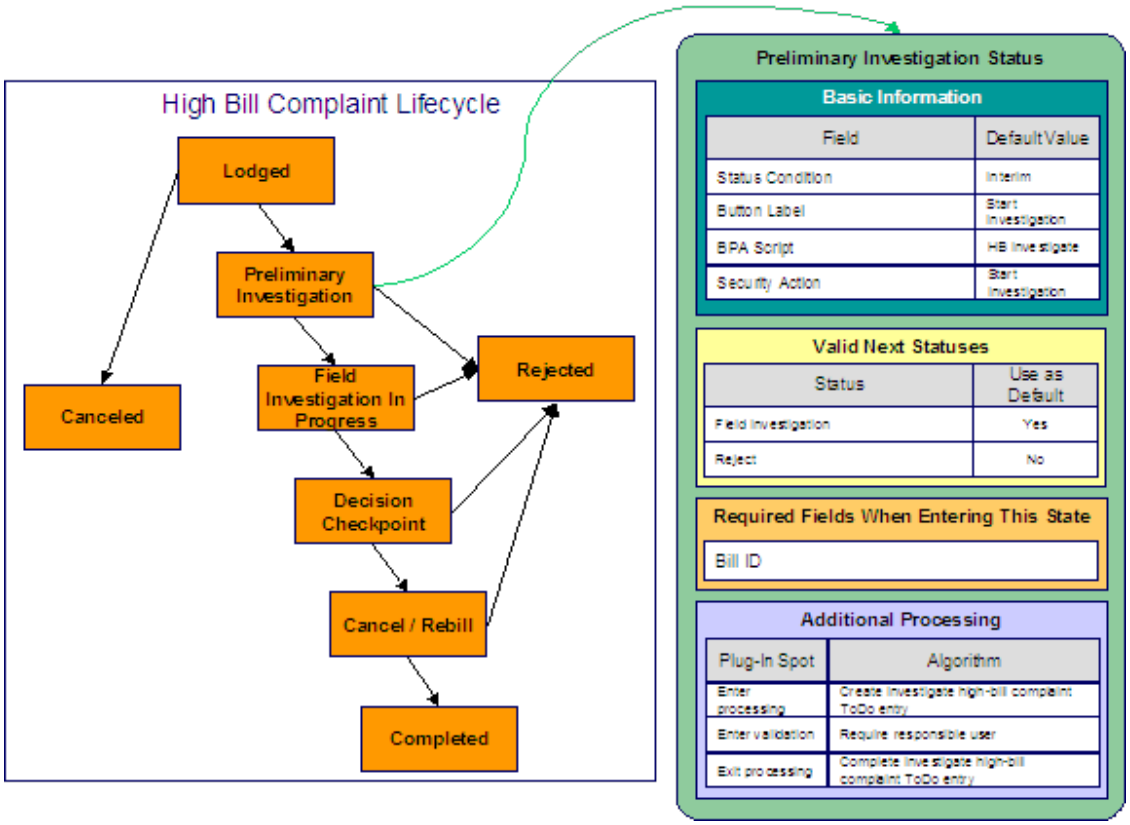


- Lodged High Bill Complaint
- Preliminary Investigation High Bill Complaint
- Field Investigation High Bill Complaint
- Decision Checkpoint High Bill Complaint
- Cancel Rebill High Bill Complaint
- Completed High Bill Complaint
- Rejected High Bill Complaint
- Canceled High Bill Complaint

Lodged High Bill Complaint

The following is an example of the configuration of the Lodged status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



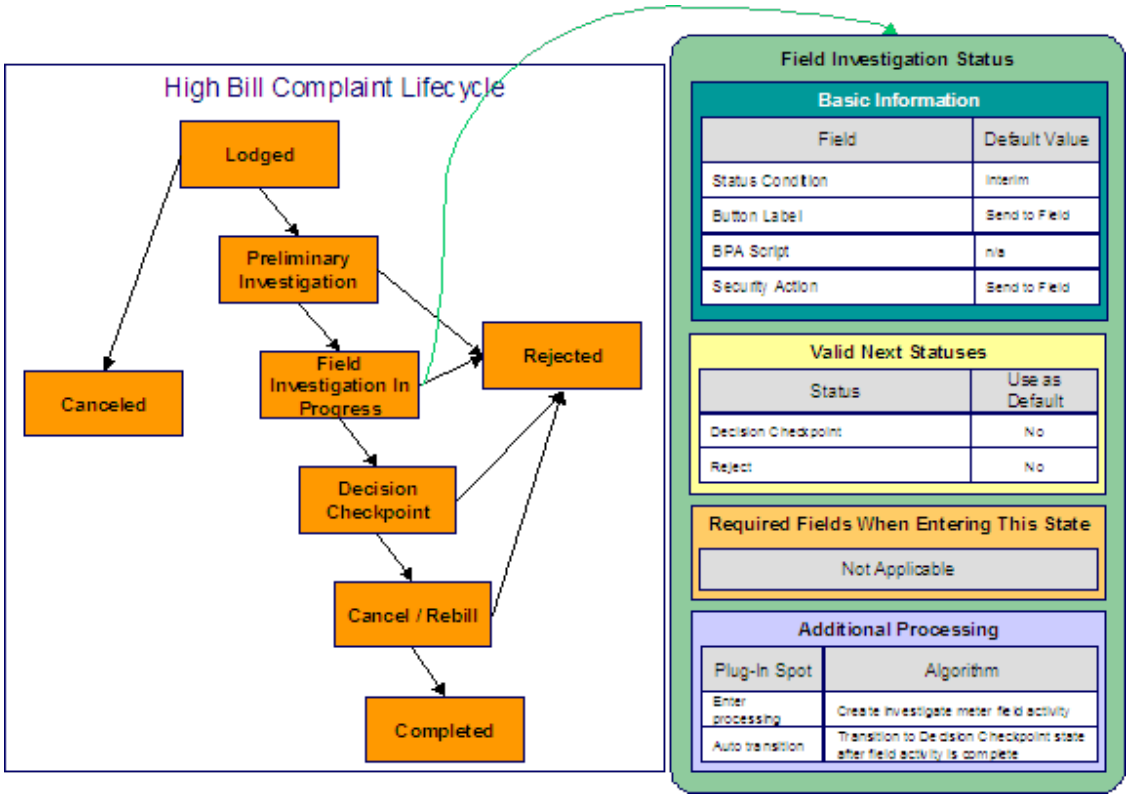
Note the following about this status:

- Lodged is the initial state. The initial state is the state populated on new cases of a given type. Remember that only one status can be defined as the initial state.
- It has a button label even though it's the initial state. The above diagram doesn't allow a user to ever transition a case into this state and therefore there will never be a button with such a label. However, it's a required field just in case you change your business rules.
- We have decided not to use a BPA script to help a user work on a high-bill complaint when it's in this state (this is probably not the best decision as BPA scripts can be quite useful).
- We have associated the Add action with this status. This means that only users with rights to the add action for the application service defined on the case type can add cases of this type.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Canceled and Preliminary Investigation states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Preliminary Investigation High Bill Complaint

The following is an example of the configuration of the Preliminary Investigation status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



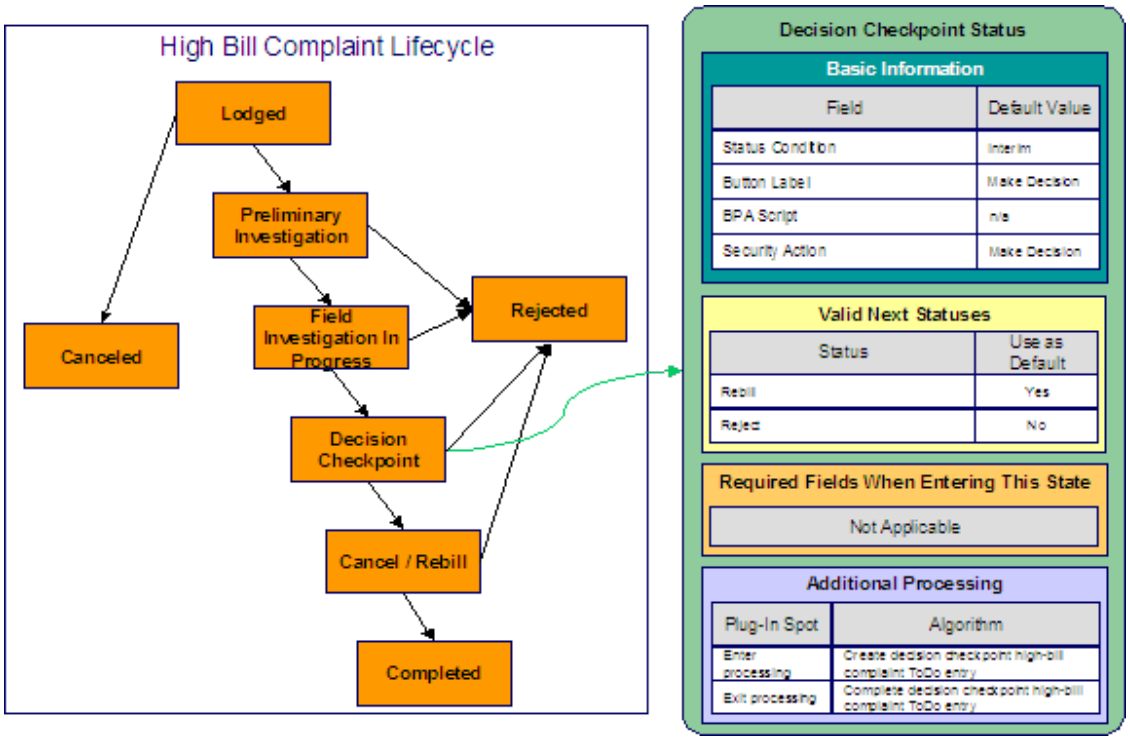
Note the following about this status:

- Preliminary Investigation is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Start Investigation**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Preliminary Investigation state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Start Investigation action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Field Investigation and Rejected states.
- Notice that a **Bill ID** must be specified on the case before it can be moved into this state.
- Notice that the Additional Processing plug-ins do the following:
  - Create and complete a To Do entry when a case enters and exits this state, respectively
  - Require a responsible user before a case can enter this state

Field Investigation High Bill Complaint

Copyright © 2026, Oracle and/or its affiliates.

The following is an example of the configuration of the Field Investigation In Progress status for high bill complaint cases.



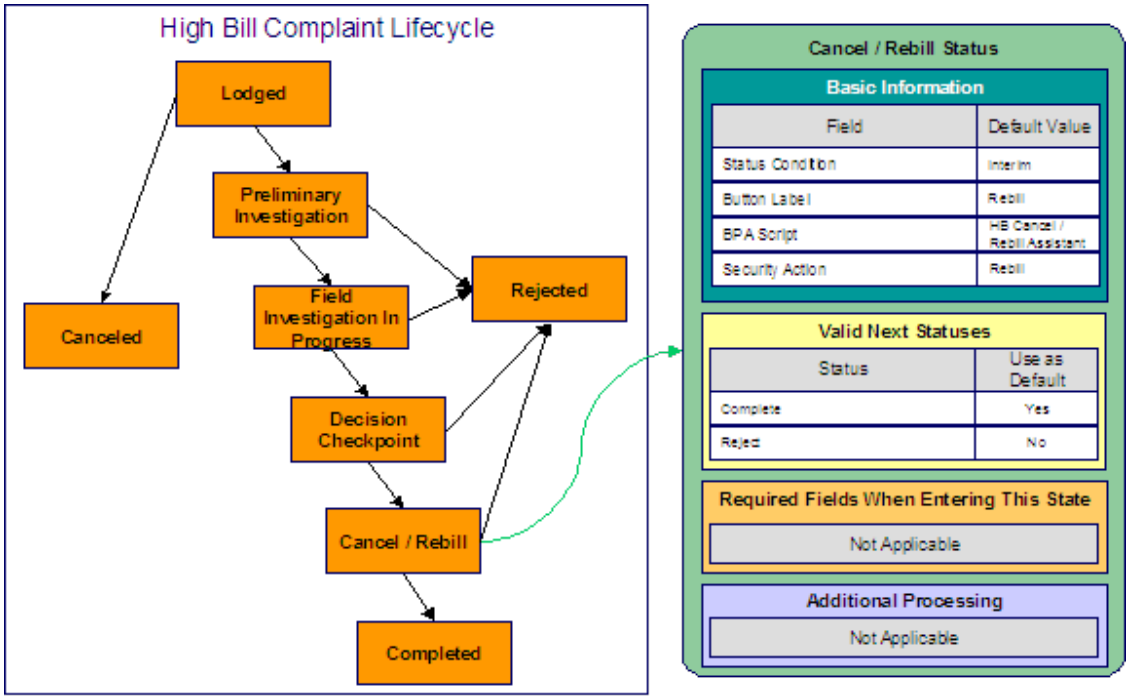
Note the following about this status:

- Field Investigation In Progress is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Send to Field**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Preliminary Investigation state as this is the only state that can transition into the Field Investigation in Progress state.
- We have decided not to specify a BPA script on this status because users don't work cases in this state (see the Additional Processing notes below for why this is the case).
- We have associated the Send to Field action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Decision Checkpoint and Rejected states.
- Notice that the Additional Processing plug-ins do the following:
  - Create a field activity when a case enters this state
  - Cause the case to automatically transition to the Decision Checkpoint state when the field activity is completed

Decision Checkpoint High Bill Complaint

Copyright © 2026, Oracle and/or its affiliates.

The following is an example of the configuration of the Decision Checkpoint status for high bill complaint cases.



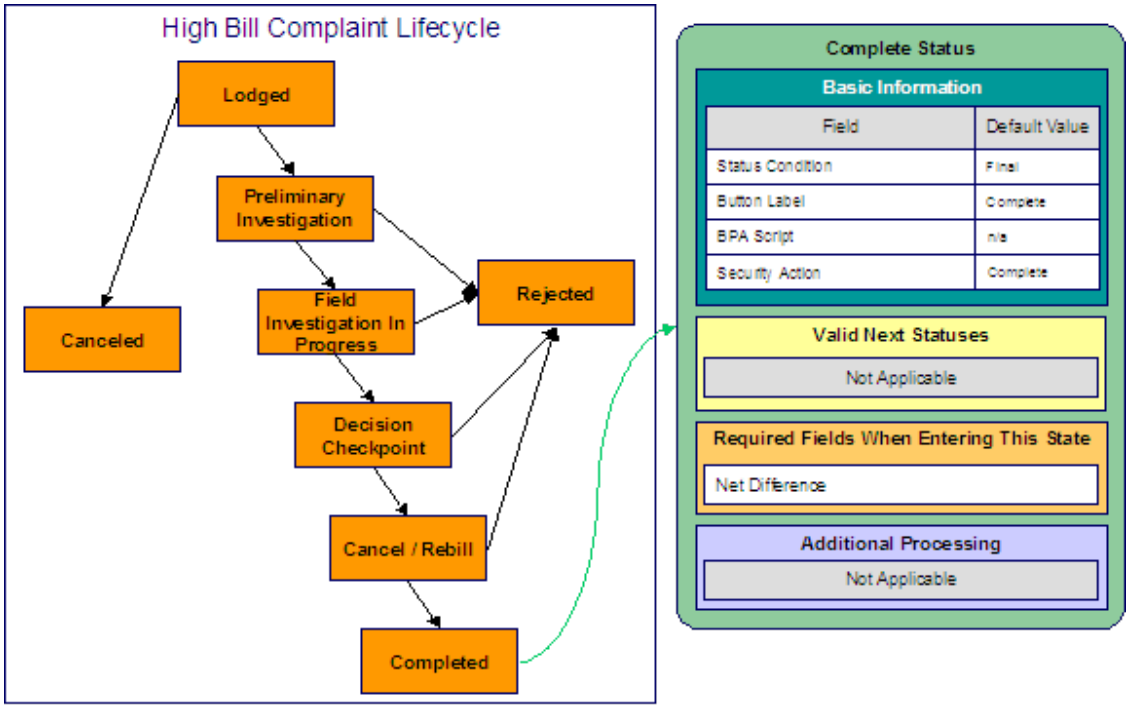
Note the following about this status:

- Decision Checkpoint is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Make Decision**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Field Investigation in Progress state as this is the only state that can transition into the Decision Checkpoint state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Make Decision action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state. Because the system will automatically transition cases into this state when the related field activity is complete, users will probably never press this button (and you may wish to prevent users from pressing this button be restricting security rights to the related action).
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Cancel / Rebill and Rejected states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Cancel Rebill High Bill Complaint

The following is an example of the configuration of the Cancel / Rebill status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



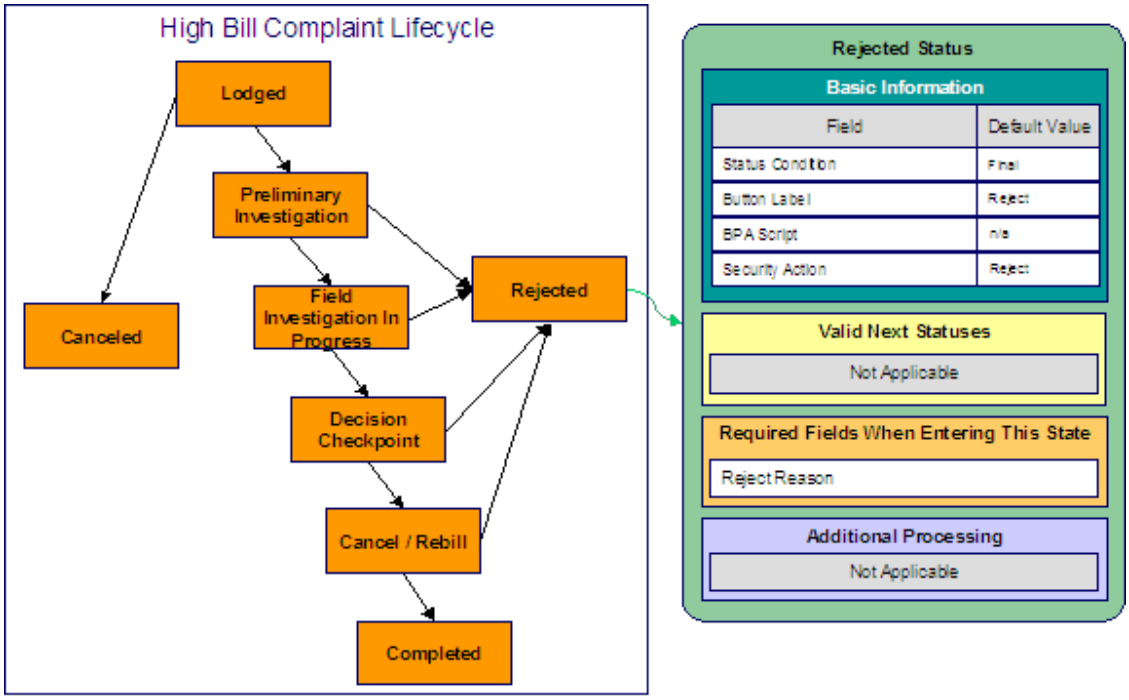
Note the following about this status:

- Cancel / Rebill is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Cancel / Rebill**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Decision Checkpoint state as this is the only state that can transition into the Cancel / Rebill state.
- We have referenced a BPA script that can assist a user in the cancel / rebill efforts.
- We have associated the Rebill action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Completed and Rejected states.

Completed High Bill Complaint

The following is an example of the configuration of the Completed status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



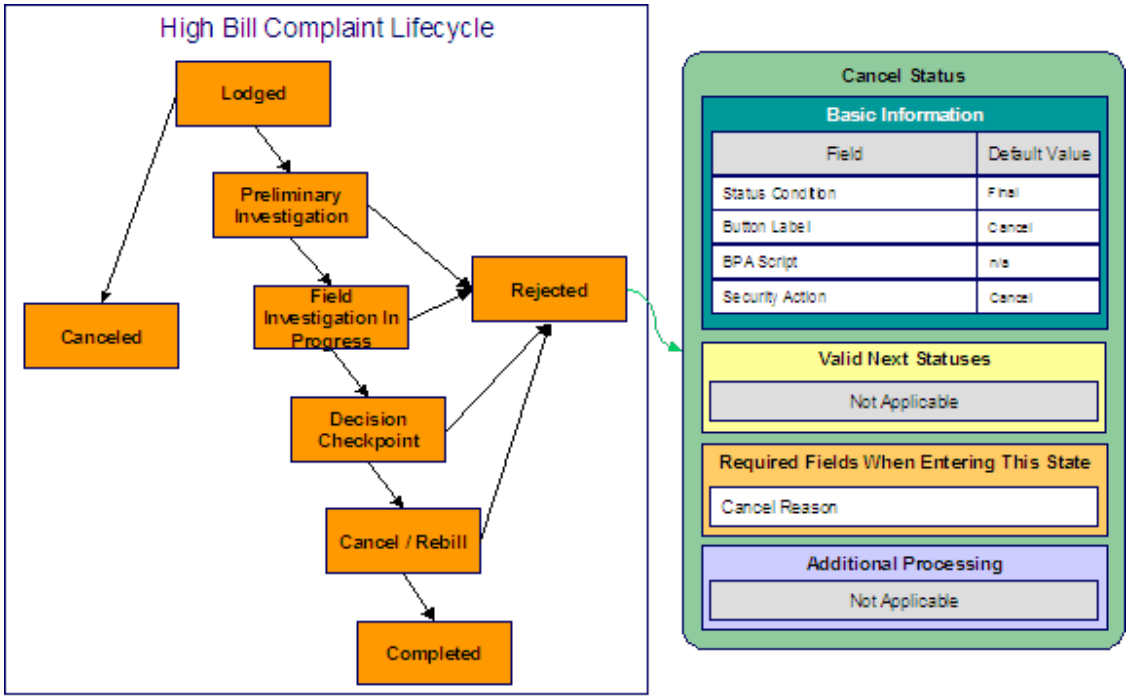
Note the following about this status:

- Completed is a final state (meaning that no further action is necessary).
- It has a button label of **Complete**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Cancel / Rebill state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Complete action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Completed case to be reopened, you would need to define the state into which a Completed case could be transitioned.
- Notice that the **Net Difference** must be specified on the case before it can be moved into this state. This would be the difference to the customer's balance after the cancel rebill took place.

Rejected High Bill Complaint

The following is an example of the configuration of the Rejected status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



Note the following about this status:

- Rejected is a final state (meaning that no further action is necessary).
- It has a button label of **Reject**. This is the label on the button that a user presses to move a case into this state. This button will appear on cases that are in the Preliminary Investigation, Field Investigation in Progress , Decision Checkpoint and Cancel / Rebill states.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Reject action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Rejected case to be reopened, you would need to define the state into which a Rejected case could be transitioned.
- Notice that a **Reject Reason** must be specified on the case before it can be moved into this state.

Canceled High Bill Complaint

The following is an example of the configuration of the Canceled status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.

Note the following about this status:

- Canceled is a final state (meaning that no further action is necessary).
- It has a button label of **Cancel**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Cancel action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Canceled case to be reopened, you would need to define the state into which a Canceled case could be transitioned.
- Notice that a **Cancel Reason** must be specified on the case before it can be moved into this state.

Setting Up Case Management Options

The topics in this section describe how to set up the system to enable case management.

> **Warning**
>
> The following topics assume you thoroughly understand the concepts described under The Big Picture Of Cases.

- Installation Options

Copyright © 2026, Oracle and/or its affiliates.

- Setting Up Application Services
- Setting Up Scripts
- Setting Up To Do Types
- Setting Up Characteristic Types
- Setting Up Case Types

Installation Options

- Case Info May Be Formatted By An Algorithm
- Alert Info Is Controlled By An Installation Algorithm

Case Info May Be Formatted By An Algorithm

An algorithm may be plugged in on the installation record to format the standard case information that appears throughout the system. Refer to CSIN-DFLT for an example of this algorithm.

This algorithm may be further overridden by a "Case information" plug-in on the Case Type. Refer to C1-CT-INFO for an example of this algorithm.

Alert Info Is Controlled By An Installation Algorithm

An algorithm that is plugged in on the installation record is responsible for formatting the alerts that highlight if the person / account / premise in context has open cases. Refer to CCAL-CASE for an example of this algorithm.

Setting Up Application Services

As described under Access Rights, you can prevent unauthorized users from accessing cases. The following points describe how to implement this type of security:

- Create an application service for each case type that needs to be secured
- Create an action on the application service for each status you need to secure
- Link the valid user groups to the application service and define which actions they can perform
- Define the application service on the case type
- Define the related action for each status on the case type / status

Setting Up Scripts

Copyright © 2026, Oracle and/or its affiliates.

As described under Scripts and Cases, BPA scripts can facilitate the creation and working of cases. Refer to the Defining Script Options for instructions describing how to set up scripts.

Setting Up To Do Types

As described under To Do's and Cases, To Do entries can be used to highlight cases that require user attention.

The following points provide a high-level description of how to create (and complete) To Do entries for a case type:

- Create a To Do type for each different type of To Do entry used during a case's lifecycle
  - On the To Do type, think carefully about the roles whose users can work on the entries
  - Also consider if you would like a BPA script launched when a user selects the entry
- Specify the To Do type on the appropriate entry processing or exit processing algorithm
- If you want the system to automatically complete To Do entries, specify the To Do type on the appropriate entry processing or exit processing algorithm

Please be aware that the case maintenance transaction highlights the number of open and assigned To Do entries linked to the case being displayed on the page. However, the system can only do this if the To Do entries reference a foreign-key characteristic whose foreign key references the case table. If you use the CSEN-TD algorithm to create To Do entries when a case enters a given state, this algorithm will do this for you if:

- You have set up a foreign-key characteristic type whose foreign key references the case table
- In addition, the characteristic type must reference a characteristic entity of To Do Entry

Setting Up Characteristic Types

As described under Additional Information, some of your cases may require additional information (in the form of characteristics). If this is true, you must set up the characteristic types before setting up the case types.

Refer to Setting Up To Do Types for instructions regarding a characteristic type that must be set up in order for the system to know the To Do entries that are associated with a case.

If you use the CSEN-CC algorithm to create customer contacts when a case enters a given state, you should set up a foreign-key characteristic type as follows:

- Its foreign key must reference the case table
- In addition, the characteristic type must reference a characteristic entity of Customer Contact

Setting Up Case Types

The case type maintenance transaction is used to maintain your case types. The topics in this section describe how to use this transaction.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture Of Cases for more information about how a case type encapsulates the business rules that govern a case.

- Case Type - Main
- Case Type - Case Characteristics
- Case Type - Lifecycle

Case Type - Main

Use this page to define basic information about a case type.

Open the case type page by selecting **Admin**, and then **Customer**, and then **Case Type**, and then **Case Type**, and then **Add.**

Note

Recommendation. Before using this transaction, we strongly recommend that you review the Examples of Case Types.

Main Information

Enter a unique **Case Type** code and **Description** for the case type.

Use **Long Description** to provide a more detailed explanation of the purpose of the case type.

If your implementation requires restricting case types by CIS Division, specify a **CIS Division** on the case type.

Person Usage controls the applicability of a person on cases of this type. Select Required if a person must be defined on this type of case. Select Optional if a person can optionally be defined on this type of case. Select Not Allowed if a person is not allowed on this type of case.

Account Usage controls the applicability of an account on cases of this type. Select Required if an account must be defined on this type of case. Select Optional if an account can optionally be defined on this type of case. Select Not Allowed if an account is not allowed on this type of case.

Premise Usage controls the applicability of a premise on cases of this type. Select Required if a premise must be defined on this type of case. Select Optional if a premise can optionally be defined on this type of case. Select Not Allowed if a premise is not allowed on this type of case.

Entity Relationship controls the validation of relationships on cases of this type. ***All*** ensures that the account belongs to the person and that the account and premise are related. ***Person and Account Only*** disables the account and premise validation. ***Premise and Account Only*** disables the person and account validation. ***None*** disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

Copyright © 2026, Oracle and/or its affiliates.

If you need to restrict access to cases of this type to specific user groups, reference the appropriate **Application Service**. Refer to Setting Up Application Services for the details of how to secure access to your cases.

If you are configuring a case type to handle the processing of data defined via a **Business Object**, associating the case type with a business object serves to link the properties of the business object (e.g. BO options) with cases of that type. Refer to Business Objects for further information. In addition, refer to Automatic Transition Rules for information on the role of BO options in case auto-transition errors.

Responsible User Usage controls the applicability of a responsible user on cases of this type. Select Required if a responsible user must be defined on this type of case. Select Optional if a responsible user can optionally be defined on this type of case. Select Not Allowed if a responsible user is not allowed on this type of case. Refer to Responsible User Applicability for more information.

Contact Information Fields

There are three contact information fields: **Contact Person & Method Usage**, **Contact Instructions Usage**, and **Case Phone Usage**. These fields are used to determine whether or not each type of contact information must be entered on case records with this case type. Select Required if the contact information must be entered, select Optional if the user can choose whether or not to include the contact information on this type of case, or select Not Allowed if the contact information cannot be entered on this type of case.

Algorithms

The **Algorithms** grid contains algorithms that control functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Case Information	Optional	We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm. Plug an algorithm into this spot to override the "Case information" algorithm on installation options or the system default "Case information" if no such algorithm is defined on installation options.

Case Type Tree

Copyright © 2026, Oracle and/or its affiliates.

The tree summarizes the case type's lifecycle. You can use the hyperlinks to transfer you to the **Lifecycle** tab with the corresponding status displayed.

Case Type - Case Characteristics

To define characteristics that can be defined for cases of this type, open **Admin**, and then **Customer**, and then **Case Type**, and then **Search** and navigate to the **Case Characteristics** page.

Description of Page

Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on cases of this type. Turn on the **Default** switch to default the **Characteristic Type** when cases of this type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** box is checked. Refer to Required Fields Before A Case Enters A State for a description of how you can make option characteristics required at later stages in a case's lifecycle.

Case Type - Lifecycle

Case types that involve multiple users and multiple potential outcomes have complex lifecycles. Before you can design a case type's lifecycle, it's important that you thoroughly understand the concepts described under Lifecycle and Status-Specific Business Rules. After thoroughly understanding these concepts, we recommend you perform the following design steps:

- Draw a "state transition diagram" as illustrated above under Lifecycle. Keep in mind that if your state transition diagram is complex, your cases will be complex. While some cases warrant complexity, you should always ask yourself if there aren't better ways to achieve the desired results if your first effort results in complexity.
- Determine which characteristics (if any) are required during each stage of a case's lifecycle
- Determine when To Do entries (if any) should be created (and completed) during a case's lifecycle
- Determine additional validation (if any) that should be executed before a case enters and exits each state
- Determine additional processing (if any) that should transpire when a case enters or exits each state
- Determine if scripts are warranted to help users work the cases and, if so, design the scripts for each applicable state

When the above tasks are complete, you will be ready to set up a case type's lifecycle.

Open the Lifecycle page by selecting **Admin**, and then **Case Type**, and then **Case Type**, and then **Search** and navigate to the **Lifecycle** page.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You can navigate to a status by clicking on the respective node in the tree on the Main tab. You can also use the hyperlinks in the Next Statuses grid to display a specific status in the accordion.

Main Information

The **Status** accordion contains an entry for every status in the case type's lifecycle.

Use **Status** to define the unique identifier of the status. This is NOT the status's description, it is simply the unique identifier used by the system.

Use **Description** to define the label that appears on the lifecycle accordion as well as the status displayed on the case.

Use **Script** to reference a BPA script that can assist a user work on a case while it's in this status. Refer to A Script That Helps A User Work Through A Case for the details.

Use **Access Mode** to define the action associated with this status. This field is disabled if an application service is not specified on the Main page. Refer to Access Rights for the details of how to use this field to restrict which users can transition a case into this state.

Use **Batch** to specify a batch control that will auto-transition the case. Any case in a status configured with a batch control will be transitioned when the batch job runs (rather than when CASETRAN is executed). For this purpose, batch process C1-CSTRS (**Case Scheduled Transition**) is supplied with base package, which will execute all Exit Status logic for the current status, and Enter Status logic for the destination status. You may choose to create a batch process with your own transition logic.

> **Note**
>
> If you wish to defer transitioning a case in a particular status until the batch process on your case type status is executed, you should not populate an Auto-Transition algorithm on that status. Otherwise, CASETRAN will transition the case according to your Auto-Transition logic.

Use **Comment** to describe the status. This is for your internal documentation requirements.

Use **Sequence** to define the relative order of this status in the tree on the Main page.

Use **Status Condition** to define if this status is an Initial, Interim or Final state. Refer to One Initial State and Multiple Final States for more information about how this field is used.

Use **Transitory State** to indicate whether a case should ever exist in this state. Only Initial or Interim states can have a transitory state value of No.

The **Alert Flag** is used to indicate whether or not an alert should be displayed for customers with cases in the state. (The alert is shown via the base package Installation - Alert algorithm.)

Algorithms

The **Algorithms** grid contains algorithms that control important functions for cases of this type. You must define the following for each algorithm:

Copyright © 2026, Oracle and/or its affiliates.

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Description
Auto Transition	This algorithm is executed to determine if a case that's in this state should be transitioned into another state. Refer to Automatic Transition Rules for the details.
Enter Processing	This algorithm holds additional processing that is executed when a case is transitioned into this state. You can also specify state transition logic within Enter Processing routines. Refer to Additional Processing When Entering A State for the details.
Enter Validation	This algorithm holds validation logic that executes before a case can enter a given state. Refer to Validation Before A Case Enters A State for the details.
Exit Processing	This algorithm holds additional processing that is executed when a case is transitioned out of this state. Refer to Additional Processing When Exiting A State for the details.
Exit Validation	This algorithm holds validation logic that executes before a case can by transitioned out of a given state. Refer to Validation Before A Case Exits A State for the details.
Script Launching	This algorithm sets the script launching option for the script associated with a given state, if any. Refer to Script Launching Option for the details.

Next Statuses

Use the **Next Statuses** grid to define the statuses a user can transition a case into while it's in this state. Refer to Valid States versus State Transition Rules for more information. Please note the following about this grid:

- Use **Action Label** to indicate the verbiage to display on the action button used to transition to this status.
- **Sequence** controls the order of the buttons that appear on Case - Main. Refer to Buttons Are Used To Transition A Case Into A State for more information.
- **Use as Default** controls which button (if any) is the default button.
- **Transition Condition** may be configured to identify a common transition path for cases of this type in the current state. This transition condition may then be referenced across multiple case types. You'll need to add values to Look Up table field **TR_COND_FLG** that fit the typical transitions for your case types (e.g. Ok, Error, etc.).

By assigning the transition condition value to a given "next status", you can design your Enter State transition or Auto-Transition logic to utilize those flag values *without specifying a status*

Copyright © 2026, Oracle and/or its affiliates.

particular to a given case type. Thus, similar logic may be used across a range of case types to transition a case into, for example, the next Ok state for the case's current status.

- **Transition Role** controls whether only the System or both System and User have the ability to transition a case into a given "next status".
- You can use the status description hyperlink to open the Status accordion to the respective status.
- When you initially set up a case type, none of the statuses will reside on the database and therefore you can't use the search to define a "next status". We recommend working as follows to facilitate the definition of this information:
  - Leave the Next Statuses grid blank when you initially define a case type's statuses
  - After all statuses have been saved on the database, update each status to define its Next Statuses (this way, you can use the search to select the status).

Required Characteristics

Use the **Required Characteristics** grid to define characteristics that are required when a case enters this state. Only Optional characteristics defined on the main page appear in this grid. Refer to Required Fields Before A Case Enters A State for more information.

Workflow and Notification Options

We use the term "notification" to reference the electronic transactions that you exchange with third parties when:

- They need information about a customer
- They need to change something about a customer

For example, an energy service provider sends a notification to an electric distribution company when a customer elects to use them as their energy provider.

When a notification is received, the system responds by creating a workflow process. The workflow process contains workflow events. These events perform the processing necessary to execute the notification.

Workflow processing is difficult to explain because its flexible design can be used to automate many different types of multi-event processes. For example,

- You can use workflow processing to manage the events associated with the inspection of a new premise.
- You can use workflow processing to manage the events that transpire in a deregulated market when a customer wants to switch energy service providers.

> **Warning**
>
> Setting up the workflow process control tables is as challenging as your organization's business rules. If you don't have automated workflow processes, you don't have to setup anything. If you have sophisticated workflow processing requirements, your setup process will be more challenging.

The Big Picture Of Workflow Processing

NOT_SUPPORTED

Refer to The Lifecycle Of A Workflow Process And Its Events for more information about workflow processes.

The Big Picture Of Workflow Events

This section describes the various types of workflow events and their lifecycle:

- How Are Workflow Events Created?
- Executing Workflow Events On Their Trigger Date
- Workflow Event Lifecycle
- Workflow Event Dependencies & Trigger Date
- Workflow Events May Be In Error
- Some Workflow Events May Fail
- Errors versus Failure
- Waiting Events And Their Waiting Process
- How Are Workflow Events Canceled?
- Workflow Processes Can Have Multiple Branches

How Are Workflow Events Created?

Workflow events may be created as follows:

- The process that uploads notification requests creates a workflow process to implement the notification request. The workflow process has one or more workflow event(s). The number and type of events is controlled by the workflow process template associated with the workflow process. Refer to What Type Of Workflow Process Is Created? for more information about how notification requests cause workflow processes to be created.

Copyright © 2026, Oracle and/or its affiliates.

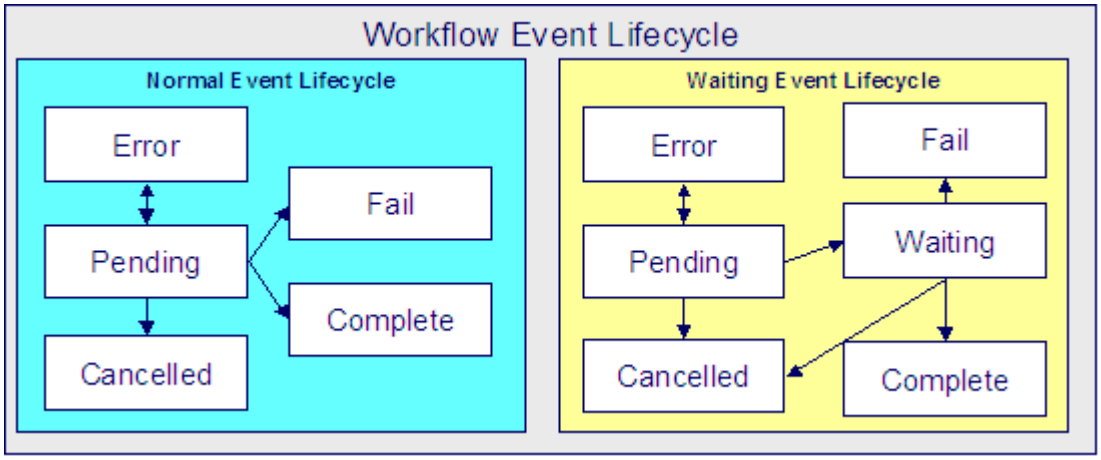
- Workflow events will be created when an operator creates an ad hoc workflow process. The number and type of workflow events are controlled by the workflow process template associated with the workflow process.
- An ad hoc workflow event may be created and linked to an existing workflow process by an operator at their discretion.
- The system may be customized to create a workflow process when something noteworthy happens in the system. Refer to System Conditions May Trigger Notification and Workflow for more information.

> **Note**
>
> **Bottom line.** Most workflow events are created by the system when it creates a workflow process to implement an incoming notification. If you need to create an ad hoc workflow event, you can either create a workflow process using a template that contains the desired event OR link the desired event to an existing workflow process.

> **NOT_SUPPORTED**
>
> For more information about creating ad hoc workflow processes and events, refer to Workflow Process Maintenance.

Executing Workflow Events On Their Trigger Date

When the background process (referred to as WFET) executes a workflow event on its trigger date, it calls the activation algorithm associated with the event's event type. Because you can add and change activation algorithms at will, the variety of workflow events is infinite.



> **NOT_SUPPORTED**
>
> Refer to Designing Workflow Event Types for more information about activation algorithms.

Workflow Event Lifecycle

The lifecycle of a workflow event is dependent on whether the event has to wait on something before it can complete or fail. For example, an event that creates a field activity has to wait until the field activity is performed before it can be considered complete.

The following diagram shows the possible lifecycle of a workflow event:

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the lifecycle of workflow events of the *normal* variety:

- *Normal* events are initially created in the pending state.
- On a pending event's trigger date, the workflow event activation process (referred to as WFET) executes the event's activation algorithm.
- An event's activation algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error. A user should correct the cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation program runs.
- An event's activation algorithm may cause a pending event to fail. For example, if an event used to validate a notification detects invalid information (e.g., an incoming notification is missing the customer's account number), the event will fail.
- A pending event becomes complete when the event's activity is successful. For example, if an event used to validate a notification determines the notification is valid, the event will complete. A user may manually change the status to complete if the event type indicates that manual completion is allowed.

> **NOT_SUPPORTED**
>
> For more information about a workflow event's trigger date, refer to Workflow Event Dependencies & Trigger Date.

- A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator). A user may cancel an event at will. Refer to How Are Workflow Events Canceled for more information.

The following points explain the lifecycle of workflow events of the *waiting* variety:

- *Waiting* events are initially created in the pending state.
- On a pending event's trigger date, the system executes the event. For example, if an event is used to create a "special read" field activity, on the event's trigger date, the field activity is created.
- An event's activation algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error. A user should correct the

Copyright © 2026, Oracle and/or its affiliates.

cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation program runs.

- If the activation algorithm did not cause the event to become in error, the event's status is changed to waiting while the system waits for the field activity to be performed.

> **NOT_SUPPORTED**
>
> For more information about a workflow event's trigger date, refer to Workflow Event Dependencies & Trigger Date. For more information about what an event might wait on, refer to Waiting Events And Their Waiting Process.

- A waiting event becomes complete when the system sees that the thing that it's waiting for is finished.
- A waiting event fails when the system sees that the thing that it's waiting for didn't complete successfully. For example, an event that sends a confirmation request to a service provider asking if it's OK for a customer to switch suppliers would fail if the service provider denies the request.
- A waiting event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).
- A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).

> **NOT_SUPPORTED**
>
> Refer to Workflow Processes Can Have Multiple Branches for more information about event transition in a process with multiple branches.

Workflow Event Dependencies & Trigger Date

The trigger date of most workflow events is blank when they are first created. This is because the trigger date can only be set when ALL of the preceding workflow events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a simple workflow process and its events:

Event Number	Workflow Event	Dependent On Event(s)	Trigger Date Set To X Calendar Days After Completion Of Preceding Events
10	Validate new customer notification	N/A - first event	0
20	Set up new customer and meter	10	0

Copyright © 2026, Oracle and/or its affiliates.

30	Send notification confirming new customer	20	0
40	Send welcome letter	20	0

This workflow process is meant to implement the following:

- On the first day, validate the incoming notification (the one that tells us about a new customer).
- If validation is successful, set up the new customer and their meter in the system.
- After the new customer and meter are set up, send a notification to the requester that everything has been set up. Also, send a letter to the customer.

The problem is that you don't want to execute event 20 until event 10 is complete. This is achieved by indicating event 20 is dependent on event 10. The system will only populate event 20's trigger date when event 10 is complete. Similarly, you can't set the trigger dates of events 30 and 40 unit the customer has been set up (event 20). So, when you set up a workflow event, you must indicate the dependent events. If you only want the next event to trigger X days after the completion of earlier events, you can indicate such.

> **Note**
>
> **Bottom line.** The trigger date of a workflow event is set to the current date plus X days where X is the number of calendar days defined on the workflow event. If this date is not a workday for your organization, the trigger date will be set to the next workday. If the resultant date is the current date (because X is zero), the event will be activated immediately.

> **NOT_SUPPORTED**
>
> Refer to How Are Workflow Events Completed? for information about how these events are executed.

Workflow Events May Be In Error

As explained under Workflow Event Lifecycle, when the background process WFET executes an event's activation algorithm, this algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error.

For every workflow event that's in error, a record is written to the workflow event exception table. To view the errors,

A user should correct the cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation process runs.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Errors versus Failure for information to help you differentiate between events that have failed versus those that are in error.

Some Workflow Events May Fail

Some workflow events may fail. For example:

- An event that validates an incoming notification may result in failure if the notification contains invalid information.
- An event that asks for the confirmation from a distribution company may fail if the distribution company rejects the request.

NOT_SUPPORTED

Refer to Errors versus Failure for information to help you differentiate between events that have failed versus those that are in error.

The background process that is responsible for activating events (referred to as WFET) is the process that can cause an event to fail (failure can happen during the activation algorithm on the workflow event). When an event fails, the system:

- Updates the workflow process with message number and message parameters describing the validation problem.
- Sets the status of the event to Failed.
- Cancels the workflow process and its outstanding events.
- Calls the failure algorithm defined on the event's event type.

It's important to note that some types of events can't fail and therefore don't have a failure algorithm. For example, an event that creates a field activity can't fail, neither can an event that creates a welcome letter.

NOT_SUPPORTED

Refer to Workflow Processes Can Have Multiple Branches for more information about event failure in a process with multiple branches.

Errors versus Failure

As explained under Workflow Event Lifecycle, an event's activation algorithm may cause a pending event to become in error or to fail (amongst other things). You control the exact state when you design your workflow event type activation algorithms.

Copyright © 2026, Oracle and/or its affiliates.

The main differences between these two states is as follows:

- As described under Some Workflow Events May Fail, a failed event causes the entire workflow process to fail (and it cannot be restarted).
- As described under Workflow Events May Be In Error, a user can correct the cause of an error event's error and then change the event's status back to pending. The pending event will be processed the next time the activation process runs.

You should follow the following guidelines when designing your validation logic in your workflow event activation algorithms:

- If the cause of the problem is correctable by a user, you should set the state of the event to be in error.
- If the cause of the problem is not correctable by a user (e.g., you were interfaced information that cannot be corrected by your users), you should set the state of the event to fail.

Waiting Events And Their Waiting Process

Some events have to wait until something else happens before they can be Completed (or Fail). These types of events exist in the Wait state until the thing they are waiting for happens. For example, consider an event that creates a field activity - it has to wait until the field activity is complete before it can itself Complete.

Every type of event that waits for something else to happen before it completes or fails must have a corresponding background process that monitors the thing on which the event is waiting. We refer to background processes that perform this monitoring as Waiting Processes.

There will be a Waiting Process for every type of event that has to wait for something to happen. The specific background process is defined on the workflow event type. For more information, refer to Designing Workflow Event Types.

The following points describe the responsibilities of a Waiting Process:

- Check on the thing on which the event is waiting. For example,
  - An event that creates a field activity has a Waiting Process that checks on the state of the field activity.
  - An event that creates a request to confirm a customer's request to switch suppliers has a Waiting Process that checks if the confirmation is accepted or rejected.
- Change the state of the event to Complete or Fail based on what transpired. For example,
  - When the field activity completes, the Waiting event can Complete
  - The acceptance or rejection is received, the Waiting event can Complete or Fail
- Detect that the event has been waiting too long and do something. For example, the Waiting Process could:
  - Create a To Do entry (this might be useful if you need an operator to do something)
  - or, create an outgoing notification informing the sender of the incoming notification that something is wrong
  - or, Fail / Complete the event (you may be able to automatically assume success or failure if an event waits longer than a predefined limit)

Copyright © 2026, Oracle and/or its affiliates.

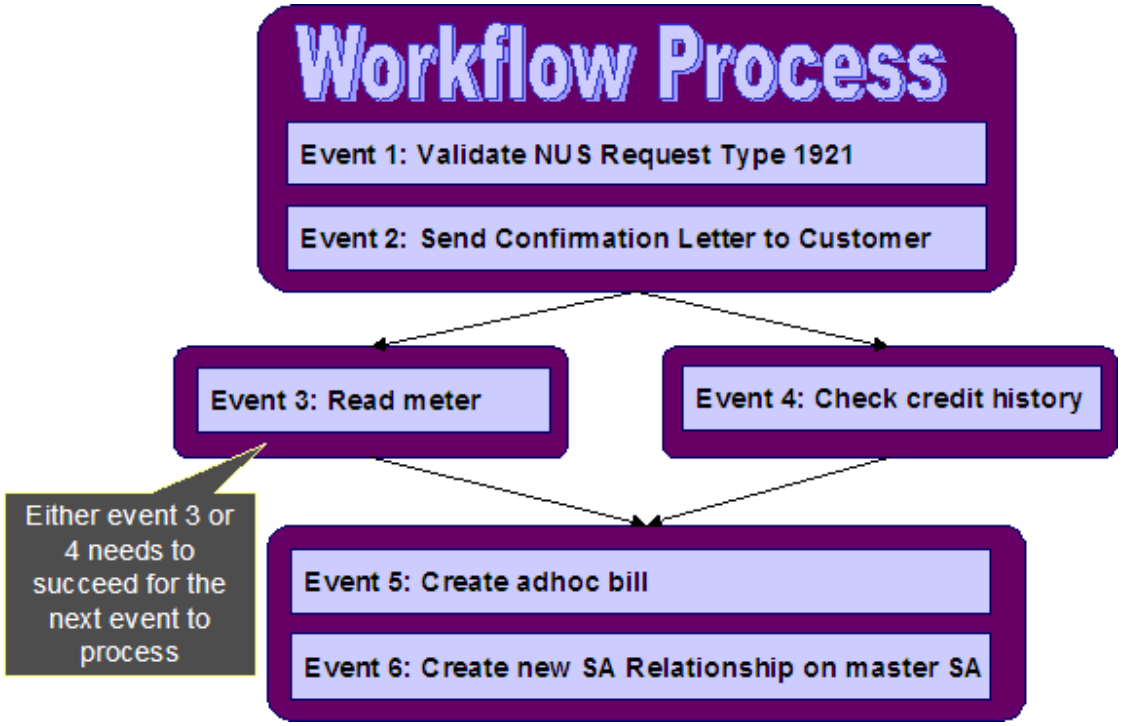
- or, execute the event again and reset the base time on the event (this might be useful if the event initiates an outgoing notification to ask permission from some other service provider - if it waits too long, you could simply create another outgoing notification)
- or, whatever else you can think of developing in the process

How Are Workflow Events Canceled?

The background process that is responsible for activating events (referred to as WFET) automatically cancels workflow events when an event fails.

A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).

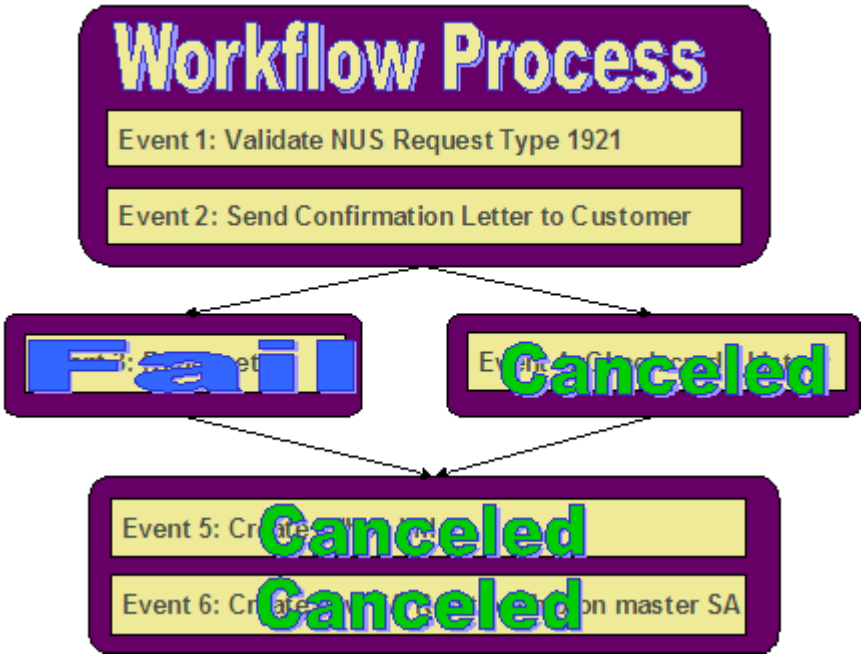
In addition, an operator may cancel a workflow event at will.



An event will be cancelled by the background process that is responsible for activating events (referred to as WFET) when it detects that ALL of its earlier, dependent events are cancelled. This is important to understand if your organization has Workflow Processes With Multiple Branches.

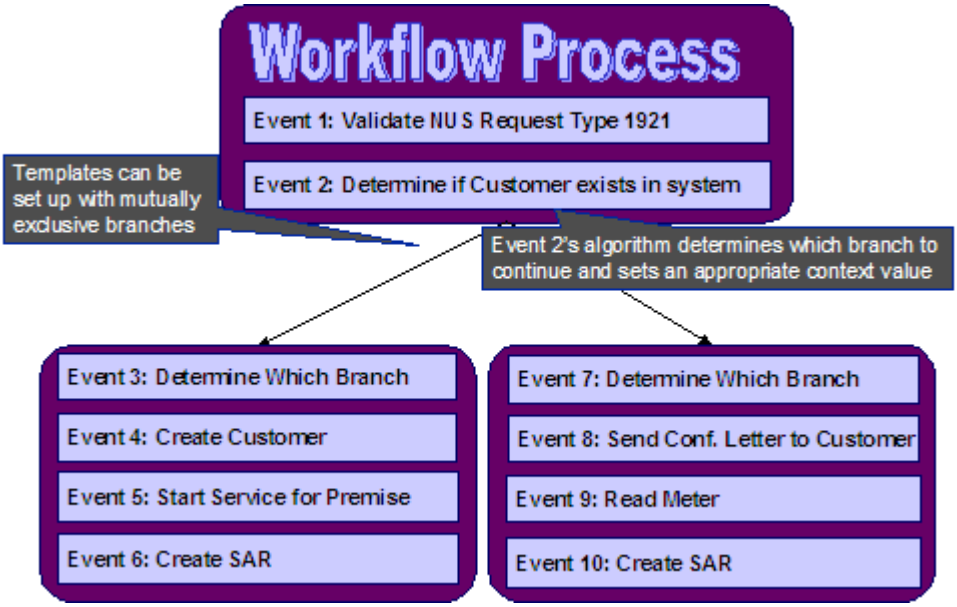
Workflow Processes Can Have Multiple Branches

Using the workflow event dependencies, a workflow process may have multiple branches. There are several reasons why you may want to set up a process to contain multiple branches:



- There may be events that can run in parallel. This is useful if the related tasks take time to execute. For example "Read Meter" and "Send Confirmation and Wait for Response". Both can be executed in parallel and event 5 will execute based on the outcome of events 3 and 4. The following is an example of such a workflow process.

Copyright © 2026, Oracle and/or its affiliates.

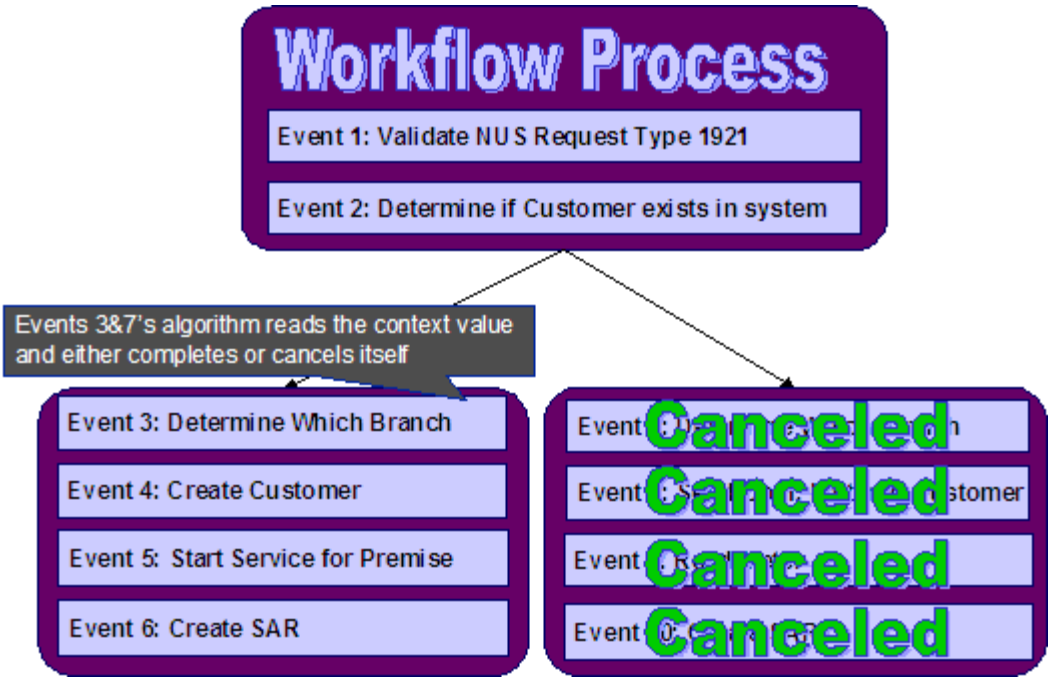


In the example above, if event 3 is canceled and event 4 completes, (or if event 4 is canceled and event 3 completes), event 5 will proceed. However, if both event 3 and event 4 are canceled, all remaining events will be canceled.

It should be noted that if either event 3 or 4 fails, ALL events in the process will be canceled, including events in a different branch.

- You may have a business process that has some common events and some events that are mutually exclusive. Rather than setting up several processes, you can set up one process that branches based on specific criteria. For example, perhaps you get to a certain point in a process that differs based on whether or not a meter is installed. If there is a meter, you follow one branch and if there is no meter, you follow a different branch.

Copyright © 2026, Oracle and/or its affiliates.



In the above example, event 2 determines if the workflow process is associated with an existing customer or a new customer.

- For a new customer; events 3, 4, 5 and 6 are executed.
- For an existing customer, events 7, 8, 9 and 10 are executed.

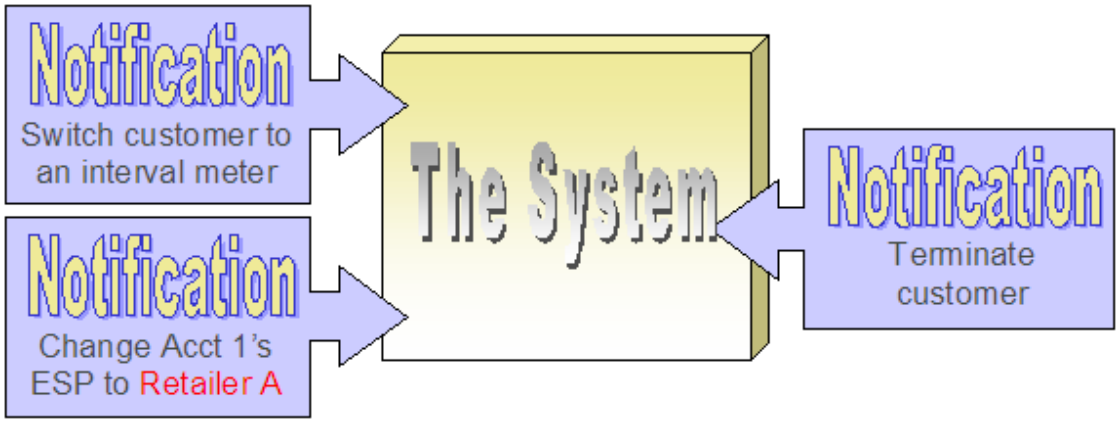
Event 2 does this by creating an entry in the Context collection indicating which branch should continue. (For example Context Type / Value of BRANCH / A). Events 3 and 7 should be special events whose purpose is to read the BRANCH context type and determine if its branch should continue or be canceled.

In this example, Event 3's algorithm will continue if the context value for BRANCH is A and Event 7 will only continue if the context value for BRANCH is B.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The above diagram and description indicates the use of context records to determine which branch to continue. If your implementation chooses to use characteristics instead, the same logic above may be implemented using characteristics as well.

The Big Picture of Notification Processing



We use the term "notification" to reference the electronic transactions that you exchange with third parties when:

- They need information about a customer.
- They need to change something about a customer.

For example, an electric service provider may send a notification to an electric distribution company when a customer elects to use them as their energy provider.

You may have to support a wide variety of notifications. For example:

- You may receive a notification that tells you to switch a customer's energy service provider to a different provider (if you are a distribution company).
- You may receive a notification that asks for the last 24 months of consumption history for a customer (if you maintain consumption).
- Etc.

When a notification is received, the system responds by creating a workflow process. The related workflow process contains workflow events and it is the events that actually do whatever needs to be done (e.g., change the customer's service provider, create field activities, stop service, etc.).

In addition to incoming notifications, the system creates outgoing notifications when:

- It needs to respond to an incoming notification. For example, if an incoming notification requests a customer's consumption history, the system must send the consumption history by creating an outgoing notification.
- It needs to apprise a third party that something has changed about the customer. For example, if a customer stops service, the system must tell the various service providers of such.

Copyright © 2026, Oracle and/or its affiliates.

The topics in this section describe how notifications are interfaced into and out of the system.

- Uploading Notifications Into The System
- What Type Of Workflow Process Is Created?
- How Are Notifications Sent Out Of The System?
- System Conditions May Trigger Notification and Workflow
- The Lifecycle of Notification Download Staging

Uploading Notifications Into The System

The following diagram illustrates the steps involved in the uploading of notifications into the system.

When a notification's electronic transaction is received, it must be inserted into the notification upload staging (NUS) table. Why? Because the system periodically looks for pending records in the NUS table and attempts to create a workflow process to implement the notification's request.

It's important to be aware that the events in a workflow process execute the notification request. To help solidify this concept, consider this - the first event in a workflow process typically validates the attributes on the NUS record.

NOT_SUPPORTED

Refer to Notification Upload Background Process for more information about the upload process.

What Type Of Workflow Process Is Created?

Given that you can receive many different types of notifications (e.g., return consumption, switch supplier, stop service), it should make sense that each type of notification upload staging (NUS) record will probably require a different type of workflow process to implement its request. The system uses the NUS record sender's external system Id and a notification upload type to determine the type of workflow process. This works as follows:

- Every external system references a workflow process profile.
- A workflow process profile defines the type of workflow process template to use to process a given notification upload type.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Different workflow processes for the same type of notification.** It's probably obvious why different notification types result in different workflow processes. You may wonder why different workflow processes would be needed by two senders who submit the same type of notification? The reason is that different senders may have different types of computer systems that handle their notification processing (or no computer system at all). For example, you may have to respond by fax to a sender who doesn't have a sophisticated computer system, whereas you may send an electronic transaction to a sender who is technically advanced. The system allows you to create different workflow process profiles for each response mechanism (e.g., sophisticated vs. fax). You then associate the appropriate workflow process with each sender.

How Are Notifications Sent Out Of The System?

In addition to processing incoming notifications from third parties, the system also sends notifications to third parties to provide them with information (and to ask them for information). It is also possible to use notifications to send information to other applications within your company.

A Notification Download Staging (NDS) record is created for every notification that is sent to the outside world. NDS records are created by workflow events (i.e., the event's activation algorithm creates a NDS record). Consider the following examples:

- Many workflow processes exist to process incoming notifications. These processes typically contain workflow events that create –NDS records to communicate with service providers. If you look at the workflow processes described under Designing Workflow Process Templates, you will see many such examples.
- When something noteworthy happens, the system may need to tell a third party about it. Or perhaps you have third party software, which contains information from the system and your company needs to keep the information in sync.

> **NOT_SUPPORTED**
>
> Refer to System Conditions May Trigger Notification and Workflow for more information about triggering notification download staging records from within the system.

System Conditions May Trigger Notification and Workflow

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Outbound Messages**. The mechanism for triggering communication to an external system described here does not take advantage of the configurable business object functionality that enables outbound messages to be triggered from a server-based script. Refer to Outbound Messages for more information about communicating with an external system using outbound messages.

There may be many noteworthy occurrences in the system, which should trigger the notification and workflow process.

Some of these occurrences may need to be communicated to an external system. Examples of when this may occur are as follows:

- You use an external software package, which uses information from the system and you need to send a message to this software package when certain attributes of the customer change.
- You need to inform third parties when something changes about a customer. For example, if you are a distribution company, you probably advise a customer's energy supply company when their meter is changed or when the customer stops. Or if a customer, who has been referred to a collection agency, makes a payment, you will need to inform the agency of the payment.

In many scenarios, you may want more than just a notification to be sent out, but you would also require a workflow process. For example, perhaps when a customer's mailing address changes, you want to a) send a confirmation letter to the customer's old address and their new address; b) inform a third party service provider about the change; and c) send the update to an external marketing system. In this case, the act of changing the mailing address could trigger a workflow process, which would perform the above steps.

You may have other scenarios where a noteworthy condition in the system should trigger a workflow process, which does not require a notification to be sent out of the system. For example, perhaps your company follows a sophisticated procedure for starting service, which requires certain events to transpire before other events can occur. You could create a workflow process, which gets triggered upon starting service to handle this sophistication.

In summary, when something occurs in the system, you may need to

- Create a notification download staging (NDS) record. You would do this if you only need to send a message to an external system.
- Create a notification upload staging (NUS) record. You would do this if you need to trigger a workflow process to do one or more steps. One of the workflow events in this process could create a NDS if an external system needs to be informed.
- Creating a Notification Download Staging Record
- Creating a Notification Upload Staging Record
- Triggering Notification & Workflow from the Application

Creating a Notification Download Staging Record

To create an NDS record directly, you need the following information:

- Service Provider (who will receive the outbound message)

Copyright © 2026, Oracle and/or its affiliates.

- NDS Type

You also need to populate relevant data using either context or characteristics. For example, if a change to a person's name should trigger an outbound message, the Person ID must be referenced.

The process that creates the NDS must determine the appropriate service provider that should receive this information based on the business rules. As for the NDS type, this is typically "hard-coded" based on what has occurred to trigger the outbound message. For example, if the customer's name changed, then the NDS Type is set to something like "Name Change".

For any NDS records automatically created by the system in sample algorithms or in system processes, the NDS type is not hard-coded. Rather, the system uses a download type condition flag value to look up the appropriate NDS type. As a result, if an implementation chooses to use these sample algorithms, but prefers to use a different NDS type, it is possible. When designing your own NDS types that are referenced by NDS records created based on system conditions, you may choose to create new download type condition flag values as well.

Refer to Designing Notification Download Types and Setting Up Notification Download Types for more information.

Creating a Notification Upload Staging Record

To create an NUS record directly, you need the following information:

- External System (to point to a service provider)
- NUS Type

You also need to populate relevant data using either context or characteristics. For example, if a change to a person's name should trigger a letter to the customer and an outbound message, the Person ID must be referenced.

The process that creates the NUS must determine the appropriate external system based on the business rules. If the steps that need to be taken as a result of this system condition are based on an internal practice, the external system could be something like "SYSTEM". That external system would reference an appropriate workflow process profile that defines the appropriate workflow process based on the NUS type.

Determining the NUS type is similar to determining the NDS type as described in the previous section.

Refer to Designing Notification Upload Types and Setting Up Notification Upload Types for more information.

Triggering Notification & Workflow from the Application

You and your implementers must determine the noteworthy events that should trigger workflow and/or outgoing notifications based on your business practice. For example, you may communicate all meter exchanges and customer address changes to the customer's various service providers.

Next, you must assess how you are going to create the appropriate records:

- Determine if there is a plug-in spot that exists where you can create an algorithm to trigger the NUS or NDS. For example, if canceling a service agreement should trigger a notification, an SA Cancel algorithm plugged in to the SA type may be used.

Copyright © 2026, Oracle and/or its affiliates.

- If there is no plug-in spot, determine if there is a user exit at the appropriate place for you to trigger the creation of an NUS or NDS
- You may also decide to use a database trigger to create the NUS or NDS

Once you have determined how and when to trigger the creation of notification records, have your implementers create the CM code to do the work.

The Lifecycle of Notification Download Staging

If a download staging record is routed to the outside world via XAI, a status is assigned to the download staging record.

Refer to Lifecycle of Notification Download Staging for more information.

Creating Notification and Workflow Procedures

A workflow process is created by copying the events defined on a workflow process template (a workflow process template contains the standard events).

> **Note**
>
> **Workflow processes can be used for any multi-event process.** While this section describes how to design workflow processes to support incoming and outgoing notifications, workflow processes can be used for other multi-step processes. For example, you can use a workflow process to manage the steps involved with the installation and inspection of backflow devices at a water service point.

The topics in this section describe how to design and setup the tables that control your notification and workflow processing.

> **NOT_SUPPORTED**
>
> For more information about notification and workflow processing, see The Big Picture Of Workflow Events and The Big Picture Of Notification Processing.

> **Warning**
>
> There are innumerable ways to design your notification and workflow procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

- Designing Notification Upload & Workflow Procedures

Designing Notification Upload & Workflow Procedures

The topics in this section describe how to design the tables that control your notification upload and workflow processing.

- Designing Workflow Process Profiles
- Designing Notification Upload Types
- Designing Workflow Process Criteria
- Designing Workflow Processes To Process Incoming Notifications
- Designing Workflow Processes To Deal With Invalid Sender or Notification Upload Type
- Designing Workflow Process Templates
- Designing Workflow Event Types
- Designing External Systems

Designing Workflow Process Profiles

The following sections describe how to design a workflow process profile. A workflow process profile controls the type of workflow process that will be created to process your incoming notifications. If you plan to use workflow processes outside of the notification upload process, you can skip to Designing Workflow Process Templates.

You associate a workflow process profile with one or more external system. Whenever a notification is received from an external system, the system uses the workflow process profile to determine the type of workflow process to create to implement the notification.

The easiest way to design a workflow process profile is to choose a representative external system and design a workflow process profile for it by filling in the matrices below. After you've designed a profile, determine how many other external systems can use it. Then design the next external system's profile and determine who can reuse it. Repeat this process until all your external systems have a profile. Once the profiles are designed, you're ready to set up the workflow control tables.

NOT_SUPPORTED

Refer to The Big Picture Of Notification Processing for more information about how workflow processes are used to implement incoming notifications.

The topics discussed below will gradually complete the following matrix using a simple case-study. We recommend that you use the following matrix as your guide. When the matrix is complete, you're ready to set up a workflow process profile.

WF Process Criteria
Notif. Upload Type

Copyright © 2026, Oracle and/or its affiliates.

Designing Notification Upload Types

You will need one notification upload type for every type of notification your organization can receive from the various service providers. To "design" your notification upload types, you document the codes used by external systems to identify the transaction types on their notification upload staging records.

We have populated the Notification Upload Type column with a few classic examples that can be received by a distribution company:

WF Process Criteria Notif. Upload Type
Retrieve a customer's consumption history
Switch a customer to a different service supplier
Switch customer to an interval meter

> **Note**
>
> It is recommended that the unique identifier of your Notification Upload Types match the "transaction types" that are referenced on incoming notifications. If it is not possible to do this, the process that creates the upload staging records must map the external transaction types to the notification upload types that you define in the system.

In addition, as described in System Conditions May Trigger Notification and Workflow, you should evaluate any condition that should cause an NUS to be created (to eventually create a workflow). A new NUS Type should be defined for each condition. For each of these, consider creating a new value for the upload condition flag so that the NUS type is not hard-coded in the system process that creates the NUS.

- Navigating to Related NUS Extension

Navigating to Related NUS Extension

When designing the types of notifications your organization may receive, you must determine where you plan to store the detailed information related to the incoming transaction: as context linked to the NUS, as characteristics linked to the NUS or by using an extension record.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Process X - Populate Notification Upload Staging for information about the different options available.

If you choose to capture the detailed information in a new extension record with a new user interface, then in order to be able to drill down to the related extension record, the following steps are required.

- Add a new lookup value for your new extension record for the field NT_UP_EXTSN_FLG. (This step is needed regardless of whether you want to drill down to the related record.)
- Add a navigation option pointing to the appropriate navigation key for your new transaction. This navigation option must reference a usage type of notification upload type.
- Indicate the appropriate lookup value and navigation option on the appropriate notification upload type.

Designing Workflow Process Criteria

The matrix's second dimension is dependent on workflow criteria algorithms. Workflow criteria are confusing. Think of them as optional conditions that, if met, will cause a different type of workflow process to be started when a given notification upload type is received.

You must define a Default criterion in case none of the override criteria are met. You MAY have override criteria if different situations result in different types of workflow processes. For example, let's assume some notification upload types have different workflow processes for industrial customers as compared to all other types of customer. This assumption necessitates the introduction of an override workflow process criteria; we'll call it Industrial Customer.

WF Process Criteria Notif. Upload Type	Default	Industrial Customer
Retrieve a customer's consumption history		
Switch a customer to a different service supplier		
Switch customer to an interval meter		

Note

The workflow process criteria are limited by your imagination (and business requirements). We have provided the workflow process criteria you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors.

New workflow process criteria may require programming. See How To Add A New Algorithm for more information.

Copyright © 2026, Oracle and/or its affiliates.

Designing Workflow Processes To Process Incoming Notifications

The next step involves populating each cell in the matrix with the workflow events that should be executed when the system receives a notification identified with a given notification upload type. If override criteria aren't relevant for a given notification upload type, we will mark the cell as "N/A".

WF Process Criteria Notif. Upload Type	Default	Industrial Customer
Retrieve a customer's consumption history	Validate notification - consumption history request Confirm requester is a valid service provider for the customer's service. Create notification download - send consumption history	N/A (meaning that industrial customers use the Default criteria)
Switch a customer to a different service supplier	Validate notification - supplier switch Confirm requester is a valid service provider for the customer's service. Check with current supplier if the switch is allowed. Switch suppliers.	N/A (meaning that industrial customers use the Default criteria)
Switch customer to an interval meter	Validate notification - change customer to an interval meter Create notification download - reject request (only industrial customers can have an interval meter)	Validate notification - change customer to an interval meter Confirm requester is a valid service provider for the customer's service. Create field activity to exchange current meter. Change rate on exchange date.

> **Note**
>
> Notice that the first event in each cell typically validates the notification upload staging record.

At this point, the matrix is complete. Before you're ready to design your workflow process templates you must design the processes described in the next section.

Designing Workflow Processes To Deal With Invalid Sender or Notification Upload Type

The system needs to know the type of workflow process to create when a notification is uploaded that does not contain a valid External System or Notification Upload Type (these two fields are the ones that control the type of workflow process that's created to process the

Copyright © 2026, Oracle and/or its affiliates.

uploaded notification). When these conditions are detected by the notification upload process, most utilities create an outgoing notification rejecting the uploaded notification when such conditions transpire. We've shown these in the following table.

Notification Condition	Workflow Process Events
Unknown Notification ID	Create notification download - reject notification, bad external system
Unknown Notification (Upload) Type	Create notification download - reject notification, bad notification upload type

> **Note**
>
> **These processes are not in a workflow process profile.** The above workflow process templates are not referenced in a workflow process profile. Rather, when you create these workflow process templates you label them with a **Notification Condition** of Unknown Notification ID or Unknown Notification Type. The notification upload process will then create workflow process when these events transpire.

Designing Workflow Process Templates

The following table shows the workflow process templates referenced in the previous section's matrix. Adjacent to each process is its events and an indication of when they are triggered.

Workflow Process Template	Event Number	Workflow Event Type	Dependent On Event(s)	Trigger Date Set To X Calendar Days After Completion Of Dependent Events
Retrieve a customer's consumption	10	Validate notification - consumption history request	N/A - first event	0
	20	Confirm requester is a valid service provider for the customer's service	10	0
	30	Create notification download - send consumption history	20	0
Switch a customer to a different service supplier	10	Validate notification - supplier switch	N/A - first event	0
	20	Confirm requester is a valid service provider for the customer's service	10	0

Copyright © 2026, Oracle and/or its affiliates.

	30	Check with current supplier if the switch is allowed	20	0
	40	Switch suppliers	30	0
Switch customer to an interval meter	10	Validate notification - interval meter switch	N/A - first event	0
	20	Confirm requester is a valid service provider for the customer's service	10	0
	30	Create field activity to exchange current meter	20	0
	40	Change rate on exchange date	30	0
Reject interval meter switch	10	Validate notification - interval meter switch	N/A - first event	0
	20	Create notification download - reject request	10	0
Reject bad notification upload type	10	Create notification download - reject request	N/A - first event	0
Reject bad external system	10	Create notification download - reject request	N/A - first event	0

Note

The workflow process for "Reject bad notification upload type" should reference the Notification Condition Unknown Notification Type. The workflow process for "Reject bad external system" should reference the Notification Condition Unknown Notification ID.

Designing Workflow Event Types

If we extract each unique event type from the above table, we end up with the following:

Workflow Event Type
Validate notification - consumption history request

Copyright © 2026, Oracle and/or its affiliates.

Confirm requester is a valid service provider for the customer's service
Create notification download - send consumption history
Validate notification - supplier switch
Current supplier confirmation
Switch supplier
Validate notification - interval meter switch
Create field activity to exchange meter
Change rate
Create notification download - reject request

Next, we have to determine the algorithm that will be used when each event is activated on its trigger date. We call this algorithm the *activation algorithm*. An activation algorithm is a stand-alone routine that does whatever you need done when an event is activated. We have populated the following table with brief descriptions of the types of activation algorithms you'd need for the above workflow events.

> **Note**
>
> **The activation algorithms are limited by your imagination (and business requirements).** We have provided the activation algorithms you see below as an example; we don't expect you'll be able to use the exact algorithms that we supply. Your algorithms will be based on any number of factors. Be aware that new activation algorithms may require programming. See How To Add A New Algorithm for more information.

Workflow Event Type	Activation Algorithm
Validate notification - consumption history request	Validate consumption history request
Confirm requester is a valid service provider for the customer's service	Confirm service provider is valid requester
Create notification download - send consumption history	Create notification download - send consumption history
Validate notification - supplier switch	Validate supplier switch request
Current supplier confirmation	Create notification download - check if it's OK to switch customer from current supplier
Switch supplier	Switch supplier
Validate notification - interval meter switch	Validate interval meter switch request
Create field activity to exchange meter	Create field activity - exchange meter
Change rate	Change rate
Create notification download - reject request	Create notification download - reject request

Next, we have to determine which types of events can fail. Refer to Some Workflow Events May Fail for background information failure. For those types of events that can fail, we will indicate their *failure algorithm* in the table. A failure algorithm is a stand-alone routine that does whatever you need none when an event fails. We have populated the following table with brief descriptions of the types of failure algorithms you'd need for the above workflow events.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The failure algorithms are limited by your imagination (and business requirements).** We have provided the failure algorithms you see below as an example; we don't expect you'll be able to use the exact algorithms that we supply. Your algorithms will be based on any number of factors. Be aware that new failure algorithms may require programming. See How To Add A New Algorithm for more information.

Workflow Event Type	Activation Algorithm	Failure Algorithm
Validate notification - consumption history request	Validate consumption history request	Create notification download - invalid request
Confirm requester is a valid service provider for the customer's service	Confirm service provider is valid requester	Create notification download - invalid requester
Create notification download - send consumption history	Create notification download - send consumption history	N/A
Validate notification - supplier switch	Validate supplier switch request	Create notification download - invalid request
Current supplier confirmation	Create notification download - check if it's OK to switch customer from current supplier	Create notification download - reject request due to supplier rejection
Switch supplier	Switch supplier	N/A
Validate notification - interval meter switch	Validate interval meter switch request	Create notification download - invalid request
Create field activity to exchange meter	Create field activity - exchange meter	N/A
Change rate	Change rate	N/A
Create notification download - reject request	Create notification download - reject request	N/A

And finally, for those events whose activation algorithm puts them into a wait state, we have to determine the waiting process that monitors the waiting events. Refer to Waiting Events And Their Waiting Process for more information about waiting.

> **Note**
>
> **The waiting processes are limited by your imagination (and business requirements).** We have provided the waiting processes you see below as an example; you may not be able to use the exact processes that we supply as your processes will be based on any number of factors. Be aware that a new waiting process will require programming.

Workflow Event Type	Activation Algorithm	Failure Algorithm	Waiting Process
Validate notification - consumption history request	Validate consumption history request	Create notification download - invalid request	N/A

Copyright © 2026, Oracle and/or its affiliates.

Confirm requester is a valid service provider for the customer's service	Confirm service provider is valid requester	Create notification download - invalid requester	N/A
Create notification download - send consumption history	Create notification download - send consumption history	N/A	N/A
Validate notification - supplier switch	Validate supplier switch request	Create notification download - invalid request	N/A
Current supplier confirmation	Create notification download - check if it's OK to switch customer from current supplier	Create notification download - reject request due to supplier rejection	Check if supplier has accepted process
Switch supplier	Switch supplier	N/A	N/A
Validate notification - interval meter switch	Validate interval meter switch request	Create notification download - invalid request	N/A
Create field activity to exchange meter	Create field activity - exchange meter	N/A	Check if field activity is complete
Change rate	Change rate	N/A	N/A
Create notification download - reject request	Create notification download - reject request	N/A	N/A

Designing External Systems

As described under What Type Of Workflow Process Is Created?, every notification upload staging (NUS) record contains an external system. An external system is the unique identifier of the sender of the notification.

To "design" your external systems, document the external id's (e.g., DUNS number) of your service providers. The following table contains a sample:

External System	Description
102910	Energy Supplier, Inc.
392191	Cheap Power, Inc.

The above example would result in 2 external systems - 102910 and 392191.

> **Note**
>
> It's obvious, but worth stressing, that the External System should be the exact number referenced on notifications sent by a sender.

Copyright © 2026, Oracle and/or its affiliates.

Designing Notification Downloads

The system creates outgoing notifications when:

- It needs to respond to an incoming notification. For example, if an incoming notification requests a customer's consumption history, the system must send the consumption history by creating an outgoing notification.
- It needs to apprise a third party that something has changed about the customer or their meter. For example, if a customer stops service, the system must tell the various service providers of such.
- It needs to exchange information with another application in the company, for example a CRM system.

A Notification Download Staging (NDS) record is created for every notification that is sent to the outside world.

The topics in this section describe how to design the tables that control your notification download processing.

- Designing Workflow Processes To Support Outgoing Notifications
- Designing Your External System Feature Configuration
- Define the Message Sender
- Designing Notif. Download Types
- Designing Notif. Download Profiles

Designing Workflow Processes To Support Outgoing Notifications

As described under How Are Notifications Sent Out Of The System? notifications are sent out via Notification Download Staging (NDS) records. NDS records are created by workflow events (i.e., the event's activation algorithm creates notification download records). There are two types of workflow processes that contain these types of workflow events:

- Many workflow processes exist to process incoming notifications. These processes typically contain workflow events that create –NDS records to communicate with service providers. If you look at the workflow processes described under Designing Workflow Process Templates, you will see many such examples.
- When something noteworthy happens, the system may need to tell a third party about it. As described in System Conditions May Trigger Notification and Workflow, you may decide that the noteworthy condition should cause a workflow process to be created where one or more of the workflow events can create an NDS. The following table shows representative workflow process templates of this type.

Workflow Process Template	Event Number	Workflow Event Type	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events

Copyright © 2026, Oracle and/or its affiliates.

Stop service	10	Create notification download - inform all parties that customer is stopping service	N/A - first event	0
Meter exchange	10	Create notification download - inform all parties that meter has been changed	N/A - first event	0

After documenting these types of workflow process templates, follow the instructions under Designing Workflow Event Types to add any new types of events to the list.

Designing Your External System Feature Configuration

For certain types of external systems, your application may define options used to configure the interaction between your product and your external system. The feature configuration table is used to define some settings applicable to the interaction with your external system, for example:

- The Options grid allows you to define information needed to communicate with the external system. For example, if you interface with an external workforce management system for booking appointments, a feature configuration for the WFM system may use an option to define whether or not the user can manually define an appointment.
- The Messages collection allows you to map each message that you may receive from the external system to a corresponding message in this system.

> **Note**
>
> **Recommendation.** We recommend creating a new message for every message that is being mapped. This ensures that changes to future base product messages do not affect the integration.

Define the Message Sender

If an of your messages are routed to an external system via XAI, the message must also be associated with an XAI Sender, which tells the system how to send the message.

> **Note**
>
> **Sender Optional**. If the NDS message does not require routing, you are not required to define a message sender.

Copyright © 2026, Oracle and/or its affiliates.

Designing Notif. Download Types

You will need one notification download type for every type of notification your organization can send to service providers. To "design" your notification download types, list:

- Every outgoing notification that you documented under Designing Workflow Event Types.
- Every outgoing notification that you documented under Designing Workflow Processes To Support Outgoing Notifications.
- Every outgoing notification that may be triggered from within the system as described in System Conditions May Trigger Notification and Workflow. For each of these, consider creating a new value for the download type condition flag so that the download type is not hard-coded in the system process that creates the NDS.

We have populated the Notification Download Type column with a few classic examples:

Notification Download Type	Download Type Condition Flag
Inform all parties that customer is stopping service	CUSTSTOP
Inform all parties that meter has been changed	METERCH
Send consumption history	
Check if it's OK to switch customer from current supplier	
Reject request	

You should also consider the priority of each NDS type with respect to the other types.

Once you know the different types of download notifications, you have to determine the physical method used to route the notification to the third party. Refer to Designing Notification Download Profiles for how to do this.

If the outbound notification may be routed via XAI, you must define an XAI inbound service. This is used by the XAI MPL to retrieve information about the record related to the outbound message.

NOT_SUPPORTED

Refer to Configuring the System for XAI Messages for more information on designing your XAI outgoing messages.

- Designing Context Values for the NDS Type
- Configuring the System for XAI Messages
- Designing Near Real Time NDS Messages

Designing Context Values for the NDS Type

A notification download staging record must reference some "relevant data" that allows the extract process or the XAI MPL process to retrieve the data needed to send to the external

Copyright © 2026, Oracle and/or its affiliates.

system. For example, if the person's name has changed, the NDS must reference the Person Id. When formatting the data to send to an external system, the appropriate process would take the person ID and retrieve the data needed to send to the external system.

The NDS may use either the context collection or the characteristics collection to enter this "relevant data". If you choose to use context, you may decide to define the context types for the NDS type (although it is not required).

If NDS records of this type are interfaced through XAI, then the context types and corresponding XPATH values are required for every piece of data that is required to call an application service to build the extract. The XPATH indicates the relative path in the XML document where the field value will be placed when building the XML document.

NOT_SUPPORTED

Refer to Configuring the System for XAI Messages for more information on designing your XAI outbound messages.

Configuring the System for XAI Messages

The following provides links so that you can easily navigate the information related to configuring the system for XAI messages:

- Designing Your Real Time Messages
- Designing the Real Time Message XSL
- Designing the Real Time Message NDS Types and Download Profile
- Designing the Real Time Message NDS Types and Download Profile
- Designing the Near Real Time Response

Designing Your Real Time Messages

Consider the following integration scenario. A page in your product is configured to send information to an external system real time. If the connection is down, the user is warned and may authorize that the message is sent in near real time. The following sections describe how to design the control tables needed for both scenarios.

Top of Page

Designing the Real Time Message XSL

During implementation, you will determine the information required to send to the external system. The real time message engine is passed all the data available in the page model as an XML document. The request XSL must be designed to map this data into a format expected by the target.

In addition, you should create two response XSLs to transform the message received from the target system.

- One XSL is used for real time responses. The XSL transforms the message into a format understood by the page service user exit. Note that any updates to a system business object as a result of the response is the responsibility of the user exit that called the real time message engine.
- One XSL is used for non-real time responses. In this case, if the response should update a system object, the response must trigger an XUS to update the system object. Therefore,

Copyright © 2026, Oracle and/or its affiliates.

the XSL must map the response into an XML request that reference the appropriate service to update the system object.

Top of Page

Designing the Real Time Message NDS Types and Download Profile

For this scenario you must create two NDS types

- One NDS type is used for the real time message. Indicate an appropriate notification download condition. This allows the mechanism that creates the NDS to refer to this condition rather than hard-coding the NDS type.
- One NDS type is used for the near real time message. This NDS type must reference a special XAI inbound service used to indicate to the download staging sender that the XDS does not need to be created.

> **Note**
>
> **Download Condition**. The real time message engine receives the NDS type as input. It is the user exit's responsibility to determine the appropriate NDS type based on a notification download condition.

You'll need to create an entry in the service provider's notification download profile for each NDS type.

Top of Page

Designing the Near Real Time Response

To process a response to the near real time message, you must also design the XAI inbound service to be used to process the response.

- The XSL transformation scripts that are referenced by the inbound service should populate the appropriate XML elements to allow XAI to recognize that the inbound message is a response.
- Otherwise, the inbound service should be designed to process this message as appropriate. For example, if the response should update the status of the record that initiated the outgoing request, the inbound service should reference the appropriate schema to update the appropriate record.

Top of Page

Designing Near Real Time NDS Messages

As described above, near real time NDS messages require you to define:

- A download staging receiver to process records on the NDS table.
- A download staging sender to process "responses" to the download staging receiver.

The following sections identify other control table design issues.

Consider the following integration scenario. A change to a certain type of record in your product should trigger a message to an external system to inform that system of the change. This will be a near real time message and we expect an asynchronous response.

Copyright © 2026, Oracle and/or its affiliates.

- Designing the XML Request and Inbound Service
- Designing the Near Real Time NDS Type
- Designing the Response

Designing the XML Request and Inbound Service

You should work with the external system to determine the information they require for this message. If a system service already exists to extract all the required information, you may use that service. However, it's possible that you would need to create a new service to extract the information you need.

Your implementers must create an appropriate service and then use the schema editor to create request and response schemas based on this service.

> **Note**
>
> **Message ID**. If you expect an asynchronous response to this message, the request and response schemas must include a private attribute to hold the MessageID.

Create an XAI inbound service for extracting the appropriate information and building the XML request.

Top of Page

Designing the Near Real Time NDS Type

Define an appropriate NDS type. The information defined here is required to successfully build the XML request.

- Indicate the XAI Inbound Service created above.
- Indicate an appropriate notification download condition. This allows the mechanism that creates the NDS to refer to this condition rather than hard-coding the NDS type.
- Use the notification download type context to identify the data required to build the request to invoke the XAI Inbound Service for this download type. In our case, context types must be defined for the business object id and the message id. Use the XPATH to indicate the relative page for this element in the request schema.

Context Type	XPATH
Maintenance Object ID	//ExtractInfoService/ ExtractInfoHeader@MaintenanceObjectID
Message ID	//ExtractInfoService/ExtractInfoHeader/ MessageID

Top of Page

Designing the Response

If you expect a response to the message sent, you must also design the XAI inbound service to be used to process the response.

- The XSL transformation scripts that are referenced by the inbound service should populate the appropriate XML elements to allow XAI to recognize that the inbound message is a response.

Copyright © 2026, Oracle and/or its affiliates.

- Otherwise, the inbound service should be designed to process this message as appropriate. For example, if the response should update the status of the record that initiated the outgoing request, the inbound service should reference the appropriate schema to update the appropriate record.

Top of Page

Designing Notif. Download Profiles

A notification download profile controls how the system routes notifications to third parties. You associate a notification download profile with one or more service providers. Whenever a notification is sent to a service provider, the system uses the notification download profile to determine the interface method and the format of notifications.

> **Note**
>
> **A notification download profile corresponds with a protocol used to route notifications to service providers.** If you electronically route all notifications using the same protocol (for example, all service providers in a given jurisdiction may conform to the same record formatting and routing method), you will have a single notification download profile. If you have to route notifications using different protocols to different providers, you will need one notification download profile per protocol.

Using the notification download profile, you can define which outgoing messages are sent as an XML document via the XAI tool and which are sent in batch format. When a message is designated as being sent via the XAI tool, then you typically define XAI routing information. If a message is designated as being sent via batch, then you must indicate the formatting algorithm used by the extract program.

> **Note**
>
> **XAI Routing Information Optional**. You may indicate that the message should be routed via XAI, but enter no XAI Routing information. You may do this when you are interfacing with one of your own external systems and where the system may be accessed directly. In this scenario, you are using the XAI functionality to communicate between systems using XML documents, but you don't need the routing logic within XAI. Refer to An NDS Message That Doesn't Require Routing for more information.

The easiest way to design a notification download profile is to choose a representative service provider and design a notification download profile for it by filling in the following matrix. After you've designed a profile, determine how many other service providers can use it. Then design the next service provider's profile and determine who can reuse it. Repeat this process until all your service providers have a profile. Once the profiles are designed, you're ready to set up the control tables.

Background Process used for batch messages	Notification Download Type	Processing Method	XAI Route Type	Format Method

Copyright © 2026, Oracle and/or its affiliates.

File Transfer	Inform all parties that customer is stopping service	Batch		Format Stop
	Inform all parties that meter has been changed	XAI	Meter Change	
	Send consumption history	Batch		Format Consumption
	Check if it's OK to switch customer from current supplier	XAI	Confirm Switch	
	Reject request	XAI	Reject	

Notice that you define the background process at the profile level, but you indicate for each download type whether it will be processed via batch or via XAI. If at least one of the processing methods is batch, then a background process must be entered, otherwise it's not applicable.

Also note that it is possible to link more than one XAI route type to each notification download type formatting method. However, this is not recommended if you expect an asynchronous response to the NDS message.

After you've designed notification download profiles to cover every protocol, you are ready to set up the control tables.

NOT_SUPPORTED

Refer to Notification Download Background Processes.

Setting Up Notification and Workflow Procedures

In the previous sections, Designing Notification Upload & Workflow Procedures and Designing Notification Downloads, we presented a case study that illustrated a mythical organization's workflow procedures. In this section, we'll explain how to set up the control tables to implement these procedures.

- Setting Up Workflow Event Types
- Setting Up Workflow Process Templates
- Setting Up Notification Upload Types
- Setting Up External Systems
- Setting Up Workflow Process Profiles
- Setting Up Notification Download Types
- Setting Up Notification Download Profiles

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Workflow Event Types

Workflow event types control what is done by a given workflow event. Open **Admin**, and then **Workflow**, and then **Workflow Event Type**, and then **Add** to define your workflow event types.

> **NOT_SUPPORTED**
>
> Refer to Designing Workflow Event Types f **or more information**.

Description of Page

Enter a unique **Workflow Event Type** and **Description** for the event type.

Turn on **Allow Manual Completion** if an operator is allowed to change the status of workflow events of this type to Complete.

The **Event Activation Algorithm** is used by the system when it activates a workflow event of this type. Refer to Executing Workflow Events On Their Trigger Date and Designing Workflow Event Types for more information. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with workflow event activation. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

The **Event Failure Algorithm** is used by the system when a workflow event of this type fails. This algorithm need only be defined if events of this type can fail. Refer to Some Workflow Events May Fail and Designing Workflow Event Types for more information. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with workflow event failure. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

The **Wait Process** is the background process responsible for monitoring workflow events of this type that are in the Waiting state. Refer to Waiting Events And Their Waiting Process for more information.

Setting Up Workflow Process Templates

A workflow process template defines the workflow events that will be created when a workflow process is created using a template.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Designing Workflow Process Templates **for more information**.

- Workflow Process Template - Main
- Workflow Process Template - Template Tree

Workflow Process Template - Main

Open **Admin**, and then **Workflow**, and then **Workflow Process Template**, and then **Add** to define your workflow process templates.

Description of Page

Enter a unique **Workflow Process Template** code and **Description** for the workflow process template.

The system needs to know the type of workflow process to create when a notification is uploaded that does not contain a valid External System or Notification Upload Type (these two fields are the ones that control the type of workflow process that's created to process the uploaded notification). If you create workflow process templates and label them with a **Notification Condition** of Unknown Notification ID or Unknown Notification Type, the notification upload process will create a respective workflow process when either of the above conditions are discovered. Note: most utilities create an outgoing notification rejecting the uploaded notification when such conditions transpire. The notification condition field is also available for use by your plug-in algorithms for any purpose where you need to identify a specific workflow process.

Note

The values for this field are customizable using the Lookup table. This field name is WF_PROC_COND_FLG.

Use **Comments.** to describe the workflow process template.

When a workflow process is created, the system links one or more workflow events to it. The information in the **Workflow Responses** scroll defines these events and when they will be triggered. The following fields are required for each event:

Event Sequence. Sequence controls the order in which the workflow events are executed. The sequence number is system-assigned and cannot be changed. If you have to insert a workflow event between two existing events, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Workflow Event Type. Specify the type of workflow event to be generated. The event type's description is displayed adjacent.

Dependent on Other Events. Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. Refer to Workflow Event Dependencies & Trigger Date for more information. If this switch is on, you must define the events on which this response depends in the **Dependent on Other Events** grid.

Copyright © 2026, Oracle and/or its affiliates.

Days After Previous Response. Specify the number of calendar days after the completion of the dependent events on which the workflow event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of calendar days after the creation of the workflow process that the related workflow event will be triggered.

When the **Dependent on Other Events** switch is on, a grid appears in which you specify the events on which this event is dependent. The following fields are required for each event:

Sequence. Sequence is system-assigned and cannot be specified or changed.

Dependent on Sequence. Specify the sequence number of the workflow event type on which the above workflow event depends.

Workflow Event Type. The system displays the ID of dependent workflow event in this column.

> **NOT_SUPPORTED**
>
> For more information about workflow event templates, see Setting Up Workflow Event Types. For more information about trigger dates, see Workflow Event Dependencies & Trigger Date.

Where Used

A Workflow Process Profile references one or more workflow process templates. Refer to Setting Up Workflow Process Profiles for more information.

A Workflow Process references a workflow process template. Refer to Workflow Process - Main for more information.

Workflow Process Template - Template Tree

Open **Admin**, and then **Workflow**, and then **Workflow Process Template**, and then **Search** and navigate to the **Template Tree** page to view information about your workflow process template.

Description of Page

This page is dedicated to a tree that shows the events linked to the workflow process and information about the event dependencies. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Setting Up Notification Upload Types

Every notification upload staging record has a notification upload type. This code is one of several fields that control the type of workflow process used to process the incoming notification. Open **Admin**, and then **Integration**, and then **Notification Upload Type** to define your notification upload types.

Copyright © 2026, Oracle and/or its affiliates.

> **NOT_SUPPORTED**
>
> Refer to Designing Notification Upload Types f **or more information**.

Description of Page

Enter a recognizable **Notification Upload Type** and **Description**.

Enter a value for the **Upload Condition Flag** when a system condition should trigger the creation of a notification record. Refer to System Conditions May Trigger Notification and Workflow for more information.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is NT_UP_TY_COND_FLG.

If NUS records of this type will be associated with an **Extension** record, indicate the extension here along with its **Navigation Option** to allow a user to navigate to the correct extension record when viewing the notification upload staging record. Refer to Navigating to Related NUS Extension for more information.

Where Used

A Notification Upload Staging record must reference a notification upload type.

A Workflow Process Profile references one or more notification upload types.

Setting Up External Systems

Every notification upload staging record references the system that sent the message. The external system is one of several fields that control the type of workflow process used to process the incoming notification. Refer to External Systems for more information.

Setting Up Workflow Process Profiles

The system uses a workflow process profile to determine the type of workflow process to create for incoming notifications sent by the service provider. A workflow process profile is associated with one or more service providers. Open **Admin**, and then **Workflow**, and then **Workflow Process Profile**, and then **Add** to define your workflow process profiles.

> **NOT_SUPPORTED**
>
> Refer to Designing Workflow Process Profiles **f or more information**.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

Define a unique ID and **Description** for each workflow **Process Profile**.

The information in the grid defines the type of workflow process that will be created for each **Notification Upload Type**. The type of workflow process may differ depending on special criteria. For example, you may have a different workflow process if the customer is industrial (as compared to commercial and residential). You must define Default criteria in case none of the override criteria are met (the Default criteria should have the lowest priority). You MAY have override criteria if different situations result in different types of workflow processes.

The following fields are required for each criterion:

Priority The priority controls the order in which the system determines if the respective workflow process should be used to process notifications of a given type. Higher priorities are checked before lower priorities.

> **Note**
>
> The values for this field are customizable using the Lookup table.

Criteria Algorithm Select the algorithm to be used to check if the workflow process should be initiated for notifications of a given type. If a condition is met, a workflow process is created using the associated workflow process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines if an incoming notification should be processed using the associated **Workflow Process Template**. The system comes supplied with a sample algorithm type called that should be used as a sample if you have to write a new algorithm type.

> **Important**
>
> You must have at least one entry in this collection otherwise the system will not start a workflow process when an incoming notification of this type is received. This entry should have the lowest priority code and should reference a **Criteria Algorithm** that references the default workflow criteria algorithm type.

Workflow Process Template Specify the workflow process template to use to process incoming notifications identified with the notification upload type.

> **NOT_SUPPORTED**
>
> Refer to Designing Workflow Process Criteria for more information.

Setting Up Notification Download Types

Copyright © 2026, Oracle and/or its affiliates.

Every notification download staging record has a notification download type. This code controls the format of the record that is sent to a service provider. Open **Admin**, and then **Integration**, and then **Notification Download Type** to define your notification download types.

> **NOT_SUPPORTED**
>
> Refer to Designing Notification Download Types f **or more information**.

- Notification Download Type - Main
- Notification Download Type - Context

Notification Download Type - Main

Every notification download staging record has a notification download type. This code controls the format of the record that is sent to a service provider. Open **Admin**, and then **Notification Download Type** to define your notification download types.

Description of Page

Enter a unique **Notification Download Type** and **Description.**

Specify the **XAI In Service Name** that will be called for this NDS type if the download profile formatting method indicates that this download type will be processed by XAI.

Enter a value for the **Download Type Condition Flag** when a system condition should trigger the creation of a notification record. Refer to System Conditions May Trigger Notification and Workflow for more information.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is NT_DWN_TY_COND_FLG.

Indicate the relative **Priority** for processing NDS records of this type with respect to other types. This value defaults to Priority 90 - Lowest.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is NT_DWN_TY_PRIO_FLG.

Notification Download Type - Context

If the notification download staging record is communicated to the external system through XAI, the NDS context is used to help build the XML document.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

The context collection functionality allows you to define a collection of **Context Types** that should be defined for a notification download staging record of this type. When the NDS record is created, with its collection of these Context Types, the Context Values would correspond to system data related to this NDS record. In addition, you may specify a **Context Value** if this is a constant value for NDS records of this type.

The **XPATH** is used by XAI NDS Types. For each context type, use the XPATH to indicate the relative path in the XML document where the field value will be placed when building the XML document.

Where Used

A Notification Download Staging record must reference a notification download type. Refer to Process X - Populate Notification Upload Staging for more information.

A Notification Download Profile references one or more notification download types. Refer to Setting Up Notification Download Profiles for more information.

Setting Up Notification Download Profiles

A notification download profile controls how the system routes notifications to service providers. You associate a notification download profile with one or more service providers. Whenever a notification is sent to a service provider, the system uses the notification download profile to determine the interface method and the format of notifications.

Open **Admin**, and then **Notification Download Profile**, and then **Add** to define your notification download profiles.

> **NOT_SUPPORTED**
>
> Refer to Designing Notification Download Profiles for more information.

Description of Page

Define a unique ID and **Description** for each **Download Profile**.

Use **NDS Extract Process** to define the background process that creates notification download records and interfaces them out of the system.

The information in the scroll controls how the **Extract Process** formats an interface record for each **Notification Download Type**. In addition to defining a **Description** and **Comments**, you must define the **Processing Method**.

If your processing method is Batch, you need to define the **Notification Format Algorithm** that actually formats the interface record. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that is associated with workflow event failure. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

Copyright © 2026, Oracle and/or its affiliates.

Defining Umbrella Agreement Options

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

> **Note**
>
> **Separately module.** The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

- The Big Picture Of Umbrella Agreements
- Setting Up Umbrella Agreement Options
- Umbrella Agreements Configuration Examples

The Big Picture Of Umbrella Agreements

The topics in this section provide background information about how to configure the system to support your umbrella agreement requirements.

- Renewable Umbrella Agreements
- Terms Of Service Covered Entities

Renewable Umbrella Agreements

When defining your umbrella agreement types, you must determine if umbrella agreements of this type are renewable. If so, you must set the renewal flag on the UA type to Renewable and determine the number of days prior to the end date of the umbrella agreement that the renewal process should start.

In addition, you must decide on your renewal procedure and design an appropriate renewal algorithm. You may use one of the sample renewal algorithms provided by the system.

Copyright © 2026, Oracle and/or its affiliates.

- The sample algorithm URNW-TD creates a To Do entry. Using this algorithm you can direct the To Do entry to an appropriate role to determine if the umbrella agreement should be renewed. If the umbrella agreement is associated with an account management group, the To Do entry could be assigned to a role defined for that AMG.
- The sample algorithm URNW-CA creates a case. Using this algorithm you can create an appropriate case to help track the steps required for renewing an umbrella agreement.

If the base algorithms do not provide the logic your organization needs, you may create a new algorithm.

> **Note**
>
> It is the responsibility of the renewal algorithm to change the renewal date as per the business requirements. If renewal requires manual review, the algorithm should reset the date to blank. If the algorithm can determine a new renewal date, the date should be changed to the appropriate value.

Terms Of Service Covered Entities

For each terms of service type you design, consider whether or not a TOS created for this type should reference one or more entities in the system that are "covered" by the terms of service. Following are some examples of covered entities:

- A special contract is created for all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement used for this contract, you want the user to link the person record representing the McDonalds corporate entity as a covered entity for the TOS.
- An umbrella agreement is created for a large customer with several types of services. Perhaps you want to group the services in the contract based on type of service. The service type may be set up as a covered entity.

The covered entities could also be used to denote eligibility. Refer to Linking To A UA For A Group Of Premises for an example of using the covered entity collection for eligibility.

The covered entities are actually characteristics. You must define the desired characteristic types if they do not already exist. In this case, they would be foreign key characteristic types. The characteristic types that you want to use must reference a characteristic entity of TOS covered entity.

A terms of service record may only reference covered entity types that you designate on the Terms of Service type record. When designing the covered entities that are allowed for TOS records of a given type, you may also configure the Terms of Service type to indicate that one or more covered entity types are required.

Refer to Terms Of Service Type - Main for more information.

Setting Up Umbrella Agreement Options

The topics in this section describe how to set up umbrella agreement options.

- Configure SA Types for Umbrella Agreements

Copyright © 2026, Oracle and/or its affiliates.

- Configure Bill Factors for Umbrella Agreements
- Configure A Campaign To Link An SA To A Terms Of Service
- Setting Up Umbrella Agreement Types
- Setting Up Terms Of Service Types
- Setting Up Terms of Service Cancel Reasons

Configure SA Types for Umbrella Agreements

For each type of service agreement that may be linked to a terms of service record, you must configure the Rate Source for the SA type to indicate if the rate should always be taken from the service agreement (Check SA Only) or if the rate should be taken from the terms of service record for the service agreement, if any (Check TOS First, then SA).

NOT_SUPPORTED

Refer to Overriding Rate Terms for more information.

Note

The rate source is only visible on SA type if the Contract Management module is not turned off.

Configure Bill Factors for Umbrella Agreements

For each bill factor that has a value in contract term, contract rider applicability or tax exemption applicability, you must indicate where the system should look for a value when a service agreement is linked to a terms of service with a template SA and where this bill factor is referenced by the rate being applied. Using the terms of service usage flag, tell the system to Check TOS Only, Check SA Only or Check TOS First, then SA.

NOT_SUPPORTED

Refer to Overriding Rate Terms for more information.

Note

The terms of service usage flag is only visible on bill factor if the Contract Management module is not turned off.

Copyright © 2026, Oracle and/or its affiliates.

Configure A Campaign To Link An SA To A Terms Of Service

The system provides a pair of column reference algorithm types that support linking a new service agreement to an existing terms of service record via an order. The pair includes a validation algorithm type CRVL-SATOS and a posting algorithm type CRPS-SATOS.

In order to take advantage of this functionality, you must:

- Create an algorithm for each of the above algorithm types. Only one algorithm is needed for each algorithm type because there are no parameters for either one.
- Setup a unique column reference for the terms of service ID column reference code and plug in the new validation and posting algorithms on the record.
- For campaigns whose orders link a new service agreement to an existing umbrella agreement, make sure to define a miscellaneous field for the terms of service ID. Note, the miscellaneous field must reference the column reference that you setup above.

Based on your business practice, you may want to further configure your campaign / package for linking a service agreement to an existing terms of service. Refer to Linking A Service Agreement To A TOS Through Orders for more information.

Setting Up Umbrella Agreement Types

The umbrella agreement type transaction is used to maintain your UA types. The topics in this section describe how to use this transaction.

- Umbrella Agreement Type - Main
- Umbrella Agreement Type - Algorithms

Umbrella Agreement Type - Main

Open **Admin**, and then **Umbrella Agreement**, and then **Umbrella Agreement Type**, and then **Add** to define basic information about an umbrella agreement type.

Description of Page

Enter a unique **Umbrella Agreement Type** code and **Description** for the UA type.

Use **Renewal** to indicate whether an umbrella agreement of this type is Renewable or Not Renewable. For renewable UA types, indicate the **Renewal Days Before Expiration**. The renewal date for umbrella agreements of this type are calculated based on this number of days before the end date.

Use the characteristics collection to define characteristics that can be defined for umbrella agreements of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on umbrella agreements of a given type. Turn on the **Default** switch to default the **Characteristic Type** when umbrella agreements of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible on an umbrella agreement record. Refer to *Setting Up Characteristic Types & Their Values* for more information.

Enter the valid **Terms of Service Type**s that may be referenced for umbrella agreements of this type.

Umbrella Agreement Type - Algorithms

Open **Admin**, and then **Umbrella Agreement**, and then **Umbrella Agreement Type**, and then **Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Description
UA Renewal	Algorithms of this type are executed by the UARENEW background process when an umbrella agreement has reached its renewal date. Only one renewal algorithm is allowed for a given UA type.

Setting Up Terms Of Service Types

The terms of service type transaction is used to maintain your Terms of Service types. The topics in this section describe how to use this transaction.

- Terms Of Service Type - Main
- Terms Of Service Type - UA Types

Terms Of Service Type - Main

Open **Admin**, and then **Umbrella Agreement**, and then **Terms of Service Type**, and then **Add** to define basic information about terms of service types.

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Enter a unique **Terms of Service Type** code and **Description** for the TOS type.

Use **Template SA Usage** to indicate whether a template SA is Optional, Required or Not Allowed. Refer to Overriding Rate Terms for more information about using template SAs.

Use the characteristics collection to define characteristics that can be defined for terms of service records of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on terms of service records of a given type. Turn on the **Default** switch to default the **Characteristic Type** when terms of service records of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible on a terms of service record. Refer to *Setting` Up Characteristic Types & Their Values* for more information.

Use the **Covered Entities** collection to define the types of entities that are "covered" by terms of service records of this type. Refer to Terms Of Service Covered Entities for more information

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible for TOS covered entity. Refer to *Setting Up Characteristic Types & Their Values* for more information.

Terms Of Service Type - UA Types

Open **Admin**, and then **Umbrella Agreement**, and then **Terms of Service Type**, and then **Add** and navigate to the **UA Types** page.

Description of Page

Enter the valid **Umbrella Agreement Type**s that may reference this terms of service type.

Setting Up Terms of Service Cancel Reasons

Whenever a terms of service record is canceled, a cancel reason must be specified. Open **Admin**, and then **Terms of Service Cancel Reason** to specify such cancellation reasons.

Description of Page

Enter an easily recognizable **Terms of Service Cancel Reason** and **Description** for the terms of service cancellation reason.

Copyright © 2026, Oracle and/or its affiliates.

Umbrella Agreements Configuration Examples

This section provides examples of how you would configure the system to support various business scenarios.

- Linking A Service Agreement To A TOS Through Orders

Linking A Service Agreement To A TOS Through Orders

As described in Configure A Campaign To Link An SA To A Terms Of Service, the system has provided a pair of column reference algorithms to enable your users to link a new service agreement to an existing terms of service record (and its umbrella agreement) when starting service via the order transaction.

When designing your campaign and packages to use this option, consider the scenarios where you may use this to determine whether or not you require additional configuration. The following topics describe some possible scenarios.

- Linking To A UA For A Given Account
- Linking To A UA For A Group Of Premises

Linking To A UA For A Given Account

Imagine that you would use this logic when an important customer is starting additional service and has an existing umbrella agreement for other services that the new service should be added to. The user creating the order is probably the account manager for that account and would know the correct terms of service record to link the new service to.

For this scenario, you do not need to provide any "help" to the user to indicate that linking to a TOS is an option or to help select the correct TOS. You simply need to ensure that the campaign that would be used by this account manager to start service for the important customer simply includes a question / miscellaneous field to link the SA to the terms of service.

Linking To A UA For A Group Of Premises

Imagine you have created an umbrella agreement for a group of premises that are not actively managed by a specific user. For example, perhaps there are several apartment complexes that have negotiated a special rate with your company. When new customers sign up for service at a premise that belongs to one of these apartments, the user should be informed that there is a special contract for this premise. The user may also need help selecting the correct terms of service record. To accomplish this logic, you must define additional algorithms to help your users.

For example, perhaps your standard campaign for residential electric customers includes a package to be used by premises linked to one of these apartment buildings and should only be eligible to one of those premises. You must create an eligibility algorithm for this package. Its logic could be designed based on the following assumptions:

Copyright © 2026, Oracle and/or its affiliates.

- The qualifying premises are linked to a parent premise
- The parent premise is linked to the appropriate terms of service record in its covered entity collection

The eligibility algorithm checks to see if the order's premise is linked to a parent premise that is referenced on a terms of service record for an umbrella agreement that is currently in effect. It could also be restricted to search for a specific umbrella agreement type or terms of service type if appropriate.

> **Note**
>
> The campaign for this scenario must include a question / miscellaneous field to link the SA to the terms of service. It should be configured with an applicability of only applicable on package. The package that is used to include the SA into the terms of service for the apartment complex would include this question / miscellaneous field.

Once the user chooses this package, user is prompted to provide the correct terms of service record via the question / miscellaneous field. To help the user, you should create a column reference retrieval algorithm to default the correct terms of service record for this premise. It would use the same logic as the eligibility algorithm described above. In other words, it would find the parent premise for this premise and then find the terms of service record covered entity collection includes this parent premise and whose umbrella agreement is currently in effect.

Reports Addendum

This chapter is an addendum to the general Defining and Designing Reports chapter.

- Configuring the System to Invoke Oracle Analytics Publisher Enterprise Real-Time
- Configuring the System for Batch Bill Print
- Description of Sample Reports

Configuring the System to Invoke Oracle Analytics Publisher Enterprise Real-Time

In order to invoke Oracle Analytics Publisher Enterprise from within the system, it must be configured. This topic describes the steps at a high level that are required to configure your system to enable BI Publisher.

- Specify Reporting Tool Options
- Reporting Tool Algorithm
- Interface with Oracle Analytics Publisher Enterprise Batch Scheduler

Specify Reporting Tool Options

The following information should be defined on Reporting Tool Options table:

Copyright © 2026, Oracle and/or its affiliates.

- **Reporting Server** is the web server URL where the reporting tool is installed.
- **Reporting Folder** defines the name of the directory on the Oracle BI Publisher server where reports are located. The system's reporting tool algorithm constructs the URL to open Oracle Analytics Publisher Enterprise based on the information provided on Reporting Options. The same folder name should be used as a report folder in Oracle Analytics Publisher Enterprise where reports are published.

Reporting Tool Algorithm

The base product provides an installation algorithm plug-in spot called Reporting Tool. This plug- in spot should contain an algorithm that invokes the reporting tool real-time. The corresponding algorithm type, called algorithm reference: F1-BIPR-INV, invokes Oracle Analytics Publisher Enterprise.

This algorithm relies on information defined in the Reporting Options table: the reporting server and folder names for accessing the reporting tool. The algorithm constructs several strings, for example, the URL of the Analytics Publisher, information about the report being requested and user info in the format expected by Oracle Analytics Publisher Enterprise. The Java program returns the correct URL to the browser. The browser then opens an Analytics Publisher Enterprise window with the appropriate URL.

To use the algorithm reference: F1-BIPR-INV algorithm type to invoke Oracle Analytics Publisher Enterprise, perform the following steps:

1. Create an algorithm for this algorithm type.
2. In the installation options, add an entry to the algorithm collection with an algorithm entity of Reporting Tool and indicate the algorithm created in the previous step.

Interface with Oracle Analytics Publisher Enterprise Batch Scheduler

Presently the base product does not provide support for batch jobs with Oracle Analytics Publisher. Please use Oracle Analytics Publisher directly in order to schedule reports to run in batch.

Configuring the System for Batch Bill Print

This section describes the steps for configuring the applications to print bills in batch.

- Configure Oracle BI Publisher for Batch Bill Print
- Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

Configure Oracle BI Publisher for Batch Bill Print

> **Note**
>
> Using BI Publisher for bill print is only supported with on-premises implementations. Cloud service implementations must use a 3rd party bill print system.

1. Configure the Oracle BI Publisher Scheduler to allow report job submission.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Refer to the Oracle Fusion Middleware Administrator's Guide for Oracle Business Intelligence Publisher for more information.

2. Ensure that the CI_BILLPR report artifacts (CI_BILLPR.rtf, CI_BILLPR.xdo, CI_BILLPR.xdm) are deployed to corresponding BI Publisher catalog folder:

Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

1. Go to **Admin**, and then **Reporting**, and then **Reporting Options** and configure the following values:
   - **Reporting Server from Browser** should point to the correct BI Publisher Server URL; for example, `http://<hostname>:port`
   - **Reporting Folder** is the name as the Catalog Folder in BI Publisher where CI_BILLPR is located; for example, CCB
   - **Reporting Engine User ID** is the BI Publisher User ID.
   - **Reporting Engine Password** is the BI Publisher Password.
2. Create a custom Bill Route Type Extract Algorithm using the C1-BLEX-BIP Algorithm Type. Ensure that the following algorithm soft parameters are set:
   - **Output Directory** is the directory in BI Publisher server where the generated output files will be placed, for example. `/tmp/`
   - **Report Absolute Path** is the path where CI_BILLPR.xdo is located in the BI Publisher Catalog, for example, `/CCB/CI_BILLPR/CI_BILLPR.xdo`
   - **Report Format** is the format of the generated output files; for example, `pdf`
   - **Report Code** is the CI_BILLPR report code; for example, CI_BILLPR
3. **Go to Admin Menu, B, Bill Route Type** and configure the corresponding Bill Route Type (such as, POSTAL) to use the RTTYPOST Batch Control and the custom Bill Route Type Extract Algorithm.

Description of Sample Reports

This section provides an overview of each sample report supplied with Oracle Utilities Customer Care and Billing that may be found in the demonstration database. They may be used by your organization as they are or as a starting point for creating a new report.

> **Note**
>
> **Account Security**. The sample reports provided with the product do NOT incorporate account security. If a user has been given security to view the report, then all the data in the report is available for viewing.

- Vacant Premises with Consumption - CI_VACANT

Active Severance Processes - CI_ACSVPR

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01.
End Date	P_TO_DT	End date to use for reporting active severance processes. If not defined to date is set to the current date.

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR

> **Note**
>
> Using BI Publisher for bill print is only supported with on-premises implementations. Cloud service implementations must use a 3rd party bill print system.

Parameters

Parameter	Parameter Code	Description
CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'.
First Bill	**P_FROM_BILL_ID**	First Bill Id to print for the Bill Range.
Last Bill	**P_TO_BILL_ID**	Last Bill Id to print for the Bill Range.

Copyright © 2026, Oracle and/or its affiliates.

Batch Code	**P_BATCH_CD**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected.
Batch Number	**P_BATCH_NBR**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected.
Extract Algorithm	**P_EXTRACT_ALG**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected.

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

- Bill Information
- Bill Segment Information

Billed Revenues by Rate - CI_BILREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.

Copyright © 2026, Oracle and/or its affiliates.

Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.

Copyright © 2026, Oracle and/or its affiliates.

End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Condition (Open, Closed)	P_COND_FLG	If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases.

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)

2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Case Statistics for a Given Status - CI_CSESGS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type/Status	P_CASE_STATUS_CD	This is the desired Case Type and Status that will be reported on.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting.

Copyright © 2026, Oracle and/or its affiliates.

Second Bucket High Limit	P_B2_LIMIT	Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Collection Summary - CI_CLLSUM

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	If from date is not set, the default is one month prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user, it is set to one month after the current date

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days.
End Date	P_TO_DT	End date to use for reporting customer contacts. If not defined, End Date is set to the current date.
Customer Contact Class / Type	P_CC_TYPE_CD	Specify a Customer Contact Class / Type to restrict the report output to a specific class / type.

Report Description

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

Parameter	Parameter Code	Description
Service Type	P_SERVICE_TYPE	Service type used to restrict the report to premises with services of this type.

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

Copyright © 2026, Oracle and/or its affiliates.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

> **Note**
>
> If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

Field Order Print in BI Publisher- CI_FOPRNT

> **Note**
>
> Field Order Print in batch for BI Publisher is not supported yet.

Parameters

Parameter	Parameter Code	Description
CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single FO print, Batch Switch is 'No' and for multiple FO print, Batch Switch is 'Yes'.
First FO	P_FROM_FO_ID	First FO ID to print for the FO Range.
Last FO	P_TO_FO_ID	Last FO ID to print for the FO Range.
Batch Code	P_BATCH_CD	Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch code are selected.
Batch Number	P_BATCH_NBR	Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch number are selected.
Extract Algorithm	P_EXTRACT_ALG	Passed in by the system the report is submitted in batch. Only field orders whose dispatch groups reference this FO extract algorithm are selected.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This report is used with BI Publisher to display the Field Order information for the field order ID entered in the input parameters. Refer to the description of the parameters above. The field order will only be displayed if the field order's status is dispatched.

The following sections highlight the data that is extracted for this report.

GL Accounting Summary - CI_GLACSM

Parameters

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report.

Report Description

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

> **Note**
>
> Generating letters in batch is not supported yet.

Parameters

Parameter	Parameter Code	Description
Batch Switch	P_BATCH_SW	For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'.

Copyright © 2026, Oracle and/or its affiliates.

Customer Contact	P_CC_ID	References the customer contact associated with the main customer linked to the account.

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the installation options. The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the installation options.

%2 is Person Id stored on the Customer Contact.

Meter Reads Performance - CI_MTREAD

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.

Report Description

This report selects bill segments for the input accounting period and displays the total number of read meters and unread meters for these bill segments grouped by route type.

Meters that are considered read are meters whose register reads have a status of Regular or Verified . Meters that are considered unread are meters whose register reads have a status of System Estimate, Office Estimate, System Prorate or Billing Force.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Open Cases By Type - CI_CSEOPN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type	P_CASE_TYPE_CD	If specified, only cases of this type are included in the report.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user it is set to the current date

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Receivables Aging - CI_RCVAGA

Parameters

Parameter	Parameter Code	Description
Cutoff Date	P_CUTOFF_DATE	The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days.
First Bucket High Limit	P_B1_LIMIT	High limit of first bucket.
Second Bucket High Limit	P_B2_LIMIT	High limit of second bucket.
Third Bucket High Limit	P_B3_LIMIT	High limit of third bucket.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days.
End Date	P_TO_DT	Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_TAX_ACCTY_CHAR	Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

Parameter	Parameter Code	Description
ToDo Entry Status	P_ENTRY_STATUS_FLG	Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and assigned To Do entries.
ToDo Type	P_TD_TYPE_CD	Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or assigned entry.

Report Description

The report shows open and assigned To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or assigned). If you don't specify a status, all open and assigned To Do entries will appear on this report.

Copyright © 2026, Oracle and/or its affiliates.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / assigned state will appear on this report.

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm RPTV-UASUMM to check these conditions.

Parameter	Parameter Code	Description
Umbrella Agreement	P_UA_ID	Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed.
Account Management Group	P_AMG	Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group.
Umbrella Agreement Characteristic Type	P_CHAR_TYPE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4).
Umbrella Agreement Characteristic Value	P_CHAR_VALUE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value.
Number of Days Before Expiration	P_EXPIRE_IN_X_DAYS	Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration.

Report Description

This report provides summary information about one or more umbrella agreements.

Copyright © 2026, Oracle and/or its affiliates.

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

Copyright © 2026, Oracle and/or its affiliates.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

The estimate for the unbilled portion is calculated as (Bill Amount / Number of Days in the Bill Period) * Number of Unbilled Days for the Accounting Period.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for $150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as 150/31*21 = $101.61.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Vacant Premises with Consumption - CI_VACANT

Report Description

This report shows all premises that are considered vacant, and provides information about the level of consumption, the period of vacancy, and the service point and register information.

This report selects service points that are linked to a service agreement that is either canceled or closed. The report excludes any service points that have never been linked to a service agreement. If consumption has been registered at such a service point since the end date of the service agreement, the service point's details are displayed.

Copyright © 2026, Oracle and/or its affiliates.

This report may be used by the utility to investigate sites where problems such as service theft or leakage may be occurring.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_SA_SP on STOP_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any effect on the production environment.

Active Severance Processes - CI_ACSVPR

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01.
End Date	P_TO_DT	End date to use for reporting active severance processes. If not defined to date is set to the current date.

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR

> **Note**
>
> Using BI Publisher for bill print is only supported with on-premises implementations. Cloud service implementations must use a 3rd party bill print system.

Parameters

Parameter	Parameter Code	Description

Copyright © 2026, Oracle and/or its affiliates.

CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'.
First Bill	**P_FROM_BILL_ID**	First Bill Id to print for the Bill Range.
Last Bill	**P_TO_BILL_ID**	Last Bill Id to print for the Bill Range.
Batch Code	**P_BATCH_CD**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected.
Batch Number	**P_BATCH_NBR**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected.
Extract Algorithm	**P_EXTRACT_ALG**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected.

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

- Bill Information
- Bill Segment Information
- Account Summary Information
- Current Charge Information
- Premise Information

MSG_ON_BILL	S15.2	CI_BILL_SA or CI_FT

Billed Revenues by Rate - CI_BILREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Condition (Open, Closed)	P_COND_FLG	If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases.

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)

2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Copyright © 2026, Oracle and/or its affiliates.

Case Statistics for a Given Status - CI_CSESGS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type/Status	P_CASE_STATUS_CD	This is the desired Case Type and Status that will be reported on.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Copyright © 2026, Oracle and/or its affiliates.

Collection Summary - CI_CLLSUM

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	If from date is not set, the default is one month prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user, it is set to one month after the current date

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days.
End Date	P_TO_DT	End date to use for reporting customer contacts. If not defined, End Date is set to the current date.
Customer Contact Class / Type	P_CC_TYPE_CD	Specify a Customer Contact Class / Type to restrict the report output to a specific class / type.

Report Description

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

Parameter	Parameter Code	Description
Service Type	P_SERVICE_TYPE	Service type used to restrict the report to premises with services of this type.

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

> **Note**
>
> If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

Field Order Print in BI Publisher- CI_FOPRNT

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Field Order Print in batch for BI Publisher is not supported yet.

Parameters

Parameter	Parameter Code	Description
CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single FO print, Batch Switch is 'No' and for multiple FO print, Batch Switch is 'Yes'.
First FO	P_FROM_FO_ID	First FO ID to print for the FO Range.
Last FO	P_TO_FO_ID	Last FO ID to print for the FO Range.
Batch Code	P_BATCH_CD	Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch code are selected.
Batch Number	P_BATCH_NBR	Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch number are selected.
Extract Algorithm	P_EXTRACT_ALG	Passed in by the system the report is submitted in batch. Only field orders whose dispatch groups reference this FO extract algorithm are selected.

Report Description

This report is used with BI Publisher to display the Field Order information for the field order ID entered in the input parameters. Refer to the description of the parameters above. The field order will only be displayed if the field order's status is dispatched.

The following sections highlight the data that is extracted for this report.

GL Accounting Summary - CI_GLACSM

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

> **Note**
>
> Generating letters in batch is not supported yet.

Parameters

Parameter	Parameter Code	Description
Batch Switch	P_BATCH_SW	For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'.
Customer Contact	P_CC_ID	References the customer contact associated with the main customer linked to the account.

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the installation options. The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and

Copyright © 2026, Oracle and/or its affiliates.

Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the installation options.

%2 is Person Id stored on the Customer Contact.

Meter Reads Performance - CI_MTREAD

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.

Report Description

This report selects bill segments for the input accounting period and displays the total number of read meters and unread meters for these bill segments grouped by route type.

Meters that are considered read are meters whose register reads have a status of Regular or Verified . Meters that are considered unread are meters whose register reads have a status of System Estimate, Office Estimate, System Prorate or Billing Force.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Open Cases By Type - CI_CSEOPN

Parameters

Parameter	Parameter Code	Description

Copyright © 2026, Oracle and/or its affiliates.

Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type	P_CASE_TYPE_CD	If specified, only cases of this type are included in the report.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

Parameter	Parameter Code	Description

Copyright © 2026, Oracle and/or its affiliates.

Start Date	P_FROM_DT	Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user it is set to the current date

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Receivables Aging - CI_RCVAGA

Parameters

Parameter	Parameter Code	Description
Cutoff Date	P_CUTOFF_DATE	The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days.
First Bucket High Limit	P_B1_LIMIT	High limit of first bucket.
Second Bucket High Limit	P_B2_LIMIT	High limit of second bucket.
Third Bucket High Limit	P_B3_LIMIT	High limit of third bucket.

Report Description

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days.
End Date	P_TO_DT	Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_TAX_ACCTY_CHAR	Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts.

Report Description

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.

Copyright © 2026, Oracle and/or its affiliates.

- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

Parameter	Parameter Code	Description
ToDo Entry Status	P_ENTRY_STATUS_FLG	Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and assigned To Do entries.
ToDo Type	P_TD_TYPE_CD	Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or assigned entry.

Report Description

The report shows open and assigned To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or assigned). If you don't specify a status, all open and assigned To Do entries will appear on this report.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / assigned state will appear on this report.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm RPTV-UASUMM to check these conditions.

Parameter	Parameter Code	Description
Umbrella Agreement	P_UA_ID	Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed.
Account Management Group	P_AMG	Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group.
Umbrella Agreement Characteristic Type	P_CHAR_TYPE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4).
Umbrella Agreement Characteristic Value	P_CHAR_VALUE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value.
Number of Days Before Expiration	P_EXPIRE_IN_X_DAYS	Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration.

Report Description

This report provides summary information about one or more umbrella agreements.

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

Copyright © 2026, Oracle and/or its affiliates.

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

Copyright © 2026, Oracle and/or its affiliates.

The estimate for the unbilled portion is calculated as (Bill Amount / Number of Days in the Bill Period) * Number of Unbilled Days for the Accounting Period.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for $150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as 150/31*21 = $101.61.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Vacant Premises with Consumption - CI_VACANT

Report Description

This report shows all premises that are considered vacant, and provides information about the level of consumption, the period of vacancy, and the service point and register information.

This report selects service points that are linked to a service agreement that is either canceled or closed. The report excludes any service points that have never been linked to a service agreement. If consumption has been registered at such a service point since the end date of the service agreement, the service point's details are displayed.

This report may be used by the utility to investigate sites where problems such as service theft or leakage may be occurring.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_SA_SP on STOP_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any effect on the production environment.

Defining Overdue Processing Options

The system periodically monitors how much your customers owe to ensure they haven't violated your collection rules. When a violation is detected, the system initiates the appropriate activities (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). The topics in this section describe how to configure the system to manage your overdue processing requirements.

> **Note**
>
> The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with algorithms that support collecting on overdue bills. If your organization practices balance-forward accounting (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under Defining Credit & Collections Options.

> **Warning**
>
> Setting up this module is as challenging as your organization's collection rules. If you have simple rules, the set up process will be straightforward. If your rules are complicated (e.g., they differ based on the type of customer, the age of debt, the type of service, etc.), your setup process will be more challenging.

Case Study - Collecting On Overdue Bills

The following topics introduce a case study that describes how overdue processing can be used to collect on overdue bills. This is just an example as virtually every aspect of overdue processing is configurable. Use this case study to familiarize yourself with the overdue processing core concepts.

- Monitoring Overdue Bills
- Cutting Service Agreements

Monitoring Overdue Bills

The following diagram illustrates the objects and processes involved with collecting overdue bills.

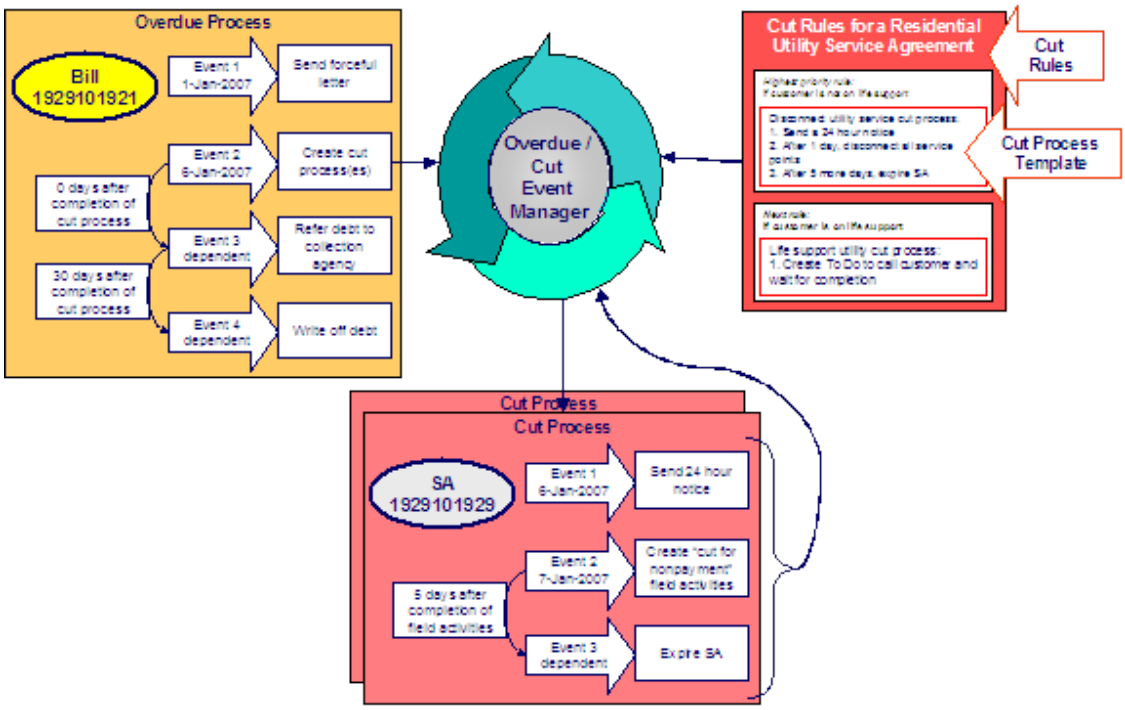
There are many important concepts illustrated above:

The Overdue Monitor checks if your accounts have bills that violate your overdue rules	The Overdue Monitor is a background process that periodically reviews your account's financial obligations. Note well: every account belongs to a collection class. There are two types of collection classes: those whose accounts are monitored by the Account Debt Monitor, and those that are monitored by the Overdue Monitor. This chapter describes the Overdue Monitor.

Copyright © 2026, Oracle and/or its affiliates.

Overdue rules define when and how unpaid bills are collected	An account's collection class overdue rules have algorithms that monitor an account's financial obligations. These algorithms are invoked by the Overdue Monitor when it's time to review an account's obligations. These algorithms can contain any type of criteria. However, most are defined using a combination of a threshold age and monetary amount. For example, a classic algorithm would check if a bill has unpaid financial transactions more than 20 days old that exceed $50. In the case of bill-oriented collection, the monitoring algorithms look at each of the account's bills to determine if they are paid. Note, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. If a monitoring algorithm finds an unpaid bill, it can check if it old enough (and large enough) to be considered a violation. When you set up a monitoring algorithm, you define the type of overdue process that should be created when an overdue bill is detected. You do this by defining the appropriate "overdue process template".
An overdue process template defines how to handle an overdue bill	An overdue process template contains one or more overdue event types. These define the number and type of events that are created to prod the customer to pay. For example, you might set up an overdue process template with event types to send a series of letters followed up by a call. The overdue process template has contains the rules defining when events are activated. The specific action that's performed by an overdue event is controlled by the Activation algorithm defined on its event type. Refer to Overdue Event Type - Main for a list of the various Activation algorithms delivered with the base package.
Multiple objects can be associated with a single process	The above diagram shows a single bill linked to an overdue process. It should be noted that an overdue process is capable of referencing multiple bills (or other objects). Note well: while a single overdue process can reference many overdue objects, all such objects must be of the same type. For example, you cannot commingle bills and service agreements under a single overdue process. The type of object managed by an overdue process is defined on its overdue process template.
If a customer pays the bill, the overdue process is cancelled	If an overdue bill is paid, the overdue process is canceled real-time. You control if and how an overdue process is cancelled by setting up the appropriate rules on the overdue process template.

Copyright © 2026, Oracle and/or its affiliates.



The Overdue / Cut Event Manager activates and triggers overdue events	The Overdue / Cut Event Manager is a background process that activates overdue events on the appropriate date. On this date, the event's Activation algorithm(s) are called. This Overdue / Cut Event Manager also has the responsibility of recursively activating later events that are dependent on the completion of earlier events.
Events can be activated real-time	Overdue Process - Main has a button that allows users to activate (and recursively trigger) overdue events online / real-time. This means you don't have to wait for a batch job to activate events.
Overdue events can wait for related activities to complete	As described above, an overdue event's Activation algorithm can create virtually any object. What wasn't explained is that the event can be set up to wait for the ancillary object to finish before it completes. For example, an event can create a To Do entry and wait for it to complete before the next event is triggered. You can introduce plug-ins to create and wait on virtually any object. While an overdue event is in the Wait state, the Overdue / Cut Event Manager monitors the state of the related object(s). When the related object completes, the event is transitioned to the Complete sate (thus triggering dependent overdue events). Please see Some Events Wait For Something Before Completing for more information.

Cutting Service Agreements

An overdue process may contain an overdue event that creates a cut process(es). A cut process is used to cut (i.e., stop) a service agreement. The following diagram illustrates the objects and processes involved with cutting a service agreement.

> **Note**
>
> **Cut processes aren't required.** It's quite conceivable to design an overdue process that doesn't cut service. For example, the overdue process may just contain an event that creates a case and the case manages the collection activities.

Copyright © 2026, Oracle and/or its affiliates.

An overdue process may contain an overdue event that cuts (i.e., stops) service	If an overdue process's bill remains unpaid, one of the latter overdue events typically creates one or more cut processes. A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement.
Cut rules define how to sever service agreements	The system allows you to define rules to control the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ... The cut rules are defined on the service agreement's SA type. This allows different rules for different types of service agreements.
Overdue events can "wait" for related activities to complete	When an overdue event creates cut process(es), it typically enters the Wait state. It enters this state as it is waiting for the cut process(es) to complete before it can itself complete. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related cut process(es). When the cut process(es) complete, the system transitions the originating overdue event to the Complete state (thus triggering dependent events).

Copyright © 2026, Oracle and/or its affiliates.

A cut process template defines how to cut a service agreement	Cut processes and events are created using a cut process template. A cut process template defines the actions involved in cutting a given type of service agreement. A cut process template usually contains several cut events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received. An Activation algorithm controls the specific action associated with a cut event and therefore an event can do practically anything. Refer to Cut Event Type - Main for a list of the various Activation algorithms delivered with the base package.
Cut events are also managed by the Overdue / Cut Event Manager	The same background process that manages the activation of overdue events manages cut events. This means you only have to submit one batch job to activate and trigger both overdue and cut events.
Events can be activated real-time	Cut Process - Main has a button that allows users to activate (and recursively trigger) cut events online / real-time. This means you don't have to wait for a batch job to activate events.
Cut events can "wait" just like overdue events	Cut events support the ability to wait for something to complete just like overdue events. For example, if a cut event creates a field activity, it enters the Wait state. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related field activities. When the field activities complete, the system transitions the originating cut event to the Complete state. And, just like for overdue events, the notion of a cut event creating something and then waiting for it to complete is not limited to field activities. For example, you could have a cut event create a To Do entry and wait for it to complete before the next event is triggered. Please see Some Events Wait For Something Before Completing for more information.
After a service agreement is stopped, it will be final billed	Many cut processes are configured so their last cut event expires the service agreement. What happens at expiration depends on the type of service agreement. However, eventually the service agreement is transitioned into the Stopped state. When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.

Copyright © 2026, Oracle and/or its affiliates.

If a customer doesn't pay their final bill, the final bill will be processed using a different type of overdue process	Final bills only differ from ongoing bills in that the service agreements associated with the bill's FTs are not active. This means that there is nothing to cut. This means that the type of overdue process used to handle a "final" bill should differ from that used to handle "ongoing" bills. As described above, overdue rules define how unpaid bills are handled (both ongoing and final). We recommend configuring your overdue rules to use different overdue process templates for final versus ongoing bills.
The last overdue event typically causes the debt to be written off	Ultimately, if the overdue and cut events fail to inspire payment, the debt will be written off. The method used to write-off a bill is controlled by an overdue event Activation algorithm.

How Does The Overdue Monitor Work?

This section describes how the Overdue Monitor background process C1-ADMOV) uses your overdue rules to collect overdue debt.

This process has an optional input parameter for CIS Division. It can be used if you implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

> **Note**
>
> **Recommendation.** We recommend that you familiarize yourself with the concepts described in the case studies before reading this section.
>
> **Collecting overdue bills.** The examples in the following section frequently refer to how the Overdue Monitor is configured for an organization that collects on unpaid bills. It should be noted that these are just examples as the Overdue Monitor can be used to collect on virtually anything (if you create the appropriate plug-in algorithms).

- Different Overdue Rules For Different Customers
- Overdue Rules Are Embodied In Algorithms
- When Is An Account Monitored?
- Collection Class Defines If And How Accounts Are Monitored

Different Overdue Rules For Different Customers

The Overdue Monitor uses rules to control how it monitors an account's debt. The system allows you to define different rules for different combinations of collection class, division and currency code. For example,

Copyright © 2026, Oracle and/or its affiliates.

- You probably have different collection rules for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different rules applied to each jurisdiction's debt. The **CIS division on each customer's account** defines the jurisdictional rules applied to the account's debt.
- You probably have different collection rules for different customer segments. For example, bills for large customers might be overdue if they are more than 10 days late, whereas small customers might have 24 days. You differentiate your customers in respect of the overdue via the **collection class on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

The above means that every combination of CIS division, collection class, and currency code can have different rules. The following matrix is used to illustrate a sample organization's rules (note, we assume a single currency and therefore avoid the third dimension):

Account's Division	Account's Collection Class: Commercial Customer	Account's Collection Class: Residential Customer
North	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 45 days, create the commercial 45 days late overdue process.	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 50 days, create the accelerated overdue process for residential customers.
	Next Priority: If a bill exists with unpaid FT's > $100 that is older than 30 days, create the commercial 30 days late overdue process.	Lower Priority: If a bill exists with unpaid FT's > $25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.
South	...	...

Notice that there can be multiple criteria for each cell in the matrix. What differentiates one criteria from another is its priority. The higher priority criteria will be compared first. If the debt violates the criteria, the overdue process is initiated and no further comparisons are performed.

Overdue Rules Are Embodied In Algorithms

Your organization's overdue rules are defined in algorithms plugged in on Collection Class Overdue Rules (in the Overdue Monitor Rule system event). When the Overdue Monitor analyzes an account, it uses the rules associated with the account's collection class, CIS division and currency code. To analyze an account, it simply invokes these algorithms in sequence order, i.e., the lower the sequence, the higher its priority.

An Overdue Monitor Rule algorithm has two responsibilities:

- it determines if an account violates its overdue rules,
- if so, it creates one or more overdue processes using an overdue process template

Copyright © 2026, Oracle and/or its affiliates.

When Is An Account Monitored?

The Overdue Monitor determines if an account violates your overdue rules at least every X days, where X is defined on the Customer Class - Controls associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, the Overdue Monitor examines an account's debt as follows:

- X days after an account's bill due date (X is defined in the field Credit Review Grace Days on customer class control).
- If a payment is canceled with a cancellation reason that indicates non-sufficient funds.
- If a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to Breaking A Bill Oriented Payment Arrangement for more information.
- If a pay plan is broken. Refer to The Pay Plan Monitor for more information.
- If a match event is added, changed or deleted.
- When a written off bill is reversed.

> **Note**
>
> **Additional events.** Your implementation can have other events trigger the analysis of an account by the Overdue Monitor. To do this, add logic to insert a row on the CI_ADM_RVW_SCH table when the event occurs. This row simply references the account ID to be reviewed and the desired review date.

Collection Class Defines If And How Accounts Are Monitored

As described above, every account references a collection class. The collection class defines if and how its accounts are monitored. There are three options:

- The accounts are monitored by the Account Debt Monitor
- The accounts are monitored by the Overdue Monitor (this is described in this chapter).
- The accounts are not monitored for overdue debt.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Migration.** If you plan to migrate from the Account Debt Monitor (ADM) method of collection to the Overdue Monitor method, a special Overdue Monitor algorithm (C1-ACT-CSW) has been supplied that will skip accounts that are eligible for review by the Overdue Monitor if they have an active collection, severance or write-off process. This algorithm should be plugged in the applicable Collection Class Overdue Rules so that it will be invoked first. This allows accounts with active ADM-oriented collection activities to work themselves through the system. When an account no longer has any active ADM-oriented activities, monitoring responsibilities will be assumed by the Overdue Monitor.

The Big Picture Of Overdue Processes

As described above, the Overdue Monitor subjects your accounts to overdue rules. If a rule is violated, an overdue process is created. The topics in this section provide background information about overdue processes.

- How Are Overdue Processes Created?
- The Components Of An Overdue Process
- Experimenting With Alternative Overdue Process Templates
- Overdue Process Information Is Overridable
- Original and Unpaid Amounts
- Overdue Processes Are Highlighted Elsewhere
- How Are Overdue Processes Cancelled?
- Overdue Processes Are Created From Templates
- The Big Picture Of Overdue Events
- The Big Picture Of Cut Processes
- Cut Events Are Like Overdue Events
- Write Offs Are Implemented Using Overdue Events
- Calendar vs Work Days

How Are Overdue Processes Created?

As described above, the system creates an overdue process when an account violates your overdue rules. In addition, a user can manually create an overdue process at their discretion.

The Components Of An Overdue Process

The following topics describe the major components of an overdue process.

- Overdue Objects

Copyright © 2026, Oracle and/or its affiliates.

- Overdue Events
- Overdue Log

Overdue Objects

When an overdue process is created, the system links the overdue object(s) to the process. For example, if an overdue bill is detected, the bill is linked to the overdue process.

When you set up an overdue process template, you define the type of object it collects on by defining the foreign key characteristic type used to reference the object. For example, when you set up an overdue process template to collect on bills, you define a foreign key characteristic type that references the bill object.

Overdue Events

An overdue process has one or more overdue events. These events are the actions designed to encourage the customer to pay. For example, you might set up overdue events that:

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to seize the customer's assets)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring overdue process templates. When the system creates an overdue process, it copies the events defined on the specified template.

It's important to note that all overdue events are created when the overdue process is created. A separate background process, the Overdue / Cut Event Manager, is responsible for activating, monitoring, and triggering overdue events. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a cut process, refer debt to a collection agency, write-off debt, etc.).

Overdue Log

Every overdue process has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When the process is created, a log entry is created to describe why the process was started.
- When an overdue event is activated, a log entry is created. These entries frequently contain a foreign key to the object that the event created so that users can easily drill down to the object from the log. For example, if an event creates a To Do entry, the To Do entry's foreign key is placed on the log and this allows a user to drill down on the log entry to see the To Do entry.
- When a process is canceled, a log entry is created to describe the circumstances of the cancellation (e.g., manual versus automated).

Copyright © 2026, Oracle and/or its affiliates.

- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.
- ...

Many of the base-package algorithms involved in overdue processing insert log entries so that a thorough audit trail is maintained. These algorithms have been designed to allow you to control the verbiage in each log entry by defining the desired message number using an algorithm parameter.

The log is viewable on the Overdue Process - Log page.

> **Note**
>
> **More than just an audit trail.** The log entries are more than just an audit trail. The system makes use of the log entries to know what it did. For example, when an overdue event needs to monitor the state of the To Do entries that it created, it uses the log to determine the identity of these To Do entries.

Experimenting With Alternative Overdue Process Templates

The system allows you to determine the efficacy of proposed overdue process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing overdue process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" overdue process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Overdue Processing Feature Configuration for every champion template. Each option's value defines:
  - the "champion" overdue process template code
  - the "challenger" overdue process template code
  - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing overdue process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, your implementation's Overdue Rule Plug-In may include logic to use the challenger template X% of the time rather than the champion template. The sample plug-in provided in the base product, called C1-CB-CR-RAT, includes this logic.

Copyright © 2026, Oracle and/or its affiliates.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination)

Overdue Process Information Is Overridable

"Overdue process info" is the concatenated string of information that summarizes an overdue process throughout the user interface. The base-package logic constructs this string by concatenating the following information:

- The description of its overdue process template
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your overdue process templates. This design allows some / all overdue process templates to have an override info string.

Original and Unpaid Amounts

There are two amounts associated with each overdue object linked to an overdue process: its Original Amount and its Unpaid Amount. These amounts are used throughout overdue processing.

You control how these amounts are calculated by defining the appropriate algorithm on your overdue process templates. For example, you can plug in a base-package algorithm (C1-CUAOA) if you collect on overdue bills and the original amount is the amount of financial transactions linked to the bill, and the unpaid amount is the sum of financial transactions that are not linked to balanced match events.

> **Note**
>
> The system captures a history of an overdue process's unpaid amounts. Refer to How to Capture Arrears History for more information.

Overdue Processes Are Highlighted Elsewhere

The topics in this section describe how other parts of the system highlight the existence of overdue and cut processes.

Copyright © 2026, Oracle and/or its affiliates.

- Alert Zone
- Credit and Collections Zone
- Account Activity History Zone

Alert Zone

If you plug-in the appropriate alert algorithm (C1-OD-PROC) on the Installation record, alert(s) will be shown for active overdue processes in the Alert Zone that appears in the Sidebar and on Control Central - Account Information.

Credit and Collections Zone

The Credit and Collections zone on Control Central - Account Information shows active overdue and cut processes.

Account Activity History Zone

The Account Activity History Zone on Control Central - Account Information shows pending and waiting events and inactive processes.

How Are Overdue Processes Cancelled?

A user may cancel an overdue process at their discretion, online / real-time using Overdue Process - Main.

The system will automatically cancel an overdue process when the object(s) associated with the overdue process are sufficiently paid. Exactly when the system checks if an overdue process should be cancelled is dependent on your organization's billing and accounting rules. For example, if you practice open-item accounting, you'd want to analyze an account's active overdue processes whenever a match event is added, changed or deleted (as match events are the only objects that impact if debt is considered paid in an open-item world). The base-package supports this specific example. If you need additional events to check if an overdue process should be canceled (e.g., the creation of a pay plan), a base-package change MAY be necessary. Please check with customer support if you have questions.

Two algorithms plugged-in on the overdue process template handle the cancellation:

- The Cancel Criteria algorithm is responsible for determining if an overdue process should be canceled. Algorithms of this type analyze the outstanding debt on the objects linked to the overdue process and indicate whether a process can be cancelled.
- The Cancel Logic algorithm is responsible for actually canceling the process. The logic involved in cancellation can be quite sophisticated as canceling an overdue process can result in the cancellation of its pending events and cut processes.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Why two algorithms?** The reason two algorithms are involved in cancellation is because we want the cancellation logic to be encapsulated in one place so it can be called during both manual and automated cancellation.
>
> **Different logic for different templates.** Because both the Cancel Criteria and Cancel Logic algorithms are plugged-in on the overdue process's template, you can have different cancellation criteria and logic for different templates.

Overdue Processes Are Created From Templates

As described above, you set up overdue process templates to define the types of events and when they are executed. When an overdue process is created, its events are created by copying the event types from an overdue process template. The remaining topics in this section provide background information to assist you in setting up your templates.

The Big Picture Of Overdue Events

This section describes the various types of overdue events and their lifecycle.

- How Are Overdue Events Created?
- Overdue Events Can Do Many Things
- Overdue Event Information Is Overridable
- Overdue Event Lifecycle

How Are Overdue Events Created?

Overdue events are created as follows:

- The Overdue Monitor invokes Overdue Monitor Rules to periodically check your accounts (refer to Overdue Rules Are Embodied In Algorithms for how this works). An Overdue Monitor Rule creates an overdue process when an account violates your overdue rules. The overdue process has one or more overdue event(s). The number and type of events is controlled by the overdue process template specified on the Overdue Monitor Rule.
- Users can create an overdue process manually on Overdue Process - Main. To do this, they specify an overdue process template. The number and type of overdue events is defaulted from the template.
- An overdue event may be manually added to an existing overdue process by a user on Overdue Process - Events.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** Most overdue events are created by the system when it creates an overdue process for delinquent obligations. If you need to create an ad hoc overdue event, you can either create an overdue process whose template contains the desired event OR link the desired event to an existing process.

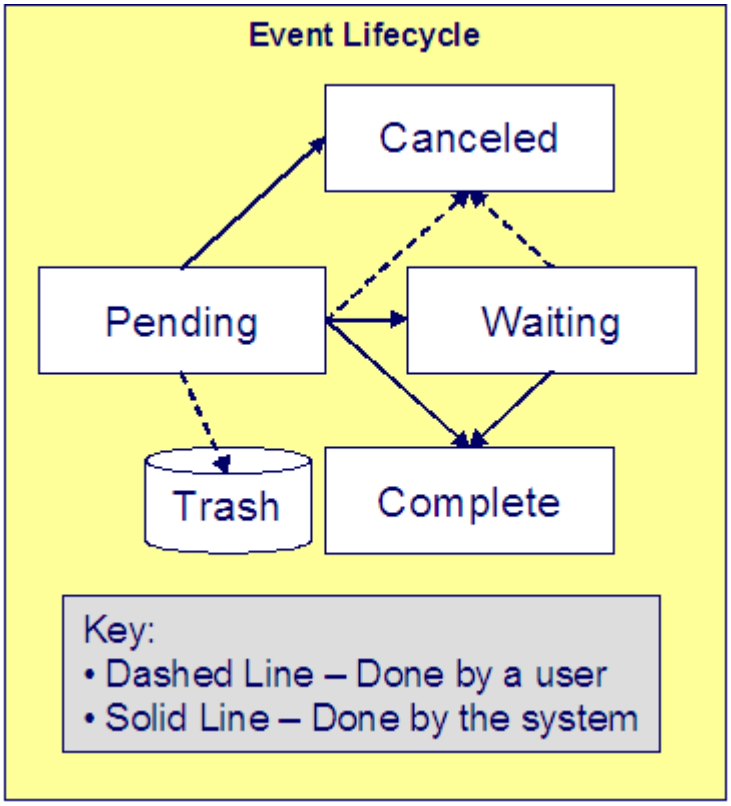
Overdue Events Can Do Many Things

An overdue event can perform a wide number of activities as the logic is embodied in an algorithm. The following points describe how this works:

- Every overdue event references an overdue event type.
- The overdue event type, in turn, references an Event Activation algorithm.
- The Event Activation algorithm is invoked when the event is triggered.

Overdue Event Information Is Overridable

"Overdue event info" is the concatenated string of information that summarizes an overdue event throughout the system. The base-package logic constructs this string by concatenating the following information:



- The event type's description
- The event's status
- If it's pending:
  - If the event has a trigger date, the number of days until it's triggered plus the verbiage day(s) from today
  - Otherwise, the verbiage dependent on other events
- If it's waiting, the number of days, hours and minutes that it's been waiting
- If it's canceled, the cancel reason code's description
- If it's complete, the number of days, hours and minutes that it's been complete

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your event types. This design allows some / all event types to have an override info string.

Overdue Event Lifecycle

The following diagram shows the possible lifecycle of an overdue event:

Copyright © 2026, Oracle and/or its affiliates.

Overdue events are initially created in the Pending state. An event can take myriad paths after it's created; it all depends on how you've configured the system. The following topics describe an event's lifecycle:

- How and When Events Are Activated
- Activating Events Should Add a Log Entry
- Holding Events
- Some Events Wait For Something Before They Activate
- How Are Events Canceled

How and When Events Are Activated

An overdue event contains the date is should be activated; this is referred to as its trigger date. On this date, the Overdue / Cut Event Manager (a background process (C1-ODET)) invokes the Event Activation algorithm plugged-in on the event's event type. The Event Activation algorithm, in turn, will decide on the state in which to leave the overdue event (e.g., it may transition it to the Complete state or the Waiting state).

If a user can't wait for the Overdue / Cut Event Manager real-time, they can click a button on Overdue Process - Main to activate (and recursively trigger) events online / real-time.

You control how an event's trigger date is populated by configuring the overdue process template. You are given two choices when you link an event type to an overdue process template:

- You can indicate the event should be assigned a trigger date when it is first created. You'd use this approach on the first event and events with no dependencies on earlier events. The following points describe how to configure the overdue process template to do this:

Copyright © 2026, Oracle and/or its affiliates.

- Indicate the event type is NOT dependent on other events, and
- Define the number of days after the process's creation to use when calculating the trigger date.

- You can indicate the event should be assigned a trigger date only after earlier events are Complete. This technique should be used whenever you have an event that is only executed after other events are Complete. The following points describe how to configure the overdue process template to do this:
  - Indicate the event is dependent on other events, and
  - Define the number of days after the completion / cancellation of all dependent event(s) that the trigger date should be set to. The Overdue / Cut Event Manager sets the trigger date on such an event when it detects that all of its dependent events are complete / canceled.

> **Note**
>
> **Calendar vs Workdays.** When an overdue event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to Calendar vs. Work Days for more information.

Activating Events Should Add a Log Entry

As described above, an overdue process has a log holding a history of meaningful events in the process's life. Most Event Activation algorithms will add an entry to the process's log.

These log entries are more than just an audit trail as they also reference the objects that are created during activation. For example, if an activation algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

Holding Events

You can prevent a pending event with a trigger date on / before the current date from activating by plugging-in a Hold Event Activation plug-in on the overdue process template. This might prove useful, for example, if you want to suspend an overdue process while a case used to investigate the assertion of a customer is outstanding. Then, when the case closes, the overdue process can start up where it left off.

This technique would prove useful, for example, if your users can grant ad hoc suspend periods (e.g., if a customer wants a few extra days to pay before a cutoff). To do this, create a case type that has two states: Open and Close. Make sure to set up the Open state to have an automatic transition algorithm to close the case after X days. Then, all a user has to do is create a case of this type when they want to provide a suspend period. When the suspend period is over and payment isn't received, the case will close and the overdue process will start up where it left off.

Some Events Wait For Something Before They Activate

Copyright © 2026, Oracle and/or its affiliates.

Consider this scenario - you want an overdue event to create a To Do entry so a user can authorize the next phase of an overdue process. When this event activates, the event's activation algorithm will create a To Do entry, but it will NOT transition the event to complete. Rather, the overdue event will exist in the waiting state. While in the waiting state, the Overdue / Cut Event Manager will monitor the state of the To Do entry. When the To Do entry completes, the original overdue event can transition to the complete state and then latter dependent events can be triggered. The following points describe how to configure the system to support this type of event:

- The event type's Event Activation algorithm should behave as follows:
  - It creates the object on which the overdue event waits.
  - It must link this object to the overdue process by creating a log entry where the prime-key of the related object is referenced (in a foreign-key characteristic). This log entry should also reference the event.
  - It should leave the overdue event in the waiting state.
- The event type must have a Monitor Waiting Event algorithm. This algorithm is invoked each time the Overdue / Cut Event Manager executes. If the related object has transitioned to a "final" state, the originating overdue event is transitioned to the complete state (and then latter dependent events are triggered).

> **Note**
>
> **Bottom line.** Two algorithms must be set up on an overdue event type to implement waiting functionality: an Event Activation algorithm that creates the monitored object and a Monitor Waiting Event algorithm to check on the state of the monitored object. The Overdue / Cut Event Manager has the dual responsibility of activating the event and monitoring its related object for completion (and then triggering the dependent events when it completes).

While the above example illustrated how an overdue event could create and then monitor a To Do entry, you can use this functionality to create and monitor any object that has an initial and final state. If the base package does not contain the algorithms you need, simply develop new ones using the base-package algorithms as examples.

How Are Events Canceled

A pending event will be cancelled automatically by the system when the overdue process is canceled. Refer to How Are Overdue Processes Cancelled for more information.

A user may cancel a pending or waiting event at their discretion.

Regardless of what triggers the cancellation, the Cancel Logic algorithm plugged in on the overdue event type handles the cancellation. This allows you to introduce additional cancellation logic should the need arise. Please note that the base package cancel algorithms insert a log entry when a user manually cancels an event.

The Big Picture Of Cut Processes

Copyright © 2026, Oracle and/or its affiliates.

While not required, many overdue processes will contain one or more events that will cut (i.e., stop) service. When such an event activates, it creates a "cut process". A cut process is very similar to an overdue process; the major difference is that a cut process is linked to a specific service agreement (the one being cut), whereas an overdue process is linked to the object(s) in arrears.

The topics in this section provide background information about cut processes.

- How Are Cut Processes Created?
- Overdue Events Wait For The Cut Process To Conclude
- Cut Processes Exist Under An Overdue Process
- The Components Of A Cut Process
- Cut Process Information Is Overridable
- How Are Cut Processes Cancelled?
- Cut Processes and Events Are Created From Templates

How Are Cut Processes Created?

The activation of an overdue event can create one or more cut processes.

In addition, a user can manually create a cut process at their discretion using Cut Process - Main.

Overdue Events Wait For The Cut Process To Conclude

Overdue events that create cut processes are perfect examples of events that wait for the object they create to complete before they, in turn, complete. After the cut process concludes, the originating overdue event will complete thus triggering its dependent events.

Cut Processes Exist Under An Overdue Process

It's important to note that a cut process exists in respect of an overdue process. In other words, you can't create a cut process without referencing a parent overdue process. There are two reasons why:

- A cut process's overdue process defines the objects in arrears. It is these objects that are monitored to determine if the cut process (and overdue process) can be cancelled.
- The log associated with a cut process's overdue process contains the history of the cut process(es) and their events; there is no log specific to a cut process.

The Components Of A Cut Process

Cut processes are simpler than overdue processes as they simply contain one or more "cut events". These events are the service agreement-specific actions designed to encourage the customer to pay. For example, you might set up cut events that:

- Create field activities to cut service

Copyright © 2026, Oracle and/or its affiliates.

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to manage a customer with life support issues)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring cut process templates. When the system creates a cut process, it copies the events defined on the related template.

It's important to note that all cut events are created when the cut process is created. The Overdue / Cut Event Manager is responsible for activating the cut events at the appropriate time. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, create a field activity, etc.)

Cut processes do not have their own log as their history is maintained on the parent overdue process's log.

Cut Process Information Is Overridable

"Cut process info" is the concatenated string of information that summarizes a cut process throughout the system. The base-package logic constructs this string by concatenating the following information:

- Its cut process template's description
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected on the cut process's overdue process

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your cut process templates. This design allows some / all cut process templates to have an override info string.

How Are Cut Processes Cancelled?

A user may cancel a cut process at their discretion, online / real-time using Cut Process - Main.

The system will automatically cancel a cut process when the overdue process is cancelled.

Regardless of what triggers the cancellation, the Cancel Cut Process algorithm plugged in on the cut process's template handles the cancellation.

If a cut process is canceled and the cut process's events created field activities, the cancel logic embodied in the algorithm can be quite sophisticated. Refer to Field Activities To Cut And Reconnect Service for an example.

Cut Processes and Events Are Created From Templates

Copyright © 2026, Oracle and/or its affiliates.

When a cut process is created, its cut events are created by copying a cut process template's event types. Cut events follow the same lifecycle and possess the same behavior as overdue events.

Cut Events Are Like Overdue Events

Cut events almost identical to overdue events. The major difference is that cut events exists under a cut process and therefore are oriented towards the cut process's service agreement. The following topics describe other differences between cut events and overdue events.

- Field Activities To Cut and Reconnect Service
- A Cut Event Expires Service Agreements (and May Trigger Final Billing)

Field Activities To Cut and Reconnect Service

A cut process that's created for a service agreement whose service can be severed will typically contain a cut event that creates field activity(s) to cut service. The base-package cut event activation algorithm will create field activities for the service points linked to the service agreement being cut. The type of activity is defined on the field activity type profile defined on each service point's SP type. Please see C1-CE-CR-FA for the exact details of the base-package algorithm.

If the cut process is canceled after field activity(s) are created and before the cut process completes, different activities can transpire. The specifics of what happens are controlled by a Cancel Logic algorithm plugged in on the cut process template. The following points summarize how a base-package algorithm (C1-CP-DWFA) works:

- It assembles all Pending, Held and Complete cut for nonpayment field activities (FA) created by the cut process (these are defined in the overdue process's log).
- Each FA is processed as follows:
  - If the FA is Pending or Held and it is not linked to a field order (i.e., it hasn't been dispatched):
    - The FA is cancelled
    - An entry is added to the overdue process log to indicate the cancellation
  - If the FA is Pending or Held and it is linked to a field order (i.e., it has been dispatched):
    - A To Do entry is created (the To Do Type is defined on the algorithm)
  - If the FA is Complete and the Cut Process's SA is pending start or active (i.e., it hasn't been expired yet):
    - Reconnect field activity(s) are created for every service point that had a cut for non-payment field activity. The type of activity is defined on the field activity type profile defined on each service point's SP type.

A Cut Event Expires Service Agreements (and May Trigger Final Billing)

The last cut event is typically set up with an activation algorithm that expires the cut process's service agreement. If earlier cut events created "cut for non-payment" field activities, these

Copyright © 2026, Oracle and/or its affiliates.

field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point.

> **Note**
>
> **Final billing.** When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).

Write Offs Are Implemented Using Overdue Events

The system has been designed to allow overdue events on the original overdue process to write-off the objects being collected. Refer to Writing Off Bills for a case-study explaining how to do this.

Calendar vs Work Days

When you set up your overdue and cut process templates, you supply information that controls how each event's trigger date is calculated. You have two options:

- You can say that an event's trigger date can only be populated after earlier, dependent events are complete. For example, the 2 nd event (cut service) is triggered 2 days after the 1 st event is complete (48 hour warning letter).
- You can say that an event's trigger date is populated when the process is first created. You simply define the number of days after the start of the process when each such event should be triggered. For example, the 2 nd event (send cutoff warning) can be triggered 7 days after the start of the process.

In addition to the above, an option defined on the Feature Configuration for Overdue Processing plays a part in the calculation of an event's trigger date:

- If you set the option to use calendar days, the trigger date of events will be set to the first workday on / after the calculated date. For example, if you indicate that the 2 nd event is triggered 7 days after the 1 st event, the system will add 7 days to the 1 st event's completion date. It then checks if this is a workday (and not a holiday); if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.
- If you set the option to use workdays, the trigger date will be calculated by counting workdays. For example, if you indicate that the 2 nd event is triggered 7 days after the 1 st event, the system will count 7 workdays and set the trigger date accordingly.

> **Note**
>
> **Account's division controls the work calendar.** The system uses the above information in conjunction with the work calendar associated with the account's division to determine workdays.

Copyright © 2026, Oracle and/or its affiliates.

Bill-Oriented Collection - Advanced Topics

The topics in this section provide information on features designed to facilitate the collection of overdue bills.

- Miscellaneous Bill-Oriented Collection Topics
- Writing Off Bills
- Bill-Oriented Payment Arrangements

Miscellaneous Bill-Oriented Collection Topics

The topics in this section provide background information about a variety of bill-oriented collection topics.

- Highlights Of The Sample Overdue Monitor Rule Algorithm
- Holding A Process's Events
- Bill Info Shows Unpaid and Write-off Amounts

Highlights Of The Sample Overdue Monitor Rule Algorithm

A base-package Overdue Monitor Rule algorithm exists to support many different types of overdue rules (see C1-CB-CR-RAT). Keep in mind that multiple such algorithms can be plugged in on Collection Class Overdue Rules. When the Overdue Monitor analyzes an account, it calls these algorithms until there are no more to invoke (or until an algorithm tells it that there is nothing more to check). The following points describe its various options:

- **Different rules based on credit ratings.** You can set up algorithms to only be applied to accounts with a credit rating <= a given value. We anticipate such algorithms will be used in conjunction with other such algorithms to apply different rules based on the customer's credit rating.
- **Different rules based on an account or service agreement characteristic.** You can set up algorithms to only be applied if an account or one of its service agreements has a given characteristic type and value effective within the last X days. For example, you could set up an algorithm that would process an account if it had a broken payment arrangement service agreement within the last 365 days (broken payment arrangement service agreements are marked with a given char type and value). You could set up a different algorithm that treated strategic customers more leniently (given that the definition of "strategic" could be held in an account or service agreement characteristic).
- **Skipping a bill if it has a future postpone date.** You can set up algorithms to ignore an unpaid bill if it has a "postpone date" that's in the future. This date would be defined on the bill using an ad hoc characteristic. The characteristic type is defined as a parameter on the algorithm.
- **Special process for bills with disputed debt.** You can set up an algorithm to create a given type of overdue process if the bill has disputed debt. By "disputed debt", we mean a bill with a financial transaction that's linked to an unbalanced match event that's marked as Disputed.

Copyright © 2026, Oracle and/or its affiliates.

- **Special process for bills with credit balances.** You can set up an algorithm to create a special overdue process if the bill's total charges are negative (i.e., a credit bill). Such bills should be very unusual as we strongly recommend that credit bills should have their credit balance applied to an overpayment service agreement during bill completion.
- **Different rules when all service agreements are inactive.** You can set up an algorithm that should only be applied if all service agreements are inactive. We anticipate this can be used to differ the type of overdue process as if an account does not have active service agreements; there is nothing to stop to encourage them to pay.
- **Different rules based on age and amount of a bill.** You can set up an algorithm to create different types of overdue processes based on the age and amount of the bills.

> **Note**
>
> **You are not limited by the base-package's rules.** If your implementation requires options that are not supported by the base-package algorithm, simply develop your own.

Holding A Process's Events

Refer to Holding Events for a description of how to prevent the activation of an overdue / cut processes events while a given condition is true. The condition is defined in an algorithm so you can set up the system to prevent event activation for practically any condition. For example, you might want to hold event activation while the bill's account has an active case (e.g., a user might set up a case to conduct an ad hoc investigation of billing discrepancies). When the case closes, you'd want the process to start up where it left off.

Bill Info Shows Unpaid and Write-off Amounts

The base-package Bill Information algorithm (plugged in on the Installation record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the unpaid and write-off amounts of each bill.

Writing Off Bills

The topics in this section provide background information on how to write off bills.

- After Service Is Cut, Write-Off Oriented Events Can Commence
- Collection Agency Referrals
- Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event
- Small Amount Write-Downs
- Bill Info Shows Written Off Amounts
- Online Write Off Of Bills Is Performed On Bill-Main
- Online Reversal Of Written Off Bills Is Performed On Bill-Main
- Write Offs And Overdue Process Cancellation

Copyright © 2026, Oracle and/or its affiliates.

- An Alert Can Show Written Off Bills

After Service Is Cut, Write-Off Oriented Events Can Commence

After the last service agreement has been stopped, overdue events to manage the write-off of the overdue process's bill(s) should be triggered. Please note that a separate overdue process is NOT created to manage write-offs. Rather, events associated with the original overdue process will handle the write-off activities.

Collection Agency Referrals

Before debt is written off, many implementations refer the unpaid bills to a collection agency. The following points describe how to implement this.

- Set up an overdue event type with an activation algorithm that refers an overdue process's bill(s) to a collection agency.
- When such an event is activated, the system creates a Collection Referral record for a collection agency. The specific agency to which the debt is referred is controlled by the event type's activation algorithm. The sample algorithm simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must develop your own algorithm.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to Setting Up Collection Agencies for more information.
- If the collection agency is successful in obtaining the funds, a payment will be added. If the payment satisfies the cancel criteria defined on the overdue process template's cancellation plug-in, the overdue process will cancel. When an overdue process is cancelled, the cancel criteria on the overdue process's template are executed. We strongly recommend plugging in an algorithm that will cancel collection agency referrals when an overdue process is cancelled.
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you set up your overdue process template to have an event that creates a collection agency cancellation X days after the referral. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).
- Collection agencies are notified of the cancellation of a referral by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithms that make and cancel collection agency referrals insert rows in the overdue process's log to audit these events.

Copyright © 2026, Oracle and/or its affiliates.

Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event

Most overdue process templates will be configured to contain an event that writes-off the unpaid balance of bills.

> **Note**
>
> **Processing is redirected to another algorithm.** The base-package overdue event activation algorithm that writes off bills simply redirects the call to the Write-Off Bill algorithm plugged in on the account's Collection Class Overdue Rules. The reason for this redirection is because users can manually write-off a bill (using Bill - Main) and when they do this, we want to invoke the same logic as when an overdue process writes-off a bill.

The base-package Collection Class Overdue Rules - Write-Off Bill algorithm determines the amount that should be written off for each distribution code on each unpaid financial transaction. It then creates a separate adjustment for each service agreement where the lines on the adjustment contain the amount to be written off for each distribution code. If the unpaid financial transactions are not linked to a match event, the write-off adjustments plus the unpaid financial transactions will be linked to a new match event. If the unpaid financial transactions were linked to an unbalanced match event, the write-off adjustments will be added to the existing match event (thus making it balanced).

If partial payments were made against a bill, the amount written off will be prorated in light of the partial payments. For example, if 20% of a bill had been paid, 80% of each distribution code will be written off.

For example, assume the original bill's FT looked as follows (note, if the bill has multiple service agreements this will need to be done for each SA's FT's):

- Debit A/R $110.00
- Credit Flat Charge Revenue ($50)
- Credit Usage Revenue ($50)
- Credit City Tax Payable ($5)
- Credit State Tax Payable ($5)

Assume the customer had made a partial payment of $11 and it was matched to this FT. At write-off time, the system will create an adjustment whose adjustment lines will cause each distribution code to be written off by 90% (100% - $11 / $110). For example:

- Debit Flat Charge Revenue (or some W/O Expense) $45
- Debit Usage Revenue $45
- Debit City Tax Payable $4.50
- Debit State Tax Payable $4.50
- Credit A/R $99

This adjustment will then be linked to the original match event on which the payment was linked (thus making it Balanced).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithm that writes off bills inserts a row into the overdue process's log for each bill written off.

Small Amount Write-Downs

Many organizations will write-down a bill whose value is small early in an overdue process. The base-package overdue event activation algorithm has parameters to support this requirement (this algorithm allows you to write-off an overdue process's bill(s) if their value is less than a threshold amount).

If your organization writes-down small amounts differently than large amount, simply set up an overdue event type to reference such an activation algorithm and position it in the appropriate place in the overdue process template.

Bill Info Shows Written Off Amounts

The base-package Bill Information algorithm (plugged in on the Installation record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the amount written-off for each bill.

Online Write Off Of Bills Is Performed On Bill-Main

If a bill's account is associated with a Collection Class Overdue Rule that has a Write Off Bill algorithm, a button appears on Bill - Main if the bill hasn't been written off. When clicked, the Write Off Bill algorithm is invoked to write-off the bill.

Online Reversal Of Written Off Bills Is Performed On Bill-Main

If a bill's account is associated with a Collection Class Overdue Rule that has a Write Off Bill algorithm, a button appears on Bill - Main if the bill has been written off. When clicked, the Write Off Bill algorithm is invoked (in reversal mode). The algorithm cancels the write-off adjustments (thus making the bill payable again). It also schedules the account for review by the Overdue Monitor the next time it runs.

Write Offs And Overdue Process Cancellation

It should be stressed that writing-off a bill may cause an overdue process to be canceled because the bill's FT will be linked to a balanced match event (note, the specific cancel criteria are in a plug-in so this is not a hard rule).

The following points highlight interesting aspects of bill write-off and overdue process cancellation:

Copyright © 2026, Oracle and/or its affiliates.

- If a user writes off a bill real time and the bill has an Active overdue process, the process's cancel criteria will be invoked. This typically results in the cancellation of the overdue process.
- If an overdue event writes off a bill, the state of the process depends on your cancel criteria and where the overdue event is positioned in the overdue process. For example,
  - Imagine an overdue process that has an overdue event that writes offs small amounts of debt early in the process. If such a process is applied against bill with a small amount of debt, the process will be canceled (when the event activates).
  - Contrast this to an overdue process where the last event writes off the bill. Because there are no other events to activate, the process will complete (i.e., it will not be canceled).

An Alert Can Show Written Off Bills

A base-package Control Central Alert algorithm (C1-WO-BILL) can be set up to highlight if the account in context has written off bills. This algorithm is plugged in on the Installation record.

Bill-Oriented Payment Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

> **Note**
>
> **Nomenclature.** Some organizations refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the payment arrangement closes and the customer's bills only contain charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

- Creating Payment Arrangements
- Installment, Payoff and Current Amounts
- Breaking A Bill-Oriented Payment Arrangement
- Online Breaking
- Online Canceling

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

Copyright © 2026, Oracle and/or its affiliates.

- It holds debt.
- It is periodically billed (thus creating unmatched bill segment financial transactions).
- When a payment is received, the payment segment financial transactions are matched to the bill segment financial transactions.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent bills at the inception of the payment arrangement.

When you transfer debt from the overdue bills to a PA SA, transfer adjustments are created to transfer debt from the delinquent SAs to the PA SA. Match events are created to link the "transfer from" adjustments to the original unpaid financial transactions (FT). When all FT's on a bill are linked to balanced match events, the bill is no longer considered overdue and any active overdue process (and its related cut processes) will be cancelled. Refer to How Are Overdue Processes Canceled for more information.

> **Note**
>
> **Use the Payment Arrangement Transaction.** Use the Payment Arrangement - Bill Oriented to set up bill-oriented payment arrangements. This transaction creates a PA SA, transfers overdue bills to it, and sets up the installment amount. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

> **Warning**
>
> If you do not understand the difference between payoff balance and current balance, refer to Current Amount versus Payoff Amount.

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, there will be no overdue bills. If the customer neglects to pay bills containing charges associated with the payment arrangement, an overdue process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the bills whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes $500 and they want to pay this off in 10 installments, you'd set up the installment amount to be $50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their bills, you can transfer additional bills to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a

Copyright © 2026, Oracle and/or its affiliates.

customer who is paying off $500 with 10 installments of $50 would have an initial payoff balance of $500 and a current balance of $0. After the first bill, the PA SA would still have a payoff balance of $500, but its current balance would be $50. When the customer pays, the PA SA's payoff balance would fall to $450 and its current balance would return to $0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff $1,000 of debt in $10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed ($50 for new debt and $10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays $60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Breaking A Bill-Oriented Payment Arrangement

If a customer neglects to pay a bill, an overdue process is created. If the bill contains charges from a payment arrangement, you'll want to "break" the payment arrangement. By "break", we mean cancel the arrangement and reinstate the debt under the originating bills. To do this, you must configure the cut process template used to cut the PA SA to contain a cut event that breaks the payment arrangement.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Processing is redirected to another algorithm.** The base-package cut event activation algorithm that breaks a payment arrangement simply redirects the call to the Bill-Based Payment Arrangement algorithm plugged in on the account's Collection Class Overdue Rules. The reason for this redirection is that users can manually break a payment arrangement (using Payment Arrangement - Bill Oriented). When they do this, we want to invoke the same logic as when a cut event activation algorithm breaks a payment arrangement.

The base-package Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm does the following:

- Creates "cancel adjustments" for all unpaid financial transactions associated with the payment arrangement (e.g., billed, but not paid installments).
- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement. When these are cancelled, the original bills will become unpaid (and the debt will be rather old by this point).
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop and expires it (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the bills that contributed debt to it (the oldest bills are paid off first). This relief will occur via transfer adjustments from the PA SA to the original SAs.
- Note, if there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), an error is issued as we don't handle new debit on a payment arrangement.
- Inserts a characteristic on the PA SA to indicate that it has been broken (you might want to use this to cause more strict overdue rules to be applied to accounts with broken payment arrangements).
- Marks the account so it will be reviewed by the Overdue Monitor the next time it runs.

> **Note**
>
> **The PA SA must final bill before it closes.** It's important to note that the PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the Overdue Monitor next runs, it will analyze the account's reinstated bills. We recommend setting up a Collection Class Overdue Rule - Overdue Monitor Rule algorithm that has more stringent rules if the account has a broken payment arrangement within the last X days. The base-package algorithm (C1-CB-CR-RAT) supports this type of processing.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithm that breaks a payment arrangement SA inserts a row into the overdue process's log.

Online Breaking

A user can click a button on the Payment Arrangement - Bill Oriented page to break a payment arrangement real time. When clicked, the Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm is called to break the payment arrangement. This is the same algorithm called when a cut event break a payment arrangement.

Online Canceling

A user can click a button on the Payment Arrangement - Bill Oriented page to cancel a payment arrangement real time. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken. The "broken" characteristic type / value can be used to apply stricter rules to the account when it's next reviewed by the Overdue Monitor.

Creating Overdue and Cut Procedures

Your overdue procedures define how your organization collects overdue debt. Your cut procedures define how your organization cuts (i.e., stops) service agreements when collection attempts fail. In this section, we describe how to set up the data that controls these procedures.

> **Warning**
>
> There are numerous ways to design your overdue and cut procedures. Some designs will result in easy long-term maintenance; others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your overdue and cut procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

- Designing Your Overdue Procedures
- Set Up Tasks
- Setting Up Overdue Processing

Copyright © 2026, Oracle and/or its affiliates.

Designing Your Overdue Procedures

The design of your overdue procedures is an iterative process. Over time, you will develop skills that will allow you to skip some steps. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the overdue processing control tables.

Account's Division	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

> **NOT_SUPPORTED**
>
> For more information about how the information in this matrix is used to monitor your customers' debt, refer to How Does The Overdue Monitor Work.

- Examples
- Designing Your Collection Classes
- Designing Overdue Monitoring Rules
- Designing Overdue Process Templates and Event Types
- Designing Cut Process Templates and Event Types

Examples

This section provides some examples:

-
-
-
-
-

Turn On PGQL Mode

This example turns PGQL mode on. The PGQL prompt appears when PGQL is enabled.

```
SQL> pgql auto on;

PGQL Auto enabled for graph=[null], execute=[true], translate=[false]
PGQL>
```

Copyright © 2026, Oracle and/or its affiliates.

Create a Property Graph and Execute a Query

This example creates a property graph and executes a query against the newly created "scott_hr" graph.

```
PGQL> CREATE PROPERTY GRAPH scott_hr
  2    VERTEX TABLES (
  3      emp KEY(empno) LABEL Employee
  4        PROPERTIES ARE ALL COLUMNS EXCEPT ( deptno ),
  5      dept KEY(deptno) LABEL Department
  6        PROPERTIES ( deptno, dname )
  7    )
  8    EDGE TABLES (
  9      emp AS works_for
 10         KEY(empno)
 11        SOURCE KEY ( empno ) REFERENCES emp
 12        DESTINATION KEY ( deptno ) REFERENCES dept
 13        NO PROPERTIES
 14    )
 15    OPTIONS(PG_PGQL);

Graph created

PGQL> column name format a15;
PGQL> SELECT e.ename AS name
  2  FROM MATCH (e:Employee) ON scott_hr
  3  ORDER by e.ename
  4  LIMIT 4;

NAME
---------------
ADAMS
ALLEN
BLAKE
CLARK
```

Define a Graph Parameter

You can define a `graph` parameter to run all PGQL queries against a particular graph. This example sets `graph` to `scott_hr`. Note that the query does not need an ON clause.

```
PGQL> pgql auto on graph scott_hr;

PGQL Auto enabled for graph=[SCOTT_HR], execute=[true], translate=[false]

PGQL> column department format a20;
PGQL> column employees format a10;
PGQL> SELECT d.dname AS department, COUNT(e) AS employees
  2  FROM MATCH (e:Employee) -[:works_for]-> (d:Department)
  3  GROUP BY d
  4  ORDER BY employees
  5* LIMIT 3;

DEPARTMENT           EMPLOYEES
-------------------- ----------
```

Copyright © 2026, Oracle and/or its affiliates.

```
ACCOUNTING          3
RESEARCH            5
SALES               6
```

Show SQL Translation Using Parallel Value 2

This example shows the SQL translation of a PGQL query using a parallel value of 2. Note that the SQL translation has a hint using the defined parallel value.

```
SQL> pgql auto on translateonly parallel 2;

PGQL Auto enabled for graph=[null], execute=[false], translate=[true]
PGQL> SELECT id(n) FROM MATCH (n) ON scott_hr;
SELECT /*+ parallel(2) */ * FROM(SELECT 7 AS "id(n)$T",
to_nchar(T0$0.VID,'TM9','NLS_Numeric_Characters=''.,''') AS "id(n)$V",
T0$0.VID AS "id(n)$VN",
to_timestamp_tz(null) AS "id(n)$VT"
FROM "SCOTT".SCOTT_HRVD$ T0$0);
```

Turn Off PGQL Mode

This example shows how to turn PGQL mode off.

```
PGQL> pgql auto off;

PGQL Auto disabled
SQL>
```

Designing Your Collection Classes

Multiple collection classes are needed when your organization has different overdue rules and / or procedures based on the type of customer. If all customers are treated the same way, you'll have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

For example, for commercial/industrial customers, you probably don't worry until they owe you more than, say, $100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, $5 after 20 days. In this situation, you will have at least two collection classes: one for commercial/industrial customers, the other for residential customers.

In our example, we assume you have two collection classes: Residential and Commercial/ Industrial.

Account's Division	**Account's Collection Class:** Residential	**Account's Collection Class:** Commercial/Industrial
North		
South		

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> There are two very different ways to monitor your accounts for overdue debt. This chapter describes the method referred to as Overdue Processing. Refer to Collection / Severance / Write Off for a description of the other method. We anticipate that most organizations will only use a single method. If your organization opts to use both methods, you will need to set up the corresponding collection classes.

Designing Overdue Monitoring Rules

At this point, we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

> **Note**
>
> **Single currency.** We've assumed that your implementation works in a single currency. If this is not true, you will need to add a 3rd dimension that will have a value for each currency code.

Each cell will contain the rules that the Overdue Monitor uses to determine if an account has overdue debt. These rules will eventually be configured using one or more algorithms on Collection Class Overdue Rules.

Account's Division	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
North		
South		

> **Note**
>
> If the Overdue Monitor encounters an account whose collection class and division does not have overdue rules set up, it will issue an error.

Determining the rules in each cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For residential debt (regardless of division) we have the following rules:
  - Highest priority. If a bill exists with unpaid FT's > $0 that is older than 50 days, create the "accelerated overdue process" for residential customers. We'll talk more about this process later.
  - Medium priority. If the account's has a broken payment arrangement within the last 60 days with an unpaid bill > $0 that is older than 20 days, create the "broken payment arrangement overdue process".

Copyright © 2026, Oracle and/or its affiliates.

- Lower priority. If a bill exists with unpaid FT's > $25 that is older than 25 days, create the "courtesy reminder overdue process" for residential customers. We'll talk more about this overdue process later.

- For commercial-industrial debt (regardless of division) we have the following rules:
  - Highest priority. If a bill exists with unpaid FT's > $0 that is older than 45 days, create the "commercial 45 days late overdue process". We'll talk more about this process later.
  - Medium priority. If the account's credit rating is < 550 and has an unpaid bill > $0 that is older than 20 days, create the "risky commercial customer overdue process".
  - Lower priority. If a bill exists with unpaid FT's > $100 that is older than 30 days, create the "commercial 30 days late overdue process". We'll talk more about this overdue process later.

Given the above, our matrix will look as follows:

Account's Division	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
North	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 50 days, create the accelerated overdue process for residential customers. Medium Priority: If the account has a broken payment arrangement within the last 60 days with an unpaid bill > $0 that is older than 20 days, create the broken payment arrangement overdue process. Lowest Priority: If a bill exists with unpaid FT's > $25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 45 days, create the commercial 45 days late overdue process. Medium priority. If the account's credit rating is < 550 and has an unpaid bill > $0 that is older than 20 days, create the risky commercial customer overdue process. Lowest Priority: If a bill exists with unpaid FT's > $100 that is older than 30 days, create the commercial 30 days late overdue process.
South	Same as above	Same as above

> **Note**
>
> **The rules are limited by your imagination (and business requirements).** While the base-package Overdue Monitor Rule algorithm (C1-CB-CR-RAT) supports the above scenarios, we'd like to stress these are just examples. Your implementation can operate using very different rules by either configuring the base-package algorithm (it has many parameters that you can use to tailor your rules) OR by introducing a new algorithm. Refer to Highlights Of The Sample Overdue Monitor Rule Algorithm for the options delivered with the base-package.

Designing Overdue Process Templates and Event Types

Copyright © 2026, Oracle and/or its affiliates.

The following table shows a sample overdue process template for one of the rules in the Residential / North cell in the previous section's matrix.

Overdue Process Template	Overdue Event Type	When Triggered
Accelerated overdue process for residential customers	Old debt letter	At inception of process
	Cut active service agreements	10 days after inception
	Reduce customer's credit rating	10 days after inception (i.e., at the same time the cut process is created)
	Write down small debt	0 days after completion of the cut process(es)
	Refer debt to collection agent	0 days after attempting the small write down (this means that either the small write-down or the agency referral will take place as if the write-down is successful, the bill's FTs will be matched to balanced match events and the overdue process will stop)
	Cancel collection agent referral	45 days after referral
	Write-off debt	0 days after collection agent cancellation

You should create a similar table for each of the distinct overdue process templates in your matrix.

At this point, you've designed the distinct overdue process templates. Next, you'll need to design the algorithms that control their overdue processes:

- A template's Calculate Unpaid and Original Amount algorithm calculates the original and unpaid amounts of the objects being collected by a process. These values are used throughout the overdue processing module.
- A template's Cancel Criteria algorithm is executed to determine if a process should be cancelled. Refer to How Are Overdue Processes Cancelled for the details.
- A template's Cancel Logic algorithm is executed to cancel a process. Refer to How Are Overdue Processes Cancelled for the details. Please note that the logic embodied in this type of algorithm can be sophisticated because it is responsible for stopping an ongoing process's activities (e.g., this could involve cancelling field activities or cases). Cancellation algorithms are also responsible for inserting log entry(s).
- A template's Hold Event Activation algorithm is invoked to determine if the Overdue / Cut Event Manager should suspend the activation of the process's events.
- A template's Information algorithm is invoked to construct the override "info string".

Next, extract each unique event type from the above table:

Overdue Event Type	Action
Old debt letter	Create a customer contact
Cut active service agreement(s)	Start a cut process for every active SA with an unpaid FT on the bill

Copyright © 2026, Oracle and/or its affiliates.

Reduce customer's credit rating	Insert an account credit rating history record
Write down small debt	Create write-down adjustments if unpaid debt is less than $x
Refer debt to collection agent	Create a collection agency referral
Cancel collection agent referral	Cancel the collection agency referral
Write off unpaid debt	Create adjustments to write-off unpaid debt

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of each event type:

- The event type's Event Activation algorithm(s) are executed by the Overdue / Cut Event Manager on its trigger date. The following points describe the logic embodied in such an algorithm:
  - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to Overdue Events Can Do Many Things for the details.
  - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to Some Events Can Wait for the details.
  - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to Activating Events Should Add A Log Entry for the details.
- The event type's Cancel Logic algorithm(s) are invoked when an event is cancelled. The following points describe the logic embodied in such an algorithm:
  - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
  - Any ancillary actions that take place during cancellation.
  - How the log entry(s) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to monitor a waiting event. These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the override "info string".

Once you've designed each event type's algorithms, you're ready to design your cut processes.

Designing Cut Process Templates and Event Types

While not required, many overdue processes will contain an overdue event that cuts (i.e., stops) service (in the hopes that stopping service will inspire the customer to pay). When such an event activates, it creates one or more cut process(es).

The system allows you to control if and how service is cut by setting up Cut Process Rule algorithms on your SA types. This allows different rules for different types of service agreements. In addition, because these rules are embodied in algorithms, a given SA type can have conditional logic that controls the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **If a service agreements of a given type should never be cut.** If you have certain SA types that should never be cut, do NOT define an algorithm in the SA type's Cut Process Rule .

Determining your Cut Process Rules can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For service agreements associated with metered service, we have the following rules:
  - Highest priority. If the customer has life support requirements, create "cut process in light of life support" process.
  - Lowest priority. Otherwise, create a "metered service" cut process.
- For service agreements associated with charitable contributions, create an "expiration only" cut process.

Once you've determined if / how each SA type is cut, you need to design your cut process templates (you'll need one for each unique method of cutting a service agreement). The following table shows the cut process templates referenced above. Adjacent to each process are its events and an indication of when they are triggered.

Cut Process Template	Event Number	Cut Event Type	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Metered service	10	Letter - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Cut process in light of life support	10	Generate delinquent life support customer To Do entry (seeking approval for the cut)	N/A - first event	0
	20	Letter - 72 hour disconnect for non-payment warning	10	0
	30	Generate impending life support cutoff To Do entry to C&C rep	20	3

Copyright © 2026, Oracle and/or its affiliates.

	40	Field activity - cut for non-payment	30	0
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Expiration only	10	Expire service agreement	N/A - first event	

At this point, you've designed the distinct cut process templates. Next, you'll need to design the algorithms that control the lifecycle of their cut processes:

- A template's Cancel Logic algorithm is executed to cancel a process. In addition to cancelling the event, these algorithms are also responsible for inserting log entry(s).
- A template's Information algorithm is invoked to construct the override "info string".

Next, extract each unique event type from the above table:

Cut Event Type	Action
48-hour warning letter	Create a customer contact - 48-hour warning letter (letters are created via customer contacts)
72-hour warning letter	Create a customer contact - 72-hour warning letter
Disconnect for non payment	Create a cut for non-payment field activity
Permission to start a cut process for a life support customer	Create To Do seeking permission to send 72 hour letter
Permission to create a cut field activity for a life support cutoff	Create To Do seeking permission to issue a cut field activity
Service has been disconnected letter	Create a customer contact - service cut letter
Expire service agreement	Expire service agreement

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of their events:

- The event type's Event Activation algorithm(s) are executed by the Overdue / Cut Event Manager on its trigger date. The following points describe the logic embodied in such an algorithm:
  - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to Cut Events Can Do Many Things for the details.
  - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to Some Events Can Wait for the details.
  - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to Activating Events Should Add A Log Entry for the details.
- The event type's Cancel Logic algorithm(s) are invoked when an event is cancelled. The following points describe the logic embodied in such an algorithm:

Copyright © 2026, Oracle and/or its affiliates.

  - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
  - Any ancillary actions that take place during cancellation.
  - How the log entry(s) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to monitor a waiting event. These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the override "info string".

Set Up Tasks

The above topics provided background information about how overdue processing works. The following discussion summarizes the various set up tasks.

- Cut Event Types
- Cut Process Templates
- SA Type - Cut Process Rules
- Overdue Event Types
- Overdue Process Templates
- Collection Classes
- Collection Class Overdue Monitor Rules
- Feature Configuration
- Overdue and Cut Event Cancellation Reasons
- Collection Agencies
- Alert To Highlight Active Overdue Processes
- Bill-Oriented Collection - Additional Set Up

Cut Event Types

You will find that most of the time spent setting up your cut event types is spent setting up the objects that are referenced on the cut event type algorithms. For example, if you use the base-package algorithms, you may need to set up the following:

- The various "types" for the objects created by the plug-ins. For example, if a cut event type creates a To Do entry, you must supply the desired To Do type.
- Foreign key characteristic types that are used to reference the ancillary objects in the log entries (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- Messages that are used to define the verbiage in the log entries. For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when

Copyright © 2026, Oracle and/or its affiliates.

customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).

- Etc.

The only way to compile the complete list is to design the parameters for each cut event type algorithm. Refer to Cut Event Type - Main for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the cut event types.

Cut Process Templates

After your cut event types exist, you can set up your cut process templates. You will find that most of the time spent setting up your cut process templates is spent setting up the objects that are referenced on the cut process template algorithms. Refer to Cut Process Template - Main for the supported system events.

SA Type - Cut Process Rules

After you've created your cut process templates, you can set up the algorithms that hold your cut process rules. These are plugged-in on SA Type - Algorithm in the Cut Process Rule system event.

Overdue Event Types

You will find that most of the time spent setting up your overdue event types is spent setting up the objects that are referenced on the overdue event type algorithms. For example, if you use the base-package algorithms, you will set up the following:

- The various "types" for the objects created by the plug-ins. For example,
  - If an overdue event type creates a To Do entry, you must set up the To Do type.
  - If an overdue event type creates a customer contact, you must set up the customer contact type.
  - If an overdue event type writes off debt, you must set up the adjustment types.
  - Etc.
- Foreign key characteristic types that are used to reference the ancillary objects in the log entries (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- Messages that are used to define the verbiage in the log entries. For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each overdue event type algorithm. Refer to Overdue Event Type - Main for the supported plug-in spots.

Copyright © 2026, Oracle and/or its affiliates.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the overdue event types.

Overdue Process Templates

After your overdue event types exist, you can set up your overdue process templates. You will find that most of the time spent setting up your overdue process templates is spent setting up the objects that are referenced on the overdue process template algorithms. Refer to Overdue Process Template - Main for the supported system events.

Collection Classes

Set up collection classes as per your overdue procedures. Make sure to indicate that these collection classes use the Overdue collection method (only accounts linked to collection classes designated as using the Overdue collection method or processed by the Overdue Monitor).

Collection Class Overdue Monitor Rules

After your overdue process templates exist, you can set up your Overdue Monitor Rules. These rules are algorithms plugged in on Collection Class Overdue Rules. You will find most of the time spent setting up these algorithms is spent setting up the objects referenced on the base-package algorithm.

Feature Configuration

You must set up a Feature Configuration to define parameters that control various overdue processing options.

The following points describe the various **Option Types** that must be defined:

- Trigger Date: Y-Workdays, N-Calendar Days. This option controls how the system computes the trigger dates on overdue and cut events. Enter Y if the system should use workdays. Enter N if the system should use calendar days. Refer to Calendar vs Work Days for the details.
- Payment Arrangement Type (B/S/A). This option indicates whether your implementation uses the Balance-Oriented Payment Arrangements (value **S**), Bill-oriented Payment Arrangements (value **B**) or both (value **A**). The value governs the navigation path for the payment arrangement lines in the Account History and Credit & Collection zones.
- Champion Template$Challenger Template$Percentage(1-100). You need only set up options of this type if your implementation implements Champion / Challenger functionality. Options of this type are entered in the format ABnnn where A is the overdue process template of the champion template, B is the overdue process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The overdue monitor uses this option to override the champion overdue process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

Copyright © 2026, Oracle and/or its affiliates.

Overdue and Cut Event Cancellation Reasons

Overdue events can be cancelled automatically and manually (at the discretion of a user). Regardless of the method of cancellation, a cancellation reason must be supplied. You set up your overdue event cancellation reasons using Overdue Event Cancellation Reason - Main and Cut Event Cancellation Reason - Main.

Collection Agencies

If you refer debt to collection agents, you must set up your collection agencies.

Alert To Highlight Active Overdue Processes

If you want an alert to appear if the account has active overdue processes, you must configure an appropriate Control Central Alert algorithm (C1-OD-PROC). This algorithm is plugged in on the Installation record.

Bill-Oriented Collection - Additional Set Up

The topics in this section provide information on additional set up requirements if you collect on unpaid bills.

- One Bill Per Match Event
- Bill-Based Payment Arrangements
- Bill-Based Write-off
- Alert To Highlight Written Off Bills
- Open-Item Bill Amount Plug-In

One Bill Per Match Event

As mentioned earlier, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. To determine a bill's outstanding amount, FTs from different bills cannot be commingled on the same match event (but it's OK for a bill's FTs to be on multiple match events). If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill. However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate.

The following Open-Item algorithm types have been provided by the base package to help enforce this rule:

- The Distribute by Bill Due Date Payment Distribution algorithm (C1-PYDS-BDU).
- The match by Bill ID Payment Distribution Override algorithm (C1-PDOV-PYBL).
- The FT cancellation FT Freeze algorithm (C1-CFTZ-COFT).

Copyright © 2026, Oracle and/or its affiliates.

If any of your customized plug-ins and processes create match events, it is important that these too enforce this rule. You may want to refer to the base package algorithms as an example of how to do this.

Bill-Based Payment Arrangements

If you set up payment arrangements for unpaid bills, you must configure the Bill-Based Payment Arrangement algorithm and plug it in on your Collection Class Overdue Rules.

It's important to set up the adjustment types used during payment arrangement creation to NOT print on bills. This is because the base-package algorithm will match the adjustments used to transfer debt to the payment arrangement with the adjustment used to reduce the payment arrangement's current amount by the amount of the transfer if all adjustment types are set up to not print.

Bill-Based Write-off

If you write-off unpaid bills, you must set up the following:

- Set up the adjustment type that will be used to write-off an unpaid financial transaction. This adjustment type must be configured as follows:
  - **Adjustment Amount Type** must be Calculated Amount
  - Its distribution code is irrelevant as a separate calculation line will be created for each distribution code on the FT's that is written off and these lines will reference the appropriate distribution code.
  - It must reference an adjustment type char type / value that identifies it as one used to write-off a bill's FTs
  - The following algorithms must be defined on the adjustment type:
- The Generate Adjustment system event must reference an algorithm that has the responsibility of determining how to write-off a FT. This algorithm should be determining the FT's GL details and creating a separate adjustment calculation line for each GL detail. The base package is supplied with a sample algorithm that does this (C1-ADJG-WO).
- The Adjustment Financial Transaction system event should reference an algorithm that impacts current, payoff and the GL by the amount being written off.
  - The distribution codes referenced on the financial transactions must be set up with a characteristic that holds the distribution code used to write-off the original amounts. For example,
    - Distribution codes used to record tax liabilities will typically reference the same distribution code for write-off (most organizations reverse tax liabilities at write-off time)
    - Distribution codes used to record revenue will typically reference a write-off distribution code used to record a write-off expense.
    - Distribution codes used to record receivables will typically not reference a write-off distribution code because receivables are implicitly written off when revenue and tax liabilities are written off.
  - Set up an adjustment cancellation code used when a users reverses a written-off bill (reversal involves canceling the write off adjustments).

Copyright © 2026, Oracle and/or its affiliates.

– Set up a Write Off Bill algorithm and plug it in on your Collection Class Overdue Rules. This algorithm will reference the adjustment type described in the previous point.

Alert To Highlight Written Off Bills

If you want an alert to appear if the account has bills with written-off debt, you must configure an appropriate Control Central Alert algorithm (C1-WO-BILL). This algorithm is plugged in on the Installation record.

Open-Item Bill Amount Plug-In

You must set up the algorithm that computes the original, unpaid, and write-off amounts of your open-item bills. This algorithm is called by other algorithms when these amounts are needed. This algorithm is plugged-in on Installation in the Determine Open Item Bill Amounts spot.

Setting Up Overdue Processing

The topics in this section describe how to set up the control tables to implement your overdue processing.

- Setting Up Overdue Event Types
- Setting Up Overdue Process Templates
- Setting Up Cut Event Types
- Setting Up Cut Process Templates
- Setting Up Collection Class Overdue Rules
- Setting Up Overdue Event Cancellation Reasons
- Setting Up Cut Event Cancellation Reasons

Setting Up Overdue Event Types

An overdue event type encapsulates the business rules that govern a given type of overdue event. Open **Admin**, and then **Credit & Collection**, and then **Overdue Event Type**, and then **Add** to set up overdue event types.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Overdue Events.

Description of Page

Enter a unique **Overdue Event Type** code and **Description** for the overdue event type.

Copyright © 2026, Oracle and/or its affiliates.

Use **Long Description** to provide a more detailed explanation of the purpose of the overdue event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel an overdue event. Refer to How Are Events Canceled for the details.
Event Activation	Required	This algorithm is executed to activate an overdue event on its trigger date. Refer to Overdue Events Can Do Many Things and How and When Events Are Activated for the details.
Event Information	Optional - only used if you want to override an overdue event's info string	This algorithm is executed to construct an overdue event's override info string. Refer to Overdue Event Information Is Overridable for the details.
Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Overdue / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details.

Setting Up Overdue Process Templates

An overdue process template encapsulates the business rules that govern a given type of overdue process. Open **Admin**, and then **Credit & Collection**, and then **Overdue Process Template**, and then **Add** to set up overdue process templates.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Overdue Processes.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

Enter a unique **Overdue Process Template** and **Description** for the overdue process template.

Collecting On Object defines the type of object managed by this overdue process. This field actually references a foreign key characteristic type that references the managed object. For example, if this overdue process template manages overdue bills, you'd reference a foreign key characteristic that references the bill object.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Calculate Unpaid & Original Amount	Required	This algorithm is executed to calculate the unpaid and original amounts of the objects associated with the overdue process. These amounts are shown on the overdue process page and in the base-package overdue info string.
Cancel Criteria	Required	This algorithm is executed to determine if an overdue process can be cancelled. Refer to How Are Overdue Processes Cancelled for the details.
Cancel Logic	Required	This algorithm is executed to cancel an overdue process. Refer to How Are Overdue Processes Cancelled for the details.
Hold Event Activation Criteria	Optional - only used if overdue processes of this type can be suspended while some condition is true	This algorithm is executed to determine if the activation of overdue and cut events should be suspended. Refer to Holding Events for the details.
Overdue Process Information	Optional - only used if you want to override an overdue process's info string	This algorithm is executed to construct an overdue process's override info string. Refer to Overdue Process Information Is Overridable for the details.

The **Event Types** control the number and type of overdue events linked to an overdue process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the overdue event types appear in the scroll.
- **Overdue Event Type.** Specify the type of overdue event to be created.

Copyright © 2026, Oracle and/or its affiliates.

- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the overdue process. Refer to How and When Events Are Activated for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
  - **Sequence** is system-assigned and cannot be specified or changed.
  - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Cut Event Types

A cut event type encapsulates the business rules that govern a given type of cut event. Open **Admin**, and then **Credit & Collection**, and then **Cut Event Type**, and then **Add** to set up cut event types.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review Cut Events Are Like Overdue Events.

Description of Page

Enter a unique **Cut Event Type** code and **Description** for the cut event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the cut event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut event. Refer to How Are Events Canceled for the details.
Event Activation	Required	This algorithm is executed to activate a cut event on its trigger date. How and When Events Are Activated for the details.

Copyright © 2026, Oracle and/or its affiliates.

Event Information	Optional - only used if you want to override a cut event's info string	This algorithm is executed to construct a cut event's override info string. Refer to Cut Event Information Is Overridable for the details.
Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Cut / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details.

Setting Up Cut Process Templates

A cut process template encapsulates the business rules that govern a given type of cut process. Open **Admin**, and then **Credit & Collection**, and then **Cut Process Template**, and then **Add** to set up cut process templates.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Cut Processes.

Description of Page

Enter a unique **Cut Process Template** and **Description** for the cut process template.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut process. Refer to How Are Cut Processes Cancelled for the details.
Cut Process Information	Optional - only used if you want to override a cut process's info string	This algorithm is executed to construct a cut process's override info string. Refer to Cut Process Information Is Overridable for the details.

Copyright © 2026, Oracle and/or its affiliates.

The **Event Types** control the number and type of events linked to a cut process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the cut event types appear in the scroll.
- **Cut Event Type.** Specify the type of cut event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the cut process. Refer to How and When Events Are Activated for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
  - **Sequence** is system-assigned and cannot be specified or changed.
  - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Collection Class Overdue Rules

Collection class overdue rules contain algorithms that impact accounts associated with a given collection class, division and currency code are managed. Open **Admin**, and then **Credit & Collection**, and then **Collection Class Overdue Rules**, and then **Add** to set up collection class overdue rules.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review Different Overdue Rules For Different Customers.

Description of Page

Enter the **Collection Class**, **CIS Division** and **Currency Code** to which the rules apply.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
  The following table describes each **System Event**.

System Event	Optional / Required	Description
Bill-Based Payment Arrangement	Optional - only specified if your implementation uses bill-oriented payment arrangements	This algorithm is executed to handle the creation, breaking and canceling of a Bill-Oriented Payment Arrangements.

Copyright © 2026, Oracle and/or its affiliates.

Overdue Monitor Rule	Required	This algorithm is invoked by the Overdue Monitor to analyze an account's debt. Refer to How Does The Overdue Monitor Work for the details. If you have multiple rules (and therefore multiple algorithms), please take care when assigning the sequence number, as the Overdue Monitor will invoke these rules in sequence order.
Write Off Bill	Option - only specified if your implementation writes-off bills	This algorithm is executed to handle the write-off and write-off reversal of a bill. Refer to Writing Off Bills.

Setting Up Overdue Event Cancellation Reasons

An overdue event cancel reason must be supplied before an overdue event can be canceled. Open **Admin**, and then **Credit & Collection**, and then **Overdue Event Cancel Reason** to define overdue event cancellation reasons.

Description of Page

Enter an easily recognizable **Overdue Event Cancel Reason** and **Description** for each cancellation reason.

Setting Up Cut Event Cancellation Reasons

A cut event cancel reason must be supplied before a cut event can be canceled. Open **Admin**, and then **Credit & Collection**, and then **Cut Event Cancel Reason** to define cut event cancellation reasons.

Description of Page

Enter an easily recognizable **Cut Event Cancel Reason** and **Description** for each cancellation reason.

Defining Interval Billing Options

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The transactions described in this section are only available if the interval billing module is turned on. This Customer Care and Billing functionality has essentially been deprecated and should be performed within a Meter Data Management system. This functional area remains within Customer Care and Billing exclusively for upgrading customers who currently use Interval Billing within an earlier version of this system.

> **Note**
>
> The interval rating and billing functionality described in this chapter was designed and developed prior to the big data requirements of the smart grid. Implementations should use a meter data management application, such as Oracle Utilities Meter Data Management, for smart grid requirements.

The system provides capability to bill complex customers who measure usage in small intervals, such as one hour, thirty minutes, fifteen minutes, etc. The "Interval Billing" subsystem covers a variety of functionality including:

- Capturing billable interval data quantities linked to a service agreement
- Capturing "raw" interval data quantities linked to service points, which may be later aggregated to create billable quantities for the service agreement
- Application of contract-based modifications to produce interval data quantities
- Apply interval prices to interval quantities. (Sometimes this is known as "direct billing")
- Support time of use mapping, including override maps created for certain special periods, such as interruptions
- Support time of use pricing and time of use contract values
- Support special contract options under which certain calculations supporting a contract's rate may be overridden or altered occasionally for specific periods of time

> **Note**
>
> The ability to capture and maintain interval prices and TOU prices is officially part of the Rates subsystem. Although we will refer to them here, the main documentation is in the Rates administration guide.

> **Warning**
>
> Setting up the interval billing control tables is as challenging as your organization's interval billing rules. If you have simple rules then your setup process will be straightforward. If your interval billing rules are complicated (e.g., specific prices for each customer, complicated TOU Mapping rules etc.), then your setup process will be more challenging.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Separate modules.** Interval billing functionality is associated with separate modules, Complex Billing and Meter Data Management. If these modules are not applicable to your business you may turn them off. Refer to Turn Off A Function Module for more information.

- Interval Billing Table Setup Sequence
- The Big Picture of Interval Billing
- Designing Interval Billing Options
- Setting Up Interval Billing Options

Interval Billing Table Setup Sequence

The following table defines the table setup sequence required if your company has purchased the interval billing component.

Function	Path
General Environment	
Seasonal Time Shift	Admin, Seasonal Time Shift
Time Zone	Admin, Time Zone
Installation - Framework	Admin, Installation Options - Framework Indicate whether Seasonal Time Shift is required.
Installation	Admin, Installation Options Set Base Time and Start Day Option.
Interval Billing Environment	
Bill Factor	Menu, Rates, Bill Factor Note: earlier, you may have created bill factors for your general Rates environment. At this point, you may need to add more bill factors to satisfy your interval billing needs.
Interval Profile Relationship Type	Admin, Interval Profile Relationship Type [Note - you won't be able to define the collection of valid Interval Profile Types until after you define the Interval Profile Types.]
Interval Profile Type	Admin, Interval Profile Type [Note - you may need to define new algorithm types and algorithms if your interval profile type requires creation or validation algorithms.]
Algorithm	Admin, Algorithm. You will need to set up the creation and validation algorithms needed for an Interval Profile Type.

Copyright © 2026, Oracle and/or its affiliates.

Shared Profiles	Menu, Interval Billing, Interval Profile Note: this is needed at this time if you want to create Start Options, which reference shared profiles.
Interval Registers	
Interval Register Type	Admin, Interval Register Type
Meter Configuration Type	Admin, Meter Configuration Type Note: earlier, you may have created meter configuration types for your general meter environment. At this point, you may need to add more meter configuration types for registers, which are used for interval or index channels.
Meter Type	Admin, Meter Type Note: earlier, you may have created meter types for your general meter environment. At this point, you may need to add more meter types for meters, which are used for interval or index channels.
Time of Use Billing	
Time of Use	Admin, Time of Use Note: earlier, you may have created time of use codes for your meter environment. At this point, you may need to add more time of use codes to satisfy your time of use mapping.
TOU Group	Admin, TOU Group
Bill Factor	Menu, Rates, Bill Factor At this point you may need to set up bill factors that are specifically for time of use pricing.
TOU Map Relationship Type	Admin, TOU Map Relationship Type [Note - you won't be able to define the collection of valid TOU Map Types until after you define the TOU Map Types.]
TOU Map Type	Admin, TOU Map Type
Algorithm	Admin, Algorithm. You will need to set up any creation algorithms needed for your TOU map types.
TOU Map Templates	Admin, TOU Map Template Note: this is not required, but will help to set up data for your TOU Maps.
Shared TOU Maps	Menu, Interval Billing, TOU Map Note: this is needed at this time if you want to create Start Options, which reference shared TOU maps.
Contract Options	
Contract Option Type	Admin, Contract Option Type
Algorithm	Admin, Algorithm. You will need to set up any validation algorithms needed for your contract option types.
Contract Option Event Type	Admin, Contract Option Event Type

Copyright © 2026, Oracle and/or its affiliates.

SA Interval Billing Rate Environment	
Rate	At this point, you are ready to set up your interval billing and time of use rates and calculation rules. Refer to the Rate Environment section in the Control Table Setup Sequence.
SA Interval Billing Controls	
SA Type	Admin, SA Type Note: earlier you may have created your SA Types. At this point you may need to modify interval related SA Types to add valid interval information. Refer to the SA Type section in the Control Table Setup Sequence.
Start Option	Admin, SA Type Start Option Note: earlier you may have created your SA Type Start Options. At this point you may need to modify interval related SA Type Start Options to add valid interval information. Refer to the SA Type section in the Control Table Setup Sequence.

> **Note**
>
> You may have customers with interval billing, time of use billing and contract options all required for their rate. For simplification of the table, these control tables were listed in separate sections.

The Big Picture of Interval Billing

This section provides an overview of important Interval Billing concepts with which you should be familiar before you set up your Interval Billing control tables.

- Interval Pricing
- Raw Data Collection and Aggregation
- Time of Use Billing

Interval Pricing

This section provides an overview of concepts related to setting up interval pricing options for your rates. Applying interval prices to interval quantities is sometimes referred to as 'direct billing'.

- Interval Pricing Rate Application
- Physical Attributes of Interval Data vs. Its Role

Copyright © 2026, Oracle and/or its affiliates.

Interval Pricing Rate Application

Interval Pricing is the term used to describe applying interval prices to interval quantities to arrive at a bill calculation line item.

What data is needed in order to apply a rate component for an interval pricing scenario and how is this data defined?

- You need prices that vary at a given interval. Interval prices are stored for a **Bill Factor**/ characteristic. Refer to Bill Factor Interval Values for more information.
- You need consumption values for each corresponding interval. The consumption values are stored for an Interval Profile linked to a service agreement. Refer to Billable Interval Quantities for a Service Agreement for more information. In order to find the correct interval profile for the service agreement, the rate component will reference a **Profile Relationship Type**. Refer to Physical Attributes of Interval Data vs. Its Role and Interval Data Serves a Role for a Service Agreement for more information.
- You need an algorithm in order to know how to apply the prices correctly. The rate component will reference a **Calculation Algorithm**, which will be executed to apply the prices to the quantities.

Refer to Designing Your Interval Rate Components for help in designing rate components of this type. Refer to Setting Up Interval Pricing Rate Components for more information.

Physical Attributes of Interval Data vs. Its Role

You will see, as you learn more about the design of interval billing, that there are two control tables that are important for defining billable interval data:

- Profile Type - this defines the physical attributes of the interval data
- Profile Relationship Type - this defines the role that the interval data is playing for a particular contract. You can also think of this as defining the business purpose of the data.

Copyright © 2026, Oracle and/or its affiliates.

- Interval Data Physical Attributes
- Business Role of Interval Data
- The Business Role Defines Interval Data Physical Attributes

Interval Data Physical Attributes

When defining a collection of billable data, there are basic attributes, which need to be defined:

- Unit of Measure
- Minutes per Interval
- Service Quantity Identifier
- Is this data owned by a service agreement or is it common data?

These are physical attributes of the data and have nothing to do with the business purpose of the data. This information is defined on the Profile Type.

The profile type may also include algorithms related to its data:

- Validation algorithms may be used to check and correct various conditions related to the interval data. Refer to Validation of Profile Data for more information.
- A creation algorithm may be used to derive data for a profile. Refer to Creation of Profile Data through Data Derivation for more information.

Refer to Designing Interval Profile Types for more information.

You will see later that classic TOU Maps also have a classic TOU Map Type. Refer to Physical Attributes of a classic TOU Map for more information.

Business Role of Interval Data

The Profile Relationship Type is used by the system to indicate the "role" that a collection of billable interval data is playing. The following are some examples of roles that interval data may play:

- Measured Demand
- Contract Demand
- Aggregated Heating Demand
- Hedge Cover
- Excess Demand
- Reactive Energy

The profile relationship type is used by the rate component to indicate the data being billed. For example, the rate is billing "excess demand". When applying the rate, the system will determine which data is playing the role of "excess demand" for the service agreement. Refer to Billable Interval Quantities for a Service Agreement and Interval Data Serves a Role for a Service Agreement for more information.

You will see later that classic TOU Maps also have a "role". Refer to Business Role of a TOU Map for more information.

Copyright © 2026, Oracle and/or its affiliates.

The Business Role Defines Interval Data Physical Attributes

To enable proper setup, you will need to define the valid profile types for each profile relationship type.

Raw Data Collection and Aggregation

This section provides an overview of concepts related to setting up your control tables to support the capturing of raw interval data.

NOT_SUPPORTED

Refer to The Big Picture of Raw Data Collection and Aggregation for more information.

Note

If your company uses an external system for collecting, adjusting and aggregating raw interval data, then you may skip this section.

- Physical Attributes of Raw Interval Data

Physical Attributes of Raw Interval Data

Raw interval data is available for use by algorithms in the system to create billable data for the service agreement. This data will not have any 'business' role, as with the billable interval data, described above.

As a result only 'physical' attributes of the raw interval data need to be defined, such as:

- Unit of Measure
- Minutes per Interval
- Service Quantity Identifier

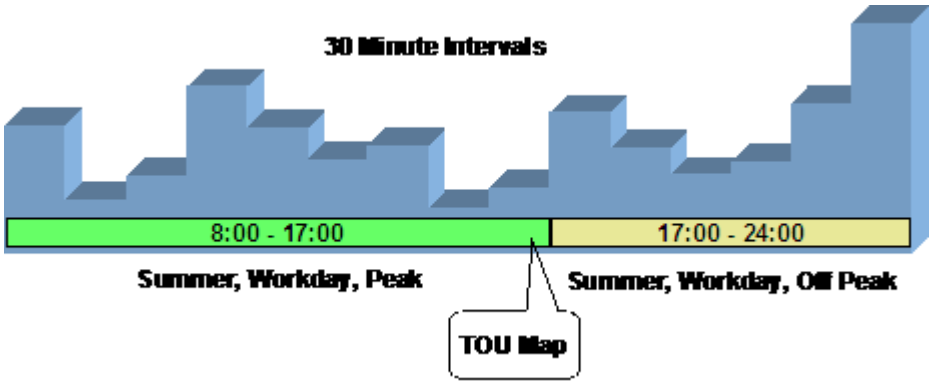
This information is defined on the Interval Register Type.

The interval register type may also include algorithms related to its data:

- Validation algorithms may be used to check and correct various conditions related to the interval data. Refer to Validation of Register Data for more information.

Time of Use Billing

This section provides an overview of concepts related to setting up your control tables to support time of use billing.



Copyright © 2026, Oracle and/or its affiliates.

- Defining Time of Use Periods
- Grouping of TOU Codes
- Time of Use Mapping and Pricing
- Physical Attributes of TOU Map vs. Its Role

Defining Time of Use Periods

Many customers choose not to price their interval data using interval prices. Time of Use Mapping enables a customer to map out time of use periods for their usage. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A classic TOU Map holds the collection of time period definitions. The TOU Map has a TOU Map Type, which defines the minutes per interval. This is similar to the interval profile and profile type.

The time period definitions for a classic TOU Map indicate the TOU code for a given date and time.

Map #123 (TOU Group 2)	
Effective 1 Jan 2000	
Interval Date/Time	
30/Apr/00 16:30	On Peak/Winter
30/Apr/00 16:45	On Peak/Winter
30/Apr/00 17:00	Off Peak/Winter
30/Apr/00 17:15	Off Peak/Winter
...	
01/May/00 7:45	Off Peak/Summer
02/May/00 8:00	On Peak/Summer
02/May/00 8:15	On Peak/Summer
...	

All the possible time of use codes for a given map are grouped together in a TOU group. Refer to Grouping of TOU Codes for more information.

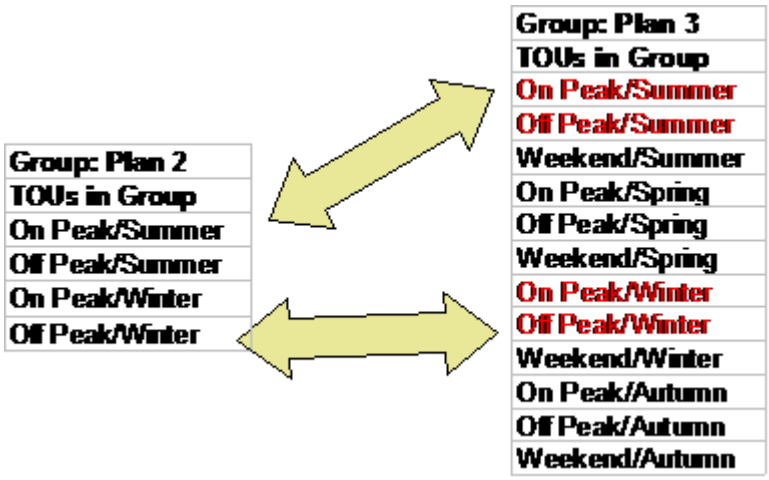
Copyright © 2026, Oracle and/or its affiliates.

Grouping of TOU Codes

- Overview
- TOU Sequence

Overview

The time of use map's purpose is to define time of use codes for given time periods. For example:



1/Jan/2001 05:00:000 is Off Peak, Winter

1/July/2001 13:00:000 is Weekend, Summer

5/July/2001 12:30:000 is On Peak, Summer

The time of use codes of "Off Peak, Winter" and "Weekend, Summer" are user-defined and use the same TOU code available for defining TOU for simple metering.

The set of time of use codes that make up a certain classic TOU map, are grouped together using the TOU group. The TOU group is a logical grouping of time of use codes. A TOU can exist on more than one TOU group.

The TOU group is used to define the collection of time of use codes available for a classic TOU map. In addition, you will see TOU group used in other areas of interval billing where a collection of time of use codes is required.

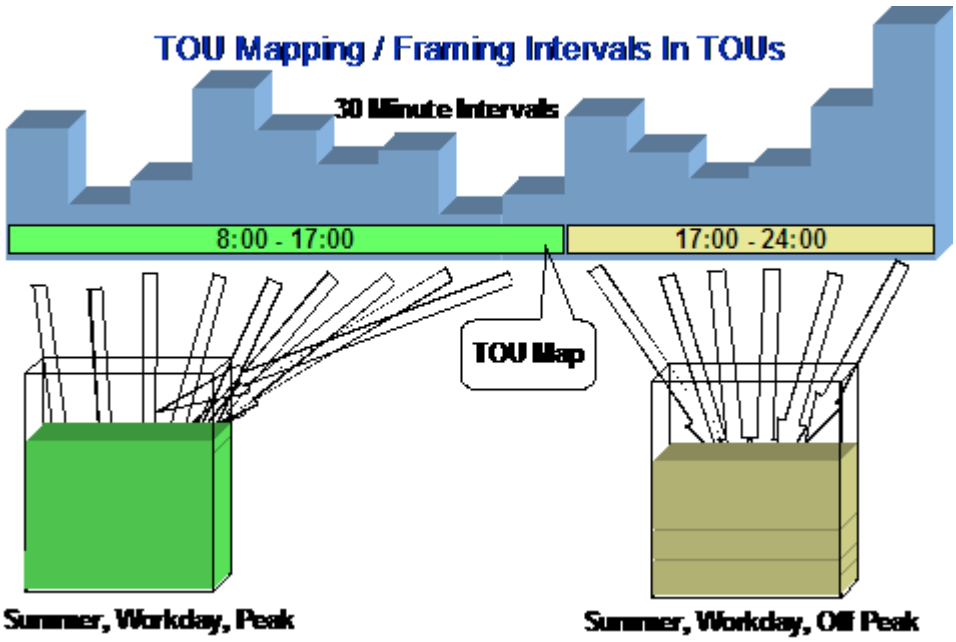
TOU Sequence

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Copyright © 2026, Oracle and/or its affiliates.

For example, assume that your customer's contract states that if the usage for the time period "ON" is below a certain contract limit, they will be charged the "ON" price. However, if the usage exceeds this contract limit, they will be charged a higher price for this usage. Let's assume the same is true for "OFF". You may choose to implement this as follows:

- Besides TOU codes of "ON" and "OFF", create additional TOU codes called "ONEXCESS" and "OFFEXCESS"
- Define the TOU codes within the TOU group with sequences values as follows:



Time of Use	TOU Sequence
ON	1
ONEXCESS	2
OFF	3
OFFEXCESS	4

- Your classic TOU map will only define time periods for ON and OFF, but you will have TOU prices for all four time of use values.
- Design your TOU pricing algorithm so that if the usage for a given TOU is within the contract limit, the price for this TOU is used. However, if the usage exceeds the contract limit, then it will find the TOU with the next highest sequence and use the price for that TOU.

Time of Use Mapping and Pricing

The following section describes the logic used by the system to map interval quantities to time of use codes using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take interval quantities linked to the service agreement and map them to time of use quantities based on a TOU Map.

Copyright © 2026, Oracle and/or its affiliates.

For simple billing, this type of data manipulation is typically handled using an SQ rule. Keep in mind that SQ Rules are processed before applying the rate components and therefore they do not have knowledge of system breaks that may cause price proration.

Proration occurs when a given price covers a period smaller than the billing period AND the system does not have readings for the period covered by the price. When this occurs, the system will prorate the usage to apply the correct price. Refer to Effective Dates & Price Proration for more information about proration.

If you read carefully the price proration information, you'll see that if the service quantities are peak quantities, the quantities are not prorated but the charges are prorated. For other cases, the system prorates the service quantities.

When your interval quantities are peak quantities, the same should apply. The mapping should occur prior to price breaks, for example, using an SQ rule. Then, the TOU pricing rate components would apply prices to the mapped SQ quantities.

For non-peak interval quantities, readings exist for any price break situation. As a result, no service quantity proration is necessary. The mapping simply needs to occur after all price breaks are determined - at the rate component level.

- TOU Pricing Rate Component
- Classic TOU Map Used For Mapping & Pricing
- TOU Price Breaks
- Overriding Mapped Quantities

TOU Pricing Rate Component

A special rate component exists to perform time of use mapping and time of use pricing. In fact, this rate component uses a calculation algorithm, so the algorithm can be written to perform whatever logic you need it to perform. The system is shipped with an algorithm, which performs mapping only and another algorithm, which may perform mapping and pricing, or just pricing.

- The mapping algorithms populate the read details collection by default because this collection can contain the quantities for each UOM/TOU/SQI along with a date range (This is important for price breaks.) In addition, you may configure the algorithm to also produce SQ quantities, which would represent the total quantities for each UOM/TOU/SQI.
- The pricing algorithm may be configured to apply prices to the SQ collection (for measures peak scenarios) or the read details collection (for non-measures peak scenarios).

Refer to Designing Your Time of Use Rate Components for help in designing rate components of this type. Refer to Setting Up TOU Pricing Rate Components for more information about setting up this type of rate component.

The TOU pricing rate component may reference a TOU bill factor, which contains prices that differ for each time of use code or a regular bill factor, which contains a single price to apply to all mapped quantities.

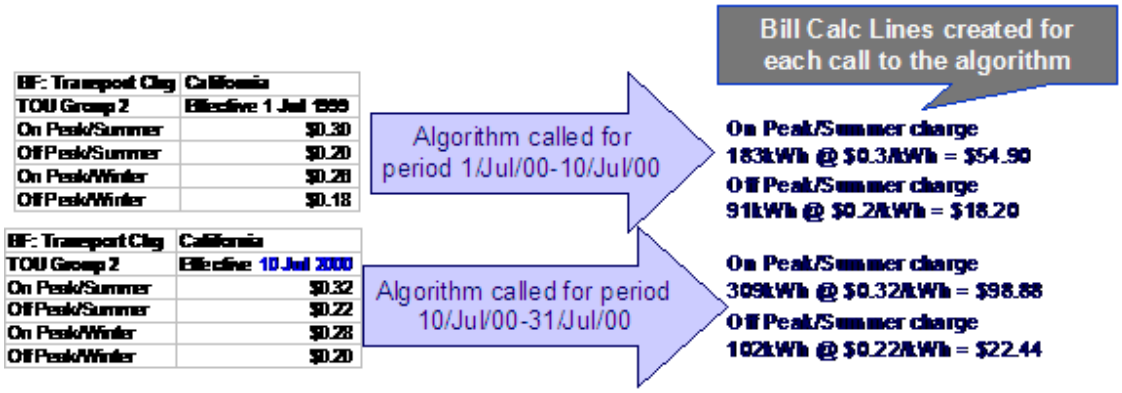
Classic TOU Map Used For Mapping & Pricing

The classic TOU map used by the rate component for mapping is defined either directly on the rate component or it is linked to the service agreement.

Copyright © 2026, Oracle and/or its affiliates.

- If ALL service agreements linked to the rate component's rate should use the same classic TOU map, then link the classic TOU Map to the rate component
- If some service agreements use different TOU maps than others, the TOU map must be linked to the service agreement. In this case, you must indicate a TOU Map Relationship Type on the rate component. The TOU map relationship type defines the business role of TOU map.

Refer to Sharing TOU Map Data for more information.



TOU Price Breaks

This section describes functionality related to price changes for time of use bill factor values. This logic is only applicable when the interval quantities do not measure peak quantities.

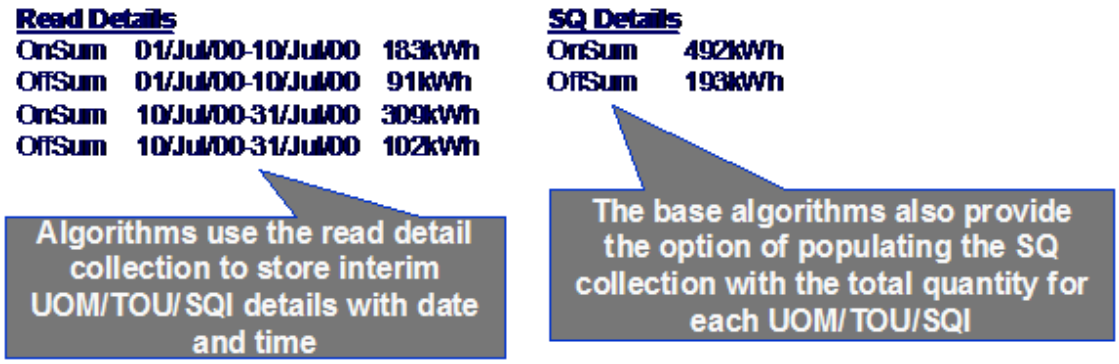
- Algorithms are Called for Each TOU Price Break
- Algorithms Are Responsible for Storing Calculation Details

Algorithms are Called for Each TOU Price Break

Rate application logic understands how to determine price breaks for the bill factor referenced on your rate component and calls the calculation algorithm for each price break. The TOU pricing algorithm will be passed the appropriate date/time range to handle mapping and pricing and will produce separated bill calculation lines for each time period.

> **Note**
>
> **Single TOU Group**. If your rate component references a TOU bill factor, the price breaks for the bill factor are determined using a single TOU group. If multiple classic TOU maps are applicable for the billing period and each refers to a different TOU group (via its TOU map type), the system uses the SA type's rate selection date to select the appropriate TOU group to use to determine the collection of prices to apply.

Top of Page



Algorithms Are Responsible for Storing Calculation Details

When the TOU mapping algorithms calculate the mapped quantities for a given date/time range, the results are stored in the calculation/audit read details collection on the bill segment.

Copyright © 2026, Oracle and/or its affiliates.

This collection enables the system to record the mapped quantities along with period represented by each quantity.

Your algorithms may opt to additionally capture the total quantity for each time of use in the SQ Details collection as an audit.

> **Note**
>
> Bill Factor prices have effective dates only. There is no effective time. When a price break occurs, the algorithm will determine the time for the price breaks in the same manner that billing time is determined. Refer to Start and End Times for Billing for more information.

The system provides one sample algorithm RCTMS that performs TOU mapping and another algorithm RCTMPS that performs TOU mapping and pricing or pricing alone. These algorithms support TOU price break logic as follows:

- The mapping functions for both algorithms populate the calculation/audit read details collection and allow you to set a parameter to indicate whether SQ entries should also be created.
- Based on a parameter, the pricing portion of RCTMPS applies the appropriate TOU prices to the mapped quantities stored in the calculation/audit read details collection.

If RCTMPS has been configured to perform mapping and pricing, it will perform the two functions as separate steps: first it maps the quantities and populates the read details, then it applies TOU prices to the read details. It does this for the following reasons:

- You may have a rate that requires manipulation of mapped quantities prior to applying prices. For example, perhaps you must add service quantities from a non-interval meter to your mapped quantities prior to applying prices.
- You may need to override the mapped quantities when recalculating a bill. The base algorithms will not re-map the quantities if the details were overridden. The pricing portion applies the prices to the overridden quantities.

Overriding Mapped Quantities

The mapping algorithms provided with the base product record the mapped quantities in the calculation/audit read details collection on the bill segment. When regenerating a bill segment, it is possible that circumstance requires you to override the details in this collection rather than allowing the system to map the interval quantities again.

Copyright © 2026, Oracle and/or its affiliates.

Refer to How To Override Service Quantities On A Specific Bill Segment for more information.

The pricing functionality in the algorithms provided by the base product detect when mapped quantities have been overridden and apply the TOU prices to the overridden quantities.

Physical Attributes of TOU Map vs. Its Role

You will see, as you learn more about the design of TOU mapping, that there are two control tables that are important for defining TOU maps:

- TOU Map Type - this defines the physical attributes of the TOU Map
- TOU Map Relationship Type - this is needed for TOU maps that are linked to a service agreement. It defines the role that the TOU Map is playing for that service agreement. You can also think of this as defining the business purpose of the data.
- Physical Attributes of a Classic TOU Map
- Business Role of a Classic TOU Map
- The Business Role Defines Valid Physical Attributes for a Classic TOU Map

Physical Attributes of a Classic TOU Map

When defining a classic TOU map, there are basic attributes, which need to be defined:

- The collection of possible time of use codes to which the data will be mapped. These are grouped together into a TOU group.
- Minutes per Interval
- Is this data owned by a service agreement or is it common data?

These are physical attributes of the data and have nothing to do with the business purpose of the data. This information is defined on the classic TOU Map Type.

The classic TOU map type may also include an algorithm used to automatically create data for the classic TOU map .

This is the same model used for interval profile data. Refer to Physical Attributes of Interval Data for more information.

Business Role of a Classic TOU Map

The TOU Map Relationship Type is used for TOU maps that are linked to the service agreement. It indicates the "role" that a classic TOU Map is playing for a particular service agreement. The following are some examples of roles that a classic TOU Map may play:

- Map for Measured Demand
- Map for Contract Demand
- Map for Excess Demand
- Map for Reactive Energy

If your rate component requires a classic TOU map but the TOU map is not common to all service agreements for the rate, then the rate component must indicate a TOU Map

Copyright © 2026, Oracle and/or its affiliates.

Relationship Type. The rate component algorithm uses this information to find the appropriate classic TOU map linked to the service agreement. Refer to Classic TOU Maps Serve a Role for a Service Agreement for more information.

This is the same model used for interval profile data. Refer to Business Role of Interval Data for more information.

The Business Role Defines Valid Physical Attributes for a Classic TOU Map

To enable proper setup, you will need to define the valid classic TOU map types for each TOU map relationship type.

NOT_SUPPORTED

For more information about defining classic TOU maps and recording the time period data, refer to Time of Use Mapping Background Topics.

Designing Interval Billing Options

Your interval billing options control how interval data may be maintained and billed for your customers with this capability.

NOT_SUPPORTED

For more information about interval billing, see The Big Picture Of Interval Billing.

Warning

There are many ways to design your interval billing options. The flexibility of the system may add to the challenge of determining the best way to set up your control tables. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production data, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

The design of your interval billing options is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. We recommend using the various steps in this section as a guide. When you are finished with this guide, you will be able to set up your interval billing options.

- Designing Your Interval Billing Rate Options
- Designing Your Interval Billing Controls
- Designing Your Raw Data Options
- Designing Your Time of Use Options

Copyright © 2026, Oracle and/or its affiliates.

- Designing Your Contract Options
- Designing Your SA Interval Billing Options

Designing Your Interval Billing Rate Options

This section assumes that you are familiar with the Rates subsystem and especially with the section Understanding Calculation Groups and Rules . Your interval billing rate components will likely contain a combination of standard rate components and interval billing rate components. The focus in this section will be on designing rate components for interval billing and time of use mapping.

- Designing Your Interval Rate Components
- Designing Your Billing Factors

Designing Your Interval Rate Components

Although your rates will likely contain a combination of interval pricing and time of use pricing, we have separated these topics with respect to walking you through the control table setup.

To set up the rate components that support interval billing, we recommend using the following table as your guide.

RC Type	Bill Factor	Interval Profile Relationship Type	Algorithm	TOU Map Relationship Type

Obtain copies of existing bills that use the rate in question. If the rate is new, then write up EXACTLY how the information should appear on the customers' printed bills.

- Next, try to identify the components of the bill that are related to interval billing.
  - Are any of the lines produced as a result of direct billing? In other words, were interval prices applied to interval quantities?
  - Are any of the lines produced using interval quantities applied to a fixed price?

Start filling out the table with descriptions of what is needed to produce each line.

- Any line that is produced as a result of taking interval quantities and applying prices will be defined with the "Interval Pricing" rate component type.
  - This rate component type will require an Interval Profile Relationship Type (which is used to define the source data to price).
  - A bill factor will need to be defined. This bill factor may contain interval quantities or simple values.
  - An algorithm, which knows how to apply the prices to the quantities, is needed. The system provides the following rate component algorithms as examples.
- Rate Components related to time of use mapping and pricing are discussed below. Refer to Designing Your Time Of Use Rate Components.

RC Type	Bill Factor	Interval Profile Relationship Type	Algorithm	TOU Map Relationship Type

Copyright © 2026, Oracle and/or its affiliates.

Interval Pricing	Strike Price	Hedge Cover	Apply prices to quantities assuming a continuous curve	N/a
Interval Pricing	Spot Market Prices	Amount in Excess of Hedge Cover	Apply prices only to positive quantities assuming a continuous curve	N/a

Designing Your Billing Factors

To apply prices to interval quantities, bill factors are recommended. In fact, to be able to handle interval prices, you will need to use bill factors.

NOT_SUPPORTED

To design and set up your bill factors, refer to Setting Up Bill Factors for more information.

Designing Your Interval Billing Controls

- Designing Interval Profile Relationship Types
- Designing Interval Profile Types

Designing Interval Profile Relationship Types

Recall that the interval profile relationship type can be thought of as the role that interval data will play. You can also think of it as the business description of the interval data.

The starting point for designing your interval profile relationship types is the rate. First, identify the relationship types that your rate needs in order to produce a bill

Using the above rate as an example, two profile relationship types have been identified

Profile Relationship Type	Description
HEDGECVR	Hedge cover
OVRHEDGE	Amount over hedge cover.

Now, you must think about what other relationship types are required to produce the above relationship types needed by rates. In our above example, we will need to define a profile relationship type whose data is compared to the hedge cover data to produce the OVRHEDGE data. Let's assume that this new profile relationship type is related to measured demand.

Copyright © 2026, Oracle and/or its affiliates.

Profile Relationship Type	Description
HEDGECVR	Hedge cover
OVRHEDGE	Amount over hedge cover.
MEASDMD	Measured Demand

In this manner, you will be able to successfully define your profile relationship types.

Designing Interval Profile Types

Now that you have your profile relationship types defined, you need to begin defining profile types. The interval profile type defines the physical attributes of the interval data.

The essential attributes of any profile type are the UOM/SQI, the minutes per interval and the associated algorithms. The easiest way to start defining your interval profile types is to start with the profile relationship type and determine what type of data each customer may have for the same profile relationship type.

Let's start with our profile relationship types and make some assumptions regarding the physical attributes of the data that a customer may have for each of these roles:

- Let's assume that a customer's demand may be measured in either 30-minute intervals or 60-minute intervals. In either case, the UOM is kW and SQI is not applicable. Let's also assume that the measured data may be interfaced from an external source or may be aggregated from interval register data.
- Let's assume that the hedge cover is common, but that these values may also be in 30-minute intervals or 60-minute intervals.
- Finally, let's assume that our spot market prices are at 60-minute intervals and that the algorithm, which rates uses to apply the interval prices, expects the "amount in excess of the hedge cover" to be in 60-minute intervals. This means that we need two different algorithms for our OVRHEDGE data. One algorithm is used for a customer with 60-minute intervals and simply subtracts the two curves and produces the resulting data. The second algorithm is used for a customer with 30-minute intervals. It performs two steps. It subtracts the hedge from the measured demand and adds together each resulting 30-minute pair to produce a 60-minute OVRHEDGE curve.

We will assume that all of our profile data will follow the same seasonal time shift as our base time zone. Refer to Time Zone and Time Changes and Designing Your Time Options for more information.

Prof. Rel. Type	Profile Type	Common/SA Owned	UOM/ SQI	Min/ Interval	Seasonal Time Shift	Algorithm
MEASDMD	DMDKW60	SA Owned	KW	60	USShift	N/a
	DMDKW30	SA Owned	KW	30	USShift	N/a
	DMDKW60AGG	SA Owned	KW	60	USShift	Aggregate interval register data
	DMDKW30AGG	SA Owned	KW	30	USShift	Aggregate interval register data
HEDGECVR	HEDGE60	Common	KW/ HG	60	USShift	N/a

Copyright © 2026, Oracle and/or its affiliates.

	HEDGE30	Common	KW/ HG	30	USShift	N/a
OVRHEDGE	OVRHG60	SA Owned	KW/ OVR	60	USShift	Compare MEASDMD to HEDGECVR to produce 60-minute over hedge curve
	OVRHG30	SA Owned	KW/ OVR	30	USShift	Compare MEASDMD to HEDGECVR and add 30-min interval pairs to produce 60-min 'over-hedge' curve

Note

The above table accomplishes two steps: defining profile types and defining the valid profile types for a profile relationship type. When setting up this data, you will need to define your profile types first and then link them to the appropriate profile relationship type.

As with most of your control table design, this is an iterative process. As you design your profile types, you may see the need for new profile relationship types. You may find that a profile type will be valid for more than one profile relationship type.

NOT_SUPPORTED

During your definition of the profile types, you may determine that new UOMs need to be defined. Refer to Setting Up Unit Of Measure Codes for more information.

During your definition of the profile types, you may determine that new pre-processing calculation groups that need to be defined. Refer to Understanding Calculation Groups and Rules for more information about defining SQI values.

Note

Now that you have designed the control table values required to support your rate, we recommend that you set up start options for your SA types to assist a CSR in setting up a customer for this rate.

All of the above steps will need to be repeated for each interval billing rate that your company offers. For each rate, you need to define your rate components, your billing factors, your profile relationship types and then the appropriate profile types.

Copyright © 2026, Oracle and/or its affiliates.

Designing Your Raw Data Options

> **Note**
>
> If your company uses an external system for collecting, adjusting and aggregating raw interval data, then you may skip this section.

The term "Channel" is often used for devices that may store interval data. A physical channel may hold interval data or index readings.

- Interval channels will contain collections of interval data
- Index channels are a collection of time of use registers and readings for these registers are no different than standard register readings

In either case, a "channel" is represented in the system by a register and a meter will represent a logical grouping of channels (index or interval). Refer to The Structure Of A Meter for more information.

- Designing Your Interval Register Types
- Designing Your Raw Data TOU Groups
- Designing Your Meter Configuration Types
- Designing Your Meter Types

Designing Your Interval Register Types

Each register, which will record raw interval data will require an interval register type.

The essential attributes of an interval register type are the UOM/SQI, the minutes per interval and any validation algorithms.

- For our examples, let's assume that raw interval data may be measured in kilowatts or megawatts and may be measured in either 30-minute intervals or 60-minute intervals.
- For our examples, let's assume that the data may be standard recorded data or it may be calculated excess data. We will use an SQI to further label the excess demand.
- For each register type in our example, we will use a validation algorithm, which will verify that the intervals are correct according to the interval size on the interval register type.

We will assume that all of our raw interval data will follow the same seasonal time shift as our base time zone. Refer to Time Zone and Time Changes and Designing Your Time Options for more information.

Interval Register Type	UOM/ SQI	Min/ Interval	Seasonal Time Shift	Validation Algorithm
KW60	KW	60	USShift	Validate interval size

Copyright © 2026, Oracle and/or its affiliates.

KW60EXC	KW/EXCESS	60	USShift	Validate interval size
KW30	KW	30	USShift	Validate interval size
KW30EXC	KW/EXCESS	30	USShift	Validate interval size
MW60	MW	60	USShift	Validate interval size
MW60EXC	MW/EXCESS	60	USShift	Validate interval size
MW30	MW	30	USShift	Validate interval size
MW30EXC	MW/EXCESS	30	USShift	Validate interval size

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See How To Add A New Algorithm for more information.

Designing Your Raw Data TOU Groups

In addition to designing TOU groups to be used by time of use maps, you may also set up TOU groups to define a valid collection of time of use values for a given meter configuration.

Designing Your Meter Configuration Types

You must define a meter configuration type for each valid collection of interval and index registers. For meter configuration types with index registers, you may indicate a TOU group, which contains the valid collection of time of use codes for the registers. For each interval register, you must check the Interval switch and indicate the appropriate Interval Register Type. A meter configuration may contain

- A single interval register
- Multiple interval registers
- A collection of index registers
- A combination of interval registers and index registers

Refer to Setting Up Meter Configuration Types for more information.

Designing Your Meter Types

You will need to set up appropriate meter type codes for the meters, which will be used to define or group index and interval channels. You must turn on the **Allow Interval Registers** switch for any meter type used by a meter, which will contain interval registers. Indicate the valid meter configuration types for this meter type.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If a meter type will only be used for meters linked to index channels, nothing special is required. Their behavior is similar to standard non-interval meters.

Designing Your Time of Use Options

- Designing Your Time Of Use Rate Components
- Designing Your Time of Use Codes
- Designing Your TOU Groups
- Designing Your Classic TOU Map Relationship Types
- Designing Your Classic TOU Map Types
- Designing Your Classic TOU Map Templates

Designing Your Time Of Use Rate Components

As you know from the rates chapter, the system can handle billing of quantities with different time of use periods using the SQ calculation rule type. Refer to How To Set Up Service Quantity Calculation Rule for more information. A more sophisticated rate component type is available, which can map interval profile data into time of use definitions and then apply prices based on time of use to produce multiple bill lines.

Obtain copies of existing bills that use the rate in question. If the rate is new, then write up EXACTLY how the information should appear on the customers' printed bills.

- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. For example, what is the source data? Which time of use map is used to define the time periods? A TOU Pricing rate component type may be used to map each curve to its time of use quantities, apply time of use prices to mapped quantities or do both mapping and pricing. It all depends on how your algorithm is written.
  - In order to perform mapping, this rate component type needs to know where to get the interval data. You must indicate an Interval Profile Relationship Type (which is used to define the source data to map). Refer to Billable Interval Quantities for a Service Agreement for more information.
  - In order to perform mapping or pricing, this rate component type needs to know the classic TOU map. If the TOU map is common to ALL service agreements for the rate, you must indicate the appropriate TOU map. If the TOU map differs for different service agreements, you must indicate a TOU Map Relationship Type. The algorithms use this to find the appropriate classic TOU map linked to the service agreement.
  - In order to perform pricing, this rate component type requires either a regular bill factor or a TOU bill factor. The bill factor may contain the collection of prices directly, or may indicate that the prices are customer specific and can be found as contract quantities for the service agreement.

Copyright © 2026, Oracle and/or its affiliates.

- A calculation algorithm to map and / or price the quantities is needed. For mapping, this algorithm must apply the classic TOU map to the quantity curve and produce entries in the calculation/audit read details collection. For pricing, the algorithm will need to use the appropriate bill factor to apply prices to the quantities in the read details collection. If this bill factor is a TOU bill factor, a separate price exists for each time of use.

For our example, let's assume that curves exist for both active demand and reactive demand and assume each curve is mapped with a different classic TOU map. In addition, let's assume that excess demand used during a specific curtailment period will be priced at a different rate.

- For active demand, we have four time periods: on-peak winter, off-peak winter, on-peak summer and off-peak summer.
- For reactive demand, there are no charges in the winter so we have only two time periods: on-peak summer, off-peak summer. This classic TOU map is common to ALL service agreements for the rate.
- The curtailment charge will only appear if there is a curtailment event and the customer used more than their maximum demand defined for the period.

RC Type	UOM/TOU	Bill Factor	Interval Profile Relationship Type	Algorithm	TOU Map Relationship Type	TOU Map ID
TOU Pricing	N/a	DMDTOU	Active Demand	Map quantities to time of use periods; apply prices	Active Demand Map	
TOU Pricing	N/a	RCTVTOU	Reactive Demand	Map quantities to time of use periods; apply prices		13849374
TOU Pricing	N/a	CURTAIL	Curtailment charge	Map quantities to time of use periods, compare with maximum demand; apply prices to excess	Curtailment	

Resulting bill calculation lines from the above TOU mappings (assuming this bill crosses the summer and winter seasons and a curtailment event occurred).

Charge for active kW On peak winter nn kW @ $0.0353/kW: $nn.nn
Charge for active kW Off peak winter nn kW @ $0.0298/kW: $nn.nn
Charge for active kW On peak summer nn kW @ $0.0483/kW: $nn.nn
Charge for active kW Off peak summer nn kW @ $0.0327/kW: $nn.nn
Charge for reactive kV On peak summer nn kV @ $0.0293/Kv: $nn.nn
Charge for reactive kV Off peak summer nn kV @ $0.0231/Kv: $nn.nn
Charge for curtailment excess nn kW @ $0.0593/kW: $nn.nn

Once you have your rate components designed, you will be able to design the other control tables needed to set up your time of use billing customer.

> **Note**
>
> Your time of use rate also requires interval profile relationship types. Refer to Designing Interval Profile Relationship Types and to Designing Interval Profile Types.

Designing Your Time of Use Codes

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. (Although it's possible that you are not billing for every time of use period.) Be sure to consider special time periods in your contracts such as holidays, curtailment days and interruption days.

Building on the above example, we have the following time of use codes defined:

Time of Use	Description
ONWIN	On Peak Winter
OFFWIN	Off Peak Winter
ONSUM	On Peak Summer
OFFSUM	Off Peak Summer
CURTAIL	Curtailment period

For more information about time of use, refer to UOM versus TOU versus SQI.

Designing Your TOU Groups

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are used in a single map. In our above example, we will have two TOU Groups because the active and reactive energy quantities are mapped to different sets of time periods. You must also decide if you want to use a sequence number to define the relative order of a TOU within a TOU group.

> **NOT_SUPPORTED**
>
> Refer to Grouping of TOU Codes for more information.

TOU Group	Description	Time of Use	TOU Sequence
4PARTS	Group for a 4-part map including On and Off Peak for Winter and Summer.	ONWIN	0
		OFFWIN	0
		ONSUM	0
		OFFSUM	0

Copyright © 2026, Oracle and/or its affiliates.

2PARTS	Group for a 2-part map including On and Off Peak for Summer	ONSUM	0
		OFFSUM	0
CURTAIL	Curtailment group, contains only one time of use	CURTAIL	0

Designing Your Classic TOU Map Relationship Types

The starting point for designing your TOU map relationship types is the rate. First, identify the relationship types that your rate needs in order to successfully map quantities.

Using the above rate as an example, only two TOU map relationship types are required because the Reactive Demand map is linked directly to the rate component. However, let's add a relationship type for reactive demand also in case it is needed in the future.

TOU Map Relationship Type	Description
ACTVDMD	Active Demand
RACTVDMD	Reactive Demand
CURTAIL	Curtailment

Now you must think of other types of maps that may need to be linked to the service agreement in order to successfully produce a bill. For example, are there any data derivation algorithms that require a classic TOU Map? If so, you need to define an appropriate classic TOU map relationship type to define the role for this map.

Designing Your Classic TOU Map Types

Now that you have your TOU map relationship types and your TOU groups defined, you can begin defining classic TOU map types. Recall that the classic TOU map type defines the physical attributes of the classic TOU map.

The essential attributes of any profile type are the TOU Group and the minutes per interval and the associated TOU map data creation algorithms.

The easiest way to start defining your classic TOU map types is to start with the classic TOU map relationship type and determine what type of classic TOU map each customer may have for the same TOU map relationship type.

Let's start with our TOU map relationship types and make some assumptions regarding the physical attributes of the data that a customer may have for each of these roles:

- For Active demand, the quantities may be recorded in 15-minute or 30-minute intervals. To facilitate efficiency in processing the data, we recommend that the TOU map data is stored in the same minutes per interval as the interval data being mapped. We'll assume that this is a common TOU map type.
- For Reactive demand, the quantities are recorded in 60-minute intervals. This is linked directly to the rate and is therefore a common TOU map type.
- For curtailment, we will assume that the override map will be in 15-minute, 30-minute or 60-minute intervals, based on the interval size of the actual demand data. In addition, we

Copyright © 2026, Oracle and/or its affiliates.

require a TOU map creation algorithm. This algorithm will produce a data for the curtailment TOU map based on the existence of a contract option event. It will generate the time of use data based on a classic TOU map template. Refer to Contract Option Background Topics for more information. This will be an SA owned classic TOU map type.

> **Note**
>
> We said above that we don't need a classic TOU map relationship type for Reactive Demand for our rate example. However, classic TOU map types must be defined. The table below includes the TOU map relationship type because we said we would add it just in case.

We will assume that all of our TOU data will not follow any seasonal time shifting. It will always be displayed in standard time. Refer to Time Zone and Time Changes and Designing Your Time Options for more information.

TOU Map Rel. Type	TOU Map Type, Classic	Common/ SA Owned	TOU Group	Min/ Interval	Seasonal Time Shift	Creation Algorithm
ACTVDMD	4PART15	Common	4PART	15	NoShift	N/a
	4PART30	Common	4PART	30	NoShift	N/a
RACTVDMD	2PART60	Common	2PART	60	NoShift	N/a
CURTAIL	CURT15	SA Owned	CURTAIL	15	NoShift	Create based on events for 'curtail' contract option type.
	CURT30	SA Owned	CURTAIL	30	NoShift	Create based on events for 'curtail' contract option type.
	CURT60	SA Owned	CURTAIL	60	NoShift	Create based on events for 'curtail' contract option type.

Now, you're ready to set up your interval billing options.

> **Note**
>
> The above table accomplishes two steps: defining TOU map types and defining the valid classic TOU map types for a TOU map relationship type. When setting up this data, you will need to define your classic TOU map types first and then link them to the appropriate classic TOU map relationship type.

Designing Your Classic TOU Map Templates

Copyright © 2026, Oracle and/or its affiliates.

In order to help your users to create and maintain data for classic TOU maps, you may define classic TOU map templates, which can be used to generate data for a classic TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as interruptions and holidays. The classic TOU map templates will reference a classic TOU map type. The system will use the TOU group and the minutes per interval from the map type to verify the setup of the template.

For our example, let us first design templates for the 15 minutes active demand TOU map type. Let's assume:

- On Peak for both winter and summer is from Monday to Friday, from 9am to 5pm, inclusive
- Off Peak for both winter and summer is all day Saturday and Sunday and from Monday through Friday, Off Peak is from 12AM to 8:45AM, inclusive and from 5:15pm to 11:45pm inclusive.

We'll worry about the season definitions for winter and summer later.

In addition, let's design the curtailment map template. Assume:

- Curtailment covers 9am to 5pm inclusive on the given curtailment day.
- Designing Daily Templates
- Designing Weekly Templates
- Designing Holiday Templates
- Designing Calendar Templates

Designing Daily Templates

We need to define four daily templates: one for summer weekdays, one for summer weekend days, one for winter weekdays and one for winter weekend days.

Before defining the template, take note of some points about defining template components:

- For our winter weekday, we can define the off peak period with one entry covering 5:15pm through 8:45am using the Start and End Sequence Numbers to indicate that the end of the time period is on the second day.
- The classic TOU map generator will create intervals for the first period AFTER the start time up to and including the end time. As a result, our Start Time must be the interval before the first interval covered by the time of use code.

TOU Map Template, Classic	TOU Map Type, Classic	Template Type	Start Seq	Start Time	End Seq	End Time	Time of Use
15MinWntrDay	4PART15	Daily	1	8:45AM	1	5PM	ONWIN
			1	5PM	2	8:45AM	OFFWIN
15MinWntrWknd	4PART15	Daily	1	12AM	2	12AM	OFFWIN
15MinSmrDay	4PART15	Daily	1	8:45AM	1	5PM	ONSUM
			1	5PM	2	8:45AM	OFFSUM
15MinSmrWknd	4PART15	Daily	1	12AM	2	12AM	OFFSUM

Copyright © 2026, Oracle and/or its affiliates.

15MinCurtail	CURT15	Daily	1	8:45AM	1	5PM	CURTAIL

Designing Weekly Templates

Now that we have our daily templates defined, we can define our weekly templates. For our example, we will need two weekly templates: one for a typical winter week and one for a typical summer week. For weekly templates, you must indicate the start day of the week.

We do not need a weekly template for the curtailment option.

TOU Map Template, Classic	TOU Map Type, Classic	Template Type	Week Start	Start Seq	Start Day	Start Time	End Seq	End Day	End Time	Template
15MinWntrWk	4PART15	Weekly	Mon	1	Mon	12AM	1	Sat	12AM	15MinWntrDay
				1	Sat	12AM	2	Mon	12AM	15MinWntrWknd
15MinSmrWk	4PART15	Weekly	Mon	1	Mon	12AM	1	Sat	12AM	15MinSmrDay
				1	Sat	12AM	2	Mon	12AM	15MinSmrWknd

Finally, we need to decide if we want to create a Calendar template for our example. The decision of whether or not to create a calendar template will be based on a few factors:

- How many different seasons exist in the TOU map, where each season has different weekly templates?
- How do your holidays behave?

First, let's consider holiday behavior.

Designing Holiday Templates

When designing your classic TOU map templates, a special consideration should be made for holidays that occur throughout the year. Look at your classic TOU map contracts and ask the following questions:

- Are special prices applicable on holidays? Do these special prices require new time of use codes?
- If holidays do not get special prices, does the daily template look like the daily template for other days for this classic TOU map, for example like a weekend day?
- Do your holidays all have the same time period definitions as each other?

For our example, let's assume that our holidays use the Off Peak time of use for the season that it is in. In other words, winter holidays will use OFFWIN for every interval in that day and

Copyright © 2026, Oracle and/or its affiliates.

summer holidays will use OFFSUM for every interval in that day. As a result, we will not need to create a new template just for holidays. Instead, we can use the 15MinWntrWknd daily template for winter holidays and the 15MinSmrWknd daily template for summer holidays.

Designing Calendar Templates

The calendar template is used to define daily and weekly templates for month and day ranges. The map components may represent dates within a single year or may cross into the following year.

Remember that a main reason for creating templates is for use on the TOU Map Generation page to create data for a classic TOU map. On that page, you will specify the dates you want to generate data for. In addition you must keep in mind that you can specify one holiday template for the time period you are generating.

In our example, we have two seasons and our holiday template is different in each season. Creating a calendar template to define the seasons will not help us, because on the TOU map generation page, we wouldn't be able to indicate a single holiday template for the whole year. For our example, rather than creating a calendar template, we could simply go to the classic TOU map generation page and indicate:

- 1st Nov <year> through 30th April <year>, use the 15MinWntrWk template. For holiday overrides, use the 15MinWntrWknd daily template
- 1st May <year> through 31st October <year>, use the 15MinSmrWk template. For holiday overrides, use the 15MinSmrWknd daily template

In fact, in our example, even if our holiday template would not vary by season, one would have to weigh the advantage of creating a calendar template to define 2 seasons vs. running the TOU map generation twice. If you have a very small number of customers using the same templates, then a calendar template may not be worth creating. However, if you have many customers using the same template, it may be worth it.

Here is a possible guideline to follow for deciding whether or not to create calendar templates:

- If the same holiday template may be used for all holidays, and your customer's contracted time period definitions contain more than one season, then creating a calendar to define the seasons is recommended.
- If the holiday template changes throughout the year based on the season, then you must weigh the advantages of your possibilities:
  - You may just create weekly templates for each season and define the dates and the holiday template when using the classic TOU map generation page. This option is recommended when the templates apply to a very small number of classic TOU maps. The time taken to generate the data based on the weekly templates would be less than the time you would have spent on defining the calendar.
  - You may define your calendar to explicitly indicate your seasons and your holidays. Then when generating the data for this template, you would not indicate an override holiday template. This option is recommended when the template applies to a larger number of customers. The time taken to define the calendar would be less than that spent on generating multiple seasons for each TOU map.

Let's go ahead and design a calendar template using our weekly templates to understand the setup. For this purpose, let's assume our holiday template would be the same all year round.

Assume the seasons are defined as follows: Winter is 1st Nov. through 30th April, Summer is 1st May through 31st October. This template shows that the summer schedule includes the

Copyright © 2026, Oracle and/or its affiliates.

interval 12 AM on 01, November. This means that summer's last interval is the one that covers from 11:46 PM on the 31st of October through 12 AM on the 1st of November. The first interval in winter is 12:15 AM on the 1st of November, which covers the period from 12:01 AM through 12:15 AM. The similar setup is true for the end of winter / beginning of summer.

TOU Map Template, Classic	TOU Map Type, Classic	Template Type	Start Seq	Start Date	Start Time	End Seq	End Date	End Time	Template
15MinClndr	4PART15	Calendar	1	01May	12AM	1	01Nov	12AM	15MinSmrWk
			1	01Nov	12AM	2	01May	12AM	15MinWntrWk

Designing Your Contract Options

- Designing Your Contract Option Types
- Designing Your Contract Option Event Types

Designing Your Contract Option Types

Contract options are used for service agreements, which may be subject to special overrides or alterations in their rate for certain temporary periods. Contract options are used to define the possible special situations and to record the actual override events. Your contract option type is a high level categorization of the possible special situation applicable to a customer or group of customers.

To design your contract option types, you will need to review each rate for your interval customers and determine whether or not there are special options. Some examples of special options are:

- Interruptions. Perhaps you warn your customers of interruption periods and any usage incurred during that period will be subject to special prices.
- Curtailment. Perhaps you define periods where you ask a customer to shed their load below a certain subscribed demand and any demand, which exceeds this subscribed demand during that period, will be subject to a special charge.

Next, must determine whether or not a given option behaves differently under different circumstances. For example, perhaps you have different types of interruptions. If these different types of interruptions are applicable to the same customer, then you will require a single contract option type and multiple contract option event types for that option type. If these different types of interruptions are not applicable to the same customer, then you would probably want to define separate contract option type values.

You need to also consider whether or not contract option events for this type of contract option may overlap in their effective periods. If you do allow overlap, then you must be sure that any algorithm, which may process the contract option events, must know how to process the overlaps.

Your next step is to determine whether or not characteristic values will be needed for each contract option of this type. The characteristic values are available for use by the algorithms,

Copyright © 2026, Oracle and/or its affiliates.

when processing the contract options. For example, perhaps subscribed demand is defined at the contract option level. On the contract option type, you must define the possible characteristic types for contract options of this type. You may also define a default value, if applicable.

Finally, you will need to determine whether or not you wish to create validation algorithms to validate your contract option event data. Algorithms may be created to be executed upon add or change of the data, where the status is Pending, Frozen or Canceled.

For our purposes, let us assume that we have only two contract option types: Interruption and Curtailment. Neither one allows overlap. The Curtailment option type will define subscribed demand as a required characteristic and will define a validation algorithm to ensure that the value of the demand falls within an appropriate range. This algorithm program will be executed for pending and frozen events.

> **Note**
>
> Because there are different algorithm entities, more than one algorithm type and algorithm are required, but both algorithm types may use the same program.

We will assume that both contract option types will follow the same seasonal time shift as our base time zone. Refer to Time Zone and Time Changes and Designing Your Time Options for more information.

Contract Option Type	Descr	Allow Overlap	Seasonal Time Shift	Char Type	Algorithm
INTERRUPT	Interruptions	No	USShift	N/a	N/a
CURTAIL	Curtailments	No	USShift	SubscrDmd, required, no default value	**Pending**: SbscrDmdPV (subscribed demand pending validation) **Frozen**: SbscrDmdFV (subscribed demand frozen validation) **Canceled**: n/a

> **Note**
>
> Once you have the contract option types required to support your rate and derivation algorithms, we recommend that you set up Start Options for your SA Types to assist a CSR in setting up a customer for this rate. Refer to Designing Your Start Options.

Designing Your Contract Option Event Types

Copyright © 2026, Oracle and/or its affiliates.

When you designed your contract option types, you were already considering the possible contract option event types. You will need to define a different contract option event type for each different type of event that may occur for the same contract option type.

Your next step is to determine whether or not characteristic values will be needed for each contract option event of this type. The characteristic values are available for use by the algorithms, when processing the contract option events. On the contract option event type, you must define the possible characteristic types for contract option events of this type. You may also define a default value, if applicable.

For our example, we will define two types of interruptions, which may be applicable for customers on the same rate. We will define only one type of curtailment event. None of the event types require characteristic values.

Contract Option Event Type	Descr	Contract Option Type	Char Type
InterruptA	Interruptions, type A	Interrupt	N/a
InterruptB	Interruptions, type B	Interrupt	N/a
Curtail	Curtailments	Curtail	N/a

Designing Your SA Interval Billing Options

- Designing Your SA Types
- Designing Your Start Options

Designing Your SA Types

Your interval service agreements will require special data to be set up, such as special rates, interval profiles, TOU maps and contract options. In addition, it will need to define a cutoff time and start day option. The system requires you to indicate a special role of Interval for SA types defined for interval billing service agreements.

Refer to Defining Service Agreement Types to help you design the standard fields required for all SA Types. Additionally, for interval SA Types, you will need to define the valid Profile Relationship Types, the valid Map Relationship Types and the valid Contract Option Types for this SA Type.

Let's assume that we set up only one SA Type for all interval billing customers. As a result, all the relationship types defined in our sample are valid.

CIS Division / SA Type	Special Role	Profile Relationship Type	Map Relationship Type	Contract Option Type
CA / E-INTBIL	Interval	HEDGECVR	ACTVDMD	INTERRUPT
		OVRHEDGE	CURTAIL	CURTAIL
		MEASDMD		
		ACTVDMD		
		RACTVDMD		

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> that this setup does not provide any link between the profile relationship types, the map relationship types and the contract option types. These are just a list of valid entries for the SA Type.
>
> Although we created a TOU map relationship type for RACTVDMD above, it is not needed for the TOU mapping rate so it is not linked to the SA Type as a valid value.

Refer to Setting Up SA Types for more information.

Designing Your Start Options

Once you have your rates defined and your SA Type defined, you should design Start Options to aid your customer service representatives in setting up these service agreements.

You will first need to design your start options with regard to standard SA information. Note that there may be other setup required before you can add your interval billing start options:

- To link common profiles to a start option you will need to create the appropriate profile first.
- To link common classic TOU maps to a start option you will need to create the appropriate TOU map first. This is only applicable to common maps that should be linked to the service agreement. In our example, it applies to the active demand map. The reactive demand map is linked directly to the rate component so no start option information is needed.
- To link shared contract options to a start option you will need to create the appropriate contract option first.

Note that when designing our rate components above, we did not give names to their rate schedules. Let's call the interval pricing rate schedule "INTPRC" and let's call the TOU Map rate schedule "INTTOU".

Recall that the classic TOU Map rate component required profile relationship types that we did not define above. We will assume that profile relationship types are defined with the same names as the map relationship types. We will also assume that the profile types define the same interval size as the map types.

You may also use Start Options to define Cutoff Time and Start Day Option, if they are different from the values defined on the installation record. Let's assume that our TOU mapping customers use a different Cutoff Time from the installation record.

The following table shows the start option definitions with the rates and the cutoff time information.

CIS Division / SA Type	Start Option	Rate Schedule	Cutoff Time	Start Day Option
CA / E-INTBIL	Interval Pricing Hedge - 30MIN	INTPRC		
	Interval Pricing Hedge - 60 Min	INTPRC		
	TOU Map - option 1	INTTOU	2:00 AM	Current

Copyright © 2026, Oracle and/or its affiliates.

	TOU Map - option 2	INTTOU	2:00 AM	Current

The following table shows the profile related start options.

CIS Division / SA Type	Start Option	Rate Schedule	Profile Relationship Type	Profile Type	Profile (Profile Type)
CA / E-INTBIL	Interval Pricing Hedge - 30MIN	INTPRC	HEDGECVR		12859302 (HEDGE30)
			OVRHEDGE	OVRHG30	
			MEASDMD	DMDKW30	
	Interval Pricing Hedge - 60 Min	INTPRC	HEDGECVR		4922018 (HEDGE60)
			OVRHEDGE	OVRHG60	
			MEASDMD	DMDKW60	
	TOU Map - option 1	INTTOU	ACTVDMD	ACTV30	
			RACTVDMD	RACTV30	
	TOU Map - option 2	INTTOU	ACTVDMD	ACTV15	
			RACTDMD	RACTV60	

The following table shows the classic TOU map related start options.

CIS Division / SA Type	Start Option	Rate Schedule	Map Relationship Type	Map Type	TOU Map (Map Type)
CA / E-INTBIL	TOU Map - option 1; no curtailment	INTTOU	ACTVDMD		12859302 (4PART30)
	TOU Map - option 2; no curtailment	INTTOU	ACTVDMD		52829947 (4PART15)
CA / E-INTBIL	TOU Map - option 3; curtailment	INTTOU	ACTVDMD		12859302 (4PART15)
			CURTAIL	CURT15	

The following table shows the contract option related start options.

CIS Division / SA Type	Start Option	Rate Schedule	Contract Option Type	Contract Option
CA / E-INTBIL	TOU Map - option 3; curtailment	INTTOU		48399239048 (CURT15)

Let's summarize what these tables define:

- The INTPRC rate requires 2 SA Owned profiles and one Common profile. The Common Profile needs to be created and linked to the start option. (For clarification, the Profile Type used for the profile is displayed in parentheses.) For the SA Owned profile, you need to indicate the profile type.

Copyright © 2026, Oracle and/or its affiliates.

- There are two possible configurations for the rate INTPRC. As a result, there are two start options, each with the correct configuration defined.
- For the rate INTTOU, the SA will need profiles, TOU maps and, if they use the curtailment option, contract options.
  - The profiles will be SA owned, so only the profile relationship type and profile types are indicated.
  - For the TOU maps, the active demand maps is common so the actual map is indicated, whereas the curtailment map will be SA owned so only the map type is indicated. (The reactive demand map is linked directly to the rate component.)
  - The curtailment option will be shared by more than one service agreement, so the contract option itself is linked to the start option.

Refer to Setting Up Start Options to learn how to enter this information.

Setting Up Interval Billing Options

- Setting Up Interval Billing Control Tables
- Setting Up Channel Control Tables
- Setting Up Time of Use Billing Control Tables
- Setting Up Contract Option Control Tables

Setting Up Interval Billing Control Tables

- Setting Up Profile Relationship Types
- Setting Up Interval Profile Types
- Setting Up Interval Pricing Rate Components

Setting Up Profile Relationship Types

Profile Relationship Types define the role that a set of interval data will serve for a customer. Open **Admin**, and then **Interval Profile Rel Type**, and then **Add** to define your profile relationship types.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **Interval Profile Rel**ationship **Type** ID and **Description** for the profile relationship type.

Copyright © 2026, Oracle and/or its affiliates.

Enter the **Interval Profile Type** collection. This is a list of valid interval profile types whose collections of data can serve the role defined by the profile relationship type.

> **Note**
>
> To aid in setup, the interval profile type is not a required field on this user interface. This will help you to define your high level interval relationship types first and then define the more detailed profile types. The valid profile types will need to be linked to the appropriate relationship types prior to creating service agreement interval profiles.

Setting Up Interval Profile Types

Interval Profile Types define values common to interval profiles of the same type. Open **Admin**, and then **Interval Profile Type**, and then **Add** to define your interval profile types.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **Interval Profile Type** ID and **Description** for the interval profile type.

Indicate whether interval profiles of this type are SA Owned or Common by entering the appropriate value in the interval profile **Sub Type**.

The **Creation Priority** will be used by the Interval Profile Derivation Process to determine the order in which the data for profiles linked to an SA should be derived. The values range from 10, being the highest priority to 90 being the lowest priority.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRE_PRIO_FLG.

Enter the **Unit of Measure** (UOM) that data values stored for interval profiles of this type are captured in.

If a service quantity identifier is needed to further qualify data stored for interval profiles of this type, enter a valid **SQ Identifier**.

Enter the **Minutes per Interval** to define the number of minutes expected in between each row of data collected for interval profiles of this type.

If the installation record indicates that seasonal time shift is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the Evenly Sized Intervals section.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains **Algorithms** that may be used to create or validate interval data for profiles of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See How To Add A New Algorithm for more information.

The following table describes each **System Event**.

System Event	Description
Interval Data Creation	These types of algorithms are used to derive interval data for a profile.
Interval Data Validation	These types of algorithms are used to validate profile data.

Setting Up Interval Pricing Rate Components

This section describes how to define your interval pricing rate components.

> **Note**
>
> **Define Rate Schedule, Rate Version and other Rate Components.** Before creating your interval pricing rate component, you must set up a rate. During this process, you will also need to set up calculation groups and rules. Refer to Rates for more information.

When you are ready to set up your interval pricing rate component, open **Menu**, and then **Rates**, and then **Rate Version Classic**, and then **Search.** Choose the rate version that this component should belong to. Use the Rate Version context menu and select Go to Rate Component + to add a new rate component.

Description of Page

Refer to Rate Component - Main Information for information about the common fields on this page. When defining an Interval Pricing rate component additional fields become available to you. The following information will help you to set up your Interval Pricing rate components.

Indicate whether or not this is **FCPO**.

Select a **Value Type** of Unit Rate. This field will be gray when the rate component is referenced on another rate component. The **Value Source** will most likely be Billing Factor. Your bill factor will likely be one with a type of Interval.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Defining Interval Values for more information about setting up bill factors with interval prices.

Indicate whether or not this rate component is **Seasonal**. Refer to Rate Component - Main Information for more information about seasonal rate components.

The **Error if No Value** field is available for you to use in the calculation algorithm.

Indicate the **Calc Algorithm** that the system will use to calculate the bill line that this rate component produces.

- The system provides an Algorithm Type that is available for use here. It is called RCIPRS.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to Setting Up Algorithms). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

Note

The calculation algorithm's main purpose is to create bill calculation lines. However, the algorithm may populate other information for the bill, for example, it may add to the SQ or register read collection or it may overwrite the description on bill.

Indicate the **Audit Alg**orithm to be used when a CSR wants to drill down into the details of a bill line that was calculated using this Rate Component.

- The system provides an algorithm type that is available for use here. It is called RCIPRS-ADT.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to Setting Up Algorithms). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

Note

The audit algorithm should produce the same results as the Calc Algorithm. They are separated because they have different responsibilities. For example, the Calc Algorithm should produce bill lines, but the Audit Algorithm should not. They share common logic related to accessing and processing the appropriate interval data records. As a result, it is recommended that these two programs share a common code which accesses and processes the interval data. The above algorithms provided by the system behave this way and should be used as samples.

Refer to Interval Billing Calculation Details to understand where a CSR may view the calculation details for a bill calc line, using this algorithm.

Indicate the **Interval Profile Rel Type**. This indicates to the system the profile, linked to the SA, which contains the interval quantities to be processed. Refer to Business Role of Interval Data and Setting Up Profile Relationship Types for more information.

Copyright © 2026, Oracle and/or its affiliates.

Turn on **GL Statistical Quantity** if GL journal lines generated for this rate component should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to Rate Version - Bill Print Info for more information about these fields.

Move to the Rate Component - GL Distribution window to define how to book moneys associated with this rate component in the general ledger.

Setting Up Channel Control Tables

- Setting Up Interval Register Types
- Setting Up Meter Configuration Types for Channels
- Setting Up Meter Types

Setting Up Interval Register Types

NOT_SUPPORTED

Refer to The Big Picture of Raw Data Collection and Aggregation for more information.

Interval register types define values common to interval registers of the same type. Open **Admin** , and then **Interval Register Type**, and then **Add** to define your interval register types.

Note

This page will not be available if Meter Data Management module is turned off.

Description of Page

Enter a unique **Interval Register Type** and **Description** for the interval register type.

Enter the **Unit of Measure** (UOM) that data values stored for interval registers of this type are captured in.

If a service quantity identifier is needed to further qualify data stored for interval registers of this type, enter a valid **SQ Identifier**.

Enter the **Minutes per Interval** to define the number of minutes expected in between each row of data collected for interval registers of this type.

If the installation record indicates that seasonal time shift is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the Evenly Sized Intervals section.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains **Algorithms** that may be used to perform actions on interval data for registers of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See How To Add A New Algorithm for more information.

The following table describes each **System Event**.

System Event	Description
Interval Register Validation	These types of algorithms are used to validate register data.

Setting Up Meter Configuration Types for Channels

You must set up meter configuration types for your interval channels and index channels.

Setting Up Meter Types

You must set up meter types to use for grouping together your index and interval registers. You must turn on the **Allow Interval Registers** switch for any meter type used by a meter, which will contain interval registers. Indicate the valid meter configuration types for this meter type.

Setting Up Time of Use Billing Control Tables

- Setting Up Classic TOU Map Relationship Types
- Setting Up TOU Pricing Rate Components
- Setting Up Time of Use Codes
- Setting Up TOU Groups
- Setting Up Classic TOU Map Types
- Setting Up Classic TOU Map Templates

Setting Up Classic TOU Map Relationship Types

Classic TOU Map Relationship Types define the role that a classic TOU Map will serve for a customer. Open **Admin**, and then **Consumption**, and then **TOU Map Relationship Type**, and then **Add** to define your classic TOU map relationship types.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **TOU Map Relationship Type** ID and **Description** for the TOU map relationship type.

Enter the **TOU Map Type** collection. This is a list of valid TOU map types whose collections of data can serve the role defined by the TOU map relationship type.

> **Note**
>
> To aid in setup, the map type is not a required field on this user interface. This will help you to define your high level map relationship types first and then define the more detailed map types. The valid map types will need to be linked to the appropriate relationship types prior to creating service agreement TOU maps.

Setting Up TOU Pricing Rate Components

This section describes how to define your TOU Pricing rate components. Refer to Time of Use Mapping and Pricing for background information.

> **Note**
>
> **Define Rate Schedule, Rate Version and other Rate Components.** Before creating your TOU pricing rate component, you must set up a Rate Schedule. Refer to Setting Up A Rate Schedule for more information. You will also need to set up a rate version and possibly set up other types of rate components. Refer to Defining Rate Versions and Defining Rate Components for more information.

When you are ready to set up your TOU pricing rate component, open **Menu**, and then **Rates**, and then **Rate Version Classic**, and then **Search.** Choose the rate schedule and version that this component should belong to. Open its context menu, and select **Go to Rate Component Classic**, and then **Add** to add a new rate component.

Description of Page

Refer to Rate Component - Main Information for information about the common fields on this page. When defining a TOU Pricing rate component, additional fields become available to you. The following information will help you to set up your TOU Pricing rate components.

If the algorithm used by this rate component, only performs mapping and does not produce bill lines, indicate that this is **FCPO**.

The **Value Type** and **Value Source** are optional. If your algorithm performs pricing logic, then you will probably need to define a bill factor here. If your calculation algorithm only performs mapping, than you may not require any value here.

Copyright © 2026, Oracle and/or its affiliates.

Indicate whether or not this rate component is **Seasonal**. Refer to Rate Component - Main Information for more information about seasonal rate components.

The **UOM** is available for use by your calculation algorithm. It could be used, for example, by a mapping algorithm to produce SQ quantities with a different unit of measure, assuming that the algorithm knows how to convert from one UOM to another. Note that the algorithms provided with the system do not use this field.

The **SQI** is available for use by your calculation algorithm. It could be used, for example, by a mapping algorithm to produce SQ quantities with a different SQI. Note that the TOU mapping and pricing algorithms provided with the system will use this field, if populated, to produce SQI quantities with this SQI value.

Measures Peak Qty and **GL Statistical Qty** behave the same way they do for SQ quantity rate components. Refer to How To Set Up Service Quantity Rate Components for more information.

The **Error if No Value** field is available for you to use in the calculation algorithm.

Indicate the **Calc Algorithm** that the system will use to map the interval quantities to time of use values.

- The system provides the following classic TOU mapping/pricing algorithms that are available for use here: RCTMS performs mapping of time of use only and RCTMPS performs both mapping and pricing, producing the necessary bill calculation lines.

If these algorithms do not provide you with the logic you require, you will need to create a new algorithm (refer to Setting Up Algorithms). The above existing algorithms should be used as a sample if you have to write a new algorithm type.

> **Note**
>
> The calculation algorithm's main purpose is to create bill calculation lines. However, the algorithm may populate other information for the bill, for example, it may add to the SQ or register read collection or it may overwrite the description on bill.

Indicate the **Audit Algorithm** to be used when a CSR wants to drill down into the details of a bill line that was calculated using this Rate Component.

- The system provides the following audit algorithm that is available for use here: RCTPRS-ADT.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to Setting Up Algorithms). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

> **Note**
>
> The audit algorithm should produce the same results as the Calc Algorithm. They are separated because they have different responsibilities. For example, the Calc Algorithm should produce bill lines, but the Audit Algorithm should not. They share common logic related to accessing and processing the appropriate interval data records. As a result, it is recommended that these two programs share a common code which accesses and processes the interval data. The above algorithms, provided by the system, behave this way and should be used as samples.

Copyright © 2026, Oracle and/or its affiliates.

Refer to Interval Billing Calculation Details to understand where a CSR may view the calculation details for a bill calc line, using this algorithm.

Indicate the **Interval Profile Rel Type**. This indicates to the system the profile, linked to the SA, which contains the interval quantities to be mapped. Refer to Business Role of Interval Data and Setting Up Profile Relationship Types for more information.

If the classic TOU map differs for different service agreements, indicate the **TOU Map Relationship Type**. The system uses this information to find the correct classic TOU map linked to the SA. Refer to Business Role of a TOU Map and Setting Up TOU Map Relationship Types for more information.

If ALL service agreements linked to the rate use the same map, indicate the classic **TOU Map ID**.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to Rate Version - Bill Print Info for more information about these fields.

Setting Up Time of Use Codes

An important step in preparing for Time of Use billing is to define Time of Use codes. Refer to Setting Up Time-Of-Use Codes for more information.

Setting Up TOU Groups

Once you have your time of use codes defined, you will need to create your TOU groups to group the codes together. Refer to Setting Up TOU Groups for more information.

Setting Up Classic TOU Map Types

The Classic TOU Map Type defines characteristics that are common to classic TOU Maps of the same type. Open **Admin**, and then **TOU Map Type Classic**, and then **Add** to define your TOU map types.

> **Note**
>
> The Classic TOU Map Type portal describes TOU Map Types that are used with the classic rate engine. For information about the differences between the classic and new style rate engines, see Rates. For details on setting up TOU Map Types for the new style rate engine, see Creating TOU Map Types.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **TOU Map Type** ID and **Description** for the classic TOU Map Type.

Copyright © 2026, Oracle and/or its affiliates.

Indicate whether TOU maps of this type are SA Owned or Common by entering the appropriate value in the **Sub Type**.

The **Creation Priority** will be used by the TOU map data creation process to determine the order in which the data for classic TOU maps linked to an SA should be derived. The values range from 10, being the highest priority to 90 being the lowest priority.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRE_PRIO_FLG.

Enter the **TOU Group** that defines the collection of TOUs for this map type.

Enter the **Minutes Per Interval** to define the number of minutes expected in between each row of data collected for classic TOU maps of this type.

If the installation record indicates that seasonal time shift is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the Evenly Sized Intervals section.

The grid contains **Algorithms** that may be used to create classic TOU map data for TOU maps of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See How To Add A New Algorithm for more information.

The following table describes each **System Event**.

System Event	Description
TOU Map Creation	These types of algorithms are used to create TOU map data automatically.

Setting Up Classic TOU Map Templates

The TOU Map Template classic page enables you to define daily, weekly and calendar templates for use by TOU data generation and automatic TOU data creation. Open **Admin**, and then **TOU Map Template Classic**, and then **Add** to define your TOU map templates.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The classic TOU Map Template portal describes TOU Map Templates that are used with the classic rate engine. For information about the differences between the classic and new style rate engines, see Rates. For details on setting up TOU Map Templates for the new style rate engine, see Creating TOU Map Templates.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **TOU Map Template** name and a **Description** for the classic TOU map template.

Enter a classic **TOU Map Type**. Daily templates use the TOU map type to determine the TOU group whose TOU codes are valid for this template. All templates use the classic TOU map type to determine the interval size to ensure that start and end times are valid for the interval size. For example, if your interval size is 60 minutes, then the amount of minutes between your start and end times must be a multiple of 60. For example, you would not be able to enter a start time of 10:00 and an end time of 10:15.

Use the **TOU Map Template Type** to indicate whether this template is Daily, Weekly, or Calendar.

The fields in the remaining portion of the page will depend on the classic TOU map template type.

A Daily template is used to define time of use periods applicable for hour/minute time ranges in an abstract day. Data in this template has no association with a specific day of the week or a specific calendar date. Each entry in the collection is used to define the time periods applicable for a given Time of Use code in this day. Enter the following information for your collection of time periods for the daily template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends on the same day or on different days. If the time period covered by the entry starts and ends on the same day, then the same number should be entered in both fields. If the time period ends on a different day (most likely one day later) than it starts, then the End sequence would be greater than the start sequence.

Enter the **Start Time** and **End Time** applicable for this **Time of Use** code. The valid time of use codes are limited to those belonging to the TOU group on the template's TOU map type.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's classic TOU Map Type. Refer to Seasonal Time Shift for more information.
>
> When the TOU data is generated, intervals for this time of use code will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

A Weekly template is used to define the collection of daily templates that make up an abstract week. Data in this template has no association with specific calendar dates. You must indicate the **Week Start Day** to tell the system which day of the week is considered "day one".

Enter the following information for your collection of daily templates for the weekly template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends in the same week or in different weeks. If the days covered by the entry are in the same week, then the same number should be entered in both fields. If the time period ends in a different week (most likely one week later) than it starts, then the End sequence would be greater than the start sequence.

Enter the **Start Week Day** and **Start Time** and **End Week Day** and **End Time** applicable for this **Reference TOU Map Template**. The valid templates are limited to those that are daily and those whose TOU map type has the same TOU group and minutes per interval as this template's TOU map type.

> **Note**
>
> The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's TOU Map Type. Refer to Seasonal Time Shift for more information.
>
> When the TOU data is generated, intervals will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

A Calendar template is used to define the collection of weekly and daily templates that make up specific months and dates for a given calendar.

Enter the following information for your collection of daily and weekly templates for the calendar template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends in the same year or in different years. If the dates covered by the entry are in the same year, then the same number should be entered in both fields. If the time period ends in a different year (most likely one year later) than it starts, then the End sequence would be greater than the start sequence.

Use the **Start Date** (month and day) and **Start Time** and the **End Date** (month and day) and **End Time** to indicate the time period applicable for this **Reference TOU Map Template**. The

Copyright © 2026, Oracle and/or its affiliates.

valid templates are limited to those that are daily and weekly and those whose TOU map type has the same TOU group and minutes per interval as this template's TOU map type.

> **Note**
>
> The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's TOU Map Type. Refer to Seasonal Time Shift for more information.
>
> When the TOU data is generated, intervals will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

Where Used

The generate button on the TOU map page allows you to specify a TOU map template and a holiday TOU map template to use for generating TOU data.

If you have a TOU map creation algorithm defined on a TOU map type, this algorithm will need to use a TOU map template to create TOU data. The mechanism for defining the TOU map template to use depends on how the algorithm is designed. The TOU map creation algorithm provided by the system ITMCCOPT expects the template to be defined as a characteristic of the service agreement.

Setting Up Contract Option Control Tables

This section describes the pages related to maintaining contract options.

- Setting Up Contract Option Types
- Setting Up Contract Option Event Types

Setting Up Contract Option Types

This section describes the pages related to maintaining a contract option type.

- Contract Option Type - Main
- Contract Option Type - Algorithms

Contract Option Type - Main

Contract Option Type defines control information required for contract options. Open **Admin**, and then **Consumption**, and then **Contract Option Type**, and then **Add** to define your contract option types.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **Contract Option Type** ID and **Description**.

Indicate whether you **Allow Overlap** of the effective period for contract events linked to contract options of this type.

If the installation record indicates that Seasonal Time Shift is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the contract option event data.

Select a **Characteristic Type** that may be used on contract options of this type. The characteristic type's Description appears adjacent.

The following fields should be defined for each characteristic type:

Sequence This field controls the order in which the characteristics appear on the contract option page.

Required Turn this switch on if this type of characteristic must be defined on all contract options of this type.

Default Turn this switch on if this characteristic type should automatically appear in the characteristic scroll area of contract options of this type.

Characteristic Value If a characteristic value can default for contract options of this type, specify the default value in this field.

Contract Option Type - Algorithms

To define validation algorithms for contract option events linked to contract options of this type. Open **Admin**, and then **Consumption**, and then **Contract Option Type**, and then **Search** and navigate to the **Algorithms** page to define validation algorithms for this contract option type.

Description of Page

The grid contains **Algorithms** that may be used to validate contract option event information. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Description
Contract Option Event Cancel	This algorithm is executed when a contract option event for a contract option of this type is canceled.

Copyright © 2026, Oracle and/or its affiliates.

Contract Option Event Freeze	This algorithm is executed when a contract option event for a contract option of this type is frozen.
Contract Option Event Pending	This algorithm is executed when a contract option event for a contract option of this type is added or changed and the status is pending.

Setting Up Contract Option Event Types

Contract Option Event Type defines control information required for contract option events. Open **Admin**, and then **Contract Option Event Type**, and then **Add** to define your contract option event types.

> **Note**
>
> This page will not be available if Complex Billing module is turned off.

Description of Page

Enter a unique **Contract Option Event Type** code and **Description**.

Indicate the **Contract Option Type** for this event type.

Use the **Characteristics** collection to define characteristics that can be defined for contract option events of this type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on contract option events of this type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Defining Prepaid Metering Options

The topics in this section describe how to set up the system to enable prepaid metering functionality.

> **Note**
>
> **Prepaid metering is optional.** The system configuration requirements described in this section are only relevant if your organization offers prepaid metering service.

- The Big Picture of Prepaid Metering
- Setting Up The System To Enable Prepaid Metering

Copyright © 2026, Oracle and/or its affiliates.

The Big Picture of Prepaid Metering

Prepaid metering allows customers to pay for energy before it is actually used.

- How Does Prepaid Metering Work?
- Debit Meter vs Credit Meter
- Prepaid Metering Transactions Result in Adjustments
- Interfacing Prepaid Transactions
- Prepaid Transactions Can Go Into Suspense

How Does Prepaid Metering Work?

A traditional electronic prepaid metering system typically operates at three levels:

- Meters that are installed at the customer's home. These meters dispense energy up to the amount that the customer prepaid.
- Vending stations located at the utility's offices or designated payment agencies. These stations/agencies sell prepaid credits to customers.
- Master stations that group vending stations together for administration, reporting and control purposes. Master stations communicate information - e.g. customer information, tariff changes, etc - to the vending stations. The vending stations, in turn, report detailed customer sales and other transaction information to the master station.

A prepaid customer goes to a vendor and purchases credits for their meter to dispense energy. The vendor has knowledge of the customer and the rate that the customer is paying. The vendor issues the credits in any of the following forms: a prepaid card, a token (to be inserted into the meter) or a series of numbers (to be keyed into the meter).

Debit Meter vs Credit Meter

Prepaid meters are commonly referred to as debit meters. Billed meter types are also called credit meters. A meter's state of being 'credit' or 'debit' translates to a specific meter configuration. Having this property set at the meter configuration level enables meters to be switched between 'credit' and 'debit' if needed.

Prepaid credits may be purchased for either new premises or existing premises. In the latter case, the existing premise could initially have a typical 'credit' meter. In this case, fieldwork may be involved in getting the meter switched from 'credit' to 'debit' (prepaid).

Prepaid Metering Transactions Result in Adjustments

There could be numerous types of prepaid transactions. But the most common types are prepaid sales and cancellations.

Copyright © 2026, Oracle and/or its affiliates.

A sale or cancellation transaction includes a total amount that usually includes tax. In order to post to the general ledger, the prepaid transaction must result in a financial transaction. Moreover, separate GL entries must be created for the breakdown of revenue and tax. In some cases, it may also be necessary to calculate the usage from the revenue amount.

Calculated Adjustments are used to book revenue from these types of transactions. A base Generate Adjustment algorithm is available to let rate application generate the appropriate GL calculation lines and calculate the corresponding usage, if needed.

Prepaid adjustments do not affect a customer's balance.

Interfacing Prepaid Transactions

An adjustment upload batch process exists for uploading prepaid transactions that result in adjustments. Refer to Interfacing Adjustments From External Sources for more information.

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to Defining Prepaid Metering Options for more information.

Prepaid Transactions Can Go Into Suspense

A prepaid transaction goes into suspense if a prepaid SA could not be determined for any of the following reasons:

- The badge number on the transaction is not a valid meter in the system
- The badge number on the transaction is a valid meter in the system, but is:
  - Not linked to a prepaid meter configuration type
  - Not linked to a non-closed, non-canceled prepaid SA

This can be a common occurrence because of the likelihood that transactions get uploaded prior to meter installation/exchange or service agreement information being updated in the system.

When this situation happens, you probably still want to recognize the revenue by posting an adjustment to a suspense SA that you designate. Refer to the base sample Get Prepaid SA Using Badge Number (C1-SABYBADGE) algorithm for an example of how the suspense SA is specified.

A batch process exists for automatically resolving suspense adjustments. Refer to How Are Suspense Adjustments Resolved for more information.

Setting Up The System To Enable Prepaid Metering

The following sections describe the steps in setting up control information for prepaid metering.

- Meter Types
- Characteristic Types
- Algorithms
- Rate

Copyright © 2026, Oracle and/or its affiliates.

- Adjustment Types
- Adjustment Type Profiles
- Service Agreement Types
- Bill Cycle
- Vendor Information

Meter Types

Prepaid meters are set up just like any other meter - i.e. the meter must reference a meter type and the meter's configuration must reference a meter configuration type.

To set up prepaid meter types you must do the following:

- Define the meter configuration types that will be used for recording prepaid usage. Mark each of these configuration types as Prepaid . Define one register with the appropriate UOM (e.g. kWh). See Setting Up Meter Configuration Types for more information.
- Define the meter types that will be used for prepaid metering. For each meter type, associate one of the Prepaid meter configuration types that you defined. You can also mark each meter type as Prepaid Capable. See Setting Up Meter Types for more information.

> **Note**
>
> Base logic does not require the meter type to be marked as Prepaid Capable. The Prepaid indicator on the meter configuration type is used to identify prepaid meters.

Characteristic Types

The following characteristic types are needed if you are going to upload prepaid transactions as adjustments and need the system to determine the prepaid SA given a prepaid meter's badge number.

Refer to Setting Up Characteristic Types for more information.

- Prepaid Entity Characteristic Type
- Badge Number Characteristic Type

Prepaid Entity Characteristic Type

Create a characteristic type that identifies whether an SA Type is used for prepaid metering. For example:

- Characteristic Type = <code>
- Description = Prepaid Entity
- Char Entities = SA Type

Copyright © 2026, Oracle and/or its affiliates.

- Subclass = predefined list
- Values = Y, N

Badge Number Characteristic Type

Create a characteristic type for specifying a badge number. For example:

- <code>
- Description = Badge Number
- Char Entities = Adjustment, Adjustment Type
- Subclass = Adhoc

Algorithms

The following algorithms need to be set up in order to store prepaid transactions in the system.

Refer to Setting Up Algorithms for more information.

> **Note**
>
> The following sections describe basic set up needed for uploading 'sale' and 'cancellation' types of prepaid transactions. Your implementation team may have to define additional specific algorithms types for any other prepaid transaction type that you need to upload into or store in the system.

- Calculation Rule - Calculation Algorithm
- Adjustment Type - Generate Adjustment
- Adjustment Type - Determine SA
- Adjustment Type - Resolve Suspense
- Adjustment Type - Adjustment Information
- Installation - Adjustment Information

Calculation Rule - Calculation Algorithm

Create an algorithm of type Determine Percent Given Total (C1-PCTGVNTOT) specifying your parameter values for UOM / TOU / SQI.

Create an algorithm of type Back Into Revenue (C1-BACKINREV) specifying your parameter values for UOM / TOU / SQI.

Adjustment Type - Generate Adjustment

Copyright © 2026, Oracle and/or its affiliates.

Create an algorithm of type Adjustment Generation - Apply Rate (ADJG-RT), specifying your prepaid rate and parameter values for UOM / TOU / SQI.

Adjustment Type - Determine SA

Create an algorithm of type Get Prepaid SA Using Badge Number (C1-SABYBADGE), specifying your badge number characteristic type, prepaid characteristic type and suspense SA ID (i.e. SA to which the adjustment needs to post when a valid prepaid SA is not found).

Adjustment Type - Resolve Suspense

Create an algorithm of type Cancel Suspense Adjustment (C1-CANSUSADJ) specifying the following:

- Badge number characteristic type
- Prepaid entity characteristic type
- Prepaid adjustment type
- Adjustment cancel reason

If you want this algorithm to create to do entries for adjustments that have been in suspense for too long, specify additional parameter values for number of days and to do type and to do role (optional).

Adjustment Type - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Installation - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Rate

In order to generate separate calculation lines for the revenue and tax breakdown of the prepaid amount, you need to set up a prepaid rate with components that calculate revenue amount and tax amount given just a total amount.

Create a rate schedule with the following components:

- Tax Calculation Rule
  - Calculation Rule Type = Calculation Algorithm
  - Value Type = Percentage
  - Value Source = Bill Factor

Copyright © 2026, Oracle and/or its affiliates.

  - Bill Factor = your tax bill factor
  - Calculation Algorithm = the one created for algorithm type C1-PCTGVNTOT. Refer to Calculation Rule - Calculation Algorithm for information.
  - Distribution Code = *your distribution code for tax liability*
- Revenue Calculation Rule
  - Calculation Rule Type = Calculation Algorithm
  - Derive SQ = checked
  - Value Type = Unit Charge
  - Value Source = Bill Factor
  - Bill Factor = your rate/kWh bill factor
  - UOM/TOD/SQI to use for the resulting calculated usage, for example kWh
  - RC Cross Reference = indicate the sequence for the tax calculation rule (above)
  - Calculation Algorithm = the one created for algorithm type C1-BACKINREV. Refer to Calculation Rule - Calculation Algorithm for information.
  - Distribution Code = your distribution code for revenue

Adjustment Types

You must define an adjustment type for each type of transaction that you want to store in the system. Refer to Setting Up Adjustment Types for more information.

For prepaid sales and cancellation transactions, you need to define calculated adjustment types. In addition, plug-in the following algorithms:

- Adjustment FT Creation - GL Only algorithm - so that transaction amounts do not affect the customer's balance. Specify calc lines as the source for adjustment distribution codes.
- Generate Adjustment
- Determine SA
- Resolve Suspense, if applicable.
- Adjustment Information, if applicable

Adjustment Type Profiles

Create appropriate adjustment type profiles for your prepaid service agreements.

Service Agreement Types

You must create a prepaid SA Type for each unique CIS Division. Each SA Type must be set up as non-billable and requiring a characteristic premise. The SA Types must also indicate that they are used for prepaid by specifying a prepaid entity characteristic value.

Copyright © 2026, Oracle and/or its affiliates.

Bill Cycle

Create at least one bill cycle that will be used for prepaid accounts. This bill cycle should not have a schedule defined.

Vendor Information

A vendor could be a vending station, payment agency or master station.

You must create a person for each of your vendors. Information about the vendor may include names, an address, phone numbers, etc.

Any other miscellaneous information about the vendor can be stored as characteristics on the person.

Hierarchical relationships between vendors can be established through characteristics. For instance, a vending station's person record may contain a foreign key characteristic that points to the master station that the vending station reports to.

Defining Conservation Program Options

Oracle Utilities Customer Care and Billing allows you to define conservation (or energy efficiency) programs and provide rebates to customers.

- The Big Picture of Conservation Programs
- GL Accounting Example
- Setting Up Conservation Programs

The Big Picture of Conservation Programs

The purpose of using conservation programs is to provide rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy. To redeem their rebates, customers have to submit a rebate application to the utility with receipts, and the utility has to administer and report on the programs.

Admin and transaction objects are provided in the product to support the definition of conservation programs (admin data) and the subsequent rebate claims (transaction data). Portals and BPA scripts are used to maintain the conservation programs and rebate claims. Adjustments are used to recognize the expense and to process refunds.

The following sections discuss the maintenance objects that support this functionality.

- Conservation Program Maintenance Object
- Conservation Program Rebate Definition Maintenance Object

Copyright © 2026, Oracle and/or its affiliates.

- Rebate Claim Maintenance Object
- Rebate Claim Line Maintenance Object

Conservation Program Maintenance Object

A conservation program is an admin maintenance object (MO) used to support the definition of a conservation program. It holds rules that control how the claims for a conservation program are managed. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- A business object option Display Statistics Service Script is provided for business objects of this type. The script plugged into this option retrieves information displayed on the **Conservation Program Statistics Zone**.
- A business object option Display Statistics UI Map is provided for business objects of this type. This is the map used on the **Conservation Program Statistics Zone** to display statistics.
- A separate maintenance object is provided to capture rebate definitions for a conservation program
- Logs are not provided.
- The standard characteristics collection is provided.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-CPROG.

Conservation Program Rebate Definition Maintenance Object

A conservation program has rebate definitions that define the rebate amounts and energy savings for different types of products. The superset of such lines is the "rebate matrix". Each row in the matrix defines the rebate and presumed energy savings for a product purchased by the consumer. If your organization wishes to use this maintenance object (MO), you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- The Rebate Definition table can be used to capture information for rebate claim lines such as, appliance type, refund amount, energy savings, and applicable manufacturers and models.
- Logs are not provided for the Rebate Definition.
- A characteristics collection is not provided.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-RDEF.

Rebate Claim Maintenance Object

When a customer files a claim for a rebate, a rebate claim will be created. The rebate claim maintenance object (MO) is used to support the definition of a claim. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- Depending on the utility's requirements, you can specify single or multiple items on the Rebate Claim. A separate maintenance object is provided to capture rebate claim lines for a rebate claim.
- The standard characteristics collection is provided.
- A log is provided. This can be used to track approval information for the claim, to capture adjustments created as the claim is processed, etc.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-RCLAIM.

Rebate Claim Line Maintenance Object

A rebate claim has a rebate claim line for each product eligible for a refund. You use the rebate claim line maintenance object (MO) to create a rebate line. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- SA (service): The SA table is the real service SA. There is a separate SA under which the rebate adjustments are stored.
- Logs are not provided for Rebate Claim Line
- The standard characteristics collection is provided.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-REBLN.

GL Accounting Example

The following table shows the financial transactions that are issued when processing energy conservation rebates. This example shows the financial transactions when a customer files a claim for a dishwasher and insulation.

Notice how the expense adjustments are atomized:

- Separate adjustments are created to expense each item individually.
- A single adjustment is created for the A/P check request.

Event	GL Accounting
Rebate adjustment is created - dishwasher	Rebate Expense 35 A/P <35>
Rebate adjustment is created - insulation	Rebate Expense 45.45 A/P <45.45>
A/P check request issued	A/P 80.45 Cash <80.45>

Setting Up Conservation Programs

Conservation Programs allow administrators to create and maintain conservation programs for which customer can submit rebate claims. To set up a conservation program, open **Admin**, and then **Customer**, and then **Conservation Program**, and then **Add.**

NOT_SUPPORTED

For additional information on working with rebate claims, see Rebate Claims.

The topics in this section describe the base-package zones that appear on the Conservation Program portal.

- Conservation Program List Zone
- Conservation Program Zone
- Rebate Definition Zone
- Rebate Claim Statistics Zone

Copyright © 2026, Oracle and/or its affiliates.

Conservation Program List Zone

The Conservation Program List zone lists every conservation program. The following functions are available:

- Click a broadcast button to open other zones that contain more information about the adjacent conservation program.
- Click the Add link in the zone's title bar to add a new conservation program.

This zone displays the following for each conservation program defined in the system:

- Conservation Program Information (Description, Status, Start Date, End Date)
- The number of Complete Claims
- The total Complete Claims Amount
- The number of Incomplete Claims
- The Statistics Date/Time is the date that the statistics were last calculated

Use the following procedure to create a new conservation program:

- Select **Admin**, and then **Customer**, and then **Conservation Program**, and then **Add** or click **Add** on the title bar of the Conservation Program List zone.
- Enter basic information about the conservation program in the **Main** section, including:
  - Conservation Program code
  - Description
  - Start Date/End Date
  - Statistic Update Frequency (in hours)
- Enter **Financial Information** about the conservation program, including:
  - CIS Division
  - SA Type
  - A/P Adjustment Type
  - A/P Taxable Adjustment Type
- Enter **Approval Information** about the conservation program, including:
  - Approval To Do Type
  - Duplicate Claim To Do Role
  - Approval Levels and Threshold Amounts
- Click **Save.** To return to the Conservation Program portal without saving the new program, click **Cancel.**

To view a specific conservation program, click the broadcast icon for the conservation program you wish to view. The remaining zones in the Conservation Program portal open displaying details about the selected conservation program.

Copyright © 2026, Oracle and/or its affiliates.

Conservation Program Zone

You use the Conservation Program zone to view and maintain individual conservation program. The Conservation Program zone displays the following information about the selected conservation program:

- Basic information about the conservation program, including
  - Conservation Program
  - Description
  - Start Date/End Date
  - Statistic Update Frequency (in hours)
  - Status
- Financial Information about the conservation program, including
  - CIS Division
  - SA Type
  - A/P Adjustment Type
  - A/P Taxable Adjustment Type
- Approval Information about the conservation program, including
  - Approval To Do Type
  - Duplicate Claim To Do Role
  - Approval Levels and Threshold Amounts

Please see the zone's help text for information about this zone's fields.

- Conservation Program Status
- Conservation Program Actions
- Editing Conservation Programs
- Deleting Conservation Programs
- Activating Conservation Programs
- Deactivating Conservation Programs
- Setting the Status of Conservation Programs to Pending

Conservation Program Status

The Status of a conservation program indicates the current state of the program within the system. Valid statuses include:

- **Pending** indicates the program is pending. This is the initial state of a conservation program when first created.
- **Active** indicates the conservation program is currently active.
- **Inactive** indicates the conservation program is currently inactive.

Copyright © 2026, Oracle and/or its affiliates.

Conservation Program Actions

You can perform a number of actions on a conservation program, including:

- **Edit:** Used to edit a conservation program
- **Delete:** Used to delete a conservation program
- **Activate:** Used to activate a pending or inactive conservation program
- **Refresh Statistics:** Used to refresh the statistics of an active conservation program
- **Deactivate:** Used to deactivate a pending or active conservation program
- **Pend:** Used to change the status of an active or inactive conservation program to Pending

The actions available are based on the current status of the conservation program. The table below summarizes the actions available at each status.

Status	Valid Action
Pending	Edit, Delete, Activate, Deactivate
Active	Edit, Refresh Statistics, Deactivate, Pend
Inactive	Activate, Pend

Editing Conservation Programs

Use the following procedure to edit an active or pending conservation program:

- Click **Edit.**
- Edit the details of the conservation program as needed.
- Click **Save.**

Deleting Conservation Programs

Use the following procedure to delete a conservation program:

- Click **Pend** to change the status of the conservation program to Pending (if needed).
- Click **Delete.**
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the conservation program, click **Cancel.**

Activating Conservation Programs

To activate an inactive or pending conservation program, click **Activate.**

Copyright © 2026, Oracle and/or its affiliates.

Deactivating Conservation Programs

To deactivate an active or pending conservation program, click **Deactivate.**

Setting the Status of Conservation Programs to Pending

To set the status of an active or inactive conservation program to Pending, click **Pend.**

Rebate Definition Zone

You use the Rebate Definition zone to add, view, and edit rebate definitions associated with a conservation program. A rebate definition defines the types of rebates allowed for a specific conservation program. The Rebate Definition zone displays the following details for each claim line:

- Rebate Definition
- Status (Active or Inactive)
- Rebate Amount per Unit
- Icons to Edit, Delete, and Activate/Deactivate rebate definitions
- Adding Rebate Definitions
- Editing Rebate Definitions
- Deleting Rebate Definitions
- Activating Rebate Definitions
- Deactivating Rebate Definitions

Adding Rebate Definitions

Use the following procedure to add a rebate definition:

- Click **Add** in the title bar of the Rebate Definition zone.
- Enter a Description of the rebate definition.
- Select the **Product** for the rebate definition from the dropdown list.
- Select the **Service Type** for the rebate definition from the dropdown list.
- Enter the **Rebate Per Unit Amount** for the rebate definition.
- Enter the **Rebate Unit of Measure** for the rebate definition.
- Select the **Expense Adjustment Type** for the rebate definition from the dropdown list.
- Enter the **Presumed Energy Savings** for the rebate definition.
- Select the **Presumed Energy Savings** Unit of Measure for the rebate definition from the dropdown list.

Copyright © 2026, Oracle and/or its affiliates.

- Enter the **Manufacturer** and **Model** for each item eligible to be submitted as a rebate claim line.
- To upload manufacturer/model information from a comma-separated-values file, click **CSV File to Upload.**
  - Click **Browse** on the File Upload dialog, and browse to the file to be uploaded.
  - Click **Upload.**
- Click **Save.** To return to the Rebate Definition zone without adding the rebate definition, click **Cancel.**

Editing Rebate Definitions

Use the following procedure to edit a rebate definition:

- Click the edit icon for the rebate definition you wish to delete.
- Edit the details of the claim line as appropriate.
- Click **Save**. To return to the Rebate Definition zone without changing the rebate definition, click **Cancel.**

> **Note**
>
> You can edit a rebate definition only when it is Active.

Deleting Rebate Definitions

Use the following procedure to delete a rebate definition:

- Click the delete icon for the rebate definition you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the rebate definition, click **Cancel.**

Activating Rebate Definitions

To activate an inactive rebate definition, click the **Activate** button for the rebate definition you wish to activate.

> **Note**
>
> You can only activate rebate definition that is currently Inactive.

Deactivating Rebate Definitions

Copyright © 2026, Oracle and/or its affiliates.

To deactivate an active rebate definition, click the **Deactivate** button for the rebate definition you wish to deactivate.

> **Note**
>
> You can only deactivate rebate definition that is currently Active.

Rebate Claim Statistics Zone

You use the Rebate Claim Statistic zone to view statistics for submitted rebate claims based on the current conservation program. This zone displays the following:

- Conservation Program
- Statistics Date/Time
- Statistics Charts
- Statistics Graphs

Statistics Graphs

This zone displays statistics for submitted rebate claims using the following charts:

- **Statistics by Status:** A pie chart that displays the number and percentage of claims for each status.
- **Statistics by Month:** A line chart that displays the number of claims completed each month.
- **Statistics by Product:** A pie chart that displays the total value, percentage, and number of claim lines completed for each product.
- **Statistics by Claim Age:** A line and bar chart that displays the number of new claims per month (line graph) and the number of claims per age grouping (bar graph).

To refresh statistics, click **Refresh Statistics** on the title bar of the Rebate Claim Statistics zone.

Defining Open Market Options

- Markets

Markets

- Understanding Market
- Configuring Market

Copyright © 2026, Oracle and/or its affiliates.

Understanding Market

The Market object is used to define a deregulated market which is a geographical area operating with a set of rules to manage premises and/or customers for a service type. Separate market instances are created for each geographic area and service type, e.g. Gas New York (GNY), Electric New York (ENY), Electric United Kingdom (EUK).

Each deregulated market has participants (Service Providers) operating within that market. Different types of Service Providers are grouped into Market Relationship Types. There are Service Providers that manage the customer at a premise - e.g. Local Distribution Company, Energy Service Provider (Retailer, Supplier) and some that manage the meter at a premise (Meter Operator, Data Aggregator). Service Providers can operate across several deregulated markets (e.g. Retailers) and they can enter and exit markets independently. Start and End dates are provided to manage Service Providers entering and exiting markets.

Service Provider types can be managed by the market object and others can be managed by Market Provider Configuration. Recommended Market Relationship types managed by the Market object are Meter Owners, Meter Aggregators. There may be markets where no Service Providers are managed by the Market object, even where Meter Owners are present. For example when Meter Owners don’t change.

Service Provider types managed by the Market Provider Configuration are recommended for Retailer and Distributor Market Relationship Types. This option provides greater flexibility for market transactions to be sent to service providers based on the market and billing options.

> **Note**
>
> Refer to Market Provider Configuration for Service Providers that are managed for each Market Billing Option.

Markets that manage a provider of last resort or fall back service provider will configure the market Fall Back Service Provider, the start and end dates allow a solution to determine who the current Fall Back Service Provider is. Not all markets have a Fall Back Service Provider.

Configuring Market

This portal is used to display and maintain a Market.

Refer to Understanding Market for more information.

To maintain markets, open **Admin**, and then **Open Market**, and then **Market**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Defining Consumer Contract Options

The topics in this section describe how to set up the system to enable consumer contract functionality.

Copyright © 2026, Oracle and/or its affiliates.

- Understanding Consumer Contracts
- Understanding Consumer Products
- Configuring Consumer Contract Type
- Configuring Consumer Contract Milestone Type
- Configuring Consumer Product
- Configuring Consumer Product Version
- Configuring Consumer Product Rule
- Configuring Consumer Product Component
- Configuring Consumer Contract Rule

Understanding Consumer Contracts

Consumer contracts record customer relationships. These relationships can encompass multiple services, multiple sites and multiple accounts. For example a consumer contract can be for a customer's gas and electricity supply at a single site or for a customer’s water supply at multiple sites.

A consumer contract can relate to one or more consumer product versions. A consumer product version records values that are common to all consumer contracts related to that consumer product version. A consumer product version also records rules that are applied by customer service requests to set up a new consumer contract or change an existing consumer contract. These rules can for example create service agreements or stop service agreements. Refer to Understanding Consumer Products for more details. A consumer contract’s consumer contract products record the links between the consumer contract and consumer product versions.

Note a consumer contract relates to consumer product versions not to consumer products. The consumer product version linked to a consumer contract is the version of the required consumer product that is applicable for that consumer contract. This could for example be the consumer product version that is effective for the date the consumer contract was agreed.

Consumer contracts group together service agreements. The relationship between a consumer contract and a service agreement is recorded in the service agreement by linking the service agreement to one of the contract’s consumer contract products. A consumer contract can record details that are common for all of the related service agreements.

All consumer contracts have a consumer contract type. A consumer contract type limits which consumer products are valid for a consumer contract of that type. Note the consumer products that are eligible are further limited by the consumer product's eligibility criteria. Refer to Understanding Consumer Products for more details.

A consumer contract can have milestones where a milestone is a date that is significant to the contract. Milestones can optional trigger an action. Refer to Understanding Consumer Contract Milestones for more details.

- Understanding Consumer Contract Milestones

Understanding Consumer Contract Milestones

Dates that are significant to a consumer contract can be recorded as consumer contract milestones. A consumer contract milestone can optionally trigger an action. For example, a consumer contract milestone could record the date when a fixed-priced period ends and trigger

Copyright © 2026, Oracle and/or its affiliates.

a change to the consumer contract when this date is reached. Another example is a consumer contract milestone that sends a notification to the customer one month prior to the end of the fixed-priced period.

A consumer contract milestone can relate to one or more of the contract's consumer contract products. A contract's consumer contract products record the links between the consumer contract and consumer product versions. In the example above of a consumer contract milestone recording the date when a fixed price period ends, the consumer contract milestone would be related to the consumer contract period whose consumer product version has the fixed priced period.

Each milestone has a consumer contract milestone type. The consumer contract milestone type indicates whether or not a milestone is executable, that is whether or not it triggers an action. For executable milestones, the action to be performed is derived from the consumer contract milestone type.

A consumer contract milestone's executable status can be: Pending, Processed, Not Executable or Canceled. Not Executable indicates that the milestone does not have a related action and Canceled indicates that the milestone is no longer applicable.

The Perform Consumer Contract Milestone Actions (C1–CCMP) batch process executes a consumer contract milestone's actions. This batch process selects the consumer contract milestones whose milestone date is today or in the past and whose executable status is Pending. The batch process performs the **Perform Action** algorithms defined on the milestone's Consumer Contract Milestone Type business object. Once a consumer contract milestone's actions have been performed, the batch process changes its executable status to Processed.

> **Note**
>
> This batch process is built using the Plug-in Driven Background Processes framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. Adjust the batch parameters according to your custom logic, if needed.

The base product provides a **Contract Milestone Type (BO) – Perform Action** algorithm that sends customer notification. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Contract Milestone Type (BO) – Perform Action** algorithm entity in the application.

Understanding Consumer Products

Consumer products record attributes and rules that are used for consumer contracts. A consumer product can for example record attributes for:

- The duration of a fixed-priced period
- The amount of a contractual change, such as an exit fee
- Prices

These attributes can be used when setting up a new consumer contract or changing an existing contract. They could also be used to display details when a product is being selected or to include details in correspondence with customers.

Copyright © 2026, Oracle and/or its affiliates.

A consumer product's rules are used to set up new consumer contracts and to change existing consumer contracts.

A consumer product's attributes and rules are recorded in the consumer product's version. Refer to Understanding Consumer Product Versions for more details.

Consumer product eligibility criteria can be used to determine which consumer products that are eligible in particular circumstances. For example a consumer product could be eligible only when autopay is being used. Consumer product eligibility criteria are optional. If a consumer product has eligibility criteria then the consumer product is eligible or not depending on the criteria. If however a consumer product does not have eligibility criteria then the consumer product is always eligible. The next sections provide more information on this functionality.

- Understanding Consumer Product Eligibility Criteria
- Understanding Consumer Product Versions
- Understanding Consumer Product Rules
- Understanding Consumer Product Components
- Understanding Consumer Product Component Eligibility Criteria
- Understanding Consumer Contract Rules

Understanding Consumer Product Eligibility Criteria

A consumer product eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Eligibility Operand**. The value of these characteristics are populated by the Operands algorithms that are defined on the related Consumer Contract Type's business object. The base product provides **Consumer Contract Type (BO) – Operands** algorithm that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Type (BO) – Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product eligibility criteria rule.

The comparison results define what action should be taken when the criteria rule is applied. If the comparison is true or false, the result can be that the consumer product is eligible, the consumer product is not eligible or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product is eligible, the consumer product is not eligible, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Product Versions

Copyright © 2026, Oracle and/or its affiliates.

A consumer product version records the product attributes and rules that are applicable for consumer contracts related to the consumer product version.

> **Note**
>
> Consumer contracts relate to consumer product versions not to consumer products. The addition of a new consumer product version will not affect existing consumer contracts.

For a consumer contract that is created or changed using a customer service request, the consumer product version is determined using the Determine Version algorithm defined on the Consumer Product business object. The base package provides an algorithm type that determines the effective consumer product version by comparing the version's offer effective date and the date the new contract or contract change was agreed. Alternative custom algorithms could use one or more of the consumer product version's offer effective date, service effective date, offer end date, service end date and consumer product version selection. To see the list of available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Determine Version** algorithm

Consumer products have two kinds of rules: consumer product rules and consumer contract rules. Consumer product rules are used to perform configurable services for a consumer product version. For example, a consumer product rule can determines the fallback product to use when a contract's product is no longer eligible. Consumer contract rules are used to set up new consumer contracts and make changes to existing consumer contracts. For example, a consumer contract rule can be used to create or stop a service agreement.

Consumer product rules relate directly to a consumer product version. Consumer contract rules are organized into groups using consumer product components. The consumer product components can be linked together into a hierarchy. The consumer product version records the consumer product component at the top of the hierarchy.

A consumer product version's attributes are recorded either as consumer product version characteristics or as consumer product component characteristics. Examples of attributes are: the duration of a fixed-price period and the amount of an exit fee.

Consumer product component eligibility criteria determine whether a consumer product component is applicable. The product attributes retrieved or consumer contract rules applied for a consumer product version will vary depending on the consumer product component eligibility criteria rules.

Understanding Consumer Product Rules

Consumer product rules are standard and custom rules that perform actions for a consumer product version. A consumer product rule class defines the type of action that is performed. A consumer product rule class is recorded in the consumer product version for each related consumer product rule. The base product provides the following consumer product rule classes:

- Determine Fallback Product
- Determine If Reapplication Required

A consumer product rule typically includes the following details:

- Basic information about the consumer product rule, including its name, description and detailed description. This is standard information for most consumer product rules.

Copyright © 2026, Oracle and/or its affiliates.

- Specific parameters used by the consumer product rule.

The base product provides the following consumer product rules:

- **Determine Fallback Product**: A rule that determines the fallback product using a consumer product class recorded in the rule.
- **Determine if Product should be Reapplied:** A rule that determines if reapplication is necessary by deriving the current consumer product component eligibility criteria operands for the consumer product and comparing these with the previous operand values.

Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product Rule (BO) – Apply Rule** algorithm entity in the application.

Understanding Consumer Product Components

Consumer product components group together product attributes and consumer contract rules.

Consumer product component eligibility criteria rules can be created for a consumer product component. These eligibility rules will determine if a consumer product component's product attributes are applicable and if a consumer product component's consumer contract rules are applied. A consumer product version could, for example, have one consumer product component that is eligible when a customer is on autopay and another consumer product component that is eligible when a customer is not on autopay.

A consumer product component can, optionally, have one or more child consumer product components. This allows consumer product components to be organized into a hierarchy. If a consumer product component is not eligible, any child consumer product components will also not be eligible.

Understanding Consumer Product Component Eligibility Criteria

A consumer product component eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product component eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Comp Eligibility Operand**. The value of these characteristics are populated by the **Contract Operands** and **Location Operands** algorithms defined on the Consumer Product business object. The base product provides a **Consumer Product (BO) – Contract Operands** algorithm type that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Contract Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product component eligibility criteria rule.

The comparison results define what action should be taken when the criteria rules is applied. If the comparison is true or false, the result can be that the consumer product component should

Copyright © 2026, Oracle and/or its affiliates.

be applied, the consumer product component should not be applied or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product component should be applied, the consumer product component should not be applied, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Contract Rules

Consumer contract rules are standard and custom rules that perform actions to set up a new consumer contract or change an existing consumer contract which is related to the consumer product version. A consumer contract rule could for example create a new service agreement.

Consumer contract rules are grouped together by consumer product components. Consumer product components determine if and when a consumer contract rule will be applied. Refer to Understanding Consumer Product Components for more details.

Consumer contract rules are applied by a customer service request when a consumer contract is being created or changed. Different consumer product rules can be applied at different stages of the customer service request and for different changes. The consumer product component defines a consumer contract rule usage that determines when a consumer contract rule is applied.

The base product provides the following consumer contract rule usages:

- On Activation – Add: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products that have been added.
- On Activation - Remove: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products whose end date time has been set.
- On Completion – Add: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products that have been added.
- On Completion – Remove: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products whose end date time has been set.
- Service Location - Add: The consumer contract rules are performed when any action required to add a service point or registration point to a contract, such as field work or a market process, has been performed.
- Service Location – Remove: The consumer contract rules are performed when any action required to remove a service point or registration point from a contract, such as field work or a market process, has been performed.

The base product provides **Consumer Contract Rule (BO) – Apply Rule** algorithms that add a service agreement and that add a consumer contract milestone. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Rule (BO) – Apply Rule** algorithm entity in the application.

Configuring Consumer Contract Type

This portal is used to display and maintain a Consumer Contract Type.

A Consumer Contract Type defines the Consumer Products that are valid for the type of contract. It also defines the information that is used in determining product eligibility.

Refer to Understanding Consumer Contracts for more information.

Copyright © 2026, Oracle and/or its affiliates.

To maintain consumer contract types, open **Admin**, and then **Consumer Contract**, and then **Consumer Contract Type**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Contract Milestone Type

This portal is used to display and maintain a Consumer Contract Milestone Type.

A Consumer Contract Milestone Type defines milestone dates that can be recorded and whether an action should be performed for the type of milestone.

Refer to Understanding Consumer Contract Milestones for more information.

To maintain consumer contract milestone types, open **Admin**, and then **Consumer Contract**, and then **Consumer Contract Milestone Type**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Product

This portal is used to display and maintain a Consumer Product, including the consumer product's versions and eligibility rules.

Refer to Understanding Consumer Products for more information.

To maintain consumer products, open **Admin**, and then **Consumer Contract**, and then **Consumer Product**.

Integration

Oracle Utilities Customer Care and Billing a provides tools to facilitate the integration other systems. This section provides technical information needed by your implementers to accomplish this.

- CTI-IVR Integration
- Call Summary and Call Tagging Integration
- Analytics Integration Overview
- Self-Service Integration
- Defining DataConnect Options

Copyright © 2026, Oracle and/or its affiliates.

- External Fieldwork System Integration
- Outage System Integration
- Oracle Utilities Customer Program Cloud Service
- Asset Management System Integration
- Business Flags
- Customer Engagement
- Customer Profile Insights
- Customer Relationship Management Integration
- RightNow Knowledge Integration
- Creating Application Links in External Applications

CTI-IVR Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system. The interface provides the following functionality:

- The ability to launch Control Central for a particular account ID or phone number from an external application
- The ability to accept the next call, as dictated by the CTI software,
- The ability to perform an outbound phone call from within Oracle Utilities Customer Care and Billing

This document provides technical information needed by your implementers to fully integrate with your CTI/IVR system.

- CTI-IVR Integration Configuration
- Launching The System From an External Application
- Receiving the Next Caller in the Queue
- Initiating an External Call

CTI-IVR Integration Configuration

The integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system requires the setup of master configuration data that controls the Next Caller and Automated Dialer functions.

To set up the CTI/IVR integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration**. You are brought to an all-in-one portal with options to add/edit the CTI/IVR Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Launching The System From an External Application

The following section describes possible options to launch the system from an external system.

Copyright © 2026, Oracle and/or its affiliates.

- Launching The Application Using a URL

Launching The Application Using a URL

You launch the application using a URL. With this option you can set the system to launch a script upon startup. You can also indicate to the system to automatically load an appropriate page (if this information is not part of the script).

The application includes a simple sample html page that can launch CCB Control Central Search by Phone Number or by Central Search Account Id. The page is called CTISample.HTM and is located in /cm_templates.

> **NOT_SUPPORTED**
>
> Refer to Launching A Script When Starting The System for further information.

Receiving the Next Caller in the Queue

If your CTI-IVR system allows users to request the next caller waiting in a queue, the system provides a mechanism to integrate with this functionality.

A BPA script called **Get Next Caller (C1-GtNxtClrC)** is available that can be used to request the next call waiting in an inbound queue managed by a CTI application.

When the **Get Next Caller** BPA is executed, it launches the **CTI Get Next Caller** and **Launch CTI** processing scripts that are defined in the CTI/IVR Integration master configuration. Your implementation creates the **CTI Get Next Caller** script that retrieves the next account in the queue. The base product supplies a sample **Launch CTI** BPA script that launches Control Central using the **C1-CCByAcct** BPA script and passing in the account that was returned by the **CTI Get Next Caller** script.

- Customize Integration to Your Next Caller Function

Customize Integration to Your Next Caller Function

Your implementation needs to create a **CTI Get Next Caller** processing script that will responsible for getting the next account in the queue, based on your integrated CTI application. The base-supplied **Launch CTI** processing script can be used to navigate to Control Central with the next caller's account passed in.

In order to integrate the next caller functionality with your CTI-IVR system, perform the following steps:

- Create your custom **CTI Get Next Caller** service script that retrieves the next account from the queue.
- Create a **Launch CTI** BPA script if your business rules require additional logic and/or need to launch a different page in the system..
- Plug in the **CTI Get Next Caller** and **Launch CTI scripts** on the CTI/IVR Integration master configuration.

Copyright © 2026, Oracle and/or its affiliates.

Initiating an External Call

This section describes the automated dialer functionality provided with the system as well as information about integrating with your own automated dialer.

- Overview of Automated Dialer
- Technical Implementation of Automated Dialer
- Customize Integration to Your Automated Dialer Software
- Customize Automated Dialer User Interface

Overview of Automated Dialer

In order to initiate a call to a customer from within the system, a context menu item **Go To Automated Dialer** is available on the Person context menu. To call a customer displayed in the current context, choose this option from the person context menu and a window appears, showing a list of phone numbers defined for that person.

Select the desired phone number and click **Dial**.

> **Note**
>
> **Context Entry Secured**. The navigation key for this window automatedDialer refers to an application service to facilitate application security. If your installation does not support an integration with external dialer software, configure the security settings to ensure that users do not have access to the application service for this context entry.

Technical Implementation of Automated Dialer

The popup window is implemented as a BPA script (**C1-LAutoDial**) that calls a configurable **Automated Dialer** BPA script that is responsible for retrieving and displaying person contacts and phone numbers (i.e. if the installation option is set to Use Legacy Person Phone and Email feature configuration option is set to 'Y'). The **C1-AutoDial** sample script provided with the system integrates to any soft phone protocol handler that launches a dialer based on overriding the "tel:" protocol from a browser, for example, Cisco IP Communicator. It launches a UI map to display the person contacts and phone numbers (i.e. if the feature option is set).

Phone Dialer Configuration

If your implementation chooses to use the functionality provided with the system and integrate with a soft-phone dialer, plug in the base-supplied **C1–AutoDial** script in the CTI/IVR Integration master configuration.

Customize Integration to Your Automated Dialer Software

Copyright © 2026, Oracle and/or its affiliates.

In order to integrate with a different automated dialer software application, your implementers must create your own **Automated Dialer** BPA script, to call your specific dialer.

- Copy the **C1-AutoDial BPA** script and make the appropriate changes to integrate with your automated dialer (e.g. change the protocol from “tel:” to “callto:”.
- Plug in your custom Automated Dialer script on the CTI/IVR Integration master configuration.

Customize Automated Dialer User Interface

Your implementation may choose to display a different user interface for the **Go To Automated Dialer** function than the one provided with the system. For example, perhaps there is more information that you would like to display in addition to the person's name and phone numbers. In order to do this, your custom **Automated Dialer** script needs to invoke a custom UI map that you create as follows:

- Copy the base-supplied **C1-AutomatedDialer** UI map and make the necessary changes.
- Invoke your custom UI map from your custom **Automated Dialer** .

Call Summary and Call Tagging Integration

Call Summary and Call Tagging uses Generative Artificial Intelligence and integration with a third-party Computer Telephony Integration (CTI) application to automatically summarize and categorize call transcripts, providing customer service agents an overview of the call. Agents can review and edit the summary and tags before saving them directly to the customer contact.

> **Note**
>
> Call Summary and Call Tagging is only available with Oracle Utilities Customer Cloud Service and Oracle Utilities Customer Care and Billing Cloud Service.

See Creating Customer Contacts Using Call Summary and Call Tagging in the *Business User Guide* for more information how users work with Call Summary and Call Tagging.

This section provides details related to implementation of Call Summary and Call Tagging, including:

- Integrating With a CTI Application
- Configuring Characteristic Types and Customer Contact Types with Characteristic Tags
- Enabling the Service Guide Zone

> **Note**
>
> Call Summary and Call Tagging relies on generative AI models that must be deployed as part of your cloud service implementation. Please contact your Oracle Customer Success Manager if you wish to use Call Summary and Call Tagging.

- Integrating with a CTI Application

Copyright © 2026, Oracle and/or its affiliates.

- Configuring Characteristic Types and Customer Contact Types with Characteristic Tags
- Enabling the Service Guide Zone

Integrating with a CTI Application

This section provides an overview of the process to integrate a third-party Computer Telephony Integration (CTI) vendor with Call lSummary and Call Tagging, utilizing the Service Guide SDK JavaScript library. By integrating CTI, your agents can use enhanced Call lSummary and Call Tagging features such as:

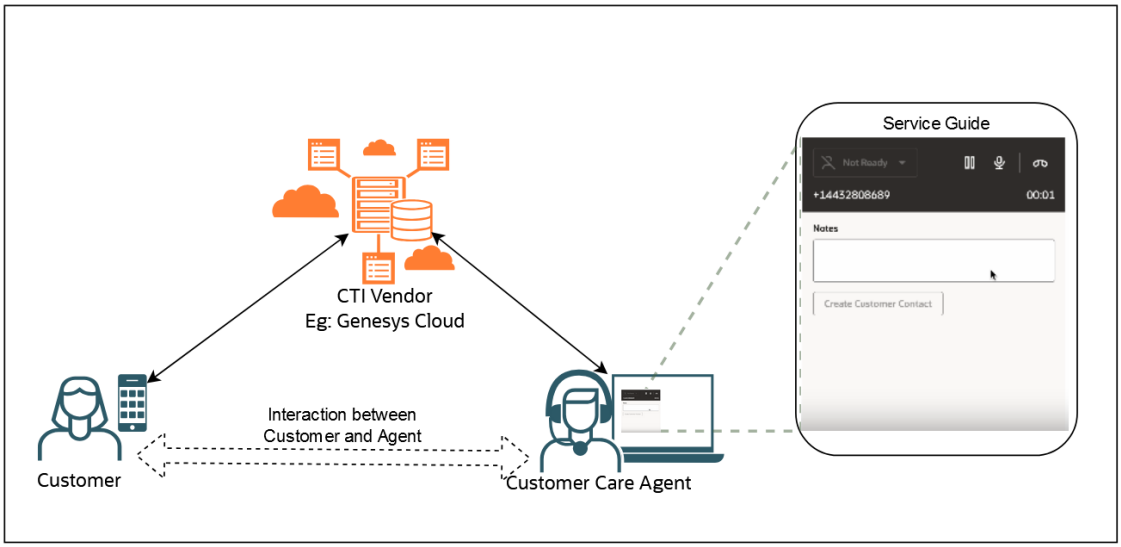
- Incoming call notifications
- Call control management, including muting, holding, and ending calls
- Access to call transcripts and summaries

> **Note**
>
> Oracle does not endorse specific CTI vendors or provide implementation instructions for third-party applications. This document focuses on the integration points supported by the Service Guide SDK, detailing relevant events and APIs. Hosting third-party applications is beyond the scope of this guide.

This section contains the following:

- Understanding Computer Telephony Integration
- Prerequisites and Technical Requirements
- Configuring the CTI iFrame
- Integrating the Service Guide SDK in the Partner Application
- Understanding Computer Telephony Integration
- Prerequisites and Technical Requirements
- Configuring the CTI iFrame
- Integrating the Service Guide SDK in the Partner Application

Understanding Computer Telephony Integration



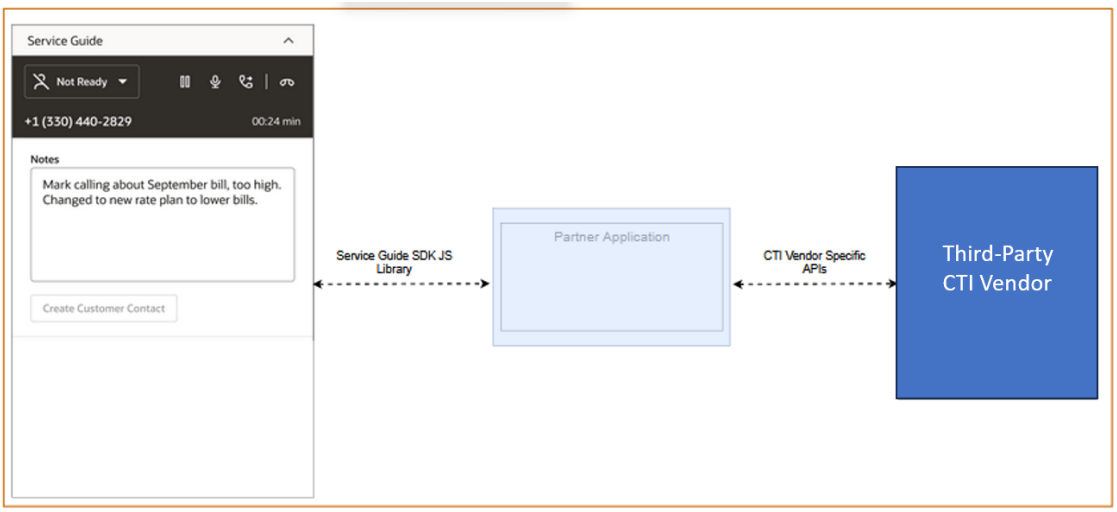
Computer Telephony Integration (CTI) is a technology that integrates computer software and telecommunication systems seamlessly. It connects a phone system to a computer, enabling users to manage phone functions directly from their desktop.

With CTI, customer calls that come into the service center are routed through a CTI system and sent to an available agent. The CTI provider facilitates this process by identifying callers, providing access to customer details, and offering call control features directly from the agent's desktop. Call controls include incoming call notifications, call control options during a call (such as hold or mute), and the ability to obtain a text transcript of the call, if supported by the CTI vendor.

This image illustrates a basic flow where a call to the utility is routed via the CTI vendor and handled by an agent. The CTI provider identifies the caller, enables the agent to view customer details, and enables the agent to mute the call, put the call on hold, or transfer the call.

Copyright © 2026, Oracle and/or its affiliates.

Figure CTI Integration Flow Example



Prerequisites and Technical Requirements

Call Summary and Call Tagging facilitates integration with third-party CTI vendors through a partner application. Oracle provides the Service Guide SDK JavaScript library for communication between the Call Summary and Call Tagging application and the CTI partner application, which runs as an invisible iFrame.

The CTI iFrame serves as a container for embedding the partner application, which is a web application developed by utility system administrators. This application communicates with the CTI backend using vendor-specific APIs to deliver the required functionality.

This image illustrates the technical components of the solution:

Figure Technical Components

Before completing the steps in this guide, complete the following tasks:

Copyright © 2026, Oracle and/or its affiliates.

1. Select a CTI vendor that meets your needs. The vendor should support both incoming and outbound calls and provide API support for accepting calls from the web application.
2. Verify that you can invoke the CTI vendor APIs.
3. Develop the partner application as a web-based solution that can be made available over https.

Configuring the CTI iFrame

After you have created your partner application, you must gather the following information, which is used to configure the application inside of the Call Summary and Call Tagging feature:

- The URL of the partner application page
- The window domain of the final page with which the partner application is loaded

URL of the Partner Application

You must provide the URL for the partner application page that will be embedded in Call Summary and Call Tagging as part of the CTI iFrame. This should include any static query parameters that the partner application expects.

Call Summary and Call Tagging appends the **`crmDomain`** query parameter to this URL, which is the window location of the Call Summary and Call Tagging application. For example:

```
https://opav12345.getway.mycti.cloud/crm/embeddableApp.html?
enableFrameworkClientId=true&dedicatedLoginWindow=true
```

This example shows an iFrame URL that is used by Call Summary and Call Tagging for loading the partner application, where, `crmDomain=<Service-Guide-window-location>` is appended by Call Summary and Call Tagging.

```
https://opav23abc5a4z.getway.mycti.cloud/crm/embeddableApp.html?
enableFrameworkClientId=true&dedicatedLoginWindow=true&crmDomain=
```

Window Domain of the Final Page

You must provide the window domain, including the protocol, host and port number, of the final page with which the partner application will be loaded. The window domain may not be same as the hostname present in the iFrame URL above, as the final window may be loaded after multiple redirections. This is common when using authentication providers, and can result in a window location that is different than the initial URL. For example:

```
https://apps.usawest.mycti.cloud
```

- CTI iFrame Considerations
- Avoiding CORS Errors

CTI iFrame Considerations

When configuring the CTI iFrame, consider the following issues.

Copyright © 2026, Oracle and/or its affiliates.

iFrame Not Visible to Agent

The CTI iFrame is not visible to the end user. Only the controls provided by Service Guide are available to the agent. However, the CTI iFrame can open any necessary windows to perform necessary operations, such as logging a user into the CTI system to establish an authenticated session with the CTI backend.

Permissions

The CTI iFrame includes the permissions listed here. These permissions allow Service Guide to handle phone calls using the browser.

```
camera *; microphone *; autoplay *; hid *
```

When prompted, agents must accept and provide these permissions in order to allow Service Guide to handle a customer call.

> **Note**
>
> Agents might have to disable pop-up blockers in their browser if the partner application uses a pop-up window for authentication purposes.

Authenticated Requests

An important aspect of CTI integration is to allow agents to make authenticated requests to the CTI system. CTI systems typically use authentication and authorization to establish a valid user login and allow the system to make appropriate API calls on behalf of the logged-in agent.

Utilities can provide a window for agents to log into the CTI system, however, Oracle recommends setting up a Single Sign On (SSO) with the Oracle Customer Cloud Service application so that a single user login is recognized when an agent accesses various systems.

> **Note**
>
> Refer to your CTI vendor documentation for information about allowing API access for agents and SSO setup.

Avoiding CORS Errors

In order to embed your partner application as an <iFrame> inside Call Summary and Call Tagging, you must set up appropriate headers to avoid Cross Origin Resource Sharing (CORS) errors from browsers.

Specifically, the partner application should be set up as follows:

```
Set only "Content-Security-Policy: frame-ancestors <Service Guide Base URL>"
response header.

DO NOT SET "X-Frame-Options" response header.
```

Copyright © 2026, Oracle and/or its affiliates.

This setup applies to the partner application and any other domains to which a request gets redirected during the initial load. When the partner application is loaded and Single Sign On (SSO) is set up, the partner application may redirect browsers to an authentication provider's URL and domain, which might differ from the partner application's domain. The browser redirects occur inside the iFrame, therefore, any such domains should follow the above recommendation to ensure successful load and redirect in the iFrame embedded in Call Summary and Call Tagging.

If the authentication provider does not allow the SSO redirect window to be embedded, the partner application can open a separate login window. The agent can then sign in using CTI system credentials or credentials for other providers that utility has configured. Once the sign in is performed and a successful authenticated session is established, this window can be closed (programmatically) and CTI initialization can proceed.

> **Note**
>
> Contact your Oracle Support team if you need assistance identifying the `<Service Guide Base URL>` for your environment.

Integrating the Service Guide SDK in the Partner Application

The partner application you implement could be a normal HTML/Javascript application. To communicate with the Call Summary and Call Tagging feature, you must inject a Javascript library, called Service Guide SDK, into your partner application. Additionally, you must:

- Invoke the APIs required for the integration, or
- Listen for necessary events

The integration between Call Summary and Call Tagging and the partner application is a frontend-to-frontend integration through the javsascript SDK library.

You can import the library in the HTML page of the partner application using either method shown below.

Import Using Script Tag

Code example:

```
<script type=“module" src="https://static.oracle.com/cdn/service-guide-sdk/
<version-number>/service-guide-sdk.umd.js" onload="onSdkLoad()"></script>
        <!-- Once the above script is loaded, SDK class will be available
under window.OUSG.ServiceGuideSdk variable. -->
<script>
      function onSdkLoad() {
         const sdkInstance = new window.OUSG.ServiceGuideSdk({...});
         // You can now use "sdkInstance" variable for referring to SDK
instance.
      }
</script>
```

Once the script is loaded, SDK can be instantiated using the class available at **`window.OUSG.ServiceGuideSdk`**.

Copyright © 2026, Oracle and/or its affiliates.

Import as Module using Dynamic Import

Code example:

```
const sdkUrl = 'https://static-stage.oracle.com/cdn/service-guide/service-
guide-sdk/<version-number>/service-guide-sdk.esm.js';
const {ServiceGuideSdk} = await import(sdkUrl);
const sdkInstance = new ServiceGuideSdk({...});
// You can now use "sdkInstance" variable for referring to SDK instance.
```

Using requirejs

Code example:

```
<!--
          First load the requirejs from appropriate source -->
<script
    id="requirejs"
    src="https://requirejs.org/docs/release/2.3.7/minified/require.js"
></script>

<!-- Now load SDK using require-js -->
<script type="module">
  const sdkUrl = 'https://static-stage.oracle.com/cdn/service-guide/service-
guide-sdk/<version-number>/service-guide-sdk.esm.js';

  require([sdkUrl], (OUSG) => {
     const sdkInstance = new OUSG.ServiceGuideSdk({...});
     // You can now use "sdkInstance" variable for referring to SDK instance.
  });
</script>
```

SDK Initialization

Once the SDK library is loaded, the partner application must create an instance of the SDK by initializing it with the appropriate parameters. Call Summary and Call Tagging will add a "`crmDomain`" query parameter while loading the partner application in an iFrame. This parameter should be used while initializing SDK.

Code example:

```
// Read "crmDomain" query parameter from the window location
let url = window.location.search;
let segments = url.replace('?', '&').split('&');
const parentDomain = decodeURIComponent(segments.find(segment =>
(segment.indexOf('crmDomain') >= 0)).split('=')[1]);

//Initialize Service Guide SDK
const sdkInstance = new ServiceGuideSdkClass({
    serviceGuideDomain: parentDomain,
    isCtiInstance: true, // Most important to set
    options: {application: 'cti'} // This is also an important parameter to
include while initializing the SDK to let Service Guide know which
application the notification is coming from.
});
```

Copyright © 2026, Oracle and/or its affiliates.

```
// You can now use "sdkInstance" variable for referring to SDK instance.
// You can also set the SDK instance on the window object in case you need to
access it later:
// window.serviceGuideSdk = sdkInstance;
```

- Operations and Events

Operations and Events

The Service Guide SDK provides two types of APIs:

1. Operations
2. Events

- Operations
- Events

Operations

When the partner application needs the Call Summary and Call Tagging feature to perform an action or send data, it must invoke an `Operation` on the SDK.

For example, the partner application wants to notify an agent, via the Service Guide zone, that it has received an incoming call. This requires the partner application to invoke the `callReceived` operation.

Available operations include:

- ctiInitialized
- agentStatusUpdated
- callReceived
- initiatedCallSession
- endCallSession
- callMuted
- callUnmuted
- callOnHold
- callResumed
- transcriptReceived
- callWrappedUp
- loggedOut

To indicate that these operations are targeted towards the Service Guide interface, the operations are added under the `"Ui"` namespace of the SDK. Below is an example code for invoking an operation:

```
// SDK loading and initialization code as demonstrated before.

// Finish rest of the CTI specific setup
// initCti(...); //illustration purpose only
```

Copyright © 2026, Oracle and/or its affiliates.

```
// After all initialization is done, notify Service Guide of it
// (Assuming the SDK instance is named "serviceGuideSdk")

serviceGuideSdk.Ui.ctiInitialized();

// This can also be done in some async callback if your setup needs an
asynchronous handling
// Assuming getAuthToken is an asynchronous function that returns auth token
for a logged in user.

getAuthToken(async (authToken) => {
    // assuming CTI vendor has a `ctiSdk` library that provides a client
initialization code

    await ctiSdk.ApiClient.initialize(authToken); // Another asynchronous
processing

    // At this point all CTI initialization is done, notify Service Guide.

    serviceGuideSdk.Ui.ctiInitialized();
});

...

/* Another example */
// Assuming CTI vendor has below API for subscribing to a client that invokes
the provided callback when a customer call is received.

ctiSdk.ApiClient.Interaction.subscribe(async (callData) => {

    // Invoke "callReceived" operation on Service Guide SDK's "Ui" module.

    serviceGuideSdk.Ui.callReceived({
        data: {
            phoneNumber: calData.ani,
            callId: callData.id
        }
    });
});
```

Operation: ctiInitialized

This table provides details of the ctiInitialized operation:

Operation Component	Details
Description	This is the first operation the partner application invokes to notify Service Guide that the application is ready to handle CTI functionalities. It should be invoked after initial setup of the partner application is complete, which includes: • Setting up communication channels and websocket connections • Initializing various SDKs, including the Service Guide SDK • Completing all other initialization code

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Payload	None
Parameter Description	Not Applicable
Notes	Service Guide expects this operation to be called when the partner application is loaded to confirm that it is ready to handle call center operations. If Service Guide does not receive a response within a predetermined time, it reloads the partner application iFrame. If the partner application can't be loaded after 3 attempts, Service Guide assumes the Partner Application is down and abandons attempts to load it. Service Guide notifies the agent about the failure to load the partner application.

Operation: agentStatusUpdated

This table provides details of the agentStatusUpdated operation:

Operation Component	Details
Description	This operation is used by the partner application to notify Service Guide of the agent's availability to take an incoming call. The Service Guide displays one of these agent statuses, depending upon the payload when the operation is invoked: • Ready • Not Ready When an agent is actively handling a call, the status is Not Ready. Be aware that the partner application must invoke this operation to notify Service Guide when the agent should be moved to Not Ready status. Depending on the CTI vendor, this could be an explicit notification that the vendor sends to the partner application or it could be done by the partner application in response to when a call is connected.

Payload	`{`
	`  data: {`
	`  isAgentReady: boolean`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**isAgentReady**: Whether the agent is currently ready to receive calls.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Error Parameter Description	If the Partner Applications receives an error while updating the agent status, it notifies Service Guide about the error by including an "error" object in the payload instead of including a "data" object. The error object has the following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occured. Possible values: – "**READY_STATUS_UPDATE_FAILED**" – "**NOT_READY_STATUS_UPDATE_FAILED**"
Notes	None

Operation: callReceived

This table provides details of the callReceived operation:

Operation Component	Details
Description	When an incoming call is received from the CTI vendor and sent to the partner application, invoke this operation to notify Service Guide about the incoming call.

Payload	`{`
	`  data: {`
	`  phoneNumber: string,`
	`  callId: string`
	`  }`
	`}`

Parameter Description	**phoneNumber**: Incoming customer phone number. **callId**: A unique identifier representing the new incoming call session.
Notes	None

Operation: initiatedCallSession

This table provides details of the initiatedCallSession operation:

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Description	To be invoked when the new call session is established with the customer in response to an incoming call. Note that the agent will not explicitly accept an incoming call, but must be automatically connected to the call using auto-answer capabilities. Depending upon the CTI vendor, this could be an explicit setting in the CTI backend, or the Partner Application might be required to invoke an explicit vendor API to accept the call when it is received. Service Guide does not display Accept or Reject options for the agent. In response to this operation, Service Guide will render the call controls that are needed for the agent to interact with the active call session.

Payload	`{`
	`  data: {`
	`  phoneNumber: string,`
	`  callId: string,`
	`  connectedTime: integer | string | Date`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**phoneNumber**: Customer phone number. **callId**: A unique identifier representing the newly established call session. **connectedTime**: An optional parameter representing the start of the conversation. If present, it can be an integer representing UNIX timestamp OR a String representing datetime in ISO-8601 OR a javascript Date object.
Error Parameter Description	If the partner applications receives an error while establishing the call session with the customer and agent, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**CONNECT_FAILED**".
Notes	Both the callReceived and initiatedCallSession operations expect a callId parameter. This is required because a CTI vendor might not generate a new call identifier until a call is connected. Therefore, the call identifier might not be available when the callReceived operation is invoked. The "connectedTime" paramater can be used if the call was already in progress via another CTI software before the Service Guide window was opened. In this case, it is useful to send the timestamp from the beginning of the conversation so that Service Guide can correctly reflect the call length instead of starting the timer from 0.

Copyright © 2026, Oracle and/or its affiliates.

Operation: endCallSession

This table provides details of the endCallSession operation:

Operation Component	Details
Description	The Partner Application can invoke this operation when the call is disconnected from the CTI vendor. Note that if the agent disconnects the call in the Service Guide interface, this operation should be invoked when the call is actually disconnected by the CTI vendor in response to the Agent disconnect request.

Payload	`{`
	`  data: {`
	`  callId: string,`
	`  callDuration: number (optional)`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**callId**: A unique identifier for the call session that ended. **callDuration**: Optional call duration in seconds.
Error Parameter Description	If the partner applications receives an error while disconnecting the call session, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**DISCONNECT_FAILED**".
Notes	None

Operation: callMuted

This table provides details of the callMuted operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to mute an ongoing call was successfully processed. This operation can also be used to notify Service Guide if the call was externally muted so that Service Guide can update itself.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details

Payload	<pre>{
	    data: {
	       callId: string
	    },
	
	    error: object<{
	        isError: boolean,
	        message: string }> (optional)
	   }
	}</pre>

Parameter Description	**callId:** A unique identifier for the call that was muted.
Error Parameter Description	If the partner applications receives an error while muting the call, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**MUTE_FAILED**".
Notes	None

Operation: callUnmuted

This table provides details of the callUnmuted operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to un-mute an ongoing call was successfully processed. It can also be used to notify Service Guide if the call was externally un-muted so that Service Guide can update itself.

Payload	<pre>{
	    data: {
	       callId: string
	    },
	
	    error: object<{
	         isError: boolean,
	         message: string }> (optional)
	    }
	}</pre>

Parameter Description	**callId:** A unique identifier for the call that was un-muted.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Error Parameter Description	If the partner applications receives an error while unmuting the call, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**UNMUTE_FAILED**".
Notes	None

Operation: callOnHold

This table provides details of the callOnHold operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to put the call on hold was successfully processed. It can also be used to notify Service Guide if the call was externally put on hold so that Service Guide can update itself.

Payload	`{`
	`  data: {`
	`  callId: string`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**callId:** A unique identifier for the call that is placed on hold.
Error Parameter Description	If the partner applications receives an error while putting the call on hold, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**HOLD_FAILED**".
Notes	None

Operation: callResumed

This table provides details of the callResumed operation:

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to resume a call that was previously put on hold was successfully processed. It can also be used to notify Service Guide if the call was externally resumed so that Service Guide can update itself.

Payload	<pre>{
	  data: {
	  callId: string
	  },
	
	  error: object<{
	  isError: boolean,
	  message: string }> (optional)
	  }
	}</pre>

Parameter Description	**callId:** A unique identifier for the call that is resumed.
Error Parameter Description	If the partner applications receives an error while resuming the call that was previously put on hold, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**RESUME_FAILED**".
Notes	None

Operation: transcriptReceived

This table provides details of the transcriptReceived operation:

Operation Component	Details
Description	This operation should be invoked in response to the request transcript event to send the text transcript of the call. The partner application should request the transcript from the CTI backend via CTI-specific APIs. It is not necessary to fetch the transcript from the CTI backend at the point when the call ends. If the appropriate CTI vendor APIs are available, a real-time transcript can be collected during the call and held in front-end memory, which then can be used at the end of the call.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details

Payload	`{`
	`  data: {`
	`  agentTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional),`
	
	`  customerTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional),`
	
	`  combinedTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional)`
	
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**agentTranscripts:** An array of collected text transcripts for the agent's side of the conversation. Each element consists of the `channel` , `text` and `offsetMS`. **customerTranscripts:** An array of collected text transcripts for Customer's side of conversation. Each element consists of the `channel` , `text` and `offsetMS`. **combinedTranscripts:** An array of collected text transcripts for the whole conversation. Each element consists of the `channel` , `text` and `offsetMS`. **channel:** Either `'internal'` or `'external'` **text:** Actual speech to text transcript **offsetMs:** Offset in milliseconds from the conversation start time.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Error Parameter Description	If the partner applications receives an error while collecting the call transcript from CTI backend, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**TRANSCRIPTION_FAILED**".
Notes	Either **only** `combinedTranscripts` **OR both** agentTranscripts and customerTranscripts must be included in the payload. The `channel` property should have one of these values, based on who the conversation owner is: **`channel='internal'`** All elements of `agentTranscripts` OR those elements in `combinedTranscripts` that belong to agent. **`channel='external'`** All elements of `customerTranscripts` OR those elements in `combinedTranscripts` that belong to customer.

Operation: callWrappedUp

This table provides details of the callWrappedUp operation:

Operation Component	Details
Description	To be invoked when the call wrap up has been completed on the CTI side and the Service Guide UI should be notified so that it can reset itself, making the agent available for the next call.
Payload	```{ data: { callId: string }, error: object<{ isError: boolean, message: string }> (optional) }```
Parameter Description	**callId:** A unique identifier for the call for which the wrapup was done.
Error Parameter Description	If the partner applications receives an error while capturing the wrap up information on CTI side, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**WRAPUP_FAILED**".

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Notes	None

Operation: loggedOut

This table provides details of the loggedOut operation:

Operation Component	Details
Description	This operation should be invoked in response to the "logout" event to notify the Service Guide that the partner application has finished performing any cleanup in response to the "logout".
Payload	None
Parameter Description	Not Applicable
Notes	None

Events

When the Call Summary and Call Tagging user interface needs to request data or perform an action in the CTI backend, it raises an SDK Event that the Partner Application must listen for.

For example, when an agent puts a call on hold in the Call Summary and Call Tagging user interface , the application would raise an event to request that the Partner Application place the call on hold. Similarly, when agent requests to summarize the call, the application requests the text transcript from the Partner Application by raising an event.

The Partner Application listens for these events and performs the requested action, typically using CTI-provided APIs, and responds by invoking appropriate operations with the requested data.

Supported events include:

- serviceGuideCti:agent:status:update
- serviceGuideCti:call:disconnect
- serviceGuideCti:call:mute
- serviceGuideCti:call:unmute
- serviceGuideCti:call:hold
- serviceGuideCti:call:resume
- serviceGuideCti:request:transcript
- serviceGuideCti:call:wrapUp
- serviceGuideCti:agent:logout

To streamline the event emitting mechanism and provide a consistent way to respond to these events, the Service Guide SDK is defined as an instance of the `EventEmitter` class. Additionally, all of these events are wrapped inside a single event that is emitted by the SDK and targeted to the CTI iFrame. Implementers can listen for a single event and inspect the event details to know which specific event has been requested.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> To minimize data entry errors, the Service Guide SDK already defines the string constants for these event names so that implementers don't need to enter the specific names.

This example shows how to handle events using an SDK instance that was initialized in an earlier code snippet and shows how to invoke another operation on the SDK in response to an event:

```
// SDK Loading and Initialization code
...

// Assuming the SDK instance is named "serviceGuideSdk"

// Read all CTI specific event names
const events = serviceGuideSdk.getCtiSdkEvents();

// "serviceGuideSdk.getSdkEventName()" gives the single, wrapper event name.
// Since the SDK is an "EventEmitter" instance, you can directly call ".on()"
function to subscribe to it.

serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(), async ({eventName,
payload}) => {

    // "eventName" will contain the actual name of the event listed above
that was emitted by Service Guide.

     switch (eventName) {

          case events.updateAgentStatus: // Refers to the constant defined by
Service Guide SDK for the "serviceGuideCti:agent:status:update" event.
               // Assuming CTI vendor has below API
               if(payload.data.isAgentReady) {
                 try {
                   const response = await
ctiSdk.ApiClient.markUserReady({...});
                   if(response.ok) {
                      // Now let Service Guide know that the agent status has
been updated to "ready"
                      serviceGuideSdk.Ui.agentStatusUpdated({ data:
{isAgentReady: true} });
                   }
                 } catch (error) {
                   // Error occurred while updating the agent status in the
backend. Let Service Guide know with an error payload.
                   serviceGuideSdk.Ui.agentStatusUpdated({ error: {isError:
true, message: 'READY_STATUS_UPDATE_FAILED'} });
                 }
               } else {
                 try {
                   const response = await
ctiSdk.ApiClient.markUserBusy({...});
                   if(response.ok) {
```

Copyright © 2026, Oracle and/or its affiliates.

```
                    // Now let Service Guide know that the agent status has
been marked as "busy"
                    serviceGuideSdk.Ui.agentStatusUpdated({ data:
{isAgentReady: false} });
                  }
                } catch (error) {
                  // Error occurred while updating the agent status in the
backend. Let Service Guide know with an error payload.
                  serviceGuideSdk.Ui.agentStatusUpdated({ error: {isError:
true, message: 'NOT_READY_STATUS_UPDATE_FAILED'} });
                }
              }
              break;

         case events.disconnectCall:
               // disconnect the call and invoke "endCallSession"
operation to let Service Guide know.
              break;

         case events.requestTranscript:
              // Assuming CTI vendor has below API to get Agent transcript
              const agentTranscript = await
ctiSdk.ApiClient.getInternalTranscript(payload.data.callId);

              // Assuming CTI vendor has below API to get Customer
transcript
              const customerTranscript = await
ctiSdk.ApiClient.getExternalTranscript(payload.data.callId);

              // map the CTI provided transcript in to the necessary format
that Service Guide understands,
              // i.e. an array of elements containing "text", "offsetMs" and
"channel" properties

              const mappedAgentTranscript =
mapToOperationFormat(agentTranscript);
              const mappedCustomerTranscript =
mapToOperationFormat(customerTranscript);

              // Provide the transcript to Service Guide as part of
"transcriptReceived" operation
              serviceGuideSdk.Ui.transcriptReceived({
                   data: {
                       agentTranscripts: mappedAgentTranscript,
                       customerTranscripts: mappedCustomerTranscript
                   }
              });
              break;
         ...
    }
});

// You can also take modularized approach and define multiple "handlers" to
handle specific event

serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(),
```

Copyright © 2026, Oracle and/or its affiliates.

```
handleAgentStatusUpdate);
serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(),
handleTranscriptGeneration);
...

// and define individual handlers above as
const handleAgentStatusUpdate = async ({eventName, payload}) => {
    if (eventName === events.updateAgentStatus) {
        ... // update agent status and let Service Guide know.
    }
});

const handleTranscriptGeneration = async ({eventName, payload}) => {
    if (eventName === events.requestTranscript) {
        ... // Retrieve the transcripts and send them to Service Guide.
    }
});
```

Event: serviceGuideCti:agent:status:update

This table provides additional details about the serviceGuideCti:agent:status:update event:

Description	Payload	Parameter Description	Notes
This event is raised when an agent updates their status to Ready or Not Ready, indicating whether they are ready to receive another call. The Partner Application should call the appropriate CTI-specific API to mark the agent's presence as defined in the payload.	`{ data: { isAgentReady: boolean } }`	**isAgentReady:** Whether the agent is ready to receive calls.	The partner application should respond to this event by invoking "**agentStatusUpdated**" operation. This should be done after receiving a confirmation from the CTI backend that the update was successful, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:disconnect

This table provides additional details about the serviceGuideCti:call:disconnect event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent disconnects the call.	`{ data: { callId: string } }`	**callId:** A unique identifier representing the call session that needs to be disconnected.	The partner application should respond to this event by invoking "**endCallSession**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually disconnected, otherwise invoke it with an error payload.

Copyright © 2026, Oracle and/or its affiliates.

Event: serviceGuideCti:call:mute

This table provides additional details about the serviceGuideCti:call:mute event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent wants to mute their audio on the call.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be muted.	The partner application should respond to this event by invoking "**callMuted**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually muted, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:unmute

This table provides additional details about the serviceGuideCti:call:unmute event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent wants to reconnect their audio after it has been muted.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be un-muted.	The partner application should respond to this event by invoking "**callUnmuted**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually unmuted, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:hold

This table provides additional details about the serviceGuideCti:call:hold event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent places the customer on hold.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be placed on hold.	The Partner Application should respond to this event by invoking "**callOnHold**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually placed on hold, otherwise invoke it with an error payload.

Copyright © 2026, Oracle and/or its affiliates.

Event: serviceGuideCti:call:resume

This table provides additional details about the serviceGuideCti:call:resume event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent removes the hold placed on the call.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be resumed.	The partner application should respond to this event by invoking "**callResumed**" operation. This should be done after receiving a confirmation from the CTI backend that the call that was previously put on hold was actually resumed (hold was lifted), otherwise invoke it with an error payload.

Event: serviceGuideCti:request:transcript

This table provides additional details about the serviceGuideCti:request:transcript event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when an agent requests the call transcript.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be answered.	The Partner Application should respond to this event by invoking "**transcriptReceived**" operation. This should be done after collecting the relevant transcript from the CTI backend. If for some reason, the transcript cannot be collected, the partner application should invoke the operation with an error payload.

Event: serviceGuideCti:call:wrapUp

This table provides additional details about the serviceGuideCti:call:wrapUp event:

Copyright © 2026, Oracle and/or its affiliates.

Description	Payload	Parameter Description	Notes

After ending the call, when the agent finishes the after-call work and is ready to move to the next call, this event allows the partner application to capture any after-call work details (wrap up) in the CTI backend.
Depending upon the CTI Vendor, this might not be a mandatory operation. Utilities should handle this event after consulting the CTI Vendor documentation.
	{
	data: {
	callId: string,
	agentNotes: string,
	tags: array<string>
	}
	}
		callId: A unique identifier for the call for which the wrapup should be done.
		agentNotes: Any notes an agent might have collected during the call. This is included to capture any after-call notes (if the CTI Vendor makes it mandatory). This is optional and may or may not be present.
		tags: An array of strings representing the call topics that the agent wants to capture as part of wrap up. These are optional and may or may not be present.
			The partner application should respond to this event by invoking "**callWrappedUp**" operation. This should be done after receiving a confirmation from the CTI backend that the wrapup update was successful. If the update was not successful, the partner application should invoke the operation with an error payload.

Event: serviceGuideCti:agent:logout

This table provides additional details about the serviceGuideCti:agent:logout event:

Description	Payload	Parameter Description	Notes
This event is raised when an agent logs out of the Service Guide. The partner application may wish to perform cleanup as part of logout or it may wish to perform a logout of its own to end the authenticated session it may have established at the beginning. This event should be used to initiate that logout and cleanup process.	None	Not Applicable	The Partner Application should respond to this event by invoking "**loggedOut**" operation, only after necessary cleanup was done. Service Guide application will wait a certain amount of time to let the partner application finish the cleanup. The partner application must invoke the "**loggedOut**" operation within that time. If not done, Service Guide will assume that the cleanup was already done and will proceed to complete the logout process on the Service Guide side.

Configuring Characteristic Types and Customer Contact Types with Characteristic Tags

The tags generated by the Call Summary and Call Tagging functionality are based on characteristic types to which the "Characteristic Tag" characteristic entity has been assigned.

In order to apply tags (characteristic types) to customer contacts, the appropriate characteristic types must be created and configured on the appropriate customer contact types. This involves the following:

1. In the **Characteristic Type** portal, add the following **Characteristic Entities** to any characteristic types to be used as tags:
    - Customer Contact
    - Characteristic Tag
2. In the **Customer Contact Type** portal, add the appropriate characteristic types to each customer contact type.

For example, if your implementation includes a "General Inquiry" customer contact type as well as "Billing Inquiry", "Payments", and "Rates" tags (characteristic types), you would do the following:

1. Created "Billing Inquiry", "Payments", and "Rates" characteristic types. The Value Type for tag characteristic values must be "Adhoc Value"
2. Add the "Customer Contact" and "Characteristic Tag" characteristic entities to each characteristic type created in step 1.
3. Create a "General Inquiry" customer contact type.
4. Add the "Billing Inquiry", "Payments", and "Rates" characteristic types to to the "General Inquiry" customer contact type.

See Characteristic Types, Setting Up Customer Contact Types, and Customer Contact Tags for more information.

Enabling the Service Guide Zone

To enable access to the **Service Guide** zone, add the Service Guide Zone (C1-SVCGUIDE) application service to the appropriate user groups.

Analytics Integration Overview

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with Oracle Utilities Analytics. Oracle Utilities Customer Care and Billing provides support for defining data load parameters, bucket configurations and characteristic mapping.

- Analytics Configuration

Analytics Configuration

This section describes functionality provided for integrating with Oracle Utilities Analytics (OUA).

Copyright © 2026, Oracle and/or its affiliates.

- **Customer Analytics Configuration Portal**

  Oracle Utilities Customer Care and Billing provides an Analytics Configuration portal that holds information on all the analytics-oriented configuration activities. This portal provides a summary of how much configuration has been set up, and also provides links and guidelines for the areas that need configuration, at the minimum, to successfully extract data from Oracle Utilities Customer Care and Billing to OUA. The following provides more information about this functionality.

  1. **Analytics-Oriented Master Configuration Details** – These data load parameters are used to extract, load, and transform data from Oracle Utilities Customer Care and Billing to Oracle Utilities Analytics. These parameters are used to identify and/or filter data when loading them into the data warehouse. Refer to the *Oracle Utilities Customer Care and Billing* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each extract parameter.
  2. **Bucket Configuration List** – This is a summary of the bucket configurations that are needed to classify and group extracted data within Oracle Utilities Analytics. The bucket configurations provide the ability to readily report and analyze data by buckets, or groups. Refer to the *Oracle Utilities Customer Care and Billing* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each bucket configuration supported by Oracle Utilities Customer Care and Billing.

- **Characteristic Mapping**

  Oracle Utilities Customer Care and Billing has identified the objects for which characteristic extraction is supported. This includes mapping the source characteristic entity to thetarget dimension, and defining which target columns are allowed to be mapped for which target dimension. The following table shows the supported mapping.

Object	Supported Target Dimension	Supported Target Columns
Account Characteristic	Account Dimension	User Defined Fields 6 - 15
Person Characteristic	Person Dimension	User Defined Fields 1 - 6
Premise Characteristic	Premise Dimension	User Defined Fields 6 - 18
Premise Characteristic	Address Dimension	User Defined Fields 7 - 16
Service Agreement Characteristic	Service Agreement Dimension	User Defined Fields 9 - 19

Self-Service Integration

The following sections describe functionality provided for the integration with self-service applications such as Oracle Utilities Customer Self Service and Oracle Utilities Digital Self Service.

- Creating Self-Service Tasks
- Setting Up Self-Service Task Configuration
- Maintaining Self-Service Tasks
- Self-Service Start/Stop/Transfer Overview
- Self-Service Start/Stop/Transfer Operations

Copyright © 2026, Oracle and/or its affiliates.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

> **Note**
>
> For products that are continuing to use XAI for external messages, the product also includes XAI inbound services for most of the supported self-service task types. Note that the product recommendation is to discontinue use of XAI and use inbound web services instead.

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

- Self-Service Task Type Defines Self-Service Task Behavior
- Creating Self-Service Tasks

Self-Service Task Type Defines Self-Service Task Behavior

Each type of self-service operation has specific processing requirements.

Self-service task type controls how a self-service task is processed. It defines the business object to use when creating the self-service task record. The business object defines the lifecycle of self-service task record.

The self-service task type can also specify common configuration data, such as settings for error handling.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

> **Note**
>
> For products that are continuing to use XAI for external messages, the product also includes XAI inbound services for most of the supported self-service task types. Note that the product recommendation is to discontinue use of XAI and use inbound web services instead.

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

- Self-Service Task Type Defines Self-Service Task Behavior

Copyright © 2026, Oracle and/or its affiliates.

- Creating Self-Service Tasks

Setting Up Self-Service Task Configuration

The following topics highlight the general configuration steps required to use self-service task functionality and to integrate with a self-service application such as Oracle Utilities Customer Self-Service (OUCSS).

- Self-Service Integration Configuration
- Defining Self-Service Task Types

Self-Service Integration Configuration

The integration with a self-service application such as Oracle Utilities Customer Self Service and Oracle Utilities Digital Self Service requires the setup of master configuration data that controls the processing of your self-service operations.

To set up self-service integration master configuration, select **Admin**, **General**, **Master Configuration**. You are brought to an all-in-one portal with options to add/edit the master configuration records. Add/edit the following master configuration:

- **•CCB Self Service Integration**: This master configuration is used for the integration of customer data with a self service application.

Refer to the embedded help for more details on how each section in this record is configured.

Defining Self-Service Task Types

A self-service task type defines properties that control how a self-service task is processed.

Refer to About Self-Service Tasks for an overview of service task functionality.

To maintain the types applicable to your product, open **Menu**, and then **Self-Service**, and then **Self-Service Task Type.**

This is a standard All-in-One portal.

The information captured on the self-service task type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Self-Service Tasks

This section describes the functionality supported for viewing and maintaining self-service tasks.

Refer to About Self-Service Tasks for an overview of self-service task functionality.

Navigate using **Menu**, and then **Self-Service**, and then **Self-Service Task**, and then **Search**. You are brought to a query portal with options for searching for self-service tasks.

Once a self-service task record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Self-Service Task** zone provides basic information about a self-service task. Refer to the embedded help for more information.

Copyright © 2026, Oracle and/or its affiliates.

Self-Service Start/Stop/Transfer Overview

> **Warning**
>
> This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

The Start Stop Transfer Tasks (C1-StartStopTransferTasks) inbound web service is used by the self-service application to support the following start/stop/transfer transactions:

- New Service
- Add Service
- Stop Service
- Transfer Service

Distinct action method roles represent each type of transaction:

- Self-Service New Service
- Self-Service Add Service
- Self-Service Stop Service
- Self-Service Transfer Service

At the beginning of the start/stop/transfer process, the action method role is used to identify the type of transaction. It is determined using the Request Mode (Start/Stop/Transfer), the New Customer indicator (Yes/No) and the New Account indicator (Yes/No):

- If Request Mode is 'Start', the Action Method Role is 'Self-Service New Service' if either the New Customer or the New Account indicator is 'Yes'. If both New Customer and New Account indicators are 'No', Action Method Role is 'Self-Service Add Service'.
- If Request Mode is 'Stop', the Action Method Role is 'Self-Service Stop Service'
- If Request Mode is 'Transfer' , the Action Method Role is 'Self-Service Transfer Service'.

Configuration information are maintained using Self-Service Task Type and Customer Service Type. Self-Service Task Type defines the self-service task BO to be used. Customer Service Request Type defines the customer service request BOs used to persist data, and the controls used throughout the transaction. Refer to the "Enhanced Start, Stop, and Transfer Service Configuration Options" section of the digital self-service user guide for more about the controls.

At the beginning of the transaction, configuration information are determined and a self-service start/stop/transfer task is created. The same service task is used for the entire transaction. The service task is used to store the information received from the self-service application and operation processing results. It will remain in Pending status until the transaction is finalized. When the transaction is finalized, the service task is transitioned out of the Pending status and the collected information are persisted.

The following is the expected sequence of IWS operation calls per type of transaction:

New Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details - operation is called if customer exists (Person ID is available).

Copyright © 2026, Oracle and/or its affiliates.

3. Service Eligibility
4. Process Other Person
5. Clear Other Person
6. Determine Services To Start
7. Validate Start SP Selection
8. Service Questions
9. Process Services To Start
10. Deposit Assessment
11. Start Service Finalization

Add Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details
3. Service Eligibility
4. Determine Services To Start
5. Validate Start SP Selection
6. Service Questions
7. Process Services To Start
8. Deposit Assessment
9. Start Service Finalization

Stop Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details
3. Determine Services To Stop
4. Retrieve Services To Stop
5. Validate Stop Service Agreement Selection
6. Service Questions
7. C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations.dita#C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations
8. Stop Service Finalization

Transfer Service

1. Retrieve RC1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations.dita#C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operationsequest Type Details
2. Retrieve Service-Related Customer Details
3. Service Eligibility
4. Determine Services To Start
5. Validate Start SP Selection
6. Service Questions - operation is called with Question Placement Group is 'Start Service'

7. Process Services To Start
8. Deposit Assessment
9. Determine Services To Stop
10. Retrieve Services To Stop
11. Validate Stop Service Agreement Selection
12. Service Questions - operation is called with Question Placement Group is 'Stop Service'
13. Process Services To Stop
14. Transfer Service Finalization

Self-Service Start/Stop/Transfer Operations

> **Warning**
>
> This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

Retrieve Request Type Details

This operation is used to retrieve the following configuration information at the beginning of the start, stop and transfer transaction:

- Action Method Role
- Action Method
- Self-Service Task Type
- Customer Service Request Type
- Person/Business Controls
- Start Service Controls
- Stop Service Controls

Action Method Role is determined based on the Request Mode, New Customer indicator and New Account indicator inputs. The Action Method Role is used to determine the Action Method. The Action Method defines the Self-Service Task Type and Customer Service Request Type configuration. Note that the Self-Service Task Type and Customer Service Request Type can differ by CIS Division and/or Customer Class. The Self-Service Task Type defines the self-service task BO to be used. The Customer Service Request Type defines the customer service request BOs used to persist data, and the controls used throughout the transaction. Controls determine the behavior of the self-service application UI, operations, and service task processing. Succeeding operations expect the Self-Service Task Type and Customer Service Request Type as inputs.

Person/Business Controls are based on the input person/business flag. Start Service Controls are returned if the input Request Mode is either 'Start' or 'Transfer'. Stop Service Controls are returned if the input Request Mode is either 'Stop' or 'Transfer'.

Time Zone is returned as part of the Start Service and Stop Service Controls. It comes from one of the following sources:

1. Customer Service Request Type

Copyright © 2026, Oracle and/or its affiliates.

2. Premise - Input premise if available. Otherwise, premise linked to the input account's most recent service.
3. Installation Options

Retrieve Service-Related Customer Details

This operation is used to retrieve the following service-related information for the input account and/or person:

- Name
- Mailing Address
- Contact Details

If the input account is populated, the input person is either the account owner (main customer) or a guest who was invited by the owner. Name, Mailing Address and Contact Details are based on the account's main customer. If input account is not populated, Name, Mailing Address and Contact Details are based on the input person. Phone and email contact information are always returned. Other contact types are returned based on the corresponding control.

This operation also uses the Should Prompt For ID controls to determine if ID should be prompted for the input account and/or person. If the input account is populated, the account's main customer is used. Otherwise, the input person is used. If ID should be prompted, the valid ID Types controls are returned for input person.

Finally, this operation indicates if a non-final self-service start/stop/transfer task exists for the input account.

Service Eligibility

This operation determines if a customer is eligible to start service. It is used when starting new service, adding service, or transferring service. If the customer is eligible, a new self-service start/stop/transfer task is created where the input customer information and the results of processing performed throughout the transaction are persisted. The service task will remain in Pending status until it is transitioned by the finalize operation. Abandoned service tasks are discarded automatically via a monitor algorithm on the Pending status. The service task ID is returned as well as the customer's eligible and ineligible accounts.

The Retrieve Request Type Details operation that determines configuration information should be called before this operation can be used.

When starting new service for new customer (input person is not populated), the Check For Existing Person Algorithm control is used to determine if an existing person in the system matches the input name, ID, and contact information. If a match is found, the operation returns a match indicator, and no further processing is performed.

When starting new service or adding new service, person identity checks may be performed based on the ID check controls. The Should Prompt For ID controls are used to determine if ID should be prompted for the input person. This is the same step performed in the Retrieve Service-Related Customer Details operation and both should have the same result. It is necessary to do this step in this operation because the result from the Retrieve Service-Related Customer Details operation is not persisted.

The Start Service Eligibility Algorithms control determines eligibility. It uses the input information to this operation, the ID check results, and the ID prompt result. This control also determines the customer's eligible and ineligible accounts.

Copyright © 2026, Oracle and/or its affiliates.

Process Other Person

This operation process additional persons when starting new service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. Eligible persons are persisted on the service task. Ineligible persons may be persisted based on the service task based on the Other Person Eligibility controls. Each person's eligibility is returned as output. Note that any additional persons that are currently in the self-service start/stop/transfer task are replaced with the input when this operation is called.

The Search For Person Algorithm control is used to find an existing person in the system that matches the input name, ID, and contact information. The search result (Match / No Match / Ambiguous Match) is returned as output. If the search resulted in an ambiguous match, the person is skipped. Person identity checks may be performed based on the ID check controls.

For new a new person, eligibility is based on ID check results. Note that if ID check is not performed, the person is considered eligible. Only eligible new persons are persisted on the service task. The Other Person Eligibility control determine the eligibility of an existing person. It is either based on ID check or a set of utility-specific eligibility algorithms. Eligibility based on ID check is evaluated the same way as a new person. Existing persons that are eligible are persisted on the service task. Existing persons that are ineligible are persisted on the service task if the Other Person Processing control is set to 'Review'.

Clear Other Person

This operation removes any additional persons that are currently in the pending self-service start/stop/transfer task.

Determine Services To Start

This operation determines the SP-based services to start at premise when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the Determine Services To Start Algorithm control to get a list of SA to start for SPs at the premise for the input start date. This information is stored in the service task's start service details. Note that SA and SP information currently in the service task are replaced when this operation is called. The operation returns the determined SPs along with badge number of the meter currently installed on the SP.

Note that the start date must be within the range defined by the start service controls. The range is calculated as follows:

- Start Date Low Limit = Current Date + Lead Days
- Start Date High Limit = Start Date Low Limit + Maximum Start Days in Future control

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Also, weekends and holidays based on the Work Calendar control are skipped when incrementing the Start Date Low Limit.

Validate Start SP Selection

This operation uses the Validate SPs To Start Algorithms controls to validate the selected SPs where service is being started if Start Level control is 'Individual Services'. It is used when starting new service, adding service, or transferring service. The SP-based services to start at the premise should be determined before this operation can be used.

Copyright © 2026, Oracle and/or its affiliates.

Service Questions

This operation uses the Read Questions algorithm on the CS request type BO to retrieve the applicable service questions when starting new service, adding service, stopping service, or transferring service. The SP-based services to start at a premise and/or the SP-based services to stop for an account should be determined, and a pending self-service start/stop/transfer task already exist before this operation can be used.

Note that when transferring service, this operation is called for two scenarios - start service and stop service. The operation uses the input Question Placement Group to distinguish between these calls. Question Placement Group is used to logically group questions, based on where the questions are shown on the user interface.

- If Question Placement Group is 'Start Service', the questions are filtered using the input premise and SPs.
- If Question Placement Group is 'Stop Service', the questions are filtered using the input premise only. Any further filtering (e.g. SP Type) will be done by the calling system using the applicability list that is returned for each question.

When invoking the algorithm, the input account and SPs are used. If the input Question Placement Group is 'Stop Service' and Stop Level control is 'Account', all premises in the service task's stop details are used. Otherwise, the input premises are used.

Process Services To Start

This operation marks which of the SPs and SP-based SAs previously determined by the Determine Services To Start operation will be started based on the input premise or SPs when starting new service, adding service, or transferring service. If Start Level control is 'Premise' all SPs and SAs are marked. If Start Level control is 'Individual Services' only the input SPs and its SAs are marked.

This operation also process response to start service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for start, set an SA's start option, or add non SP-based SAs to the services being started.

All services being started are validated using Validate Service To Start Algorithms control.

Deposit Assessment

This operation determines the deposit requirements when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the deposit controls and the customer information in the service task to determine if deposit is required. If deposit is required, the deposit amount is calculated using the Recommendation Algorithm associated with the Deposit SA Type control's deposit class. The deposit required indicator and deposit amount are persisted on the service task and returned as output. The Allow Pay In Full control is also returned as output.

If the deposit is required, the operation returns deposit installation options collection. Each entry has two attributes:

- Number of Installments
- Installment Amount

Number of Installments is based on the Number of Installments control. The corresponding Installment Amount is the deposit amount divided by the Number of Installments. Note that Installment Amount must be greater than or equal to the Minimum Installment Amount control

Copyright © 2026, Oracle and/or its affiliates.

an option to be included in the collection. If Allow Pay In Full control is 'true', the following entry is included in the collection:

- Number of Installments = 1
- Installment Amount = Deposit Amount

The operation will fail if deposit is required and not one deposit installation option can be determined.

Start Service Finalization

This is the final operation called when starting new service or adding service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP). Refer to the self-service task BO (C1-SSStartStopXferServiceTask) for more information.

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Determine Services To Stop

This operation uses the Determine Services To Stop Algorithm control to determine the SP-based services to stop for an account at a given stop date when stopping service or transferring service. It returns number of premises that have stoppable services.

This operation can be called read-only mode. This mode is used by the self-service application to determine if stop service is available as an option to the user. When not in read-only mode, a self-service start/stop/transfer task containing the determined SP-based services is created if one doesn't exist (initial call when stopping service). The service task will remain in Pending status until it is transitioned by the finalize operation. The ID of the newly created service task is returned as output. If service task already exists (transferring service or stop date is changed when stopping service), the service task ID is passed to this operation and its stop details are replaced with the determined SP-based services.

Note that the stop date must be within the range defined by the stop service controls. The range is calculated as follows:

- Stop Date Low Limit = Current Date + Lead Days
- Stop Date High Limit = Stop Date Low Limit + Maximum Stop Days in Future control

Copyright © 2026, Oracle and/or its affiliates.

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Note that weekends and holidays based on the Work Calendar control are skipped when incrementing the Stop Date Low Limit.

Retrieve Services To Stop

This operation retrieves the premises with stoppable service that were previously determined and persisted on the self-service start/stop/transfer task. A list of SAs is returned for each premise. Each entry has two attributes:

- Service Type
- Badge Number of the meters currently installed on the SPs associated with the SA

Pagination is applied to the returned premise list using the page offset and page limit input parameters.

Validate Stop Service Agreement Selection

This operation uses the Stop Level, Require SAs At Same SP To Behave Together, and Validate Services To Stop Algorithm controls to validate the selected SP-based services to stop. It is used when stopping service or transferring service. The SP-based services to stop for the account should be determined before this operation can be used.

Process Services To Stop

This operation marks which of the premises and SP-based SAs previously determined by the Determine Services To Stop operation will be stopped based on the input premises and SAs when stopping service or transferring service. If Stop Level control is 'Account' all premises and SAs are marked. If Stop Level control is 'Premise', all SAs for the selected premises are marked. If Stop Level control is 'SA', only the selected SAs are marked.

This operation also process response to stop service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for stop or add non SP-based SAs to the services being stopped.

All services being stopped are validated using the Validate Services To Stop Algorithms control.

Stop Service Finalization

This is the final operation called when stopping or transferring service. It is used to update the self-service start/stop/transfer task with any additional contact information for the main customer and to transition it out of the pending status.

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages.

Copyright © 2026, Oracle and/or its affiliates.

Transfer Service Finalization

This is the final operation called when transferring service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Defining DataConnect Options

Oracle Utilities DataConnect facilitates data extraction from Oracle Utilities applications such as Oracle Utilities Customer to Meter and Oracle Utilities Customer Care and Billing for use in external applications; such as, analytics applications and energy management systems.

This section describes how Oracle Utilities DataConnect works and how to implement and configure the system to support data extract processing.

> **Note**
>
> There are two versions of DataConnect. The initial version is referred to as “Legacy DataConnect”. The current and recommended version is simply referred to as “DataConnect” or “Current DataConnect”. Implementations are recommended to use the current version. “Legacy DataConnect” remains available for implementations that used the initial version, but is not recommended for new implementations.

- DataConnect Data Extracts
- Customer and Premise Data Extracts
- Characteristic Data Extracts
- Billing Data Extracts
- Extract Flat File Formats
- File Naming Formats

Copyright © 2026, Oracle and/or its affiliates.

DataConnect Data Extracts

Oracle Utilities DataConnect can be used to extract two types of data:

- **Master Data**

  (see Customer and Premise Data Extracts for more information)

  - Service agreement, account, and person related information
  - Service point and premise related information
  - Service point / meter history related information
- **Billing Data**

  (see Billing Data Extracts for more information)

The extraction processes used for each type of data can be run to produce separate extracts or combined into one.

If individual flat files are preferred, the data can be correlated in external systems through service agreement and/or service point data that is included in each type of extract. All data extracts contain the following data elements that can be used for this correlation:

- **Service Point ID**: The service point ID in Oracle Utilities Customer Care and Billing and/or
- **Service Agreement ID:** The service agreement ID in Oracle Utilities Customer Care and Billing

External systems receiving data extracted from the Oracle Utilities DataConnect facilities can use these IDs to associate billing data to extracted master data.

If a single flat file is preferred, meaning an extract that contains billing data and master data in one export file, the Billing Data extraction process can be configured to retrieve the associated master data of the bills and place the information in the same row as the billing data.

> **Note**
>
> There is a version 1 and version 1+ for the DataConnect extracts. In the following pages where a system object such as a batch control or data area is noted the objects are listed as (v1/v1+). When only a single object is noted it applies to both v1 and v1+.

Customer and Premise Data Extracts

Customer and premises data extracts are performed through the use of data synchronization, audit algorithms, business objects, and related batch processes.

Batch processes are used to create initial load extracts for service point/premise and meter master data, and service agreement / account / person related master data. The initial load includes the historical data in the system (either all or a subset, depending on how the batch process is configured). Following the initial load, data synchronization requests are created when master data is added or changed.

- Customer and Premise Data Extracts: Maintenance Object Audit Algorithms
- Master Data Extracts: Business Objects and Algorithms

- Setting Up and Executing Master Data Extracts

Customer and Premise Data Extracts: Maintenance Object Audit Algorithms

Detecting changes in customer and premise data can be identified by audit algorithms on the following maintenance objects:

- Service Agreement
- Account
- Person
- Service Point
- Premise
- SP/Meter History
- Meter

The Generic Change Data Capture algorithm type (F1-GCHG-CDCP), which is provided in the base package, can be used to create audit algorithms for following maintenance objects:

- Service Agreement
- Service Point
- SP/Meter History

In addition, the following audit algorithm types can be used to create audit algorithms for customer and premise data:

- Account Change Data Capture (Customer Data Extract) (C1-ACCECDCCU)
- Person Change Data Capture (Customer Data Extract) (C1-PERECDCCU)
- Account Mailing Address Change Data Capture (C1ACCMACDC)

The following algorithm types are used with v1 ONLY.

- An **Account Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Account maintenance object to determine if a service agreement sync request record is to be created for each of the account's non-closed, non-canceled service agreement(s). A change in a related account's details will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-ACCECDCSA) that is based on this algorithm type.
- A **Person Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Person maintenance object to determine if a service agreement sync request record is to be created for each of the person's non-closed, non-canceled service agreement(s). A change in the main person details linked to the service agreement's account will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-PERECDCSA) that is based on this algorithm type.
- A **Premise Change Data Capture (SP-Based)** algorithm type (C1-PREMCDCSP) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Premise maintenance object to determine if a service point sync request record is to

Copyright © 2026, Oracle and/or its affiliates.

be created for each of the premise's service point. A change in the premise details will instantiate a Service Point Extract Sync Request (of the type defined for the SP Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service point. The base package also contains an algorithm (C1-PREECDCSP) that is based on this algorithm type.

- A **Meter Change Data Capture (SP/Meter History-Based)** algorithm type (C1-MTRCDCSPH) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Meter maintenance object to determine if a SP / Meter History sync request record is to be created for the meter's current installation. A change in the meter details will instantiate a SP / Meter History Extract Sync Request (of the type defined for the SP/Meter History Sync BO algorithm parameter) if one does not already exist in the initial state for the current meter installation. The base package also contains an algorithm (C1-MTRCDCSPH) that is based on this algorithm type.

Master Data Extracts: Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests in the following manner:

- If the Generic Change Data Capture (F1-GCHG-CDCP) algorithm type (provided in the base package) is used, the synchronization requests are based on the Sync Request BO maintenance object options.
- Alternatively, if the base package supplied Maintenance Object – Audit algorithm types, which are outlined in the Customer and Premise Data Extracts: Maintenance Object Audit Algorithms section are used, the synchronization requests are based on the Sync Request BO defined in the algorithm parameters.

Extraction of service agreements, service points and SP/Meter History related information are supported by the following data synchronization business objects.

- **SA/Account/Person Sync for DataConnect (C1-ExternalRepoSASync/C1-ExternalRepoPlusCusDataSync):** used to extract service agreement / account / person related information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object.
- **SP/Premise Sync for DataConnect (C1-ExternalRepoSPSync/C1-ExternalRepoPlusSPMeterSync):** used to extract service point/premise related information. This business object should be defined as a value for the Sync Request BO option on the Service Point maintenance object.
- **SP/Meter History Sync for DataConnect (C1-ExternalRepoSPMtrHistSync/C1-ExternalRepoPlusSPMeterSync):** used to extract SP/meter history related information. This business object should be defined as a value for the Sync Request BO option on the SP/meter history maintenance object.

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture SA-Based Initial Snapshot for DataConnect (C1-CEXTRCSAI/C1-CEXTRCSAD)
- Capture SP-Based Initial Snapshot for DataConnect (C1-CEXTRCSPI/C1-CEXTRSPMI)
- Capture SP/Meter History Initial Snapshot for DataConnect (C1-CEXTRCSHI/C1-CEXTRSPMI)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Copyright © 2026, Oracle and/or its affiliates.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture SA-Based Final Snapshot for DataConnect (C1-CEXTRCSAF/C1-CEXTRPSAF)
- Capture SP-Based Final Snapshot for DataConnect (C1-CEXTRCSPF/C1-CEXTRSPMF)
- Capture SP/Meter History Final Snapshot for DataConnect (C1-CEXTRCSHF/C1-CEXTRSPMF)

The Prepare Delimited Extract Data (Ignore Custom Sync Records) Enter algorithm (C1-PRPEXDNCU/C1-PRTBDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Customer and Premise Data Extracts: Batch Controls

Customer Data

The customer data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
  - **Customer Data Initial Load for DataConnect (C1-CDTIL):** This batch control creates initial synchronization requests for account data (service agreements/accounts/persons) and SA's SP data (SA/SP). The appropriate sync business objects for the two extracts should be plugged in as parameters to the batch job.
  - **Mail Address Initial Load DataConnect (C1-MADIL):** This batch control creates initial synchronization requests for accounts.
- Legacy DataConnect
  - **SA-Based Initial Load for Legacy DataConnect (C1-SAEIL):** This batch control creates initial synchronization requests for service agreements / accounts / persons.
  - **SP Initial Load for Legacy DataConnect (D1-SPEIL):** This batch control creates initial synchronization requests for service points.

The following batch processes are used to create extract files from synchronization requests.

> **Note**
>
> These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- Current DataConnect
  - **Customer Data Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
  - **SA/SP Data Extract for DataConnect (C1-SSDTX)**
  - **Mailing Address Extract DataConnect (C1-MADTX):** This batch control creates extract file(s) that contain mailing address information.

Copyright © 2026, Oracle and/or its affiliates.

- **SA-Based Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.

- Legacy DataConnect
  - **SP Extract for Legacy DataConnect (D1-SPESR):** This batch control creates extract file(s) that contain service point information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Premise Data

The premise data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
  - **SP/Meter Initial Load for DataConnect (D1-SPMIL)**: This batch control creates initial synchronization requests for service points, device configurations, and devices.
- Legacy DataConnect
  - **Install Event Initial Load for Legacy DataConnect (D1-IEEIL):** This batch control creates initial synchronization requests for install events.

The following batch processes are used to create extract files from synchronization requests.

> ⓘ **Note**
>
> These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- Current DataConnect
  - **SP/Meter Extract for DataConnect (D1-SPMSR)**: This batch control creates extract file(s) that contain service point, device configuration, and device information.
- Legacy DataConnect
  - **Install Event Extract for Legacy DataConnect (D1-IEESR):** This batch control creates extract file(s) that contain install event information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Master Data Extracts

Copyright © 2026, Oracle and/or its affiliates.

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Service Agreement, Account, Person, Service Point, Premise, SP/Meter History and Meter maintenance objects.
    a. Add the Generic Change Data Capture algorithm as an audit algorithm on the Service Agreement, Service Point, and SP/Meter History maintenance objects.
    b. Add the Account Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Account maintenance object.
    c. Add the Person Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Person maintenance object.
    d. Add the Premise Change Data Capture (SA-Based) algorithm as an audit algorithm on the Premise maintenance object.
    e. Add the Meter Change Data Capture (SP/Meter History-Based) algorithm as an audit algorithm on the Meter maintenance object.
2. Add the DataConnect synchronization request business objects as Sync Request BO options on the Service Agreement, Service Point and SP/Meter History maintenance objects.
3. Execute initial load batch processes related to service agreements and service points.
4. Once the initial load synchronization has been executed, changes to service agreements, accounts, persons, service points, premises, SP/Meter History records or meters will trigger the creation of new synchronization requests and resulting extraction files.
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to service agreements and service points.

Characteristic Data Extracts

Characteristic data extracts are performed through the use of audit algorithms, data synchronization business objects, and related batch processes.

Batch processes are used to create initial load extracts for Account, Person, Premise, Service Agreement, and Service Point characteristic data. The initial load includes the historical data in the system (either all or a subset, depending on how the batch process is configured). Following the initial load, data synchronization requests are created when characteristic data is added or changed.

Maintenance Object Audit Algorithms

Detecting changes in characteristic data can be identified by the Characteristic Change Data Capture (C1MOCHARCDC) audit algorithm on the following maintenance objects:

- Account
- Person
- Premise
- Service Agreement
- Service Point - CCB
- Service Point- MDM

Detecting changes in characteristic type data can be identified by the Characteristic Type Change Data Capture (C1CHARTYPCDC) audit algorithm on the Characteristic Type (CHAR TYPE) maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests based on the Sync Request BO defined in the audit algorithm parameters:

Audit Algorithm	Data Synchronization Request Business Object
Characteristic Change Data Capture (C1MOCHARCDC)	Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync)
Characteristic Type Change Data Capture (C1CHARTYPCDC)	Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync)

Extraction of characteristic data, including account, person, premise, service agreement, and service point information, is supported by the following data synchronization business objects.

- **Characteristic Data Sync for DataConnect** (C1-ExternalRepoPlusCharDatSync): used to extract characteristics data for accounts, persons, premises, service agreements, and service points. The specific maintenance objects for which characteristics data is extracted is defined in the Characteristic Entities Included in DataConnect Extract (C1-DataConnectIncludedCharEnty) extendable lookup. This lookup maps characteristic entities and maintenance objects to mappings business objects that define the characteristic data to be extracted.
- **Characteristic Type Sync for DataConnect** (C1-ExternalRepoPlusCharTypSync): used to extract data for characteristic types.

The Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync) business object uses the following Enter algorithm on the Pending state to take initial data snapshots:

- Capture Characteristic Data's Initial Snapshot (C1CAPMOCHARI)

The Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business object uses the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture Characteristic Type Data's Initial Snapshot (C1CAPCHTYI)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture Characteristic Data's Final Snapshot (C1CAPMOCHARF)
- Capture Characteristic Type Data's Final Snapshot (C1CAPCHTYF)

The Prepare Tab-delimited Extract Data (C1-PRTBDEXDT) algorithm on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Batch Controls

The characteristic data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

Copyright © 2026, Oracle and/or its affiliates.

- Account Characteristic Data Initial Load for DataConnect (C1-CHACI): This batch process creates initial sync request records for Account Characteristics.
- Person Characteristic Data Initial Load for DataConnect (C1-CHPEI): This batch process creates initial sync request records for Person Characteristics.
- Premise Characteristic Data Initial Load for DataConnect (C1-CHPRI): This batch process creates initial sync request records for Premise Characteristics.
- SA Characteristic Data Initial Load for DataConnect (C1-CHSAI): This batch process creates initial sync request records for Service Agreement Characteristics.
- SP - CCB Characteristic Data Initial Load for DataConnect (C1-CHSPI): This batch process creates initial sync request records for SP - CCB Characteristics.
- SP - MDM Characteristic Data Initial Load for DataConnect (X1-CHSPI): This batch process creates initial sync request records for SP - MDM Characteristics.
- Characteristic Type Data Initial Load for DataConnect (C1-CHTIL): This batch process creates initial Characteristic Type Data sync request records for the specified CHAR TYPE maintenance object

The following batch processes are used to create extract files from synchronization requests:

- Account Characteristic Data Extract for DataConnect (C1-ACCHX): This batch process creates Account flat file(s).
- Person Characteristic Data Extract for DataConnect (C1-PECHX): This batch process creates Person flat file(s).
- Premise Characteristic Data Extract for DataConnect (C1-PRCHX): This batch process creates Premise flat file(s).
- SA Characteristic Data Extract for DataConnect (C1-SACHX): This batch process creates service agreement flat file(s).
- SP - CCB Characteristic Data Extract for DataConnect (C1-SPCHX): This batch process creates CCB service point flat file(s).
- SP - MDM Characteristic Data Extract for DataConnect (X1-SPCHX): This batch process creates MDM service point flat file(s).
- Characteristic Type Data Extract for DataConnect (C1-CHTYX): This batch process creates characteristic type flat file(s). This batch control is defined as values for the Batch Process for Extract algorithm parameter on the Pre-Processing algorithm on the Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Characteristic Data Extracts

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Account, Characteristic Type, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    a. Add the Characteristic Change Data Capture (C1MOCHARCDC) algorithm as an audit algorithm on the Account, Characteristic Type, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    b. Add the Characteristic Type Change Data Capture (C1CHARTYPCDC) algorithm as an audit algorithm on the Characteristic Type maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

2. Add Sync Request BO options on the Account, Person, Characteristic Type, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects
    a. Add the Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync) business object as Sync Request BO options on the Account, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    b. Add the Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business object as a Sync Request BO option on the Characteristic Type maintenance object.
3. Execute initial load batch processes related to accounts, persons, premises, service agreements, and service points.
4. Once the initial load synchronization has been executed, changes to accounts, characteristic types, persons, premises, service agreements, and service points will trigger the creation of new synchronization requests and resulting extraction files.
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to accounts, characteristic types, persons, premises, service agreements, and service points.

Billing Data Extracts

When sending billing related data to an external system, both historical and current data needs to be extracted.

Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data includes data history for all bill segments for a specified historical period that are:

- Linked to completed bills.
- Not linked to bills but are linked to frozen FTs that are linked to completed bills.

Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any billing corrections should be extracted as well.

Extraction of billing data is performed through use of data synchronization, post bill completion algorithms, business objects and related batch processes.

- Billing Data Extracts: Business Objects and Algorithms
- Billing Data Extracts: Batch Controls
- Setting Up and Executing Billing Data Extracts
- Billing Data DataConnect Master Configurations

Billing Data Extracts: Business Objects and Algorithms

Billing generates synchronization requests when bills complete through a Customer Class – Post Bill Completion algorithm. The Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type provided in the base package can be used to create a Customer Class – Post Bill Completion algorithm that creates a billing synchronization request record for each of the bill's bill segments if one does not exist in the initial state.

Billing related information extracts are supported by the following data synchronization business objects.

Copyright © 2026, Oracle and/or its affiliates.

- Current DataConnect
  - Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)
  - Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)
- **Legacy DataConnect**
  - Billing Sync for Legacy DataConnect (Tab-delimted) (C1-ExternalRepoPlusBillingSync)
  - Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)

These business objects should be defined as an algorithm parameter on the algorithm based on the Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type. These business object use the following Pre-Processing algorithms to take an initial data snapshot, and define the batch control used to extract data and export to a flat file. However, since billing data are always synched when it gets completed, no actual initial snapshot is taken. Instead, the parameters used for building the snapshots are taken and stored on the sync request record for later use when building the final snapshot.

Current DataConnect

Business Object	Pre-Processing Algorithm
Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)	Capture Bill Data Initial Snapshot (C1EXTCBILLI)
Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)	Capture Bill Segment Data Initial Snapshot (C1EXTRCBSI)

Legacy DataConnect

Business Object	Pre-Processing Algorithm
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Capture Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP)
Billing Sync for Legacy DataConnect (Tab-delimited) (C1-ExternalRepoPlusBillingSync)	Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states extract a final snapshot of the data if the billing related data is to be extracted and exported. These include:

- Algorithms that check if there is a need to export the billing data. It will discard the synchronization request if one of the following is true:
  - The synchronization request is for a cancelled bill segment whose original usage has not been previously sent out.
  - The synchronization request has been marked for non-synchronization (such as, the bill segments related SA Type is not configured to be extracted on the Billing Data Configuration for DataConnect master configuration record).

Copyright © 2026, Oracle and/or its affiliates.

Business Object	Algorithm
Billing Sync for Legacy DataConnect (Tab—delimted) (C1-ExternalRepoPlusBillingSync)	Determine if the Billing Sync is Needed (C1-DSCANUSNS)
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Determine if the Billing Sync is Needed (C1-DSCANUSNS)

- Algorithms that capture the billing data information and stores it on the synchronization request.

  Current DataConnect

Business Object	Algorithm
Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)	Capture Bill Data Final Snapshot (C1EXTCBILLF)
Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)	Capture Bill Segment Data Final Snapshot (C1EXTRCBSF)

  Legacy DataConnect

Business Object	Algorithm
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN)
Billing Sync for Legacy DataConnect (Tab-delimted) (C1-ExternalRepoPlusBillingSync)	Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN)

When using Legacy DataConnect, if a single extract file that combines both the billing and master data (customer and premise) information is preferred, the following algorithms can be used to capture the master data information of the bill. These algorithms should be plugged in on the Determine if Sync Needed state after the Capture Billing Data Final Snapshot for DataConnect algorithm.

- Capture Billing's SA Final Snapshot for DataConnect (C1-CEXTRCSA) - This is the algorithm that captures the service agreement, account and person information associated with the bill.
- Capture Billing's SP Final Snapshot for DataConnect (C1-CEXTRCSP) - This is the algorithm that captures the service point and premise information associated with the bill.
- Capture Billing's Meter History Final Snapshot for DataConnect (C1-CEXTRCSM) - This is the algorithm that captures the meter history associated with the bill.

When using DataConnect v1, the Prepare Delimited Extract Data (Process All) Enter algorithm (C1-PRPEXDCUS/C1-PRPTDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the extract batch control defined by the pre-processing algorithm).

Billing Data Extracts: Batch Controls

The billing data extraction process uses a set of batch processes to create data synchronization requests and extract files.

Creating Initial Synchronization Requests

Copyright © 2026, Oracle and/or its affiliates.

The following batch processes are used to create initial synchronization requests for bills:

- Current DataConnect
  - Bill Data Initial Load for DataConnect (C1-BLDIL)
  - Bill Segment Data Initial Load for DataConnect (C1-BSDIL)
- **Legacy DataConnect**
  - Billing Data Initial Load for Legacy DataConnect (C1-BLEIL)

These batch processes should be run to create initial load data synchronization requests based on the sync business objects described above.

Creating Extract Files

The following batch process is used to create extract files from synchronization requests for billing related information.

- Current DataConnect
  - Bill Data Extract for DataConnect (C1-BLDTX)
  - Bill Segment Data Extract for DataConnect (C1-BSDTX)
- **Legacy DataConnect**
  - Billing Data Extract for Legacy DataConnect (C1-BSYEX)

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the sync business objects described above.

The following batch controls are used to extract bill segment lines and service quantities:

- Bill Seg Lines Extract - DataConnect (C1-BSLDX)
- Bill Segment SQ Extract - DataConnect (C1-BSSQX)

These should be run after bill segment extract has been run.

Use the **Batch Control** portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file) for a delimited flat file containing extracted data.

Setting Up and Executing Billing Data Extracts

Setting up billing data extracts involves the following steps:

1. Configure the Billing Data Configuration for the DataConnect master configuration record. This is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.
2. Add the Capture Bill and Bill Segment Extract for DataConnect v1+ (C1CAPBILBSEG) related post bill completion algorithm to the applicable customer classes.

   If using DataConnect v1, use the Capture Billing Data for DataConnect (Comma-delimited) (C1-CAPBILLEX) algorithm.
3. Execute initial load batch processes related to billing data.
4. Once the initial load synchronization has been executed, current data should be extracted on a regular ongoing (or incremental) basis. In addition to sending current data, any billing corrections will be extracted as well (data related to bill segments not linked to bills but are linked to frozen FTs that are linked to completed bills).

Copyright © 2026, Oracle and/or its affiliates.

5. Execute the sync request monitor process.
6. Execute the extract batch processes related to billing.

Billing Data DataConnect Master Configurations

The master configuration business objects for billing data Configuration for DataConnect define general configuration details for the DataConnect functionality.

Billing Data Configuration for Legacy DataConnect

The Billing Data Configuration for Legacy DataConnect master configuration is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.

Billing Extract Master Configuration for DataConnect

The Billing Extract Master Configuration for DataConnect master configuration is used to define the configuration used to extract billing data. This includes the extraction types, including bill and bill segment sync request business objects, as well as CIS Divisions and SA Types for each, the number of historical periods for initial load, and the calculation line's category based on the rating engine used (billing extract assumes that only one rating engine is used by the system).

Navigate using**Admin**, then **General**, then **Master Configuration.** In the Master Configuration list, scroll to the appropriate master configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Extract Flat File Formats

This section outlines the format of output flat files created by master and billing data extracts.

File Naming Formats

This topic provides details concerning how DataConnect extract files are named.

Master Data and Billing Data Extracts

Extract files for master data and billing data extracts (except extracts for Bill Segment Lines and Service Quantities, see below) use the following naming format:

<provided_file_name><data_source_indicator><batch_number><batch_thread_number><sysdate date/time>.dat

Copyright © 2026, Oracle and/or its affiliates.

where:

- <provided_file_name> is the file name as specified for the Flat File Name parameter on the batch control.
- <data_source_indicator>is the Data Source Indicator value, which comes from the Environment ID field on the Installation Options table (CI_INSTALLATION.ENV_ID). This field is 6 digits, with left padded zeros as appropriate.
- <batch_number> is the batch number of the batch process that created the file. This field is 10 digits, with left padded zeros as appropriate.
- <batch_thread_number> is the thread number of the process that created the file. This field is 3 digits, with left padded zeros as appropriate.
- <sysdate date/time> is the date and time at which the file was created, if the Include Run Date/Time on Flat File Name parameter on the batch control was set to "Y", displayed as YYYYMMDDHHMMSS.

Example: If run with the following parameters and values:

- D_ACCT_EXT is the value in the Flat File Name parameter
- 000004 is the Data Source Indicator value
- 0000000003 is the batch number
- 001 is the thread number
- 20141001123020 is the system date/time (2014-10-01.12.30.20)

the extract file name would be as follows:

```
D_ACCT_EXT000004000000000300120141001123020.DAT
```

This file naming format is used for extracts created using the following batch controls:

- Account Characteristic Data Extract for DataConnect (C1-ACCHX)
- Bill Data Extract for DataConnect (C1-BLDTX)
- Bill Segment Data Extract for DataConnect (C1-BSDTX)
- Characteristic Type Data Extract for DataConnect (C1-CHTYX)
- Customer Data Extract for DataConnect (C1-CUDTX)
- Mailing Address Extract for DataConnect (C1-MADTX)
- Person Characteristic Data Extract for DataConnect (C1-PECHX)
- Premise Characteristic Data Extract for DataConnect (C1-PRCHX)
- SA/SP Data Extract for DataConnect (C1-SSDTX)
- SA Characteristic Data Extract for DataConnect (C1-SACHX)
- SP and Meter Data Extract for DataConnect (C1-SPMSY)
- SP - CCB Characteristic Data Extract for DataConnect (C1-SPCHX)
- SP - MDM Characteristic Data Extract for DataConnect (X1-SPCHX)
- Billing Data Extract for Legacy DataConnect (C1-BSYEX)
- Meter History Extract for Legacy DataConnect (C1-SMSYX)
- SA-Based Extract for Legacy DataConnect (C1-SASYX)

Copyright © 2026, Oracle and/or its affiliates.

- SP-Based Extract for Legacy DataConnect (C1-SPSYX)

Bill Segment Line and Service Quantity Extracts

Extract files for for bill segment lines and service quantities use a naming format as specified on the File Name parameter. This can include the following system variables

- {BC} or {batchCode}: the batch code for the batch control.
- {BN} or {batchNumber}: the batch number of the batch process that created the file. This field is 4 digits, with left padded zeros as appropriate.
- {RN} or {rerunNumber}: the rerun number of the batch process that created the file if rerun. This field is 2 digits, with left padded zeros as appropriate.
- {TN} or {threadNumber}: the thread number of the process that created the file. This field is3 digits, with left padded zeros as appropriate. For multi-threaded runs, {threadNumber} will be inserted if not supplied.
- {RDT} or {runDateTime}: the date and time at which the file was created, displayed as yyyyMMddHHmmss.
- {RD} or {runDate}: the date on which the file was created, displayed as yyyyMMdd.
- {RT} or {runTime}: the time at which the file was created, displayed as HHmmss.

Example: Specifting 'EXTRACT_FILE_{BN}_{RN}_{TN}.zip' as the File Name will create the following files for batch number 10, rerun number 0, with 3 threads:

```
EXTRACT_FILE_0010_00_001.zip

EXTRACT_FILE_0010_00_002.zip

EXTRACT_FILE_0010_00_003.zip
```

This file naming format is used for extracts created using the following batch controls:

- Bill Segment Lines Extract for DataConnect (C1-BSLDX)
- Bill Segment SQ Extract for DataConnect Extract (C1-BSSQX)

External Fieldwork System Integration

The following section describes functionality provided for integrating your field activities with an external system.

> **Note**
>
> **Separate module.** Field activity integration functionality is associated with separate Field Activity Integration module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

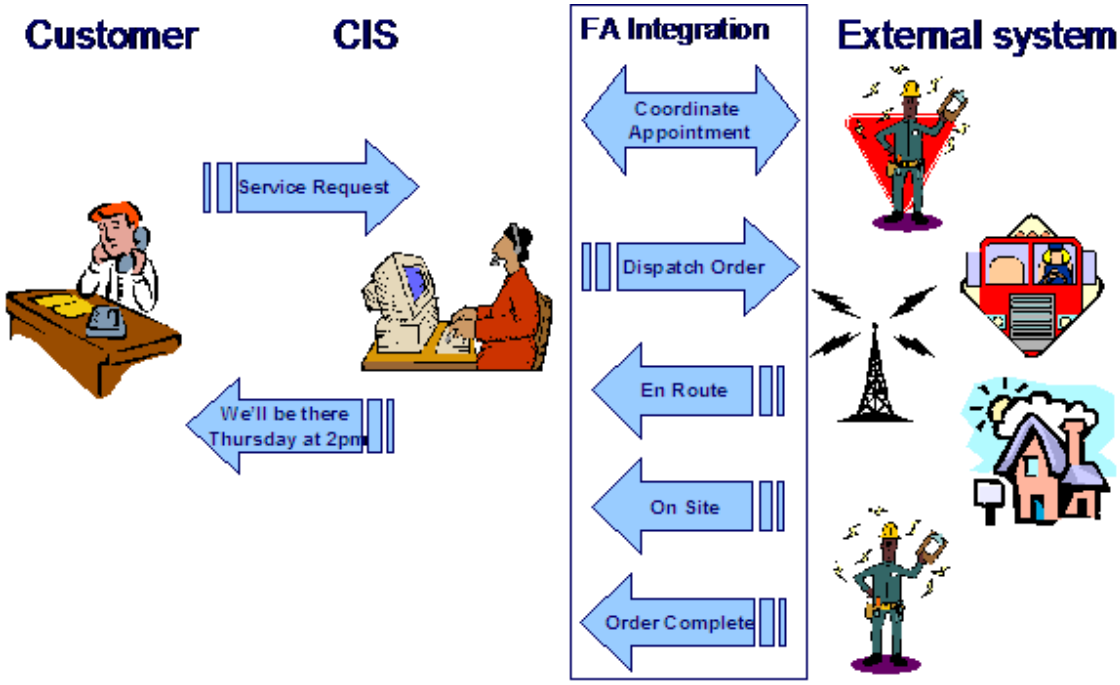
- The Big Picture of External System Integration

Copyright © 2026, Oracle and/or its affiliates.

- Integration Through XAI
- Dispatching Field Activities
- Incoming Messages from the External System
- Booking Appointments Via An External System
- Validating Meter / Item Installations
- Setting Up The System To Enable FA Integration

The Big Picture of External System Integration

Many utilities use other systems to coordinate work that goes out to the field. The following are examples of functionality provided by fieldwork management systems:



- Defining crews, skills, availability for work
- Scheduling appointments
- Tracking individual field activities, usually utilizing handheld devices to get up-to-the-minute status
- Balancing the workload

Since Oracle Utilities Customer Care and Billing can generate many work orders, you can integrate it with your external systems. The most common type of external system used to coordinate fieldwork is a Workforce Management (WFM) system. However, some companies may set up their business such that certain field activities should be sent to other types of systems. For example,

- Maybe new meter installations are the responsibility of the Asset Management system. A field activity of this type originated in Oracle Utilities Customer Care and Billing should be sent to the asset management system. That type of system may support its own crew dispatching logic or perhaps it performs some simple processing for the field activity and then interfaces the field activity to the WFM system.
- Outage related field activities are typically sent to an outage management system. The outage management system uses information from several outage calls to determine the source of the outage problem. The outage system may support its own crew dispatching logic or it may integrate with a WFM system to dispatch a crew.

The following diagram illustrates the typical integration with an external system:

Copyright © 2026, Oracle and/or its affiliates.

The following points describe the diagram:

- While speaking with the customer and entering information into the system, information about available appointments may be accessed from an external system and displayed on an Oracle Utilities Customer Care and Billing user interface. Information about the appointment that is booked with the customer is sent to the external system.
- Information about new field activities created in Oracle Utilities Customer Care and Billing is sent to the appropriate external system using XAI. The external system performs the dispatching and tracking for the field activity.
- Intermediate field activity states may be interfaced from the external system to Oracle Utilities Customer Care and Billing.
- Completion information is interfaced from the external system to Oracle Utilities Customer Care and Billing.
- Mapping Field Activity Types to an External System
- Cancelling a Field Activity
- Field Activities Not Related to a Premise
- Override Phone Number

Mapping Field Activity Types to an External System

When integrating with an external system, you must determine how to map your field activity types in Oracle Utilities Customer Care and Billing to your related task identifier in the external system.

Decide whether Oracle Utilities Customer Care and Billing provides information on its field activity types that map to the task in the external system. For more information, see Designing Your Field Activity Profiles & Types. You can leverage Oracle Utilities Customer Care and Billing field activity types and the messages sent from Oracle Utilities Customer Care and Billing to indicate the appropriate task in the external system. If tasks in the external system

Copyright © 2026, Oracle and/or its affiliates.

already have the information that maps to the field activity types in Oracle Utilities Customer Care and Billing, then the messages in Oracle Utilities Customer Care and Billing can pass the field activity types to the external system. You need to determine where your mappings will exist to decide how to map the field activity types and where.

In the sample integrations provided, it is assumed that the Oracle Utilities Customer Care and Billing field activity types map to the external system tasks using characteristics on the field activity type. You can use one or more characteristics on the field activity type to map it to the task in the external system.

Cancelling a Field Activity

Various business processes in the system create field activities (for example, start/stop, severance or cut process, device test selection). If the process that creates a field activity is canceled, the system attempts to automatically cancel the related field activity. If an implementation integrates with an external system, typically messages can be sent real-time to the external system AND to a field worker dispatched to work on the field activity to indicate that an FA is being canceled.

However, it's possible that there are situations where it is known ahead of time that a message cannot be successfully sent real-time. (For example, some field workers do not have real time communication with the dispatcher while in the field).

If this situation exists, you may configure the external system feature configuration to identify intermediate status values that should prevent a field activity from automatically completing. All processes that attempt to automatically cancel a field activity whose dispatch group references an external system will first check to see if it's in an intermediate status that should prevent auto-cancellation.

> **Note**
>
> Each business process must define what should occur when a field activity is not allowed to be auto-canceled.

Field Activities Not Related to a Premise

There are often field activities generated that do not relate to a specific premise. Because Oracle Utilities Customer Care and Billing requires a service point for every field activity, implementations must define one or more premises to represent the "no address premise" to use for one of these field activities. The decision as to whether to use one premise or more than one premise depends on how you plan to interface this information to an external system. For example

- Maybe the external system expects the user to use the field activity instructions to describe the location of the problem. In this case only one "no address" premise is needed
- You may decide that the operations area on a field activity's service point is interfaced to the external system and that you want to create a different "no address" premise for each of your operations areas.

Regardless of how many "no address" premises you decide to define, you must create at least one service point to be able to create a field activity. You may choose to create a service point

Copyright © 2026, Oracle and/or its affiliates.

for each service type you support. You must also be sure that your users know how to find the correct premise and service point in the search when creating the field activity.

We recommend that you create a special premise type to use for these premises and reference that premise type in the No Address Premise Type option on the feature configuration. The base product Extract FA Information service resets the Address fields if the premise linked to the field activity's service point is a "no address" premise type.

Override Phone Number

When entering field activity information for a customer, you may want to capture a specific contact phone number to interface to the external system. We recommend that you create a field activity characteristic type to capture the contact phone number and reference that characteristic type in the Phone Number Characteristic Type option on the feature configuration. The base product Extract FA Information service overrides the Account's phone number if it finds a characteristic on the field activity with this characteristic type.

Integration Through XAI

The integration between Oracle Utilities Customer Care and Billing and the various external systems is through XAI.

- The XAI real time outgoing message engine is used to retrieve appointment information and book appointments.
- Information about field activities is interfaced to the external system using near real time NDS messages.
- When the system receives messages from the external system, records are received as inbound messages.
- External System Feature Configuration Refers to a Service Provider

External System Feature Configuration Refers to a Service Provider

In order to communicate to the external system using XAI, the system must be able to identify a service provider related to the external system. The service provider associated with an external system is defined as an option on the external system's feature configuration.

Dispatching Field Activities

When your implementation integrates with an external system, field activities are created in Oracle Utilities Customer Care and Billing and interfaced to the external system. The external system manages the assigning and dispatching of work associated with this field activity.

If your external system can supply interim status information, this can be passed to our system and logged with the field activity. For example, if the external system can indicate that the field worker is en route or on site, this can be logged for the field activity so that if the customer calls to inquire about the status, the user is able to communicate the information.

Copyright © 2026, Oracle and/or its affiliates.

When work is completed, full completion information related to the field activities is interfaced from the external system back to the system.

> **Note**
>
> that field activities are interfaced to the external system, not field orders. Field orders are not necessary because they are used to bundle field activities together, an activity now managed by the external system. You may still choose to create field orders for these types of field activities if you want to group field activities for your own purposes.

- Integration with Multiple External Systems
- Algorithms Control FA Integration
- Sample FA Integration Algorithm
- Extract FA Information

Integration with Multiple External Systems

Some organizations use more than one external system to manage different types of field activities. For example, line work may be handled in one system and meter service work in another. To achieve this the external system's feature configuration is defined at the dispatch group level. Field activities are interfaced to an external system based on their dispatch group information.

Algorithms Control FA Integration

The interaction between Oracle Utilities Customer Care and Billing and your external systems is handled entirely via algorithms that are plugged into the appropriate dispatch group. If your dispatch group indicates that it should interface with an external system, then you must specify one or more FA Integration algorithms. These algorithms are called when the following system events occur

- A field activity linked to the dispatch group is created, whether online or in batch
- A field activity linked to the dispatch group is canceled, whether online or in batch
- The "header" information for a field activity linked to the dispatch group is changed, whether online or in batch

> **Note**
>
> **Header information**. "Header" information for a field activity refers to information on the field activity record. It does NOT include steps, characteristics, remarks or log records.

- The characteristics collection for a field activity changes online. Changing the characteristics via a batch routine will not trigger the FA integration algorithms.

Copyright © 2026, Oracle and/or its affiliates.

Sample FA Integration Algorithm

The system provides a sample algorithm for FA integration called FWFM-FA-INT. This algorithm creates outbound messages (by creating NDS records) to notify an external system if any field activities are created or if any changes are made to existing FAs so that their corresponding orders are created or updated respectively. Refer to the algorithm type description for more detail about the algorithm's logic.

> **Note**
>
> **Alert For Problems With Message**. The base product provides an alert algorithm (CCAL-FAERMSG) that may be plugged in to the installation options. This algorithm displays an alert if there is an error associated with an outbound message for the field activity or if a response has not been received within a specified time limit.

Extract FA Information

When XAI processes the outgoing messages generated by the sample FA integration algorithm, it builds the XML request by calling the service referenced on the NDS type's XAI inbound service.

The base product provides a service, called CIPOEFIP, which extracts field activity information along with information related to the service point, meter, item, premise and account for the field activity (if applicable). If this service does not provide the functionality required by your implementation, you may create your own version using this one as a basis.

Note that this service defines an input parameter to exclude Financial Information. You can set this to Yes to avoid the account financial information (see below).

The following tables list the data that is extracted.

Incoming Messages from the External System

If your implementation requires general updates to the field activity from your external system, for example, updating the priority based on a change to the priority in the external system, the XAI Inbound Service that processes this message may reference the standard field activity service.

The base product supplies two additional services to handle special incoming messages from your external system.

- One service processes responses to outgoing messages initiated by Oracle Utilities Customer Care and Billing.
- One service processes field activity completion information.
- FA Response
- Intermediate Status Updates
- Field Activity Completion

FA Response

The sample integration is designed to expect a response, whether positive or negative, from the external system when an outgoing message is sent.

The base product provides a service, called CIPORFAP, which processes this response. Note that we also provide an XAI Inbound Service, FA Response, defined to invoke this service. This service provides the ability to do the following for positive responses:

- Update information about the field activity (refer to Populating FA Response for details)
- Create a field activity log entry

If the incoming message is a negative response to a message originally sent by Oracle Utilities Customer Care and Billing, the service supports the following functionality:

- Create a field activity log entry.
- Create a To Do Entry

For both the log entry and the To Do entry, if the external system has provided an external message category and code in the message that have been mapped to an internal message category and code on the feature configuration table, the system looks up the message text and includes it in the log message. Refer to FA Log Entry Events for more information.

The following topics provide some additional information.

- Create a Log Entry
- Create a To Do Entry

Copyright © 2026, Oracle and/or its affiliates.

- Populating FA Response

Create a Log Entry

In order to create a log entry, the system needs to know the log type to use. The service accepts a log type as input and your XSL that maps data to this service may assign an appropriate log type.

If a log type is not provided, the system can try to default one of the base sample log types if information is provided about the type of base sample message that this is a response to. To do this, the service needs to identify the notification download condition of the original message.

NOT_SUPPORTED

Refer to Sample FA Integration Algorithm for information about the notification download conditions used for the sample integration.

Your XSL may provide

- The notification download condition flag.
- The notification download type. Using the NDS type, the system can find the appropriate notification download condition flag.
- The external system and the message id that the system generated and sent to the external system. Using that information, the original outbound (NDS) message can be retrieved and the NDS type and its corresponding notification download condition flag can be determined.

NOT_SUPPORTED

Refer to Sample FA Integration Algorithm for more information about creating the message ID.

Refer to Field Activity Log for a list of the base sample log types and the type of message they are generated for.

Create a To Do Entry

In order to create a To Do entry, the system needs to know the To Do type to use. The service accepts a To Do type as input and your XSL that maps data to this service may assign an appropriate To Do type. If you don't pass in a To Do type the system looks up the **To Do Type for FA Response** indicated on your external system's feature configuration.

Populating FA Response

The following table lists the fields to populate for an FA response message.

Copyright © 2026, Oracle and/or its affiliates.

General information
FA ID
Positive Switch (Y if response is positive, N if response is negative)
Outbound Message Information (used to identify the original outgoing message that this is a response to)

Schedule Date/Time
Dispatch Group
Instructions
Comments
External ID
FA Intermediate Status
Appointment Information
Field Activity Characteristics

Intermediate Status Updates

Oracle Utilities Customer Care and Billing supports receipt of intermediate status updates for a field activity from an external system. To process messages from the external system regarding status update changes, the system call the standard Field Activity service with a change action updating the intermediate status as provided.

If your organization's external system supports different intermediate status values for a field activity, your implementers must customize the lookup value that defines the list of valid intermediate status values.

Field Activity Completion

The system provides a staging table to use to upload and complete field activities. However, this staging table has limitations as described in field activity completion considerations. For

Copyright © 2026, Oracle and/or its affiliates.

these reasons and to enable to support integration through XAI, the base product provides a sample service (called CIPOASTP) that can be invoked by XAI to support completion of the all step types, including the "generic" step types and the "standard" step types. We provide an XAI Inbound Service, C1FACompletionWithSteps, defined to invoke this service. The sample service:

- Creates field activity upload staging and FA step upload staging records
- If meter read information has been provided, it creates a meter read record and its corresponding register reads.
- For any of the "generic" steps, the process updates or creates the appropriate record(s) and populates the id of the record updated as the foreign key for the FA step record. For example, for the Change Meter step type, the process updates the meter record with the information provided through XAI and links the meter id to the FA step record.
- The process then performs the standard "complete step" logic. For the "generic" step types, the FA step should simply be marked as complete because the foreign key is already linked. For the "standard" step types, the completion logic described in FACOMPL - Upload and Complete Field Activities is performed.

> **NOT_SUPPORTED**
>
> Refer to Field Activity Completion Considerations for the list of "generic" and "standard" step types.

- Creates an FA log entry with a log type of Order Completion to indicate that the field activity has been completed by an external system.
- Standard FA completion logic is also performed. For example, completion algorithms are executed, etc.

> **Note**
>
> The sample service provided by the system may not provide all the functionality your implementation requires for completing every "generic" step. For example, not all service point, meter or item fields are included in the list of fields that may be updated. If the sample process does not satisfy your needs, your implementers should copy the sample process and modify the new process as needed.
>
> **Characteristic limitation**. The sample service limits the number of field activity characteristics that may be uploaded to 100.
>
> **Error Handling**. If any error is found during step completion, this sample service backs out all changes and issues an error indicating the problem.

- Populating Field Activity Completion

Populating Field Activity Completion

Device Test Information
All fields for main Device Test table
External System. Used to record a test done by a third party.
Device Test Component / Result Extra Information.
This additional information is used to identify the meter readings that should be associated with component test results that are meter readings. Note. This FA completion service supports providing information for a single meter reading (in the FA upload staging info above). If your device test produces multiple readings, the assumption is that the readings are entered separately prior to this upload of completion information.
Component sequence. Indicate the sequence of the Device Test Component
Read Sequence for the register for that component. This should correspond to the register's relative sequence within the meter configuration.
Component Result sequence. Indicate the sequence of the Component Result
Read Date/Time. For each result that is related to a meter read, indicate the read date / time so that the system can find the associated meter read for this result.

Booking Appointments Via An External System

If your field activity requires an appointment, the user navigates to the appointment page to book the appointment. If the dispatch group for your field activity is associated with an external system's feature configuration, the appointment page includes a user exit to provide the ability to communicate with the external system for the following actions:

- Display available appointments
- Book an appointment
- Cancel an appointment

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Implementation specific behavior**. The actual behavior of your appointment integration is dependent on your external system behavior. For example, some systems store appointment booking, which may be done real time, independently from storing field activities, which are interfaced in near real time. Other systems may display available appointments real time but may book appointments as part of storing the field activity, which is near real time.

This section describes the tools provided to interface with your external system along with a description of sample integration of real time appointment interaction provided with the system.

> **Note**
>
> **Oracle Utilities Mobile Workforce Management integration**. In addition to general FA integration logic, the system provides integration with Oracle Utilities Mobile Workforce Management. Refer to the documentation for integration for more information.

- Configuring Appointment Options
- Appointment Periods vs Reservations
- Real Time Appointment Interaction

Configuring Appointment Options

There are several configuration options available to customize the interaction with your external system for appointments.

- Manual Appointments
- Narrowing Appointment Window
- Forced Appointments
- User Defined Search and Result Fields

Manual Appointments

If your external system books appointment in real time, it's possible that there is a problem with the communication to the external system while the user is attempting to book an appointment. You may configure your external system's feature configuration options to allow manual booking of appointments so that the user is able to book appointments even if the system is down. If you set the option Allow Manual Appointments to Y,

- If the communication is available to show appointments, but the connection is down when you attempt to book one of the displayed appointments, you can click OK to book the appointment using a "near real time" message. This is applicable for systems that book appointments real-time via the appointment page.

Copyright © 2026, Oracle and/or its affiliates.

- If the communication is unavailable while you are attempting to show appointments, you may add your own appointment period. When you click OK, a "near real time" message is created.

> **NOT_SUPPORTED**
>
> Refer to Book Appointment for more information about the creation of "near real time" messages.

> **Note**
>
> If the user has created an appointment or has chosen an appointment that is not available in the external system, it is possible that the manual appointment is not accepted and a negative response is received. You may configure your system to allow forced appointments to force the external system to accept the chosen appointment.

If there is a problem with the communication to your external system while attempting to cancel an appointment, you may configure your external system's feature configuration options to Allow Manual Appointment Cancellation. If this option is set to Y and the communication is unavailable while you are attempting to cancel an appointment, you can click OK to cancel the appointment using a "near real time" message.

Narrowing Appointment Window

If you have set the external system's feature configuration option Allow Narrowing Of Appointment Window to Y, then your users are able to enter a more granular appointment time than what is displayed. For example, if the list of available appointments shows an appointment period of 1pm to 4pm and this option is turned on, the user could enter an appointment period of 2pm to 2:30pm.

Forced Appointments

If your external system allows the user to choose appointment periods that are not available in the system, set the external system's feature configuration option Allow Forced Appointments to Y. When this option is turned on a Forced checkbox is visible on the search for an appointment page. The user should check this if the desired appointment is not available.

> **Note**
>
> **Forcing manual appointments**. If your system allows manual appointments and allows forced appointments, the book appointment logic provided with the system automatically flags manual appointments as forced to ensure that they are accepted by the external system.

Copyright © 2026, Oracle and/or its affiliates.

If an appointment is forced, the system populates a field activity characteristic indicating this. The characteristic type to use is defined as a feature configuration option.

User Defined Search and Result Fields

It is possible that your external system allows the user to provide additional information prior to searching for available appointments. For example, imagine that your customer wants the appointment to be in the afternoon and your external system allows you to request "afternoon" appointments only. To enable this functionality, you define a User Defined Search Criteria field on the external system's feature configuration options.

You may define up to 10 user defined search criteria fields. The information is passed to the message engine to get available appointments. It is assumed that your XSL scripts correctly map the information into a format understood by the external system to determine the desired appointment periods.

The result grid for the available appointments displays the start date / time and end date / time. If your external system provides additional information for each appointment period that would help the user choose the best appointment, you may define a User Defined Result Field on the external system's feature configuration options.

You may define up to 10 user defined result fields. If you have configured the external system to define extra result fields, it is assumed that your response XSL correctly maps the information from the external system to the appropriate column in the available appointments collection so that it can be displayed to the user.

For any custom field that you want to include in the search or the results, you must define a field in the system to indicate the type of data and the label for this field.

Appointment Periods vs Reservations

When an external system is used for appointments, it is not necessary to set up appointment period records in Oracle Utilities Customer Care and Billing ahead of time. The external system is responsible for providing the available appointment periods. When a user books an appointment with an external system, Oracle Utilities Customer Care and Billing creates an appointment period as an audit. This enables the user to view the appointment information when viewing the field activity in the system.

If the external system creates a reservation record for the appointment in its system, the unique identifier of that reservation may be stored with the field activity in Oracle Utilities Customer Care and Billing as a characteristic. The characteristic type to use is defined as a feature configuration option. The sample integration provided with the system populates the field activity characteristic with a reservation number received.

Real Time Appointment Interaction

The appointment page communicates with the external system for appointments. This section describes some technical information related to the logic delivered with the system.

- Appointment Page User Exit
- Sample Appointment Java Class

Copyright © 2026, Oracle and/or its affiliates.

Appointment Page User Exit

The base product appointment page provides java user exit code that is invoked when the dispatch group is associated with an external system (i.e., it references a feature configuration). The user exit code does the following:

- It determines the service provider
- It finds the NDS types that are associated with the following notification download condition flags:
  - Get Available Appointments. This is passed to the engine to retrieve the available appointments
  - Appointment Book. This is passed to the engine to book an appointment real time.
  - Appointment Book - Near Real Time. This is passed to the engine to book an appointment in near real time.
  - Appointment Cancel. This is passed to the engine to cancel an appointment real time.
  - Appointment Cancel - Near Real Time. This is passed to the engine to cancel an appointment in near real time.
- It invokes the Appointment Java Class Interface defined on the external system's feature configuration options passing all the data available on the page service.

> **Note**
>
> **Implementation specific business logic.** The intention is that any unique business logic required to interact with your implementation's external system is encapsulated in the appointment java class interface plugged in on your feature configuration options. However, if your implementation has unique logic that must be coded in the java user exit on the appointment page, that code may also be replaced by implementation specific appointment page user exit code.

Sample Appointment Java Class

The Appointment Java Class Interface referenced on your external system's feature configuration is responsible for interaction with the XAI real time outbound message engine to communicate with the external system for appointment logic.

The base product provides a default java class (called com.splwg.wfmi.workforce.DefaultWFMSystem) for appointment integration that may be used if it provides the logic your implementation needs.

> **Note**
>
> **Oracle Utilities Mobile Workforce Management**. Refer to documentation on integration for information about the java class provided for integration with Oracle Utilities Mobile Workforce Management.

Copyright © 2026, Oracle and/or its affiliates.

The default java class provided with the base product does the following:

- Extracts additional field activity information not provided by the appointment page service
- Converts the data in the page service and the additional FA information into an XML document
- Invokes the real time outgoing message engine.

Responses received from the engine are in the form of an XML document. The java class transforms the information into a format recognized by the page data model and sends it back to the user exit.

> **Note**
>
> The CILOAPTP.xml found on the xmlMetaInfo directory describes the base structure of the Show Appointment, Book Appointment and Cancel Appointment request XML. The selected field activity to be booked or canceled has an additional faExtraInfo element. The faExtraInfo element follows the structure described by CILOEFIP.xml.

The following sections describe more detail about the logic provided by the sample base product appointment Java class interface.

- Get Available Appointments
- Book Appointment
- Cancel Appointment

Get Available Appointments

For obtaining available appointments, the user exit passes the NDS type that references the Get Available Appointments condition flag. All the data available on the page service is passed to the engine as an XML document including any user defined search fields.

The user exit expects a response to this message to return a collection of records to display in the available appointments grid on the appointment page, including any user defined result fields. Any errors received are communicated to the user.

> **Note**
>
> **Translate Message**. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the external system's feature configuration.

Top of the Page

Book Appointment

Once the user has confirmed the desired appointment with the customer, the user attempts to book the appointment. The generic appointment integration java class provided with the system sends a message to books appointments real time. The user exit passes the NDS type that references the Appointment Book condition flag.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **One FA at a time**. The sample user exit provided by the system only supports booking appointments for one field activity at a time. As a result, if you want to use the sample user exit, your external systems should be configured with the option Allow Multiple Reservations set to N. If your organization would like to support booking appointments for multiple field activities at once, you may create your own user exit to provide this capability.

The sample user exit provided with the product expects either a positive or negative response to this message.

- If a positive response is received, the user exit expects to be passed a reservation number and an indication of whether or not the appointment was forced. It populates the field activity characteristics collection with these values using the **Reservation Characteristic Type** and **Appointment Forced Characteristic Type** defined as options on the external system's feature configuration.
- If a negative response is received, an error message is displayed to the user.

> **Note**
>
> **Translate Message**. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the external system's feature configuration.

If the message engine cannot communicate with the external system, it returns an indication to the user exit. The user exit proceeds as follows:

- If the external system indicates that Allow Manual Appointments is set to false an error is displayed to the user.
- If manual appointments are allowed, the user exit issues a warning to the user asking if the message should be logged and sent when the communication is up again. If the user agrees, the user exit invokes the java class asking it to post a near real time message near real time message.
  - The user exit calculates a unique outgoing message ID for the external system. The message id is calculated using a database sequence whose name is referenced in the option **Message ID Database Sequence Name** on the external system's feature configuration. This message id is passed to the real time message engine to be populated as an NDS context entry to support an asynchronous response to the message.
  - The user exit passes the NDS type that references the Appointment Book - Near Real Time condition flag. The FA Id is also passed to the real time message engine to be posted as an NDS context entry. The system expects that the response to this message will create an XAI upload staging record and that this record will update the field activity's characteristics with the reservation and forced appointment information (if applicable). Refer to Near Real Time NDS Messages for more information about responses to near real time messages and XAI upload staging.
  - If the external system's configuration indicates that forced appointments are allowed, the message is sent to the external system with the forced indication set. If the

Copyright © 2026, Oracle and/or its affiliates.

external system does not allow forced appointments, it's possible that this manual appointment could be rejected by the external system.

If no error is received, the appointment page continues with the "change" action. An appointment period is created for the chosen appointment time if one doesn't already exist and the appointment period is linked to the field activity.

> **Note**
>
> that the appointment period is created and linked to the field activity even if the message is sent to the external system in near real time and no confirmation has been received. This was done to record the requested appointment in our system to cater for the situations when the customer wants to change or cancel the appointment prior to receiving the acknowledgement from the external system.

Top of the Page

Cancel Appointment

If the customer wants to cancel the appointment, the user navigates to the appointment page. The generic appointment integration java class provided with the system sends a message to cancel an appointment real time. The user exit passes the NDS type that references the Appointment Cancel condition flag. The user exit expects either a positive or negative response to this message.

- If a positive response is received, the appointment page continues with the change action. (See below).
- If a negative response is received, an error message is displayed to the user.

> **Note**
>
> **Translate Message**. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the external system's feature configuration.

If the message engine cannot communicate with the external system, it returns an indication to the user exit. The user exit proceeds as follows:

- If the external system indicates that Allow Manual Appointment Cancellation is set to false an error is displayed to the user.
- If manual appointments are allowed, the user exit issues a warning to the user asking if the message should be logged and sent when the communication is up again. If the user agrees, the user exit invokes the java class asking it to post a near real time message.
  - The user exit calculates a unique outgoing message ID for the external system. The message id is calculated using a database sequence whose name is referenced in the external option **Message ID Database Sequence Name** on the external system table. This message id is passed to the real time message engine to be populated as an NDS context entry to support an asynchronous response to the message.
  - The user exit passes the NDS type that references the Appointment Cancel - Near Real Time condition flag. The FA Id is also passed to the real time message engine to

Copyright © 2026, Oracle and/or its affiliates.

be posted as an NDS context entry. A response to this message will be an acknowledgement. No further updates to field activity data are expected.

If no error is received, the appointment page continues with the "change" action. The appointment period is unlinked from the field activity and if no other field activities are linked to this appointment period, the appointment period is deleted. In addition, the field activity characteristics for the reservation number and forced appointments are removed from the FA.

> **Note**
>
> The above updates are performed even if the message is sent near real time and no response has been received. This was done to cancel the appointment in our system to cater for the situations when the customer wants to rebook the appointment prior to receiving the acknowledgement from the external system.

Validating Meter / Item Installations

- Incoming Validate Meter / Item Message
- Outgoing Validate Meter / Item Message

Incoming Validate Meter / Item Message

When Oracle Utilities Customer Care and Billing receives the incoming message to validate a meter or item, the service, called CIPOVMIP, which processes the message, creates a pending notification download staging record (using the NDS type whose notification download condition is Validate Meter/Item). It creates context records for the Badge Number being validated along with an indication of whether the badge number is for a Meter or an Item.

> **NOT_SUPPORTED**
>
> For more information about NDS types available in product integrations, refer to Oracle Utilities Mobile Workforce Management NDS Types and Oracle Utilities Work and Asset Management NDS Types listed in the documentation on integration.

The system provides an XAI Inbound Service, ValidateMeterItemRequest, defined to invoke this service. The following table lists the fields to populate for this service.

General Information
Message ID
FA ID
FA External ID
Meter / Item Flag (M or I)
Badge Number

Copyright © 2026, Oracle and/or its affiliates.

Outgoing Validate Meter / Item Message

The service provided with the product that processes the Validate Meter / Item notification download staging record does the work of validating the badge number. The service, called CIPOVRSP, does the following:

- Finds a unique device (meter or item) corresponding to the badge number provided.

> **Note**
>
> The validation is only possible if the badge number is unique for a meter or item. If multiple values are found, a negative acknowledgement is returned.

- Verifies that the device is not retired
- Verifies that the Meter type or Item type of the device being verified is defined as valid for the SP Type associated with the field activity's service point.
- It verifies that the device is not already installed somewhere else.
- If the device is a meter, it verifies that there is an effective Meter Configuration for the meter on or before the message date/time.

> **Note**
>
> **Return Meter Configuration Type**. The meter configuration type and the collection of the meter's registers are included in the output record returned to Oracle Utilities Mobile Workforce Management/Oracle Utilities Work and Asset Management.

- If the device is an item, it verifies that the item's receive date is on or before the message date.

The system provides an XAI Inbound Service, ValidateMeterItemResponse, defined to invoke this service. The following table lists the fields populated by this service.

General Information
Message ID
FA ID
FA External ID
Meter / Item Flag (M or I)
Badge Number
StatusFlag (Y - positive acknowledgement, F - negative acknowledgement.)
Meter Config Type (populated only for meters)
Collection of registers (populated only for meters)
ErrorCode (populated only for negative acknowledgement)
Error Message (populated only for negative acknowledgement)

Copyright © 2026, Oracle and/or its affiliates.

Setting Up The System To Enable FA Integration

The following section provides an overview of how to enable FA integration with an external system.

- Service Provider Setup
- Defining Characteristic Types For FA Integration
- Setting Up Outbound Messages
- Designing Your External System Feature Configuration
- Designing Your External System Field Activity Types
- Designing Your Dispatch Groups
- Considerations When Switching To External System Integration

Service Provider Setup

In order to use XAI to interface with an external system, you must define a service provider. Once the service provider is defined, you must design your outbound messages.

Defining Characteristic Types For FA Integration

The following characteristic types must be defined to facilitate FA integration.

> **NOT_SUPPORTED**
>
> Refer to Defining Characteristic Types for information on how to set up characteristic types.

External System Task Characteristic Type

If you have decided to map the tasks on your external system to the Oracle Utilities Customer Care and Billing field activity types, then you need to define the characteristic types based on your decisions. It is possible to map a combination of fields from the external system to a field activity type in Oracle Utilities Customer Care and Billing.

- Refer to the following topics in the documentation on integration for more information about how you should define characteristics in product integrations:
  - Oracle Utilities Mobile Workforce Management Characteristic Types
  - Oracle Utilities Work and Asset Management Characteristic Types
- Include Field Activity Type in the characteristic entity collection

Forced Appointments Characteristic Type

If your implementation supports forced appointments, the appointment booking logic attempts to store a characteristic on a field activity with a forced appointment.

Copyright © 2026, Oracle and/or its affiliates.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Reservation Characteristic Type

If your external system defines a separate reservation ID for appointments, the appointment booking logic attempts to store a characteristic on a field activity with the appointment reservation number.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Override Phone Characteristic Type

Create a characteristic type for override phone if your implementation supports capturing a contact phone number on the field activity.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Field Activity ID Characteristic Type

The sample FA integration algorithm may be configured to populate the field activity ID as a characteristic on any NDS records it creates. This facilitate in drilling down from the NDS record to the field activity. To support this logic,

- Create a foreign key characteristic type (if you don't already have one defined for Field Activity Id).
- Include Notification Download Staging in the characteristic entity collection

Setting Up Outbound Messages

The sample integration provided with the base product includes a predefined list of messages that are sent to an external system under various conditions. The messages are generated either from the sample FA integration algorithm or the sample real time appointment interaction. In each case, an NDS type is required to define properties of the message. Rather than hard-coding an NDS type, the integration algorithm and the user exit that manages the real time appointment interaction use a Notification Download Condition to reference the NDS type.

At implementation time, you should define an appropriate NDS type for each notification download condition listed below if it is applicable to your business.

The following download conditions are used in the sample FA integration algorithm:

- FA Cancellation
- FA Creation
- FA Changed
- FA Rescheduled
- Appointment Cancel via FA Cancel

For each of the above NDS types, you must reference the following context types: Field Activity ID, Message ID. They should also reference an XAI inbound service that has been defined for the Extract FA Info service. The system provides an XAI inbound service called ExtractFAInfo, which you may use.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You can refer to the demonstration data provided with the system to view samples for pre-configured NDS types and their condition flags.

The following download conditions are used in the sample real time appointment interaction:

- Get Available Appointments
- Appointment Book
- Appointment Cancel

The above NDS types do not need to reference a real XAI inbound service because the real time appointment interface is responsible for building the XML request.

> **Note**
>
> You can refer to the demonstration data provided with the system to view samples for pre-configured NDS types and their associated XAI inbound services.

The following download conditions are used to send real time appointment messages in near real time.

- Appointment Book - Near Real Time
- Appointment Cancel - Near Real Time

Because the XML request is built by the appointment interface prior to the creation of the NDS, these NDS types should reference a special XAI inbound service called CDxProcessXDS. This service basically tells the download staging sender that the XDS already exists and doesn't need to be created.

Designing Your External System Feature Configuration

For each external system, you must define a feature configuration with a feature type of FA Integration.

Note that it is also possible for you to define multiple entries in the feature configuration table for a single external system. You would do this if your external system may be configured in multiples ways for different dispatch groups. For example, maybe your service territory includes urban areas and rural areas. Perhaps your rules for scheduling appointments differ based on the location of the premise. You could define two separate feature configurations and define the appropriate appointment options for each one. When defining your dispatch groups, be sure to define separate dispatch groups based on the operations area and link the appropriate feature configuration accordingly.

If you define multiple feature configurations, consider whether they should all reference the same service provider. One consideration is whether or not the method of communication with the external system is the same for all feature configurations.

Configure the options for your external system interaction.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Your implementation may define additional options types. You do this by add new lookup values to the lookup field WFM_OPT_TYP_FLG.

Option	Description
Account Rel. Type - Company Contact	Identify the account relationship type used to define a company's contact person.
Allow Forced Appointments	Use this option to indicate if forced appointments are supported. Possible values are Y and N.
Allow Manual Appointment	Use this option to indicate if a user is allowed to manually set up an appointment. Possible values are Y and N.
Allow Manual Appointment Cancellation	Use this option to indicate if a user is allowed to manually cancel an appointment. Possible values are Y and N.
Allow Multiple Reservations	Use this option to indicate if booking appointments for multiple field activities is allowed. Possible values are Y and N.
Allow Narrowing Of Appointment Window	Use this option to indicate if the user is allowed to further narrow down a selected appointment window. Possible values are Y and N.
Appointment Forced Characteristic Type	When an appointment reservation is forced, a characteristic of this type is added to the field activity. Note that the field activity's FA type must also define this as a valid characteristic type.
Appointment Java Class Interface	This is the java class implementation used to interface with the external system to support real time appointment interaction.
Default Days of Available Appointment	This option is used to determine the end date of the search period when choosing a dispatch group on the appointment page.
Hi-Low Review	Use this option to indicate if meter reads coming from the external system should be reviewed for Hi-Low failures and trended. Possible values are Y and N.
Intermediate Status to Prevent FA Cancel	This option is used to identify FA Intermediate Status values that should prevent the system from automatically canceling a Field Activity. The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG.
Intermediate Status to Prevent FA Type Change	This option is used to identify FA Intermediate Status values that should prevent users from changing the FA Type. The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG.

Copyright © 2026, Oracle and/or its affiliates.

Intermediate Status to Skip Message	This option is used to identify FA Intermediate Status value used when a Field Activity is created by an external system or when other information for a field activity is updated by an external system. The base FA integration algorithm uses this information to ensure that messages sent to the external system to highlight new field activities or changes to field activities are only triggered when additions / changes are initiated in our system. The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG.
Message ID Database Sequence Name	The name of the database sequence to be used to get the next unique message ID for this external system. This is used to facilitate an asynchronous response to the message. If you interface with more than one external system, you may choose to use the same sequence name for all external systems or to define a separate sequence name for each external system. If you choose to define multiple feature configuration records for the same service provider, be sure that each feature configuration references the same sequence name because generated message IDs must be unique for the service provider. The base product provides the database sequence CI_WFM_MSGID_SEQ, which may be referenced here.
No Address Premise Type	Indicate the premise type used to identify a premise that is used for field activities that are not related to a specific premise.
Phone Number Characteristic Type	Indicate the characteristic type used to identify an override phone number on the field activity.
Phone Type - Business	Indicate the phone type used to identify a business phone number.
Phone Type - Fax	Indicate the phone type used to identify a fax number.
Phone Type - Home	Indicate the phone type used to identify a home phone number.
Plant Source	Some external systems require a reference to a Plant in our system. There are several options for where an implementation may define this value. This option is used to identify where the Plant is defined. - enter FECO if the plant field is defined in Feature Configuration - enter OPAR if the plant field is defined in the SP Operations Area - enter SPCH if the plant field is defined in the SP Characteristic

Copyright © 2026, Oracle and/or its affiliates.

Plant Value	If the Plant Source is FECO enter the value of the Plant. If the Plant Source is OPAR enter the field service class used to identify the plant value on the SP operations area. If the Plant Source is SPCH enter the characteristic type used to identify the plant value on SP characteristic. Only one option value may be defined for a given feature configuration.
Reservation Characteristic Type	When an appointment is successfully booked for the field activity, the external system often assigns a unique reservation number to the appointment. This reservation number is linked to the field activity as a characteristic using this characteristic type. Note that the field activity's FA type must also define this as a valid characteristic type.
Service Provider	This is the service provider defined for your external system.
To Do Type for FA Response	Indicate the To Do type to use to create a To Do entry. The system supplies the To Do type TD-FARSP that may be plugged-in here. The program populates the To Do Entry with the sort keys, drill keys and message parameters as shown in this base package To Do. If you want to create your own To Do Type, you must set up the values to match those in the base To Do Type.
User Defined Criteria Field	This is used on the appointment page to add specific appointment selection criteria. The value of this option should reference a Field defined in the system metadata. The appointment page allows up to 10 user defined criteria fields.
User Defined Result Field	This is used on the appointment page to add specific appointment selection result information. The value of this option should reference a Field defined in the system metadata. The appointment page allows up to 10 user defined result fields.

For each message that may be received from an external system, map the external system message to an internal system message. Refer to Defining Feature Configuration s for more information.

Designing Your External System Field Activity Types

For each type of field activity that is interfaced to an external system, create an appropriate FA type.

- Indicate that the FA type is eligible for dispatch.
- Configure the appropriate value for Appointment Booking based on your business requirements.

Copyright © 2026, Oracle and/or its affiliates.

- If you have decided to map your external system tasks to the Oracle Utilities Customer Care and Billing field activity type, then for each field activity type, create one or more characteristics to identify how it is mapped to the equivalent task in the external system.

- Indicate the FA characteristics that are valid for field activities of this type
  - If your external system allows forced appointments, define the forced appointment characteristic type created above and referenced on your external system feature configuration.
  - If your external system defines a separate reservation ID for appointments and this FA type allows appointments, define the reservation characteristic type created above and referenced on your external system feature configuration.

Refer to the following topics in the documentation on integration for more information about how you should use characteristics in product integrations:

- Oracle Utilities Mobile Workforce Management Characteristic Types
- Oracle Utilities Work and Asset Management Characteristic Types

Designing Your Dispatch Groups

When a field activity is created, the system uses the Field Service Control to assign the field activity to a dispatch group based on the type of activity, the type of service point and the operations area that manages the service point. If the dispatching for this service point is managed by an external system, the dispatch group should be configured to interface with the external system:

- The dispatch group references the appropriate external system feature configuration.
- You must indicate an appropriate FA integration algorithm.

Considerations When Switching To External System Integration

If your implementation is currently using the field order functionality and is planning to switch to interface field activities to an external system, here are some considerations.

Field orders are not required when integrating field activities to an external system. As a result you may choose to disable the field order related functionality:

- The automatic dispatch background process (FOD) and download field order background processes (FDS) no longer need to be scheduled. In addition, the printing processes FODL and DSGPFODL no longer need to be scheduled.
- The menu items Field Order, Group Premise FAs and Field Order Search are no longer applicable. Consider disabling security for these pages.

When switching over to begin using an external system, you will undoubtedly have pending field activities that need to be interfaced to the external system. If you change the field activity's dispatch group from one that does not reference an external system to one that does, the sample field activity integration algorithm will generate an FA Creation message to the external system.

It is possible that your pending field activities are already linked to field orders. If that is the case, you will not be able to change the dispatch group on the field activity. The recommendation for switching to an external system for dispatching is to change your pending

Copyright © 2026, Oracle and/or its affiliates.

field activities to remove the link between the field activity and the field order. As mentioned above, the field order is no longer needed. Once you remove the link then you are able to change the dispatch group on the field activity.

If you prefer to leave the field order / field activity link in place then you must change the dispatch group on your field order to one that references the new external system.

Outage System Integration

The following section describes functionality provided for the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

- The Big Picture of Outage System Integration
- Setting Up The System To Enable Outage Integration

The Big Picture of Outage System Integration

Oracle Utilities Customer Care and Billing is the central repository for customer information; for example, name, address, phone number, etc. Oracle Utilities Network Management System is the central repository for outage information; for example, outage calls, affected supply nodes, expected restoration time, etc.

In an integrated environment, each system provides information to the other system so that they can operate together seamlessly.

- The outage system uses the set of current customers to determine and manage outages to minimize their impact
- The outage system is informed of outages captured in Oracle Utilities Customer Care and Billing
- Oracle Utilities Customer Care and Billing uses the current status of an outage at a given premise for customer service
- Customer Information Integration
- Interfacing Outage Calls
- Outage Inquiry

Customer Information Integration

The outage system needs information about current customers to determine and manage outages to minimize their impact. The current customer information must be made available in Oracle Utilities Network Management System. This can be done via data synchronization.

Depending on the specific edge application and version you are using, there are components of the integration that use Sync Request for the change data capture step. The following points highlight how to get more information:

- Refer to your products integration to Oracle Utilities Network Management System Implementation Guide to configure the Sync Request and change data capture functionality.

Copyright © 2026, Oracle and/or its affiliates.

- Review the Sync Request Business Objects provided by your product for NMS integration.
- Refer to Data Synchronization for a high level understanding of the process.

NOT_SUPPORTED

Refer to The Big Picture of Sync Requests for more information about synchronizing data.

Interfacing Outage Calls

The following points describe the integration:

- Oracle Utilities Customer Care and Billing is able to record trouble calls for a particular service point that exists in the system, as well as for an unknown service point, i.e. a fuzzy call. For a fuzzy call, the caller must provide either a street intersection, or a street segment.
- When an outage call is created and sent to the external system, an algorithm on the outage call business object is responsible for creating an outbound message that's sent to the external system. This is a real-time synchronous interface between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.
- Oracle Utilities Network Management System processes the Calls table and creates Incidents.

NOT_SUPPORTED

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage call integration.

Outage Inquiry

Oracle Utilities Customer Care and Billing provides query transactions that can be used to make real-time synchronous calls to NMS and inquire on one of the following:

- Job History for a particular customer, service point, location or call identifier
- Call History for a particular customer, service point, location or call identifier
- Planned Outage Jobs for a particular service point

NOT_SUPPORTED

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage query integration.

Copyright © 2026, Oracle and/or its affiliates.

The product also supports the option of storing key Outage Event information in snapshot database tables for the purpose of reporting on active, planned and recently resolved outages. This information is made available by Oracle Utilities Network Management System as part of the integration flow that notifies impacted customers of outage event updates. The outage notification integration flow can be enabled to also share records for the latest updates of an outage event. Having outage data readily available within the application allows for more robust inquiries and insight analysis that does not overload the outage management system with real-time calls.

NOT_SUPPORTED

Refer to the *Oracle Utilities Notifications Hub Configuration Guide* for information about enabling outage data snapshot integration. When enabled, outage data is interfaced in using the **Outage Event Notifications** (C1-OutageEventNotifications) web service.

You may review outage snapshot data in the following portals:

- Outage Event.
- Customer Outage Information.

Setting Up The System To Enable Outage Integration

The following section provides an overview of how to enable the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

- External System Setup
- Define Characteristic Types
- Schema Constants - Feature Configuration
- NMS Outage Integration - Master Configuration
- Outage Notification Preferences

External System Setup

An external system must be setup in order integrate Oracle Utilities Network Management System. Define message senders for the following Outbound Message Types and associate them to the external system:

- NMS Outage Call (C1-NMSOUTCAL)
- NMS Job History Query (C1-NMSJOBHST)
- NMS Call History Query (C1-NMSCALHST)
- NMS Planned Outages Query (C1-NMSPLNOUT)

For synchronizing outage related notification preferences to NMS, define a message sender for the Outbound Message to Notify Edge Applications (C1-NTFOUTMSG) Outbound Message Type and associate it to the external system.

Copyright © 2026, Oracle and/or its affiliates.

Once the external system is defined, configure the NMS Outage Integration Master Configuration so the system knows which external system to use for outage queries.

Define Characteristic Types

The following characteristic types must be defined to facilitate Outage integration:

> **NOT_SUPPORTED**
>
> Refer to Defining Characteristic Types for information on how to set up characteristic types.

Outage Group Code Characteristic Type

These characteristics are used to describe the outage problem.

- Create at least one pre-defined characteristic type
- For each characteristic type, define its list of valid values
- Include Service Task Type in the characteristic entity collection

> **Note**
>
> **Integration with Outage Management**. The outage codes must be defined in both Oracle Utilities Customer Care and Billing and the outage management system. Refer to your Oracle Utilities Network Management System documentation for information about defining the outage codes there.

Contact Name Characteristic Type

This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Contact Name Characteristic Type feature option

Contact Number Characteristic Type

This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Contact Number Characteristic Type feature option

Call Identifier Characteristic Type

Copyright © 2026, Oracle and/or its affiliates.

This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Identifier Characteristic Type feature option

Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Street Name Characteristic Type feature option

Cross Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Cross Street Name Characteristic Type feature option

Block Number Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Block Number Characteristic Type feature option

City Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on theSchema Constants Feature Configuration using the Outage Call City Characteristic Type feature option

State Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection

Copyright © 2026, Oracle and/or its affiliates.

- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call State Characteristic Type feature option

Schema Constants - Feature Configuration

Create a feature configuration with the type Schema Constants. Populate entries for all the options listed below.

> **Note**
>
> **Only one**. The system expects only one Schema Constants feature configuration to be defined.

Configure the options for your interaction with the outage system.

> **Note**
>
> Your implementation may define additional options types. You do this by adding new lookup values to the lookup field F1CN_OPT_TYP_FLG.

Option	Description
Outage Call Contact Name Characteristic Type	This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call Contact Number Characteristic Type	This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call Identifier Characteristic Type	This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call Street Name Characteristic Type	This is used to link the street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call Cross Street Name Characteristic Type	This is used to link the cross street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.

Copyright © 2026, Oracle and/or its affiliates.

Outage Call Block Number Characteristic Type	This is used to link the block number supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call City Characteristic Type	This is used to link the city supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.
Outage Call State Characteristic Type	This is used to link the state supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Define Characteristic Types for more information. Only one value is allowed for this option.

NMS Outage Integration - Master Configuration

The integration with Oracle Utilities Network Management System (NMS) requires the setup of master configuration data that controls the processing of master data synchronization and outage management operations.

Navigate to **Admin**, and then **General**, and then **Master Configuration**

Set up the **NMS Outage Integration Master Config**: This master configuration relates to the outage call and outage query integration with NMS.

Refer to the embedded help for more details on how each section is configured.

Outage Notification Preferences

The system supports the ability to synchronize notification preferences that are owned by other edge applications. For example, during an outage event, Oracle Utilities Network Management System (NMS) is the system responsible for sending notifications to impacted customers that are subscribed or opted-in to receive notifications for these events. To support this functionality, notification preference statuses for outage related notification types that are updated under a customers account must be synchronized to NMS.

To configure your system to synchronize outage related notification preferences to NMS, perform the following steps:

- Configure the outage notification types that are owned by NMS (e.g. Planned Outage, Unplanned Outage, Outage Started, Estimated Restoration Type, Outage Restored). Notification types can be configured as template based subscription, or template based parent/individual push. Refer to Setting Up Notification Preference Options for more information.
- Configure the **Notification Preferences** master configuration. Under the master configuration's Edge Application Notification section, add the notification types along with the edge application (Network Management System) and External System/Outbound Message Type for each entry. Refer to the embedded help for more details.

Copyright © 2026, Oracle and/or its affiliates.

Once configured, the **Notification Preference Sync Initial Load (C1–NCPIL)** batch process is used to create initial synchronization requests. This batch control creates initial synchronization requests for Notification Contact Preference data (Maintenance Object C1–NT-PREF). The maintenance object and sync business object (C1-NtfContactPreferenceSync) are plugged in as parameters to the batch job.

For ongoing synchronization requests, the **Sync Request Monitor batch control (F1-SYNRQ)** is responsible for monitoring synchronization requests in the Pending state and transitions them to the Determine if Sync Needed state. Use the following parameters when running the F1-SYNRQ batch job:

- Maintenance Object: F1-SYNC REQ
-
- Restrict By Business Object: C1-NtfContactPreferenceSync
- Restrict By Status Code: PENDING

> **NOT_SUPPORTED**
>
> Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage notification integration.

Oracle Utilities Customer Program Cloud Service

The Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Customer Program Cloud Service provides the following functionality:

- Initial and incremental extract of customer data including persons, service points, and service agreements from Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing).
- Initial and incremental import of customer data into Oracle Utilities Customer Program Management Cloud Service.

This section describes the customer data extract functionality within Oracle Utilities Customer Care and Billing (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) used with this integration.

> **Note**
>
> This integration is only used if Oracle Utilities Customer Cloud Service and Oracle Utilities Customer Program Management Cloud Service are deployed in separate environments.

- Customer Data Extract

Customer Data Extract

Customer information including persons, service points and service agreements in Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) can be extracted and sent to Oracle Utilities Customer Program

Copyright © 2026, Oracle and/or its affiliates.

Management Cloud Service (or Oracle Utilities Customer Program Management) for use in enrolling customers in demand response programs.

- An initial extract is used to duplicate customer information data as of a given date in Oracle Utilities Customer Cloud Service in Oracle Utilities Customer Program Management Cloud Service. This is typically done during initial set up of the Digital Asset Cloud Service implementation.
- Following the initial extract, audit algorithms track new data and changes to existing data and create data synchronization requests, which can be used to create incremental extract files via batch processing.

Extracted data is sent to Customer Program Management in a delimited file, which is uploaded into the system via batch processing and data synchronization. See **Importing Customer-Related Data from a Customer Information System** in the *Oracle Utilities Customer Program Management Cloud Service User Guides* for more information about the import process.

Extract Process Overview

This section provide an overview of the extract process and outlines the various system objects used for each type of data (contacts, service points, and service agreements). The overall process is as follows:

1. An initial "extract" batch process is used to extract customer data into files that can be imported into Digital Asset Cloud Service.
2. Audit algorithms on the Contact, Service Point, and Service Agreement maintenance objects create synchronization requests.
3. Sync requests are processed using the specific batch processes (a separate batch control is provided for contacts, service points, and service agreements) to create incremental extracts.

Initial Load vs. Incremental Downloads

Customer data can be extracted in one of two modes: Initial or Incremental.

Initial extracts are used when setting up the system to export contact, service point, and service agreement data from Oracle Utilities Customer Cloud Service.

Incremental extracts are used to update customer data in Customer Program Management Cloud Service as customer data changes in Oracle Utilities Customer Cloud Service.

Initial Extract Batch Processes

Extract files are created using object-specific "extract" batch processes. See Extract Process Object Summary below for the specific "extract" batch process used for each type of customer data. These are used only for the initial extract.

These processes use the following parameters:

- **File Name**: The name of the extract file. File names can use wildcards (Required)
- **Flat Path**: The file location where the extract file is created. This can be a file location on a local server or a location in Object Storage. See Referencing URIs in the *Framework Administrative User Guide* for more information. (Required)
- **File Format**: The file format used for extract file. This should be FIXD. Each extract type has its own format.
- **Low SP Id Override Value**: A service point ID used to define the low value in a a range of IDs to limit the data extracted.

Copyright © 2026, Oracle and/or its affiliates.

- **High SP Id Override Value**: A service point ID used to define the high value in a a range of IDs to limit the data extracted.

Use the **Batch Control** portal to learn more about these and other parameters used by these batch processes.

Audit Algorithms and Sync Request Business Objects

Sync requests are created by audit algorithms, and are based on data specific sync request business objects. See Extract Process Object Summary below for the specific audit algorithms and "Sync Request" business objects used for each type of customer data.

The table below outlines the stages of the sync request lifecycle. Use the **Business Object** portal to learn more about these business objects and the details of each lifecycle state.

State	Notes
Pending	Sync requests begin in this state. An Enter algorithms creates the initial snapshot of the Customer Program Management Cloud Service (CPMCS) data (contact, service point, or service agreement). The Sync Request Monitor (F1-SYNRQ) batch process is used to transition sync requests in this state to the Determine if Sync Needed state.
Determine if Sync Needed	An Enter algorithms creates the final snapshot of the CPMCS data. An Enter algorithms compares the initial and final snapshots. If there is no difference, the sync request moves to the Discarded state. Otherwise, the request moves to the Send Request state,
Discarded	Sync requests for which there is no different between the initial snapshot and final snapshot are sent to this state.
Send Request	An Enter algorithm creates a General Process record for the sync request. The request then moves to the Awaiting Acknowledgement state.
Awaiting Acknowledgement	Requests remain in this state until the system receives an acknowledgement that CPMCS has received the data contained in the request.
Synchronized	Sync requests enter this state following the Awaiting Acknowledgement state when the system receives an acknowledgement that CPMCS has received the data contained in the request. If an error occurs, the request moves to the Synchronized with Error state.
Error	Sync requests enter this state if an error occurs while in the Awaiting Acknowledgement state. An Enter algorithm creates a To Do entry.
Canceled	Sync requests enter this state if canceled in either the Error or Synchronized with Error states.
Synchronized with Error	Sync requests enter this state if an error occurs while in the Synchronized state . An Enter algorithm creates a To Do entry.

Copyright © 2026, Oracle and/or its affiliates.

Incremental Extract Batch Processes

Incremental extract files are created from General Process records using "Incremental Extract" batch processes. See below for the specific "Incremental Extract" batch processes used for each type of customer data. These should be run as needed for incremental updates.

Use the **Batch Control** portal to view the parameters used by these batch processes.

Extract Process Object Summary

The table below lists the batch controls, algorithms, and business objects used by each type of customer data.

Object Type	Initial Extract Batch Process	Audit Algorithms	Sync Request Business Object	Incremental Extract Batch Process
Person	Migrate Person to DACS Contact (C1-DCTIL)	Sync Person as DACS Contact (C1_DAPERSYNC)	Sync CCB Person to DACS Contact (C1-DACSContactSyncRequest)	Contact Incremental Sync Batch Control (C1-DCTEX)
Service Point	Migrate CCB SP to DACS MSP (C1-DSPIL)	Sync Service Point as DACS Metered Service Point (C1_DASPSYNC)	Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest)	SP Incremental Sync Batch Control (C1-DSPEX)
Service Agreement	Migrates SA to DACS Metered Service (C1-DMSIL)	Sync Service Agreement as DACS Metered Service (C1_DASASYNC)	Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest)	MS Incremental Sync Batch Control (C1-DMSEX)

Acknowledgement Messages

When Customer Program Management Cloud Service processes incremental updates, it can send an acknowledgement back to Customer Cloud Service.

Refer to the Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Customer Program Cloud Service documentation for more information about configuring Customer Program Management Cloud Service to send acknowledgements.

- Extracting Persons
- Extracting Service Points
- Extracting Service Agreements

Extracting Persons

This topic provides additional details related to extracting Persons from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Persons are converted to Contacts in Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for persons are created using the Migrate Person to DACS Contact (C1-DCTIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Person as DACS Contact (C1_DAPERSYNC) audit algorithm tracks new person data and changes to existing person data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Person sync requests are based on the Sync CCB Person to DACS Contact (C1-DACSContactSyncRequest) business object.

Incremental Extract Batch Process

Incremental person extract files are created from sync requests and General Process records using the Contact Incremental Sync Batch Control (C1-DCTEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Person (Contact) Extract File Format

Person (Contact) extract files use the following tab-separated values format:

Field Name	Optional/Required	Notes
External Reference Id	Optional	The contact's reference ID in the CIS application
Change Date Time	Optional	The date and time on which the contact was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same contact.
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**
External Id	Required	The contact's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Contact Type	Required	The type of contact. When importing data from Customer to Meter or Customer Cloud Service this will be either Person or Business. If the provided contact type has not been defined as a Program Subscription Contact Type in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Contact Type used in Digital Asset Management / Digital Asset Cloud Service.
Name	Required	The contact's name. For format for this is <FIRST_NAME> <LAST_NAME> (note the space between them.
Home Phone	Optional	A home phone number associated with person-type contacts.
Mobile Phone	Optional	A mobile phone number associated with person-type contacts.
Phone	Optional	A phone number associated with business-type contacts.
Email	Optional	An email address for the contact.
Life Support Sensitive Load	Required	A flag that indicates if the contact requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Digital Asset Management / Digital Asset Cloud Service
Life Support Sensitive Load Description	Optional	An optional description for Life Support Sensitive Load.
Is Erased	Optional	A flag that indicates if the contact has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default) **Applicable only to Incremental Uploads** This should be set to "N" if Object Erasure is not supported in the CIS application.

Extracting Service Points

This topic provides additional details related to extracting service points from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for service points are created using the Migrate CCB SP to DACS MSP (C1-DSPIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Point as DACS Metered Service Point (C1_DASPSYNC) audit algorithm tracks new service point data and changes to existing service point data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Service point sync requests are based on the Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest) business object.

Incremental Extract Batch Process

Incremental service point extract files are created from sync requests and General Process records using the SP Incremental Sync Batch Control (C1-DSPEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Point Extract File Format

Service point extract files use the following tab-separated values format:

Field Name	Optional/Required	Notes
External Reference Id	Optional	The metered service point's reference ID in the CIS application.
Change Date Time	Optional	The date and time on which the metered service point was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same metered service point.
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
External Id	Required	The metered service point's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Point External ID.
Metered SP Type	Required	The type of metered service point. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Point Type. If the provided metered service point type has not been defined as a Metered Service Point Type in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Metered Service Point Type used in Customer Program Management / Customer Program Management Cloud Service.
SP Source Status	Required	The metered service point's source status. Valid values are values for the Source Status (SP_SRC_STAT_FLG) lookup, and include: • **D1CN (Connected)** • **D1DC (Disconnected)**
Division	Optional	The metered service point's division. If the provided division has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Division used in Customer Program Management / Customer Program Management Cloud Service.
External Premise Id	Optional	The ID of the premise associated with the metered service point in the CIS application.
Time Zone	Required	The time zone in which the metered service point is located.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Country	Optional	The country in which the metered service point is located.
Postal	Optional	The metered service point's postal code.
Address 1	Optional	The metered service point's address.
Address 2	Optional	Additional details regarding the metered service point's address (if applicable).
Address 3	Optional	Additional details regarding the metered service point's address (if applicable).
Address 4	Optional	Additional details regarding the metered service point's address (if applicable).
City	Optional	The city in which the metered service point is located.
County	Optional	The county in which the metered service point is located.
State	Optional	The state in which the metered service point is located.
Longitude	Optional	The metered service point's longitude.
Latitude	Optional	The metered service point's latitude.
Life Support Sensitive Load Flag	Required	A flag that indicates if the metered service point requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Customer Program Management / Customer Program Management Cloud Service
Life Support Sensitive Load Description	Optional	An optional description for Life Support Sensitive Load.
Status	Required	The current state of the metered service point. Valid values are "ACTIVE" and "INACTIVE".
Is OK to Enter?	Optional	
SP Warning	Optional	
SP Instructions	Optional	
SP Instructions Details	Optional	
Is Key	Optional	
Key Id	Optional	
Device Location	Optional	
Device Location Details	Optional

Extracting Service Agreements

This topic provides additional details related to extracting service agreements from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for service agreements are created using the Migrates SA to DACS Metered Service (C1-DMSIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Agreement as DACS Metered Service (C1_DASASYNC) audit algorithm tracks new service agreement data and changes to existing service agreement data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Service agreement sync requests are based on the Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest) business object.

Incremental Extract Batch Process

Incremental service agreements extract files are created from sync requests and General Process records using the MS Incremental Sync Batch Control (C1-DMSEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Agreement Extract File Format

Service agreement extract files use the following tab-separated values format:

Field Name	Optional/Required	Notes
External Reference Id	Optional	The metered service's reference ID in the CIS application.
Change Date Time	Optional	The date and time on which the metered service was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same metered service point.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**
External Id	Required	The metered service's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Agreement External ID.
Metered Service Type	Required	The type of metered service. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Agreement Type. If the provided metered service point type has not been defined as a Metered Service Type in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Metered Service Type used in Customer Program Management / Customer Program Management Cloud Service.
External Contact ID	Optional	The ID of the contact associated with the metered service in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID.
External Account ID	Optional	An ID used to identify the account associated with the metered service record in the CIS application.
Start Date Time	Required	The date and time on which the metered service record started.
End Date Time	Optional	The date and time on which the metered service record ended or will end (if applicable).

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Division	Optional	The metered service's division. If the provided division has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Division used in Customer Program Management / Customer Program Management Cloud Service.
SA Status	Optional	The metered service's status. If the provided status has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to a Status defined in Customer Program Management / Customer Program Management Cloud Service.
Rate Schedule List	Optional	A concatenated list of rate schedules and effective dates associated with the metered service. **Each row in this list is composed of the following:** • **Rate Schedule** • **Effective Date** Each element in the row will be delimited by comma (,). Each row in the list will be delimited by semi-colon (;). **For example:** **ERES-1,2022-01-01ERES-2,2021-01-01**

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Metered SP List	Optional	A concatenated list of metered service points associated with the metered service. **Each row in this list is composed of the following:** • **External Metered SP Id (Required)** • **Start Date Time (Required)** • **End Date Time (Optional)** Each element in the row will be delimited by comma (,). Each row in the list will be delimited by semi-colon (;). **Example:** **6800401571,2022-12-13T14:30:00-05:00,1703304223,2022-12-13T14:30:00-05:00,**
Is Erased	Optional	A flag that indicates if the customer has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default) **Applicable only to Incremental Uploads** This should be set to "N" if Object Erasure is not supported in the CIS application.

Asset Management System Integration

The following section describes functionality provided for the integration with an asset management system, such as Oracle Utilities Work and Asset Management (OUWAM).

- Interfacing Service Calls
- Setting Up The System To Enable Asset Management System Integration

Interfacing Service Calls

Oracle Utilities Customer Care and Billing is able to record service calls for a particular service point in the system, as well as for an unknown service point, i.e. a fuzzy call. Service call information is sent to the asset management system that will process any work that may be required due to the service call.

Copyright © 2026, Oracle and/or its affiliates.

When recording a service call, the system creates a service call process flow and assigns it a service call communication type. The process flow type and service call communication type are determined from the action method with Action Method Role of **Service Call**. See Action Method for more information about setting up action methods. Service call communication type defines the rules and controls for creating service call communication. It also defines the service call communication business object.

The system is delivered with the following objects that are used to record a service call:

- Process Flow Type **C1-SERVICECALL**
- Service Call Communication Type business object **C1-ServiceCallCommTaskType**
- Service Call Communication business object **C1-ServiceCallCommunication**

Refer to Service Calls for more details.

Setting Up The System To Enable Asset Management System Integration

The following section describes how to enable the integration between Oracle Utilities Customer Care and Billing and your asset management system.

- External System Setup
- WAM Integration Master Configuration

External System Setup

An external system must be setup to integrate with Oracle Utilities Work and Asset Management (WAM).

For sending service call information to WAM, define message senders for the following outbound message types:

- **New Service Call Communication Request Outbound Message (C1-SVCCALNEW)**. This is used to send new service call information.
- **Update Service Call Communication Request Outbound Message (C1-SVCCALUPD)**. This is used to send service call comments and service call cancel request.

For retrieving service call information from WAM, define message senders for the following outbound message types:

- **Service Call Search (C1-SVCCLSRCH)**. This is used by the service call search panel to retrieve service calls from the external system.
- **Service Call Details (C1-SVCCALDTL)**. This is used in the service call details pop up window to retrieve details of a service call from external system.
- **Retrieve Work Documents (C1-RETWRKDOC)**. This is used in the service call details pop up window to retrieve work documents related to a service call.

Once the external system is defined, configure the WAM Integration Master Configuration so the system knows which external system and outbound message types to use.

WAM Integration Master Configuration

The integration with Oracle Utilities Work and Asset Management (WAM) requires the setup of master configuration data that controls the processing of service call information.

To maintain master configuration, open **Admin**, and then **General**, and then **Master Configuration**

Copyright © 2026, Oracle and/or its affiliates.

Set up the **CC&B WAM Integration** master configuration, which defines the external system and outbound message types to send and receive service call information. It also defines the URL of the WAM environment. This is used by the service call details pop-up window to render the service call hyperlink. The hyperlink is available if the user has access to the **Go To WAM (C1-GOTOWAM)** application service. Note that the login user to WAM should have access to the service call transaction. This authorization needs to be done in WAM.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems. See Business Flagsfor more information.

This section provides further information about this.

- Service Point Business Flags

Service Point Business Flags

Overview

This product has implemented business flags that represent situations that exist at a customer's service point that are shared across external applications; such as, meter data management, mobile work force management, and analytics applications. The situations that a business flag can represent ranges from critical knowledge that requires manual analysis for resolution to purely informational notifications.

This sharing of information allows users of each system to quickly understand the status of a service point as it relates to situations that users of the system would benefit from. For example, the analytics system may identify potential theft situations that should be investigated prior to releasing the next bill.

The subsequent sections describe business flag functionality that is specific to the service point business flag as implemented by this product.

See Undertstanding Business Flags in the *Oracle Utilities Framework Administration User Guide* for a detailed understanding of the components of business flags.

- Business Flags Can Require Analysis
- Business Flag Can Prevent Bills from Freezing
- A Field Activity Can Determine Business Flag Confidence
- Business Flags Can Create Alerts

Business Flags Can Require Analysis

For more serious situations a business flag can require manual analysis from a user. These types of business flags will generate a To Do when they are received from the external application. To resolve the To Do a user will investigate the service point based on the type of business flag present. Generally this investigation will result in the business flag being either confirmed or rejected. To reach the conclusion of whether the business flag should be

Copyright © 2026, Oracle and/or its affiliates.

confirmed or denied the user can be provided with a set of available actions that can be performed on the business flag.

See the C1-BFANL algorithm type for more information.

- Business Flag Available Actions
- Business Flag Adding Available Actions
- Making Allowed Actions Available

Business Flag Available Actions

Allowed actions are implemented as BPA scripts that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity** - This will initiate a field activity associated to the business flag's service point. The type of field activity will be selected by the user.
- **Create Case** - This will initiate a case associated to the business flag's service point. The type of case will be selected by the user.
- **Create Notification** - This will initiate communication with the customer for the business flag's service point. The type of communication will be determined by the notification type selected by the user.

Business Flag Adding Available Actions

To extend the actions that are available to the user for investigating a business flag the following steps can be taken:

1. A new BPA script should be developed that provides the functionality for your particular business use case
2. That BPA script will be added to the transactional business object for the business flag using the option type "Valid Action"
3. Edit the business flag type to include the newly created action in the "Allowed Actions" section of the business flag type

Making Allowed Actions Available

Allowed actions are only accessible on those business object statuses that have been configured to support them. To permit access to the available actions on a given status one must add a business object status option for the type "Execution of Valid Actions Permitted" with a value of "Y".

Business Flag Can Prevent Bills from Freezing

Some business flags, particularly those that require investigation, should place a hold on the billing process to prevent potentially incorrect bills from being issued to the customer. When certain types of business flags are present on a service point it indicates that there may be a problem with the reported usage that is underlying the bill and as such it may not be desirable to allow the billing process to complete until the investigation into that usage has been completed. For example, if the business flag indicated potential theft or abnormally high usage it may be preferable to delay issuing the bill until an investigation can be performed and the issue rejected or resolved.

Copyright © 2026, Oracle and/or its affiliates.

This functionality can be enabled through configuration of the Prevent Bill Segment Freeze Due to Business Flag algorithm.

See the Prevent Bill Segment Freeze Due to Business Flag (C1-PRVBSFBF) algorithm type for more detail.

A Field Activity Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will drive the resolution of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark – activation plug-in spot.

Pease refer to the Business Flag Confidence Update (C1-BSFLGCFUP) algorithm type for more detail.

Business Flags Can Create Alerts

Some business flags have a high enough importance that they should be highlighted to any user that is viewing data for the service point the business flag is related to. Whether a business flag should create an alert is controlled on the business flag type. Furthermore, the appropriate algorithm must be configured in the “Installation Options – Framework” “Algorithms” tab for the “Control Central Alert” system event.

The product delivers the algorithm type “Highlight Open Business Flags”

Pease refer to the Business Flag Confidence Update (C1-BSFLGCFUP) algorithm type for more detail.

Customer Engagement

Customer engagement integration allows information about communications sent from an external system such as Opower to be stored in the system as customer contacts. This information includes who the communication was for, what it was about, a reference to the communication content (content path), and a unique identifier from the external system (external reference ID). The account and person defines who the communication was for, while the communication product and event type defines what the communication was about. The content path allows the user to view the content of the communication. A single customer contact is created for each external reference ID.

Receiving Communication

For a customer contact to be created, a one-to-one mapping between the communication product/event type combination and a notification event type lookup value must be defined in the Communication Product Event Type Mapping (C1-CustEngageValueMapping) extendable lookup. The system is delivered with mappings for the Opower communication products and event types. Additionally, the following must also be defined for the notification event type lookup value:

- Notification Event Type

Copyright © 2026, Oracle and/or its affiliates.

- Notification Type
- Customer Contact Type with Contact Action set to 'Record Customer Engagement'.

> **Note**
>
> An error is raised if a Notification Event Type or Notification Type is not defined. If a Customer Contact Type is not defined, the communication is skipped.

The system receives communications in two ways:

- Customer Engagement (C1-CustomerEngagement) inbound web service
- On-demand retrieval of communications for an account

The inbound web service is the primary mechanism through which communication are received. It is expected to be invoked periodically to receive communications for one or more accounts.

To enable on-demand retrieval of communications for an account, set the **Enable On Demand Communication Query** parameter in the Customer Engagement Integration Configuration (C1-CustEngageIntegration) extendable lookup. When enabled, recent communications for an account are retrieved from the external system in real time when the Customer Activity History zone is loaded. The on-demand retrieval is limited to communications sent after the contact date/time of the most recent customer engagement customer contact, if one exists. Otherwise, all communications for the account are retrieved. The **On Demand Communication Query Interval (Minutes)** parameter in the same extendable lookup determines how soon after that contact date/time the on-demand retrieval can be performed again. Set this parameter to zero to perform the on-demand retrieval each time the zone loads. The external system and outbound message type used in this process are defined in the same extendable lookup.

Error Handling

If an error occurs while processing a communication, a Customer Engagement Error (C1-CustomerEngagementError) business object instance, or error record, is created to store the communication information for later remediation and reprocessing. Only one non-final error record can exist for each communication external ID. Error records can be viewed and maintained in the Inbound Sync Request portal. An error record is created in the Error state and remains there until it is reprocessed or discarded. Communication information in the error record is reprocessed the same way as information received through the inbound web service or on-demand account communication retrieval.

Viewing Communication Content

Communication content can be viewed using the **View Communication** action button in the **Customer Contact** portal. On click of the button, a real-time outbound message is sent to the external system to retrieve a pre-authenticated resource (PAR) link for the content path stored in the customer contact. The PAR link then opens in a new window to display the communication content. The validity of the PAR link is determined by the external system. The external system and outbound message type used in this process are defined in the Customer Engagement Integration Configuration (C1-CustEngageIntegration) extendable lookup.

Customer Profile Insights

Copyright © 2026, Oracle and/or its affiliates.

The following section describes how customer insights from external sources can be stored in Accounts' Customer Profiles.

Refer to Understanding Customer Profiles for more information on the Customer Profile maintenance object.

- Uploading Customer Insights

Uploading Customer Insights

There are certain types of customer insights that can be uploaded from an external system. For example, the system could receive flat files containing affordability information, indicating specific Accounts that may be in the low-to-moderate (LMI) income segment. This customer insight can be loaded into the Account's Customer Profile, using the Customer Profile Business Flag Upload (`C1-CPRUP`) batch process.

Refer to Understanding Business Flags for general information on how Business Flags are processed.

How the Customer Profile Upload Works

The Customer Profile Upload is a plugin-driven upload process that reads a flat file (e.g. a CSV file) and invokes the 'File Upload' algorithm that is plugged in on the Batch Control.

The base product provides a 'File Upload' algorithm for the purposes of the LMI/affordability use case: Add LMI Customer Profile Business Flag (`C1-CPRBUSFLG`). This algorithm maps the LMI indicator's external name - i.e., `lmi_selection_flag` (referenced in the input file) - to the Standard Name that is configured in the External Insight Standard Name (F1-BusinessFlagStandardName) lookup value, `C1-LMI`. This Standard Name value maps`lmi_selection_flg` as a Valid External Name.

The Standard Name determines the Business Flag Type, which in turn, determines the Business Flag object to create.

The 'Additional Processing' algorithm plugged in on the Business Flag Type is then invoked, to add or update the Account's Customer Profile. The base product provides the algorithm, Add/Update Customer Profile Attributes (`C1CPAUCPA`), which is meant to be plugged in for a specific Customer Profile Type (defined in the algorithm parameter). The base algorithm performs the following:

- Checks if the Account already has an active Customer Profile of the configured type.
- Creates the Customer Profile when one does not exist.
- Adds new attributes to (or updates existing attributes in) the Customer Profile, based on the Customer Profile Attribute Type definition. Existing attributes are updated based on the Occurrence setting:
  - If set to `Single`, the existing value is updated.
  - If set to `Single - Per Related Object`, the attribute that references the same related object (e.g., Service Agreement) is updated.
  - If set to `Multiple`, the new values are compared with the existing values. to determine what to add or delete.

Customer Profile creation and attribute changes are captured on the Customer Profile log, for audit purposes.

Copyright © 2026, Oracle and/or its affiliates.

Customer Profile Upload Validation and Error Handling

The Customer Profile Upload performs initial validation of the file record, including confirmation that the account ID is provided and valid. Detailed validation of Customer Profile and attribute information occurs during Customer Profile Business Flag BO and Customer Profile BO processing. If an error is encountered, the Business Flag is moved to the Validation Error state and an exception log entry is created. Users can review, make corrections and retry processing. The upload record skips the record in error and proceeds to process the next records in the file.

Refer to the `C1-CustomerProfBusinessFlag` and `C1-CustomerProfile` business objects in the application, for more information on the Business Flag and Customer Profile schemas and lifecyle processing.

Setting Up the System for Customer Profile Uploads

The following are the steps to enable Customer Profile Batch Upload processing:

- Set up a Customer Profile Attribute Type for each unique attribute to capture in the Customer Profile. For example, with the LMI use case, there could be two attribute types - one for the LMI indicator (true/false switch) and another for the LMI Selection Reason (extendable lookup). Refer to Setting Up Customer Profile Attribute Types for more information.
- Set up the Customer Profile Type and link the new Customer Profile Attribute Types to it. Refer to Setting Up Customer Profile Types for more information.
- Add an Algorithm for the Add/Update Customer Profile Attributes (`C1CPAUCPA`) Algorithm Type and set its algorithm parameter to the new Customer Profile Type.
- Update the External Insight Standard Name (`F1-BusinessFlagStandardName`) Extendable Lookup, with the applicable Standard Name (lookup value) and its associated Valid External Name(s). For the LMI use case, the base product provides the `C1-LMI` lookup value. It just needs to be updated with any additional implementation-specific Valid External Name(s) that differ the `lmi_selection_flg` name that is already included.
- Set up a Customer Profile Business Flag Type using the Customer Profile Business Flag Type (`C1-CustomerProfBusFlagType`) business object:
  - Set the Standard Name. For example, in the LMI use case, set the Standard Name to the `C1-LMI` extendable lookup value or an implementation-specific Valid External Name, if any.
  - Configure attribute relationships, if any. This applies to cases where multiple attribute types are received and some attribute types provide more information related to the key attribute type. For example, with the LMI use case, the LMI indicator is defined with LMI Selection Reason as a related attribute. The LMI Selection Reason's external name (in the input file) is mapped to a corresponding Customer Profile Attribute Type.
  - Configure the 'Additional Processing' Algorithm with the new algorithm instance of Add/Update Customer Profile Attributes (`C1CPAUCPA`) algorithm type, created above.
- Set up other implementation-specific configuration. For example, for LMI Selection Reasons, add the valid values for the LMI Selection Reason extendable lookup, `C1-LMISelectionReasonLookup`.
- Set up Object Storage access. Refer to External File Storage for more information.

Copyright © 2026, Oracle and/or its affiliates.

Customer Relationship Management Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with customer relationship management applications such as Oracle Social Relationship Management (SRM).

The following sections describe this functionality.

- About Customer Relationship Requests
- Setting Up Customer Relationship Request Configuration
- Maintaining Customer Relationship Requests

About Customer Relationship Requests

A customer relationship request is used to process requests that are initiated from an external customer relationship management system.

The following sections highlight customer relationship request functionality.

- Social Relationship Management Requests
- Creating Customer Relationship Requests

Social Relationship Management Requests

Oracle Social Relationship Management (SRM) is an example of an external system that can initiate customer relationship requests.

Social network posts cover a vast range of topics, a number of which could be related to the users' concerns with their utility service. For example:

- A Facebook user could post on a community page about a power outage in a specific area.
- A Twitter user might post about specific problems with their utility service (*e.g.*, high bill complaints).

Social conversations of this nature can be monitored and managed via Oracle SRM. Oracle SRM's Engage module allows its users to see all social conversations, identify customer-specific issues and route the messages to the appropriate systems/channels.

Requests from social relationship management systems typically include:

- Information about the original posting on the social network/community (*e.g.*, author's identifier, link to the post, etc.).
- Information about the posting within the social relationship management system (*e.g.*, the user that sent the request to the utility, link to the post, etc.).
- Additional details that will help with processing/resolution (*e.g.*, customer/account numbers, address, bill IDs, etc.).

Creating Customer Relationship Requests

Most customer relationship requests will be initiated from an external system.

The base product provides an Add Customer Relationship Request (C1–AddCustRR) inbound web service that can be used in a customer relationship management integration to create customer relationship request records. This inbound web service invokes a processing script

Copyright © 2026, Oracle and/or its affiliates.

that is configured in Customer Relationship Integration master configuration. The base product supplies an example of this processing script. It maps the inbound service's input data into the customer relationship request record. Refer to the C1-CreCustRR service script system data for processing details.

Setting Up Customer Relationship Request Configuration

The following topics highlight the general configuration steps required to use customer relationship request functionality and to integrate with a customer relationship management application such as Oracle Social Relationship Management (SRM).

- Customer Relationship Management Integration Configuration
- Defining Customer Relationship Request Types

Customer Relationship Management Integration Configuration

The integration with a customer relationship management application such as Oracle Social Relationship Management (SRM) requires the setup of master configuration data that controls the processing of your customer relationship requests.

To set up customer relationship integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Customer Relationship Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Defining Customer Relationship Request Types

A customer relationship request type defines properties that control how a customer relationship request is processed.

Refer to About Customer Relationship Requests for an overview of customer relationship request functionality.

To maintain customer relationship request types, open **Admin**, and then **Integration**, and then **Customer Relationship Request Type**, and then **Search**.

This is a standard All-In-One Portal.

The information captured on the customer relationship request type depends on the business objects supported by your implementation. Refer to the embedded help text for more information.

Maintaining Customer Relationship Requests

This section describes the functionality supported for viewing and maintaining customer relationship requests.

Refer to About Customer Relationship Requests for an overview of customer relationship request functionality.

Navigate using **Menu**, and then **Integration**, and then **Customer Relationship Request**, and then **Search**. You are brought to a query portal with options for searching for customer relationship requests.

Once a customer relationship request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

Copyright © 2026, Oracle and/or its affiliates.

The **Customer Relationship Request** zone provides basic information about a customer relationship request. Refer to the embedded help for more information.

The **Notes** zone allows users to capture additional notes to the customer relationship request.

RightNow Knowledge Integration

Oracle Utilities Customer Care and Billing provides an integration with Oracle RightNow Knowledge that allows users to view frequently asked questions about business processes/ functions that relate to the portal or page that they are currently viewing and/or working on.

The following sections describe this functionality.

- Displaying Frequently Asked Questions
- RightNow Knowledge Integration Configuration

Displaying Frequently Asked Questions

The Oracle RightNow Knowledge application can be used to develop content for frequently asked questions about business processes. It also functions within the Oracle Customer Care and Billing application. The RightNow KnowledgeSyndication widget defines the interface for the retrieval of this content.

The Oracle Customer Care and Billing application provides a **Frequently Asked Questions** sidebar zone that uses the RightNow KnowledgeSyndication widget to retrieve content from a RightNow Knowledge base instance. This zone is context-sensitive.

Configuration data controls how information is displayed in the **Frequently Asked Questions** sidebar zone. Refer to RightNow Knowledge Integration Configuration for more details.

RightNow Knowledge Integration Configuration

The integration with Oracle RightNow Knowledge requires the setup of master configuration data that controls how content from the RightNow Knowledge base is retrieved and presented on the **Frequently Asked Questions** sidebar zone. This configuration includes the following settings:

- The URL of the RightNow Knowledge base instance.
- The list of portals and pages for which the **Frequently Asked Questions** sidebar zone will display.
- Settings for each portal / page:
  - Search terms to pass to the RightNow KnowledgeSyndication widget. The base product supplies a number of common search term types. Implementation-specific search term types can be added.
  - Number of results/answers to display in the **Frequently Asked Questions** sidebar zone.

To set up the RightNow Knowledge Integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration.** You are brought to an all-in-one portal with options to add/edit the RightNow Knowledge Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Copyright © 2026, Oracle and/or its affiliates.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts that direct the user to the appropriate target portal or page for a specific entity such as an account or service point. Refer to Creating Application Links in External Applications in the *Application Framework Administrative User Guide* for more information about creating links.

Note: When creating application links, the use of the following parameters will help speed up launching the target page

- **initNav=false**: skips launching the default home page for the user
- **minSidebar=true** minimizes the sidebar for the user

Go to Portal Script

The Framework provides a generic script (F1-GoToPrtl) that can be used to navigate to the maintenance portal for a specified maintenance object and entity. Refer to Navigating to a Given Record's Maintenance Portal in the *Application Framework Administrative User Guide* for more information about using this script.

Go To CCB Script

Oracle Utilities Customer Care and Billing includes the Go To CCB script (C1-GoToCCB) that can be used to navigate directly to a specific page on Control Central. This script uses the following syntax:

```
script=C1-GoToCCB&FLAG=<FLAG_VALUE>&PKVALUE1=<ID>
```

Where:

- **<FLAG_VALUE>**: A value from the C1_TARGET_PORTAL_FLG lookup that specifies which Control Central page to open.
- **<ID>**: The primary key value for the entity (such as a Account, Person, or Premise) you wish to view.

Examples:

Script	Flag Value	ID	Example
C1-GoToCCB	FLAG=C1CC (Control Central Account)	Account ID	script=C1-GoToCCB&FLAG=C1CC&PKVALUE1={your Account ID}
C1-GoToCCB	FLAG=C1CP (Control Central Person)	Person ID	script=C1-GoToCCB&FLAG=C1CP&PKVALUE1={your Person ID}
C1-GoToCCB	FLAG=C1CR (Control Central Premise)	Premise ID	script=C1-GoToCCB&FLAG=C1CR&PKVALUE1={your Premise ID}

Copyright © 2026, Oracle and/or its affiliates.

Full URL Example:

```
https://<ENV_BASE_URL>/ouaf/cis.jsp/?minSidebar=true&initNav=false&script=C1-GoToCCB&FLAG=C1CC&PKVALUE1={your Account ID}
```

Customer Care and Billing Control Table Setup Sequence

The topics in this section describe the order in which the control tables should be set up.

- Core Control Table Setup Sequence
- Cross-Reference To The Remaining Chapters
- Open-Item Accounting Table Setup Sequence
- Fund Accounting Table Setup Sequence
- Payment Event Distribution Table Setup Sequence
- Loans Table Setup Sequence
- Quotes Table Setup Sequence
- Non-Billed Budget Table Setup Sequence
- Appointments Table Setup Sequence
- Scripting Table Setup Sequence
- Reports Setup Sequence
- External Messages Setup
- Case Management Setup Sequence
- Workforce Management Setup Sequence
- Umbrella Agreement Management Setup Sequence
- Outage Management Setup Sequence
- Prepaid Metering Setup Sequence
- Batch Scheduler Setup Sequence
- Zone Set Up
- To Do Options Setup

Core Control Table Setup Sequence

To implement the system, you must set up your organization's business rules in "control tables". Setting up these tables is time-consuming because we allow you to tailor many aspects of the system to meet your organization's requirements. We strongly recommend that you take the time to document how you plan to set up all of these tables before you use the following roadmap to enter the core control data. Time spent understanding the interrelationships between this data will reap the rewards of a clean system that meets your current and long term needs.

Copyright © 2026, Oracle and/or its affiliates.

While we describe the transactions and options in more detail in other sections of this manual, use the following chart (and the remaining sections of this chapter) as your roadmap. Here we list the order in which you perform tasks and the pages you'll use to set up your system. The order is important because some information must exist before other information can be defined (i.e., many dependencies exist).

> **Note**
>
> **Auto setup.** The Auto Setup column in the following table contains suggestions to save you time. It also indicates if a control table contains information when the system is installed.

> **Note**
>
> **You don't have to set up every control table.** You need only set up those control tables that govern functions that are applicable to your organization.

Function	Menu	Auto Setup
Global Context		
Algorithm	Admin, Algorithm. You will need to set up an algorithm that populates global context values. The global context is used by various zones in the system to display relevant data. This algorithm is plugged-in on the installation record.	
Accounting Environment		
Country & State	Admin, Country	
Currency Codes	Admin, Currency Code	USD is automatically populated
Accounting Calendar	Admin, Accounting Calendar	
GL Division	Admin, General Ledger Division	
Security Environment		
Application Service	Admin, Application Service	All base package transactions are automatically populated
Security Type	Admin, Security Type	

Copyright © 2026, Oracle and/or its affiliates.

User Group	Admin, User Group Note, you won't be able to set up users at this point	One user group, ALL_SERVICES, is automatically setup. It references all other application services and a single user called SYSUSER.
Language	Admin, Language	ENG is automatically populated
Display Profile	Admin, Display Profile	Two display profiles are automatically setup: NORTHAM displays currencies and dates in a classic American format; EURO displays information in a classic European format
Data Access Role	Admin, Data Access Role	
Access Group	Admin, Access Group	

> **Note**
>
> The SYSUSER used is provided for use with on-premises implementations. It is disabled by default in cloud service implementations.

Copyright © 2026, Oracle and/or its affiliates.

User	Admin, User	SYSUSER is automatically set up. Note that you may import your users (and user groups) from an external source.
Return to User Group	You must return to your user groups and define all of their users	
Customer Class Environment		
Customer Class	Admin, Customer Class. At this point, you'll only be able to set up your customer class codes. You will return to these customer classes throughout the setup process to populate additional information.	
Financial Transaction Environment		
Work Calendar	Admin, Work Calendar	
CIS Division	Admin, CIS Division	
Revenue Class	Admin Revenue Class	
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs a distribution code's corresponding GL account when it is interfaced to the general ledger	
Distribution Code	Admin, Distribution Code	
Bank & Bank Accounts	Admin, Bank	
Billable Charge Template	Admin, Billable Charge Template. Note, if you want the system to default service quantities onto billable charges created using this template, you must setup the appropriate unit of measure code, time-of-use code and/or service quantity identifier.	
Billable Charge Upload Line Type	Admin, Billable Charge Line Type	
Algorithm	Admin, Algorithm. You will need to set up several algorithms. These algorithms: 1) retrieve a bill segment's consumption, 2) calculate a bill segment's bill lines, 3) construct a bill segment's financial transaction, 4) cancel previously estimated bill segments	
Bill Segment Type	Admin, Bill Segment Type	

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Bill Segment information that is displayed throughout the system for a specific Bill Segment Type. This algorithm is plugged-in on the Bill Segment Type.
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs a payment segment's financial transaction
Payment Segment Type	Admin, Payment Segment Type
Algorithm	Admin, Algorithm. You will need to set up the algorithm that constructs an adjustment's financial transaction
Algorithm	Admin, Algorithm. Several plug-in spots are available to perform additional logic when processing adjustments. For example, if you have the system calculate adjustments, you must set up an adjustment generation algorithm. Refer to Adjustment Type for other available plug-in spots that may be used by your implementation.
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system for a specific Adjustment Type. This algorithm is plugged-in on the Adjustment Type.
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Adjustment Type	Admin, Adjustment Type
Adjustment Type Profile	Admin, Adjustment Type Profile

Copyright © 2026, Oracle and/or its affiliates.

Approval Profile	Admin, Approval Profile. Note, an approval profile references a To Do type and one or more To Do Roles; these must be set up before you can set up the approval profile. After the approval profile(s) are set up, they must be referenced on the adjustment types that they govern.
Cancel Reason - Bill	Admin, Bill Cancel Reason
Cancel Reason - Payment	Admin, Payment Cancel Reason
Cancel Reason - Adjustment	Admin, Adjustment Cancel Reason
Tender Type	Admin, Tender Type
Tender Source	Admin, Tender Source
A/P Request Type	Admin, A/P Request Type
Issuing Center	Admin, Issuing Center. You will need to set up issuing centers if your organization assigns document numbers to bills.
Installation	Admin, Installation Options - Framework and Admin, Installation Options. Many fields on the installation record impact the financial transaction environment. Refer to the description of the Billing and Financial Transaction pages and the Messages tab in the Framework page for more information.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that distributes payments.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that handles overpayment situations.
Algorithm	Admin, Algorithm. You may need to set up an algorithm if specific customers can have individual bill due dates.
Algorithm	Admin, Algorithm. You may need to set up an algorithm if you want the system to delete bills that contain only information about historical payments.

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. You may need to set up an algorithm if you want the system to levy a non-sufficient funds charge if a payment is canceled due to non-sufficient funds.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the bill information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the payment information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that defaults the amount when a payment is manually added. This algorithm also calculates the amount of an automatic payment for a bill for an account with an active auto pay option. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. Refer to Customer Class for other available plug-in spots that may be used by your implementation to perform additional logic when processing payments and bills.
Return to Customer Class	Admin, Customer Class. You will need to plug-in the algorithms defined above on your customer classes.
Budget Environment	
Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: How To Calculated The Recommended Budget Amount, How To Periodically True Up A Customer's Budget Amount, The Circumstances When The System Should Highlight A Customer As Having An Anomalous Budget.
Budget Plan	Admin, Budget Plan

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. Budget eligibility is set at the SA type level. You will need to set up an override budget eligibility algorithm if some service agreements for an SA type are not eligible for budget based on certain conditions.
Customer Environment	
Account Management Group	Admin, Account Management Group. Note, you will probably have to set up To Do Type and To Do Roles before you can setup account management groups. Refer to Assigning A To Do Role for more information on how account management groups may be used to define an entry's role.
Account Relationship	Admin, Account Relationship Type
Alert Type	Admin, Alert Type
Bill Message	Admin, Bill Message
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your bill image software.
Bill Route Type	Admin, Bill Route Type
Contract Quantity Type	Admin, Contract Quantity Type
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a letter in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your letter image software.
Letter Template	Admin, Letter Template
Customer Contact Class	Admin, Customer Contact Class
Customer Contact Type	Admin, Customer Contact Type

Copyright © 2026, Oracle and/or its affiliates.

Conservation Programs	Admin, Conservation Program. You will need to set up conservation programs if your organization provides rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy.
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if person ID's are in a predefined format.
Person Identifier Type	Admin, Person Identifier Type
SICs	Admin, SIC Code
Tax Exempt Type	Admin, Tax Exempt Type
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if phone numbers are in a predefined format.
Phone Type	Admin, Phone Type.
Person Relationship Type	Admin, Person Relationship Type.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the person information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You will need to set up an algorithm to validate a person's name. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You can override the system's standard account information string by setting up an algorithm that produces this string of information. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a letter in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record.

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record.
Installation	Admin, Installation Options. Many fields on the installation record impact the Customer Environment. Refer to the description of the Main, Person, and Account tabs for more information.
Statements	
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your statement image software.
Statement Route Type	Admin, Statement Route Type
Statement Cycle	Admin, Statement Cycle
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record.
Automatic Payment (EFT) Environment	
Algorithm	Admin, Algorithm. You will need to set up an algorithm to create automatic payments. This algorithm is plugged-in on the installation record.

Copyright © 2026, Oracle and/or its affiliates.

Tender Source	Admin, Tender Source Note: earlier, you created tender sources for the remittance processor and your cash drawers. At this point, you'll need to add at least one tender source for automatic payments. Why? Because automatic payments get linked to a tender control (which, in turn, gets linked to a tender source) when they are interfaced out of the system.
Algorithm	Admin, Algorithm. You will need to set up the appropriate automatic payment date calculation algorithm to populate the extract, GL interface and payment dates on automatic payments.
Auto Pay Route Type	Admin, Auto Pay Route Type
Tender Type	Admin, Tender Type Note: earlier, you created tender types for things like cash, checks, etc. At this point, you'll need to add a tender type for each type of automatic payments (e.g., direct debt, credit card, etc.).
Work Calendar	Admin, Work Calendar. You need only set up additional work calendars if the auto pay sources (i.e., the financial institutions) have different working days than does your organization
Algorithm	Admin, Algorithm. If you need to validate the customer's bank account or credit card number, you will need to set up the appropriate validation algorithms.
Auto Pay Source Type	Admin, Auto Pay Source Type
Algorithm	Admin, Algorithm. You may need to set up an algorithm if your customers can define a maximum withdrawal limit on their autopay options.
Return to Customer Class	Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class.
Deposit Environment	

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: The Definition Of A Good Customer, When To Refund A Deposit To A Customer, When To Recommend An Additional Deposit, How / When To Calculate Interest, How To Generate The Recommended Deposit Amount.
Deposit Class	Admin, Deposit Class
Non Cash Deposit Type	Admin, Non Cash Deposit Type
Field Work Environment - Phase 1	
Representative	Admin, Representative
Operation Area	Admin, Operation Area
Field Service Class	Admin, Field Service Class
Algorithm	Admin, Algorithm. You will need to set up the algorithms that execute special functions (if any) when a field activity is completed
Field Activity Type & Steps	Admin, Field Activity Type
Field Activity & Field Order Cancellation Reason	Admin, Fieldwork Cancel Reason
Field Activity & Field Order Reschedule Reason	Admin, Fieldwork Reschedule Reason
Algorithm	Admin, Algorithm. If you need anything special to happen when a remark is associated with a field activity (e.g., generate a To Do), you will need to set up an algorithm to do whatever you need to do and associate it with the respective Field Activity Remark.
Field Activity Remarks	Admin, Field Activity Remark
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a field order in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your field order image software.
Dispatch Group	Admin, Dispatch Group
Disconnect Location	Admin, Disconnect Location
Field Activity Type Profiles	Admin, Field Activity Type Profile

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Field activities for Start/Stop will only be created if the SA Type linked to the service point has a SASP field work creation algorithm. Refer to the SA Type section below.
Algorithm	Admin, Algorithm. If you have software that's capable of reconstructing an image of a field order in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record.

Credit & Collections Environment (if you collect on overdue bills (as opposed to overdue debt), you will NOT set up these tables; refer to Overdue Processing - Set Up Tasks for the list of control tables required to collect on overdue bills)

Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard collection events.
Collection Event Type	Admin, Collection Event Type
Algorithm	Admin, Algorithm. You may need to set up a collection process cancellation algorithm if your organization allows individual service agreements to be removed from a collection process if they are paid (rather than performing cancellation based on all SAs in a debt class).
Collection Process Template	Admin, Collection Process Template
Collection Class	Admin, Collection Class
Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: Collection process cancellation criteria, Severance process cancellation criteria, and Override arrears due to pay plans.
Debt Class	Admin, Debt Class
Write Off Debt Class	Admin, Write Off Debt Class
Algorithm	Admin, Algorithm. You will need to set up Collection Condition algorithms.
Collection Class Control	Admin, Collection Class Control
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard severance events.

Copyright © 2026, Oracle and/or its affiliates.

Severance Event Type	Admin, Severance Event Type
Algorithm	Admin, Algorithm. You may need to set up a severance process cancellation algorithm if your organization allows a severance process to be canceled when the related service agreement is paid (rather than performing cancellation based on all SAs in a debt class).
Severance Process Template	Admin, Severance Process Template
Algorithm	Admin, Algorithm. You will need to set up several algorithms at this time: How to refer debt to a collection agency, How to transfer debt to another active service agreement, How to write down small amounts of debt, and How to refund credit balances to a customer.
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have non-standard write-off events.
Write Off Event Type	Admin, Write Off Event Type (Note, you'll have to wait until you have defined your SA Types before you can set up the Write Off Events because SA Type is a necessary parameter to write off debt).
Write Off Process Template	Admin, Write Off Process Template
Write Off Control	Admin, Write Off Control
Collection Agency	Admin, Collection Agency. Note, each collection agency references a person therefore you must set up a person for each agency before you can enter collection agency information.
Algorithm	Admin, Algorithm. You may need to set up algorithms if you have special logic that should be executed when a pay plan is canceled.
Pay Plan Type	Admin, Pay Plan Type
Payment Method	Admin, Payment Method
Third Party Payor	Admin, Third Party Payor. Note, you must create an account before you can create a third party payor.

Copyright © 2026, Oracle and/or its affiliates.

Installation	Admin, Installation. Several fields on the installation record impact the Credit & Collections Environment.	
Algorithm	Admin, Algorithm. You will need to setup an algorithm that's called when a user write-off debt real time.	
Return to Customer Class	Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class.	
Services & Characteristics		
Service Type	Admin, Service Type	
Algorithm	Admin, Algorithm. If you have ad hoc characteristic types, you may need to set up the algorithms that control how they are validated	
Foreign Key Reference	Admin, FK Reference. If you have foreign key characteristic types, you may need to set up foreign key references to control how the user selects the characteristic values (and how the foreign key values are validated).	All base package FK references are automatically populated
Characteristic Type & Values	Admin, Characteristic Type	
Device Testing Environment		
Algorithm	Admin, Algorithm. If you need to validate a specific device test component result, you will need to set up the appropriate validation algorithms.	
Device Test Component Type	Admin, Device Test Component Type	
Algorithm	Admin, Algorithm. If you need the system to determine if a device test's results are considered "passing", you will need to set up an algorithm to perform this processing.	
Device Test Type	Admin, Device Test Type	
Algorithm	Admin, Algorithm. If you have the system select meters / items for testing, you will need to set up an algorithm to perform this processing.	
Meter & Item Environment		

Copyright © 2026, Oracle and/or its affiliates.

Meter Type	Admin, Meter Type [Note - you won't be able to define the collection of valid Equipment Types and Item Types until after you define the Item Types. You also will not be able to define the collection of Meter Configuration Types until after you define the Meter Configuration Types.]
Meter ID Type	Admin, Meter ID Type
Manufacturer / Model	Admin, Manufacturer
Unit of Measure	Admin, Unit of Measure
Time of Use	Admin, Time of Use
Meter Configuration Type	Admin, Meter Configuration Type
Retirement Reason	Admin, Retire Reason
Protocol	Admin, Protocol
Read Out Type	Admin, Read Out Type
Algorithm	Admin, Algorithm. You will need to set up an algorithm to generate estimated consumption.
Trend Area	Admin, Trend Area
Trend Class	Admin, Trend Class
High / Low	Admin, High Low Factor
Algorithm	Admin, Algorithm. You will need to set up an algorithm that calculates the high / low limits used on meter reads. This algorithm is plugged-in on the installation record.
Meter Location	Admin, Meter Location
Meter Read Instructions	Admin, Meter Read Instruction
Algorithm	Admin, Algorithm. If you need anything special to happen when a meter read with a given remark is uploaded (e.g., generate a field activity), you will need to set up an algorithm to do whatever you need to do and associate it with the respective Meter Read Remark.
Meter Reader Remarks	Admin, Meter Reader Remark
Meter Read Source	Admin, Meter Read Source
Meter Read Warning	Admin, Meter Read Warning
Item Type	Admin, Item Type

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. You will need to set up an algorithm to format the standard meter info that appears throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You will need to set up an algorithm to format the standard item info that appears throughout the system. This algorithm is plugged-in on the installation record.
Premise & Service Point Environment	
Premise Type	Admin, Premise Type
Algorithm	Admin, Algorithm. You will need to set up an algorithm to format the standard premise info that appears throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You will need to set up an algorithm that formats the service point information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You may need to set up the algorithms that determine if geographic ID's are in a predefined format.
Geographic Type	Admin, Geographic Type
Service Point Type	Admin, SP Type. [Note - you won't be able to define the SP Type's SA Types until after you define the SA Types or the FA Type Profiles until after you define the Field Activity Type Profiles.]
Facility Level 1 to 2	Admin, Facility Level 1 to 2
Facility Level 2 to 3	Admin, Facility Level 2 to 3

Service Schedule	Admin, Service Schedule	
Rate Environment		
Frequency	Admin, Frequency	
Service Quantity Identifier	Admin, Service Quantity Identifier	
Algorithm Type	Admin, Algorithm Type. If you create new pre-processing calculation rules, you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the calculation rule).	All base package algorithm types are automatically populated
Bill Factor	Main, Rates, Bill Factor	
Algorithm Type	Admin, Algorithm Type. If you create new Register Rules you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the register rule).	All base package algorithm types are automatically populated
Rate	Main, Rates, Rate Schedule	
Calculation Group	Main, Rates, Calculation Group	
Algorithm	Admin, Algorithm. If you use algorithms to dynamically change step boundaries, calculate prices, or implement calculation rule eligibility rules, you must set up these algorithms.	
Calculation Rule	Main, Rates, Calculation Rule	
Bill Factor Value	Main, Rates, Bill Factor Values	
Bill Factor Interval Values	Main, Rates, BF Interval Values	
Item Type SQ Estimate	Admin, Item Type SQ Estimate	
Degree Day	Admin, Degree Days	
Late Payment Environment		
Algorithm	Admin, Algorithm. You will need to set up the algorithm that determine if customers in a customer class are eligible for late payment charges	
Algorithm	Admin, Algorithm. You will need to set up the algorithm that levies late payment charges for customers in a customer class	
Return to Customer Class	Admin, Customer Class. You will need to plug-in the late payment charge algorithms set up above.	
SA Configuration		

Copyright © 2026, Oracle and/or its affiliates.

Algorithm	Admin, Algorithm. You will need to set up the algorithms that determine: • How to calculate the late payment charge amount for service agreements of a given type • Special criteria to be tested before a service agreement is severed. • How to create field activities for service agreements of a given type. • Special processing that should take place prior to the completion of a bill that references service agreements of a given type. • Special processing that should take place during completion of a bill that references service agreements of a given type. • Special processing that should take place when service agreements of a given type are created. • Special processing that should take place when a financial transaction is frozen for service agreements of a given type.
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system. This algorithm is plugged-in on the installation record.
Algorithm	Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system for a specific SA Type. This algorithm is plugged-in on the SA Type.
Algorithm	Admin, Algorithm. If you want a Control Central alert to highlight when the current account has any stopped service agreement(s), you will need to set up the algorithm that does this. This algorithm is plugged-in on the installation record.
Service Agreement Type	Admin, SA Type

Copyright © 2026, Oracle and/or its affiliates.

Terms and Conditions	Admin, Terms and Conditions
SA Type Start Options	Admin, SA Type Start Option
Update SP Types with initial SA types and with FA Type Profiles	Admin, SP Type
SA Relationships	
SA Relationship Type	Admin, SA Relationship Type
Service Provider	Admin, Service Provider. Note, you must create a person before you can create a service provider. If you have financial relationships (you bill for them or they bill for you), you must also create an account and a financial settlement service agreement before you can create the service provider.
SA Type / SA Relationship	Admin, SA Type SA Relationship Type
Notification and Workflow	
Workflow Event Type	Admin, Workflow Event Type
Workflow Process Template	Admin, Workflow Process Template

Service Credit Membership	
Algorithm	Admin, Algorithm. You may need to set up algorithms for the service credit membership type and service credit event type to control behavior for the service credit membership and its events.
Credit Unit	Admin, Credit Unit. If your service credits record non-monetary units.
Service Credit Membership Type	Admin, Service Credit Membership Type
Service Credit Event Type	Admin, Service Credit Event Type
Membership Inactive Reasons	Admin, SC Membership Inactive Reason
Wrap Up	
Algorithm	Admin, Algorithm. You will need to set up the algorithms that determine: #x2022; Special alerts on Control Central (assuming you have special alerts)
Installation Options	Admin, Installation Options - Framework and Admin, Installation Options. At this point, it's a good idea to double-check everything on the installation record.
Postal Default	Admin, Postal Code Default

If you have cash drawers you will also need to set up the following information:

- Create a person / account to which you will link your over / under service agreement. Refer How To Get An Unbalanced Tender Control In Balance (Fixing Over/Under) for more information.
- Create a service agreement to which your over/under payments will be linked. This service agreement will reference your over / under SA type. Refer to Over / Under Cash Drawer Segmentation for more information.

If you upload payments from an external source (e.g., a remittance processor or lock box), you must set up the following information:

- Create a person and account to which the system will link payments with invalid account. Refer to Phase 3 - Create Payment Events, Tenders, Payments and Payment Segments for information about the process that books invalid payments to this account. Refer to How To Transfer A Payment From One Account To Another for how a user transfers the payment from the invalid account to the correct account (once known).
- Create a service agreement for this account. This service agreement will reference your payment suspense SA type. The system needs this service agreement so that it can distribute the invalid account's payment (and this is necessary so that cash will reflect the payment). Refer to Payment Upload Error Segmentation for more information.

Copyright © 2026, Oracle and/or its affiliates.

- Update the tender source associated with the respective source of payments to indicate the service agreement created in the previous step should be used for payments with invalid accounts. Refer to Setting Up Tender Sources for more information.
- Because the payment upload process simply books payments that reference invalid accounts to the account associated with the suspense service agreement on the payment's tender source, this account should belong to a customer class with the appropriate payment distribution algorithms. This may entail creating a new customer class that will only be used on suspense accounts. This customer class would need the following algorithms:
- We'd recommend using a simple payment distribution algorithm like PYDIST-PPRTY (distribute payment based on SA type's payment priority).
- We'd recommend using an overpayment distribution algorithm like OVRPY-PPRTY (distribute overpayment to highest priority SA type).

The remaining sections describe additional control tables that must be set up for specific functional areas.

Cross-Reference To The Remaining Chapters

The table in the previous section describes the order in which you should enter your control tables. These tables are described at length in the following chapters.

- Refer to Defining General Options Addendum and Defining General Framework Options for a discussion of the control tables associated with general functionality (e.g., country codes, state codes, etc.).
- Refer to Defining Financial Transaction Options for a discussion of the tables affecting your financial transactions (e.g., bill segment types, payment segment types, etc.)
- Refer to Defining Customer Options for a discussion of the control tables affecting persons, accounts and service agreements.
- Refer to Defining Fieldwork Options for a discussion of the control tables affecting fieldwork.
- Refer to Defining Credit and Collections Options for a discussion of the control tables affecting your collection activities.
- Refer to Defining Meter and Item Options for a discussion of the control tables affecting your meters and items.
- Refer to Defining Cycles and Schedules for a discussion of the control tables affecting your cyclical processes.
- Refer to Rates for a discussion of the control tables affecting your rates.
- Refer to Defining SA Type Options for a discussion of the control tables affecting your service agreement types.
- Refer to Defining Background Process for a discussion of the control tables affecting your background processes.
- Refer to Defining Algorithms for a discussion of the control tables affecting the algorithms referenced on many control tables.
- Refer to Defining SA Relationships for a discussion of the control tables affecting the relationships between service providers.

Copyright © 2026, Oracle and/or its affiliates.

- Refer to Defining Workflow and Notification Options for a discussion of the control tables affecting the processing of notifications to and from service providers.
- Refer to Defining Interval Billing Options for a discussion of the control tables affecting the interval billing options for your customers.
- Refer to Statements for a discussion of the tables affecting the statement setup options for your customers.
- Refer to Defining Service Credit Options for a discussion of the tables affecting the service credit membership setup options for your customers.

Open-Item Accounting Table Setup Sequence

Open-item accounting tables need only be set up if your organization practices Open Item Accounting. Refer to Setting Up The System To Enable Open Item Accounting for a description of the tables that must be set up to enable this functionality.

Fund Accounting Table Setup Sequence

Fund accounting tables need only be set up if your organization practices Fund Accounting. Refer to Setting Up The System To Enable Fund Accounting for a description of the tables that must be set up to enable this functionality.

Payment Event Distribution Table Setup Sequence

Payment event distribution tables need only be set up if your organization opted to use the distribution rules method to create payment events. Refer to Setting Up The System To Use Distribution Rules for a description of the tables that must be set up to enable this functionality.

Loans Table Setup Sequence

Loans need only be set up if your organization offers loans to your customers. Refer to Setting Up The System To Enable Loans for a description of the tables that must be set up to enable this functionality.

Quotes Table Setup Sequence

Quotes need only be set up if your organization sends quotes to customers or prospects. Refer to Defining Quotation Options for a description of the tables that must be set up to enable this functionality.

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budget Table Setup Sequence

Non-Billed Budgets need only be set up if your organization allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Refer to Setting Up The System To Enable Non-Billed Budgets for a description of the tables that must be set up to enable this functionality.

Appointments Table Setup Sequence

Appointments need only be set up if your organization allows your customers to make appointments for field activities. Refer to Enabling Appointments for a description of the tables that must be set up to enable this functionality.

Scripting Table Setup Sequence

Scripts need only be set up if your organization opts to create scripts to step your users through business processes. Refer to Defining Script Options for information about scripting and the tables that must be set up to enable this functionality.

Reports Setup Sequence

In order to use the reporting tool, you will need to set up reporting options. Refer to Configuring The System To Enable Reports for more information.

External Messages Setup

To configure the system to communicate with an external system, refer to to External Messages.

Case Management Setup Sequence

Case management options need only be set up if your organization uses cases to manage issues. Refer to Setting Up Case Types for more information.

Workforce Management Setup Sequence

Copyright © 2026, Oracle and/or its affiliates.

Workforce management options need only be set up if your organization interfaces with an external workforce management system. Refer to Setting Up The System To Enable FA Integration for more information.

Umbrella Agreement Management Setup Sequence

Umbrella agreement management options need only be set up if your organization uses umbrella agreements to manage contracts. Refer to the integration documentation for more information.

Outage Management Setup Sequence

Outage management options need only be set up if your organization interfaces with Oracle Utilities Network Management System. Refer to the integration documentation for more information.

Prepaid Metering Setup Sequence

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to Defining Prepaid Metering Options for more information.

Batch Scheduler Setup Sequence

Batch scheduler options need only be set up if your organization uses the batch scheduling functionality provided by the system rather than a third party batch scheduling system. Refer to Setting Up The Batch Scheduler for more information.

Zone Set Up

Most zones are delivered with the base-package and do not require any configuration. However, some zones are only available if configured by your implementation. Refer to Configuring Zones for more information.

To Do Options Setup

Refer to Setting Up To Do Options for more information on how to configure the system to match your organization's To Do management needs.

Defining Dashboard Options

Copyright © 2026, Oracle and/or its affiliates.

- Configuring the Customer Operational Dashboard

Configuring the Customer Operational Dashboard

This section describes the process for configuring the Customer Operational Dashboard.

Refer to the Using the Customer Operational Dashboard section of the *Oracle Utilities Customer Care & Billing Business User Guide*. for more information on this functionality.

Configuration for the Customer Operational Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, configure the **Customer Operational Dashboard Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. Use the embedded help to guide you through the meaning of each configuration field.

This dashboard also leverages a method of pre-staging data known as Statistics Snapshots. Refer to About Statistics in the *Oracle Utilities Application Framework Administrative User Guide* for more information.

A method for tracking Performance Targets (also known as Service Level Agreements) is also available in the Customer Operational Dashboard. To understand how to set up Performance Targets, refer to About Performance Targets in the *Oracle Utilities Application Framework Administrative User Guide*. The Performance Targets you configure will then be leveraged on the **Batch Performance** page of the Customer Operational Dashboard.

Information Lifecycle Management (ILM)

- Understanding Information Lifecycle Management (ILM)
- Archiving Financial Objects
- Preparing For Financial Transaction (FT) ILM

Understanding Information Lifecycle Management (ILM)

Information Lifecycle Management (ILM) is a separately licensable component of Oracle Utilities Customer Care & Billing that works in tandem with the Oracle database feature of the same name.

For general information about the ILM process and how ILM works with OUAF applications, refer to the Information Lifecycle Management chapter of the Oracle Utilities Application Framework *Administrative User Guide*.

This section provides an overview of the components used by the Information Lifecycle Management functionality.

ILM-Enabled Maintenance Objects: Retention Period

The majority of Maintenance Objects support a single retention period. They can either inherit the system-wide retention days that are configured on the ILM Configuration master

Copyright © 2026, Oracle and/or its affiliates.

configuration or they can have a retention period specified via the Maintenance Object option ILM Retention Period in Days.

Adjusting Eligibility of Non-Final Transactions

As delivered, Oracle Utilities Customer Care & Billing maintenance objects allow non-final transactions to be eligible for archive. This is a logical approach when transactional data has a very long retention period.

If non-final transactions should not be eligible for archive this can be controlled at either the Maintenance Object (MO) or Business Object (BO) level:

- **MO - ILM Restrict By Status (Y/N)**: Setting this to "Y" opts into the ability to restrict archiving by status. This is required to be set for either of the MO or BO level restrictions to be considered. To enforce the status, it requires that either the **ILM Restrict By BO Final Status (Y/N)** option or **ILM Final Status Field Value** option is also configured.
- **MO - ILM Restrict By BO Final Status (Y/N)**: Setting this to "Y" indicates that the transactions for the MO must be in a final status to be eligible for ILM. A status is considered to be final, based on the BO lifecycle configuration. This can be overridden by the BO option **Final Status Required for Archive (Y/N)**. This is only applicable for an MO that is maintained by business objects.
- **BO - Final Status Required for Archive (Y/N):** Setting this to "Y" indicates the transactions for this particular BO must be in a final status. This setting overrides the MO level **ILM Restrict By BO Final Status (Y/N).**

The following table helps to illustrate how these three settings impact whether a given transaction must be in a final status:

MO: ILM Restrict By Status	MO: ILM Restrict By BO Final Status	BO: Final Status Required for Archive	Final Status Required for Eligibility?
N	Y	Y	N
N	Y	N	N
N	N	Y	N
Y	N	N	N
Y	Y	N	N
Y	Y	Y	Y
Y	N	Y	Y
Y	Y	Not Provided	Y
Y	N	Not Provided	N

> **Note**
>
> There are a few MOs that do not support the BO level setting. To best understand how these fields are interpreted for an MO, refer to the detailed description of the algorithm plugged into the **ILM Eligibility** system event for the MO. For example, the generic ILM Eligibility Based on Status (F1-ILMELIG) algorithm does not support the BO level override option.

CCB ILM-Managed MOs

The CCB MOs support only a single retention period and many do not support the BO level setting.

Copyright © 2026, Oracle and/or its affiliates.

Refer to ILM Master Configuration for the list of ILM-managed MOs. Most of the CCB MOs on this list either have a specific ILM eligibility algorithm or use the common F1-ILMELIG algorithm with a restriction on BO final status.

The following table lists exceptions to the above rule. These MOs are not BO-based. Thus, the MOs that use the F1-ILMELIG algorithm will be restricted by the specific status(es) mentioned.

Maintenance Object	ILM Eligibility Algorithm Type	Restrict By Status
Billable Charge	F1-ILMELIG	Yes. Status: Canceled
Case	F1-ILMELIG	Yes. Status: Closed
Field Activity	F1-ILMELIG	Yes. Statuses: Complete, Canceled
Financial Transaction	N/A. Eligibility checks are performed directly from the FT ILM crawler batch process.	N/A
Order	F1-ILMELIG	Yes. Statuses: Complete, Canceled
Payment	N/A. Included in Payment Event ILM processing (C1-PEVILMELG)	N//A

The following MOs are considered ILM-managed even if the ILM fields, ILM eligibility algorithm and ILM crawler batch process do not exist. The tables are partitioned on Create Date/Time, as the record's age is sufficient for archive eligibility.

- Collection Process
- Severance Process
- Overdue Process
- Cut Process
- Write Off Process

Proactive Archive Eligibility for Transactional Data

Some types of transactional data can be analyzed for archive eligibility as they are received rather than waiting until their retention period has expired. This means that these records are judged ready to be archived as they are created and do not need to be read, analyzed, and updated during the ILM crawling process. This greatly reduces the number of records to be crawled at the end of the retention period and shortens the window of time required for ILM crawling. This approach exists in Oracle Utilities Meter Data Management and Oracle Utilities Customer to Meter. For more information, refer to the user documentation of these applications.

Archiving Financial Objects

This section describes considerations related to the ILM-enabled financial objects, such as bills, payments, adjustments, match events and financial transactions.

Retention Periods of Financial Objects

Each financial MO's eligibility criteria include checks on the status of related objects. For instance, financial transactions (FTs) are eligible for archive only if the related bill segment, payment segment, adjustment or match event is either archived (dropped from partition) or

Copyright © 2026, Oracle and/or its affiliates.

eligible for archive (record still exists with the ILM Archive Switch set to 'Y'). So it's important that the retention periods of the related financial objects align with each other.

Archiving Historical Bill Segments

For historical bill segments being archived, your implementation should not archive bills and bill segments that are eligible to be rebilled or those that are required for re-billing subsequent bills or bill segments - e.g., for determining bill segment start dates, if historical service quantities are required for calculation purposes, etc.. From a billing perspective, these may still be considered active.

Preparing For Financial Transaction (FT) ILM

This section describes the preliminary tasks needed for enabling Financial Transaction (FT) Information Lifecycle Management. Note that while the FT table (CI_FT) has the ILM Date and ILM Archive switch, the actual partitioning of the FT table is not yet enabled. However, the batch processes described in this section are provided, to allow your implementation to prepare your financial transaction data in the meantime.

For general information on ILM enabling, see Enabling ILM for Supported Maintenance Objects in the Oracle Utilities Application Framework *Administrative User Guide*.

The tasks described in the OUAF guide must be applied in conjunction with the batch processes that are described here.

FT ILM Objects

Since FT data is typically high-volume, the FT ILM crawler is a specific plugin-driven batch process that retrieves and updates the FTs in bulk (i.e. set-based update). This is for performance considerations. The template ILM crawler batch process in OUAF evaluates one record at a timeline and is unlikely to perform well on high-volume FT records.

The other aspect that sets the FT MO apart from other ILM-enabled MOs is that it does not use the **ILM Eligibility** plugin spot. The eligibility criteria checking is built into the FT ILM crawler's processing, for efficiency. It saves from having to call another plugin spot, which can make a difference in high-volume batch processing.

An FT will be marked as eligible for ILM if the FT is already marked as Redundant (switch is set to **Y**) and the FT is linked to a Bill Segment, Pay Segment, Adjustment or Match Event that either has the ILM Archive Switch set to **Y** or no longer exists (i.e., dropped from the partition).

Refer to the FT ILM Crawler (C1-FTCRL) batch process, for more information.

FT ILM Batch Processes

There are several batch controls involved with FT ILM. The batch processes are listed in the order in which they should run:

1. **Update FT ILM Fields** (C1-FTUPD) is a plugin-driven batch process that is meant to be run after the upgrade, at which point, the ILM Dates and ILM Archive switches in the FT table are null. This upgrade batch process sets the ILM Date to the FT's creation date and the ILM Archive Switch to **N**. The FT records are updated in bulk, for performance considerations.
    - Due to typical high volumes of FT data, the batch runs should be staggered by Cutoff Date, to manage the load of each run.

Copyright © 2026, Oracle and/or its affiliates.

- To facilitate the set-based processing of FTs, specify the appropriate Thread Option, which is either by Service Agreement ID or by Accounting Date. The default option is Accounting Date.
- This batch process is required to be run if the FT table has records with null values in the ILM Date and/or ILM Archive Switch. This will be true for FT records created before the upgrade to 25.10. All FT records must have the ILM Date and ILM Archive Switch populated, to enable the FT MO for ILM.

2. An FT is eligible for ILM only if it is marked as redundant. FTs are marked as redundant when, together with other old FTs on the same SA, their balance sums to zero.

   The base product provides two batch processes for marking old FTs as redundant - one each for balance forward accounting and open item accounting. Run the applicable batch process before running the FT ILM crawler. Both processes consider an FT as old if the FT's arrears date is less than or equal to the input Cutoff Date, which is either supplied in the batch parameter, or the default (process date minus the Installation record's Oldest Bucket Age (in days)).

   - **Mark FTs Redundant for Balance Forward Account** (C1FTRDBF) is a plugin-driven batch process that marks old FTs of balance-forward account SAs.
   - **Mark FTs Redundant for Open Item Accounts** (C1FTRDOI) is a plugin-driven batch process that marks FTs as redundant for balanced match events where all associated FTs are considered old.

3. **ILM Crawler - Financial Transaction** (C1-FTCRL) is a plugin-driven batch process that reviews FTs and marks the ILM Archive Switches to **Y**, if the FT meets the eligibility criteria. An FT is considered eligible for archiving if:

   - The FT is marked as Redundant (switch is **Y**).
   - The FT's ILM Date is before the retention period.
   - The associated bill / payment / adjustment / match event is either marked for archiving or already archived (removed from partition).
   - Due to typical high volumes of FTs, the batch runs should be staggered by Cutoff Date, to manage the load of each run.
   - The Process Algorithm associated with this batch process performs the eligibility criteria checks prior to the FT updates
   - To facilitate the set-based processing of FTs, specify the appropriate Thread Option, which is either by Service Agreement ID or by Accounting Date. The default option is Accounting Date.

Refer to these batch controls in the application, for more information.

For general information on batch processes, see the Batch Processes section the Oracle Utilities Application Framework *Administrative User Guide*.

Part V
Oracle Utilities Cloud Service Foundation

Welcome to the Oracle Utilities Cloud Service Foundation Administrative User Guide. This document describes how to administer features associated with Oracle Utilities Cloud Service Foundation.

> **Note**
>
> This document does not apply to all implementations. Contact your system administrator to confirm if your implementation includes Oracle Utilities Cloud Service Foundation.

- Process Automation Tool
- Data Conversion Support for Cloud Implementations
- Batch Scheduler for Cloud Implementations
- Batch Queues Overview
- Batch Alerts
- ILM Dashboard for Cloud Implementations
- Oracle Cloud Infrastructure Identity and Access Management Integration
- Oracle Cloud Object Storage
- Maintaining Customer Code

Process Automation Tool

The Process Automation Tool allows customers and implementers to orchestrate and automate a set of infrastructure related multi-step processes. The tool provides the ability to monitor the progress of such process and each of the steps. The tool also supports user actions at the process and step level.

The process automation tool is made out of the following system entities:

- Infrastructure Process - a Business Object of the Service Task MO.
- Infrastructure Process Step - a Business Object of the Service Task MO.
- Infrastructure Process Type - a Business Object of the Service Task Type MO.
- Infrastructure Process Step Type - a Business Object of the Service Task Type MO.

An Infrastructure Process references a type that includes the steps that are a part of that process. The steps are executed one by one according to their sequence as long as the previous step ended successfully. When a step in a process fails, the process will stop and wait for a user to take further actions.

Copyright © 2026, Oracle and/or its affiliates.

An Infrastructure Process can span up to two product environments. This means that it can invoke and monitor steps in two systems. This, for example, allows it to orchestrate a configuration migration (using the Content Migration Assistant, described in your cloud service's *Administrative User Guide*) from one product environment to another. Such a migration can include steps to create the export data on the **source** environment, move the export file to the **target** environment and execute all the import tasks on the target environment, all as a single Infrastructure Process. In this case the Infrastructure Process will be created on the **target** environment and will pull the configuration from the **source** environment.

> **Note**
>
> This is done in order to ensure that only application users with sufficient security privileges in any system environment can create Infrastructure Processes that can update that environment.
>
> The rule is that when an Infrastructure Process is created to run processes on two systems, the process will always be created on the **environment with the higher security requirements**. For example, if you need to run processes on the Development and Test environments, the infrastructure process will be created and executed from the Test environment (assuming that the Test environment has higher security requirements than the Development environment).

The steps that make an Infrastructure Process reference a step type that governs their behavior. A comprehensive set of process and step types is provided with the product. This set can be extended by implementers as needed.

- Creating an Infrastructure Process
- Executing an Infrastructure Process
- Monitoring Infrastructure Process Progress
- Process Automation Tool Setup
- Configuring New Infrastructure Processes
- CMA Migration Infrastructure Process Types

Creating an Infrastructure Process

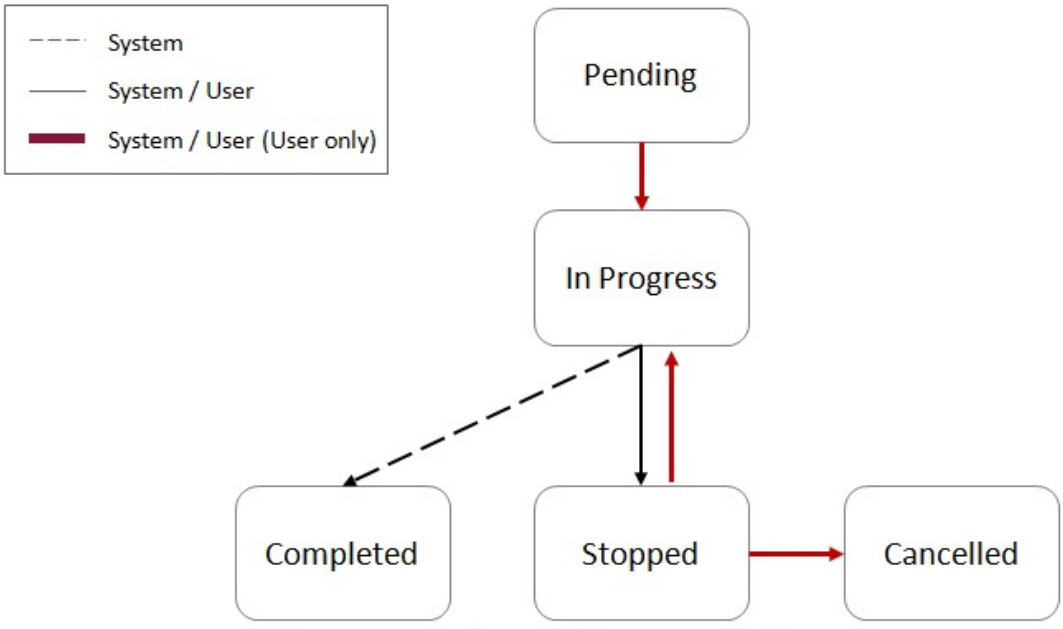
To create a new process, navigate using **Admin > Implementation Tools > Infrastructure Process**. Use the Infrastructure Process Query to search for an existing process. One an Infrastructure Process is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following points provide information about creating a new Infrastructure Process.

Infrastructure Process references an **Infrastructure Process Type**. When creating a new process you need to select the type that the process will be based on.

The **Name** of the process is used for tracking purposes. The name doesn't have to be unique in the system.

The **Process Steps** list is read-only and represents the steps that were configured on the Infrastructure Process Type.



Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Changing information on the Infrastructure Process Type, including the steps, will not affect existing Infrastructure Process records.

The **Process Details** section represents additional information that is required according to the corresponding process type definition.

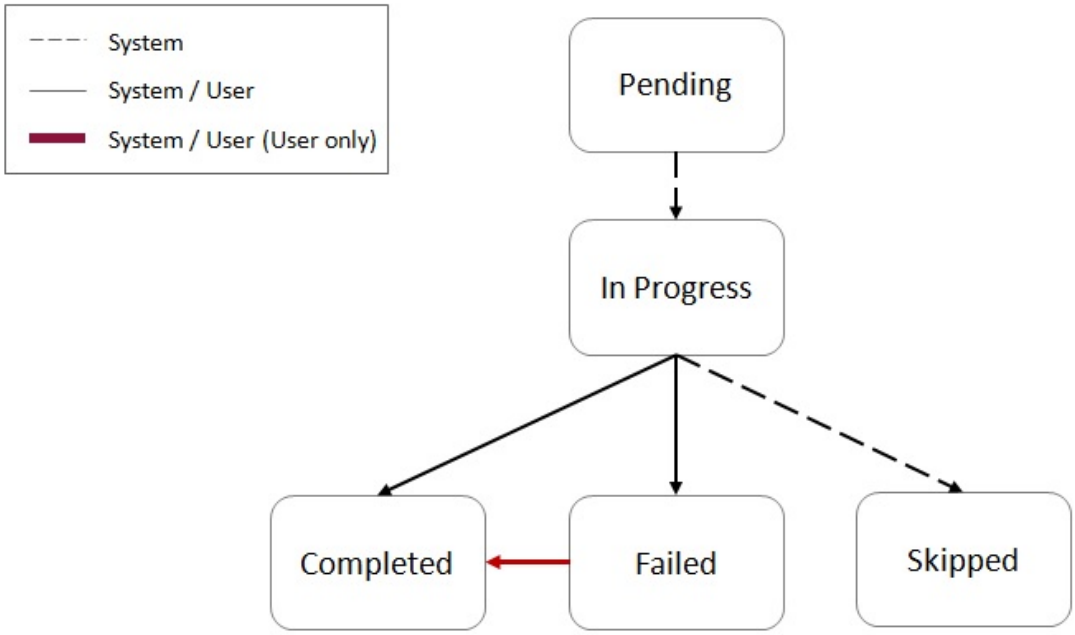
Executing an Infrastructure Process

Infrastructure Process Lifecycle

New processes are created in a Pending status. While in this status the Infrastructure Process record can be modified, deleted or duplicated.

> **Note**
>
> Once an Infrastructure Process record is created, its type cannot be changed. To change the type, you can delete the process that was created with the wrong type (if it is still in Pending status) and create a new process with the correct type.

Use the **Start** action, on the maintenance portal to begin the process execution. The process status will change to **In Progress**.



Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> While the Infrastructure Process is in **Pending** status, the steps will not have a status or any available actions. When the process transitions to **In Progress** status the process step records are created. From that point on they have a status and actions according to the step that and status.

While the process is **In Progress** the steps of the process will execute one by one according to their sequence. The process can be stopped using the **Stop** action. In this case the current step that is in progress will continue but the next step will not be executed. If any of the steps fail, the process will also transition into **Stopped** status and will not execute the next step.

When the process is in **Stopped** status it can be resumed by selecting the **Resume** action, or it can be cancelled by selecting the **Cancel** action.

Infrastructure Process Step Lifecycle

A process steps is created in **Pending** status and is transitioned to **In Progress** by the process logic when its turn to execute arrives.

When a step is **In Progress**, the following transitions are possible:

- Transition the step into Completed status upon successful completion of the step's work or by selecting the **Complete** action.
- Transition the step into **Failed** status when an error was detected during the step's work or by selecting the **Fail** action.
- Steps may include logic that will transition the step into **Skipped** status if that logic determines that the step should not be executed.

When the step is In Progress, selecting the **Job Status** action will display information about the job running status (if it is a batch job type of step).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Manually changing the step status to **Completed** or **Failed** while the step is In Progress should be carefully considered. This should only be done when step stays **In Progress** status for a long time and upon investigation it is clear that some manual intervention is required.

When a step is in **Failed** status it is still possible to manually transition the step into Completed status.

> **Note**
>
> Transitioning the step from **Failed** to **Completed** status should only be done if it is clear that the step was able to successfully accomplish its task. This will likely be established after some investigation.

Monitoring Infrastructure Process Progress

- Infrastructure Process Control
- Monitoring a Running Infrastructure Process
- Dealing with Exceptions

Infrastructure Process Control

The Infrastructure Process Control portal provides an overview of Infrastructure Processes that are active (i.e. in **Pending** or **In Progress** status) or processes that did not complete (i.e. in **Stopped** status) within the last X days.

Navigate to Infrastructure Process Control portal, using **Admin > Implementation Tools > Infrastructure Process Control**.

Available actions on this portal are:

- **New Process** - creates a new Infrastructure Process
- **Environment Setup** - directs the user to the master configuration related to the process automation tool

Select any of the processes from the portal lists for more information.

Monitoring a Running Infrastructure Process

When a process is running (in **In Progress** status), you can monitor its progress by refreshing the page. To configure automatic page refresh, refer to the User Portal Preferences for this portal.

The Infrastructure Process maintenance portal provides information about the status of the overall process as well as each of the steps.

Copyright © 2026, Oracle and/or its affiliates.

You can also view the details of each individual step including their log for more information or to investigate exceptions.

Dealing with Exceptions

Infrastructure Process steps can be divided into two main categories:

- Steps that start a batch process (job)
- Steps that are not batch process related

In addition, steps can be local or remote. Local steps execute on the same product environment that the process is executing while remote steps are executed on a different product environment.

- Batch Job Step Exceptions
- Non-Batch Step Exceptions

Batch Job Step Exceptions

Batch job steps start a batch job either locally or on a different product environment.

Batch Job Step in Failed Status as a Result of a Batch Job Error

When a batch process (local or remote) ends with an error, the process step is automatically transitioned to **Failed** status.

In this case, you should:

1. Ascertain the cause of the job failure (in the local or remote environment).
2. If the issue is temporary or can be fixed, fix it and then rerun the batch job manually using the Batch Job Submission page (in the local or remote environment). If the resubmitted job ended successfully, you can transition the process step to the **Completed** status and use the **Resume** action at the process level to continue the process execution.

If the issue cannot be resolved, further investigation is required. In this case the process should remain in **Stopped** status.

Batch Job Step in In Progress Status While Batch Job Ended With an Error

When an Infrastructure Process Step that is associated with a batch job stays in **In Progress** status while the batch job ended with an error, further investigation is required. One possible cause for that situation could be an error that causes the job to fail and at the same time also prevents the job from communicating its status back to the originating process step.

In this case you should manually transition the step into **Failed** status and continue your investigation.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If you decide to stop the Infrastructure Process altogether (as a result of the exception), it is a good idea to mark the batch job that failed "Do Not Attempt Restart" in the Batch Run Control for that batch run. This will ensure that the next time the Infrastructure Processes runs, when it gets to that batch process step it will not attempt to resume the execution that ended with an exception, possibly causing a repeat of the exception.

Batch Job Step in In Progress Status While Batch Job Ended Successfully

When an Infrastructure Process Step that is associated with a batch job stays in **In Progress** status while the batch job ended successfully, further investigation is required. In this case, once you ascertained that the job did actually end successfully, you can manually transition the process step into **Completed** status and use the **Resume** action at the process level to continue its execution.

Non-Batch Step Exceptions

Infrastructure Process Steps that are not associated with batch jobs can experience errors as well and therefore can fail. As a reminder, the logic for these steps can experience local or remote errors. When such a step fails, information about the failure can be found in the process step log.

Process Automation Tool Setup

The process automation tool requires the setup of the following components:

- Master Configuration
- External Systems
- Message Senders

In addition, a security setup is required.

The setup itself is done automatically as part of the environment provisioning process. The information in this section is provided for reference and in case changes in existing setup are required.

- Security Setup
- Master Configuration Setup
- External Systems and Message Senders

Security Setup

Before the process automation tool can be used, the security credentials of the Message Senders, used by the process automation tool, must be updated.

In order to execute the security setup, navigate using **Admin > Implementation Tools > Process Automation Security Setup**.

The setup script will ask you to provide a User ID, a Password and to indicate whether or not to override the existing security setup.

Copyright © 2026, Oracle and/or its affiliates.

Please contact your system or security administrator for more information about what User ID should be used for this setup.

You should select to override existing security setup when you need to update the User ID or the Password on the existing Messages Senders, used by the process automation tool. A common use case will be mandatory periodic password rotation for the user account that was selected for the setup.

> **Note**
>
> At the end of the process, you will be asked to flush all the system cache. This is required in order for the information update to take effect.

Master Configuration Setup

The process automation tool relies on master configuration settings in order to identify all the product environments that are available to it. The Master Configuration is automatically setup as part of the system provisioning process.

This section describes the setup options in case manual changes are needed.

To access the configuration for the process automation tool, navigate using **Admin** > **General** > **Master Configuration** and look for Process Automation Configuration.

The Main section includes the definition of the **Current Environment** code and the **default file extension** for CMA export files.

The Current Environment code is a **unique** code that is given to each product environment.

The Environment List section describes all the existing product environments that the process automation tool need to interact with, for example, in order to run a process that moves integration configuration from one environment to another.

The environment in the list includes the following details:

- Environment: the environment code.
- **Product**: defined in the Process Automation Product extendable lookup.
- **Domain**: defined in the Process Automation Domain extendable lookup.
- **Migration Source**: select "Yes" if you can migrate configuration data from this environment.

  > **Note**
  >
  > You should not allow automated migration of configuration from your development environment directly to your production environment but you would allow migrating from the development to test environments.

- **External System**: reference to the External System definition that will support communication with the row"s environment.

External Systems and Message Senders

Copyright © 2026, Oracle and/or its affiliates.

The process automation tool communicates with other product environments through Outbound Messages.

The automated setup for the process automation tool creates a set of Message Senders and External Systems to support communication with other product environments.

Each product environment which is defined on the Process Automation Configuration has a corresponding unique External System. Each External System contains the details of all the message types that it supports, the message sender for each message type and additional data if required.

Configuring New Infrastructure Processes

The process automation tool configuration is essentially a collection of process types and step types that support the automation of various multi-step processes. A set of Infrastructure Process Types and Infrastructure Process Step Types is provided with the base product. Customers and implementers can create new process and step types.

This section describes the actions required to configure new Infrastructure Process Type and Infrastructure Process Step Type.

- Configuring a New Infrastructure Process Step Type
- Configuring a New Infrastructure Process Type

Configuring a New Infrastructure Process Step Type

In order to configure a new step type, navigate using **Admin > Implementation Tools > Infrastructure Process Step Type**. Use the Infrastructure Process Step Type Query to view existing step types.

> ⚠ **Caution**
>
> Base product step type names start with "K1" and should not be change. Changing these step types can break the process and step types that are provided with the product.

The following points provide information about creating a new Infrastructure Process Step Type.

When creating a new step type, a business object has to be selected first. The Infrastructure Process Step Type BO contains the information necessary for the Infrastructure Process Step that references that step type. For example, a batch process step type BO contains information related to the batch code that should be submitted and the parameters that will be passed to it. You can use existing Infrastructure Process Step Type BOs or create new BOs according to your business requirements.

The **Related Transaction BO** references the Infrastructure Process Step BO. The step BO contains the business logic associated with the step. For example, a batch process step BO is responsible to submit a batch job with to the information from the step type. You can use existing Infrastructure Process Step BOs or create new BOs according to your business requirements.

The **Process Step Type Details** section represents additional information that is required for this specific step type BO.

Copyright © 2026, Oracle and/or its affiliates.

Configuring a New Infrastructure Process Type

In order to configure a new process type, navigate using **Admin > Implementation Tools > Infrastructure Process Type**. Use the Infrastructure Process Step all-in-one portal to view existing process types.

> ⚠ **Caution**
>
> Base product process type names start with "K1" and should not be change. Changing these process types can break the base product process types that are provided with the product.

The following points provide information about creating a new Infrastructure Process Type.

When creating a new process type, a business object has to be selected first. The Infrastructure Process Type BO contains information necessary for the Infrastructure Process that references that process type. You can use existing Infrastructure Process Type BOs or create new BOs according to your business requirements.

The **Related Transaction BO** references the Infrastructure Process BO. The process BO contains the business logic associated with the process. This includes the orchestration of the process steps. The process BO also contains information that is shared by step business logic during the process. For example, a process BO that handles migration of data between product environments can have a buffer that will hold the information pulled from the source environment using one step so that another step can use it to push that to the target environment. You can use existing Infrastructure Process BOs or create new BOs according to your business requirements.

The **Process Type Steps** section includes a collection of step types. The sequence of steps has to be unique and this will be sequence of execution.

> ⚠ **Caution**
>
> When selecting step types for a process type you need to consider the fact that not all step types can be used on all process types. For example, some steps need to get or save information in the process itself so it can be used by other steps of that process. These types of steps can only work with a certain type of process. Please refer to the detailed description in each of the base product provided Infrastructure Process Step Types to see what process types they can be referenced on.

The **Infrastructure Process Type Details** section represents additional information that is required for the specific process type BO.

CMA Migration Infrastructure Process Types

The following Infrastructure Process Types are provided to support the following configuration migration use cases:

- CMA Accelerator Load - import an exported file created by the Content Migration Assistant export process.

Copyright © 2026, Oracle and/or its affiliates.

- CMA Migration - a wholesale or piecemeal configuration migration (using the Content Migration Assistant), exporting configuration from a source environment and importing it to a target environment.
- CMA Accelerator Load (K1-CMA-LOAD)
- CMA Migration (K1-CMA-MIGRATE)

CMA Accelerator Load (K1-CMA-LOAD)

The K1-CMA-LOAD Infrastructure Process Type supports importing of an exported CMA file.

K1-CMA-LOAD is based on K1-CMAMigrationProcessType Infrastructure Process Type BO and uses the K1-CMAMigration as the Infrastructure Process BO.

The CMA Accelerator Load process type includes load an exported CMA and to run all the batch processes that are a part of the CMA import.

> **Note**
>
> This process type does not include a step for a manual user review. It is assumed that when loading an accelerator, there shouldn't be anything to review and the new configuration content is expected to be new for the most part or OK to override existing configuration.

Using the CMA Accelerator Load Infrastructure Process Type

In order to import a CMA export file (e.g. an accelerator), you need to:

- Upload the file to the system designated storage location for CMA uploads. The location is configured on the CMA Master Configuration entry and is automatically defaulted to an Oracle Cloud Object Storage location during the system installation process.
- Create a new infrastructure process with the K1-CMA-LOAD Infrastructure Process Type and provide the following additional details:
  - **Name**.
  - The **Process Steps** list is for reference only.
  - **Export filename**: specify the CMA export file name that was uploaded to the system. You should specify the full name including the file extension name.
  - **User Review Needed**: select "Yes" only if you are expecting the CMA file to include data that already exists in the system and need to be reviewed before changes are applied.
  - **Default Status For Add**, **Default Status For Update** are relevant in case you selected to have a user review. In this case define the default status of migration data items when imported into the target environment.
- Once the process is saved, you can start it by selecting the Start action.

CMA Migration (K1-CMA-MIGRATE)

Copyright © 2026, Oracle and/or its affiliates.

The K1-CMA-MIGRATE Infrastructure Process Type supports a full or partial migration of configuration data, from a remote environment (the source) to the environment that the process is running on (the target).

> **Note**
>
> The configuration migration process is done as a PULL (running on the target environment and pulling data from the source environment) to make sure that users without security privileges to make changes in a product environment "A" won"t be able to run a process from a remote environment "B" that will force changes into "A".

K1-CMA-MIGRATE is based on K1-CMAMigrationProcessType Infrastructure Process Type BO and uses the K1-CMAMigration as the Infrastructure Process BO.

This configuration migration process type includes all the necessary steps to create an export CMA file from a migration request on the source environment, store the file in a shared file location (accessible by the source and target environment processes) and to run all the import batch processes on the target environment to process the file. This process type also includes a step for a manual user review of the imported data if needed.

> **Note**
>
> The shared file location is configured on the Migration Assistant Configuration master configuration entity and is defaulted to an Oracle Cloud Object Storage location during the system installation process.

Using the CMA Migration Infrastructure Process Type

In order to migrate configuration data from a remote environment (the source environment) to the current environment (the target environment) you need to:

- Create a new infrastructure process with the K1-CMA-MIGRATE Infrastructure Process Type and provide the following additional details:
  - **Name**.
  - **From Environment**: select the source environment from which the data will be migrated to the target environment (the current environment). The list of valid environments to choose from is taken from the Process Automation Master Configuration. The target environment is always the current environment - the one that this process is created on.
  - The **Process Steps** list is for reference only.
  - **Migration Request**: specify the CMA Migration Request ID that will be used for the migration process. The migration request should exists on the source environment and will be validated against that environment.
  - **Export filename**: specify the CMA export file name that will be used for the export and import process. You should specify the full name including the file extension name. If you leave this field empty, the system will default the file name according to the migration request ID and the default file extension name.
  - **User Review Needed**: select "Yes" only if you are expecting the CMA file to include data that already exists in the system and need to be reviewed before changes are applied.

Copyright © 2026, Oracle and/or its affiliates.

  - **Default Status For Add**, **Default Status For Update** are relevant in case you selected to have a user review. In this case define the default status of migration data items when imported into the target environment.
- Once the process is saved, you can start it by selecting the Start action.

> **Note**
>
> Before using this Infrastructure Process Type, make sure that the import and export directories for the Migration Assistant Configuration master configuration entry are pointing to the SAME shared location. This is required for a successful completion of this process type.

Data Conversion Support for Cloud Implementations

This chapter provides information and requirements on data conversion support for Oracle Utilities Cloud implementations.

- Data Conversion Overview
- Configuring Conversion Data Upload
- Input Data Files
- Add an Annotation
- Security Setup for Conversion
- Conversion Reconciliation Reports

Data Conversion Overview

The ability to convert customer data from legacy systems to OUAF based products is critical for every implementation. The following chapter describes the overall process, tools and considerations that are specific to OUAF based product implementations on Oracle Cloud.

- Conversion Steps
- SQL Loader
- Conversion Artifacts

Conversion Steps

In general data conversion effort in the cloud is divided into the following steps:

- Prepare for conversion
- Create conversion data files
- Upload conversion data files to the cloud
- Process conversion data files
- Process converted data in cloud application

Copyright © 2026, Oracle and/or its affiliates.

- Approve converted data for production mode

> **Note**
>
> It is important to note that the conversion process is a highly iterative process. All the steps above are likely to be done (completely or partially) multiple times during the conversion process.
>
> For example, customer typically start with a small set of data to convert, they fix issues discovered with that data and then re-create new data files and proceed to convert them. This can happen many times, each time with either a different data sample or bigger and bigger data conversion sets until all the required data has gone through the conversion process.

- Prepare for Conversion
- Create Conversion Data Files
- Upload Data Conversion Files to the Cloud
- Process Conversion Data Files
- Process Converted Data in Cloud Application
- Approve Converted Data for Production Mode

Prepare for Conversion

Preparing for conversion will typically include the following actions:

- Identify the OUAF product entities (Maintenance Objects) for which data will be converted. Refer the specific OUAF product documentation for information about converted entities for that product. Typically, each of the product converted entities will have a set of conversion staging tables that will receive the data from your legacy system before they get processed into the system.

  > **Note**
  >
  > Conversion staging schema design may vary between products, please refer to specific product's documentation for more details.

- Evaluate your project's requirements for the Information Lifecycle Management (ILM) and Data Archiving. If your implementation uses ILM, the ILM Date must be provided as part of the legacy data extract for each eligible table.

  > **Note**
  >
  > ILM support may vary between products, please refer to specific product's documentation for more details.

- Identify tables and maintenance objects whose data requires special treatment. That may include high volume tables, extremely large CLOB data, tables with multiple CLOB fields or any other special considerations related to the legacy data being converted.

Copyright © 2026, Oracle and/or its affiliates.

Address the special circumstances by customizing the default configurations:

- Enable conversion for tables that are not marked for conversion in the metadata use the Master Configuration
- If your table(s) contain multiple CLOBs, but you don't plan to supply the legacy data for all of them, create Conversion Task Type for this table(s) and populate **Exclude CLOB Field** list and then add a corresponding entry to Master Configuration's Special Instructions
- If you dealing with high volumes of data, you may want to adjust the load parameters and options for the SQL Loader. In this case, create a **custom Control File Header** (Managed Content), configure a dedicated Conversion Task Type referencing this custom Control File Header and then add a corresponding entry to Master Configuration's Special Instructions. Note that creating the custom Control File Header will result in a control file composed from the custom fragment and the generated fields list.
- If the generated field definitions list in the control file doesn't satisfy your requirements, you may completely override the control file. In this case, create a **custom Control File** (Managed Content, same as above), configure a dedicated Conversion Task Type referencing this custom Override Control File and then add a corresponding entry to Master Configuration's Special Instructions. Make sure your custom Control File contains all the run-time substitution variables that appear in the base Control File Header.

See Conversion Task Types and Conversion Master Configuration chapters for more details.

- Generate the conversion artifacts for the product entities you plan to convert data for. This will include, for example, a set of data specification files that describe the format of data required for each file.
- Explore conversion tasks generated for tables and/or maintenance objects, examine the input data specifications and file lists and determine the expected data formats and input file names.
- Identify your various sources of data and extraction methods.

Create Conversion Data Files

In this step you create the set of data conversion files that were identified for the conversion process. You can choose to generate data files for each staging table or create a smaller set for each converted Maintenance Object.

The data conversion files typically do not include all the data to begin with but start small and grow with every iteration of the conversion process until they reach their maximum size at the end.

> **Note**
>
> When performing data conversion in the cloud, customers don’t have access to the database staging tables. Data scrubbing and transformation activities has to take place before the data files are generated (in each conversion iteration) so the result of these activities is reflected on the data files that are moved to the cloud to be loaded into the staging tables.

Copyright © 2026, Oracle and/or its affiliates.

Upload Data Conversion Files to the Cloud

Since data conversion files are created locally they have to be uploaded to the cloud environment in order to be processed and loaded into the conversion staging tables.

In this step you should setup a dedicated input location on the object storage and upload the input data files there.

For more details refer to File Locations .

Process Conversion Data Files

After uploading the files to the cloud, you should run a set of batch processes that will process the data files using Oracle SQL Loader and insert the data to the product conversion staging tables.

The staging table load process also produces output files that provide feedback on the load process.

You can download these output files for review.

> **Note**
>
> The process that imports the data in the files to the staging tables, using Oracle SQL Loader, is using the artifacts that were generated in the "Prepare for Conversion" step.

For more details refer to Understanding Load Data Process .

Process Converted Data in Cloud Application

When the data intended for conversion (for a conversion iteration) is loaded into the appropriate conversion staging tables, the OUAF application in the cloud can process that data according to the product's data model, technical and business rules.

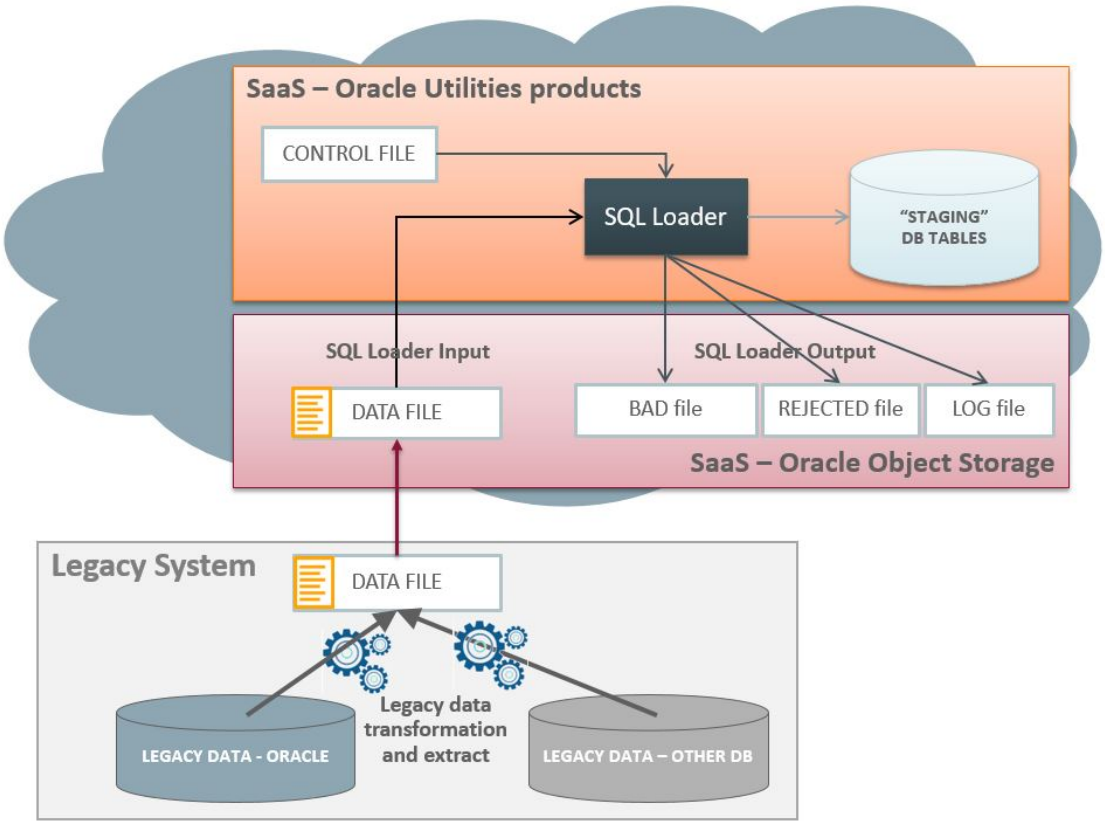
Refer to the OUAF product specific documentation for further guidelines and information on the specific processes and guidelines related to data conversion.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This is one step of the overall iterative process but it is also includes many internal steps, for example:
>
> 1. Validation of the data in the conversion staging tables.
> 2. Generation of the system assigned keys for the converted entities.
> 3. Migration of the converted data from the staging tables into the actual system tables.
>
> When the processing of the converted data in this iteration is completed, information from the system is used to identity changes necessary to source data, the extraction process or other activities involved in producing the data to be converted.
>
> The process can then start over by loading a new set of data into data conversion files, load them to the staging tables in the cloud and process them once more to get more feedback.

Approve Converted Data for Production Mode

When the quality and scope of data converted has reached its target, the process can stop. Once the overall data has been approved for production mode the conversion process comes to an end. The process of approving the data includes many activities, for example:



- Running various reports to compare converted data with legacy data to verify the quantity and quality of the data.
- Running reports and tests in the new application to verify the data and the system's behavior using that data.
- Manual review of random and key data in the system.

SQL Loader

Loading the data in the data conversion files into the product conversion stating tables is done using Oracle SQL Loader.

Oracle SQL Loader is an Oracle Database Tool that enables mass upload of data from various sources into database tables in a fast and safe way.

Copyright © 2026, Oracle and/or its affiliates.

SQL Loader processing is determined by Control Files. The control files for the data conversion process are provided for each of the product conversion staging tables as part of the artifact generation which is a part of the preparations activities before starting the conversion process.

The Control Files typically define:

- The location of input files to load.
- The character set of the input data.
- The target table(s) for the load and how to insert the data (e.g. append to or override).
- How to map the data in the input file to tables and fields.
- The location of the output files (e.g. log, bad or rejected records).
- Options for parallel processing and load balancing.

The control files that are generated for the product include all the parameters necessary to load the product conversion staging tables. There are some customization options for these files that are discussed later.

After loading the control files, SQL Loader reads the records in the input data file(s), converts the input into database tables and columns that are inserted into the database.

SQL Loader has 2 modes of operation:

- **Conventional Path Load** â€“ data is inserted to the database by using database SQL INSERT statements.
- **Direct Path Load** â€“ data is inserted into the database using data blocks that are written directly to the database. This method is much faster and therefore is the method selected for the data conversion process.

Copyright © 2026, Oracle and/or its affiliates.

SQL Loader has the ability to deal with multiple data files mapped to multiple tables as well as loading data into CLOB fields.

- Using SQL Loader When Processing Conversion Data Files

Using SQL Loader When Processing Conversion Data Files

Processing of uploaded conversion data files is done via a Batch Process (for each staging table or MO) that does the following:

- Prepares parameters for the SQL Loader process and retrieves Control File for an input table or MO
- Invokes SQL Loader and processes the legacy data extract files that were uploaded to the dedicated File location on cloud
- Archive the input file(s) and upload the SQL Loader output files to the File location so they can be subsequently downloaded by the customer for review.

Conversion Artifacts

The base product includes a set of artifacts that support the conversion process. These artifacts are provided on demand (generated as a result of a user request in the system).

The available artifacts are:

- Input Data Specifications
- SQL Loader Control Files
- Files List
- Conversion Input Data Specifications
- SQL Loader Control Files

Conversion Input Data Specifications

The system will generate a text file with data specification instructions for each of the conversion tables that are supported by the base product.

The specification files are for reference ONLY and are not used by the system at run time. These files describe the data format for each table so that the data specified can be loaded correctly with the Control File that is also generated by the system.

For more details refer to Conversion Artifact Generator .

SQL Loader Control Files

The control files are for internal use and are generated for each of the conversion tables that are supported by the product. These files are used by SQL Loader to interpret and load the data that is provided in the conversion data files.

The control file contains:

- General load parameters and options
- Data field specifications and table-specific load instructions

For more details refer to Conversion Artifact Generator .

Copyright © 2026, Oracle and/or its affiliates.

Configuring Conversion Data Upload

The following sections describe the settings and configurations used by various conversion data upload processes.

- Conversion Master Configuration
- Conversion Task Types
- Conversion Artifact Generator
- Conversion Tasks
- Conversion Batch Controls

Conversion Master Configuration

The **Conversion Data Upload Master Configuration** controls generic aspects of the legacy data load process.

The **Main** section captures the definitions globally applicable for all converted objects (tables and/or maintenance objects):

- **Default Conversion Instructions for Artifact Generator** reference conversion task types that define load parameters for individual tables or maintenance objects.
  The Master Configuration captures conversion task types with default configurations for:
  - Typical Table
  - Typical maintenance Object
  - Key Table.

Special Instructions section captures the definitions that support various idiosyncratic data upload scenarios

- **Override Conversion Eligibility â€" Table** list allows you to specify tables that are not marked for conversion in the metadata, but your implementation wishes to include in the conversion data upload and cleanup scope and vice versa - to exclude tables that are marked for conversion in the metadata from the data upload-related operations

> **Note**
>
> If the table you wish to convert has a related key table, this key table has to be explicitly added to this list.
>
> The sequences and the batch run history and other batch operation-related tables are never eligible for conversion operations.

- **Override Instructions** for **Tables** and **Maintenance Objects** define Conversion Instructions (conversion task types) for objects that require special processing or data formatting. For example, the default conversion instruction defines that CLOB data is supplied as a secondary file. The special instruction for a specific table may define that CLOB data is supplied in the main data file.

Copyright © 2026, Oracle and/or its affiliates.

Conversion Task Types

To configure a new conversion task type, navigate using Admin > Conversion Support > Conversion Task Type.

Conversion task type controls the data load parameters for the target table or maintenance object. Conversion task type also defines the transactional business object for Conversion Task. The algorithms linked to the transactional business object are responsible for the generation of the Conversion Artifacts: control files, input data specifications and file lists.

> **Note**
>
> The product is delivered with several conversion task types whose names start with 'K1'. These configurations should not be changed directly as they reflect the default behavior of the product. The task types get refreshed with base values at each upgrade.. Use them as a templates; if needed, create a copy and modify it according to your requirements.

Conversion Task Types defines:

General Input Data Instructions (all Conversion Task Types Business Objects)

- **Control File Header** - a fragment of the control file that contains general load parameters. This fragment is included in the generated control file. This is a Foreign Key reference to the **Managed Content** entry.
- **Override Control File** - a full text of the control file that contains both load parameters and field definitions. The entire text is copied into generated control file 'as is'. This is a Foreign Key reference to the **Managed Content** entry.
- **Date and DateTime fields' formats**. These attributes are referencing the Extendable Lookup values for *K1-ConvLoadDateFormatLookup* and *K1-ConvLoadDateTimeFmtLookup business objects*
- Strings to use as **data delimiters** and **data enclosing characters**. These attributes are referencing the Extendable Lookup values for *K1-ConvFileDelimiterLookup* and *K1-ConvFileEnclosingCharLookup* business objects
- **CLOB data extract rule** indicates whether the CLOB data is supplied as part of the input data file or as a separate, secondary file
- **CLOB data line separator** defines how the records are separates in the secondary (CLOB) data file. This value should be set according to the operating system where the legacy data extract was created. This attribute is referencing the Extendable Lookup values for *K1-ConvCLOBLineSeparatorLookup* business object.

  For Linux CLOB Line Separator set the value to ***LF***, for Windows, set the value for ***CR+LF***

CLOB Field Instructions for Tables/MO-s that contain multiple CLOB fields (Business Objects *K1-ConvArtMultClobMOTaskType* and *K1-ConvArtMultClobTblTaskType*)

- Target Object - **Table** or **Maintenance Object**
- **Exclude CLOB Fields** list - the list of CLOB fields that are not expected to be provided with the legacy data extract and therefore should be excluded from the generated control file.

The following Conversion Task Types are pre-configured in the product:

Copyright © 2026, Oracle and/or its affiliates.

- **K1-CNV-TABLE** - meant to be used for a single table load. It is referencing a Transactional Conversion Task Business Object whose algorithms generate Table Conversion Artifacts
- **K1-CNV-MO** - meant to be used for a single maintenance object load. It is referencing a Transactional Conversion Task Business Object whose algorithms generate Maintenance Object Conversion Artifacts
- **K1-CNV-KEY-TABLE** - meant to be used for the Key Tables. Key Tables are index-organized tables (IOT) and as such cannot be loaded in multiple concurrent sessions of SQL loader. This Task Type is referencing a Control File Header (Managed Content) where ***Parallel Load*** parameter is set to ***false***

Special configurations for tables that include more than one CLOB field

- Configure a dedicated Conversion Task Type for tables with multiple CLOB fields. Determine and control which CLOB fields to migrate and avoid creating unnecessary empty data files.
- If you wish to migrate all CLOB fields, create a dedicated Conversion Task Type for the Table or Maintenance Object, using business objects *K1-ConvArtMultClobMOTaskType* or *K1-ConvArtMultClobTblTaskType*). Do not populate **Exclude CLOB Fields** list. As a result, the generated Control File and Input Data File Specifications will reference **all CLOB fields**.
- If you wish to migrate only some CLOB fields, create a dedicated Conversion Task Type for the Table or Maintenance Object, using business objects Business Objects *K1-ConvArtMultClobMOTaskType* or *K1-ConvArtMultClobTblTaskType*. Populate the **Exclude CLOB Fields** list. As a result, the generated Control File and Input Data File Specifications will **omit excluded CLOB fields.**
- If no dedicated Conversion Task Type is configured and defined on the Master Configuration as Override Instruction for the Table or MO, the system uses the default Conversion Instruction defined on the Master Configuration. In this case, the generated Control File and Input Data File Specifications will reference a **single CLOB field** among Table's multiple CLOB fields (the one with the lowest table field sequence).

Conversion Artifact Generator

Conversion Artifacts is a set of supporting files used for data upload with SQL Loader. The artifacts are generated based on the table and maintenance object metadata and the definitions from Conversion Master Configuration and Configuration Task Types. Conversion artifacts include SQL Loader control files, input data file specifications and other supplemental files.

- **Input data file specifications** provide detailed field-by-field description of the expected data type and format, field order and other instructions. Your implementation may use these specifications to create the legacy data extract.
- **Control file** defines the rules and options of the data upload
- **File List** enumerates input data files expected to be provided for upload

The generator reads Conversion Master Configuration in order to determine the conversion task type associated with the table or maintenance object.

The generator creates **Conversion Tasks**, one instance per table and/or per maintenance object, creates attachments that store the artifacts and links the attachments to the Conversion Task as Related Objects.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> IMPORTANT: The regeneration is necessary each time the metadata or conversion configurations are amended.

Conversion Tasks query is provided with the base product.

You can choose to generate artifacts for table-level and/or maintenance object-level load, or for the entire system or for specific Table or Maintenance Object:

Generate Artifacts in bulk â€" for all Tables and/or Maintenance Objects

- Submit new batch job for Batch Control K1â€“CNVGA. This process performs a complete refresh of the conversion artifacts. It deletes existing and creates new Conversion Tasks for every Table and/or Maintenance Object that includes tables marked for conversion.

Generate Artifacts for an individual Table or Maintenance Object

- Navigate to **Admin**, then **Conversion**, then **Support**, then **Generate Conversion Artifacts**.
- Select one of the options:
  - **Table search** allows you to select specific target table
  - **Maintenance Object search** allows you to select specific target Maintenance Object.

> **Note**
>
> The process overrides all previously generated artifacts and replaces existing files.

Accessing the Artifacts

Navigate to Conversion Task query and search for the task that is corresponding to a table or a maintenance object. or use other available search criteria. Explore the Attachments collection to view the artifacts.

Conversion Tasks

The following sections provide information about Conversion Tasks and generated conversion artifacts.

- Conversion Task Query
- Conversion Task

Conversion Task Query

Conversion Task query allows to search by variety of criteria:

- Creating User, Conversion Task Type and Status
- Linked Object â€" Table or Maintenance Object
- Exact Conversion Task ID

Copyright © 2026, Oracle and/or its affiliates.

Conversion Task

The purpose of the **Conversion Task** is to maintain the conversion artifacts for Table or Maintenance Object. Please consider the following with respect to conversion tasks.

- The business object lifecycle supports multiple attempts to re-generate the artifacts.
- The re-generation could be triggered either manually or by the Conversion Artifact Generator. Only one set of the artifacts is relevant at any point of time, hence only one Conversion Task at the time can exists for a given Table or Maintenance Object.
- Typically, Conversion Tasks are created by Conversion Artifact Generator. However, it can also be created manually by navigating to **Admin**, then **Conversion**, then **Support**, then **Conversion Task**.
- Use the Conversion Task Query to search for an existing entry. Select the entry from the search results to navigate to the maintenance portal to view and maintain the selected record.
- Conversion Task references a Conversion Task Type and contains standard business object record information, including the creation date/time, status update date/time and creating user.
- The task references the object - **Table or Maintenance Object** - for which the artifacts are generated.
- The collection of task's **Related Objects** store references to the Attachments that store a snapshot of the generated files. A new attachment is created after each generation run and linked to the Conversion Task for audit purposes.

Conversion Batch Controls

The following batch controls are delivered with the base product:

Batch Control	Description
K1-CNVLD	Conversion - Load Data using SQL Loader. This process facilitates the legacy data extract upload using SQL Loader. The input data files are expected to be uploaded to a file storage location. See Input and Output File Location for more information about file storage locations. One run uploads the data into a single target Table or Maintenance Object. The process is multi-threaded. This process is discussed in more details in the Data Load Batch chapter

Copyright © 2026, Oracle and/or its affiliates.

Batch Control	Description
K1-CNVDS	Conversion - Disable Conversion This process resets the environment indicators and prevents further conversion activities. Once conversion is disabled, the following actions are blocked: • Switching between Conversion and Production • Table truncation • Disable Indexes and Rebuilding the Statistics • Data insertion into Production • Data upload into staging **Note** The process should be executed only once and only after all of the conversion activities are completed and the application is ready for the real production use.
K1-CNVEN	Conversion - Enable Conversion This process resets the environment indicators and enables it for conversion activities. It should be executed at the start of the Conversion project.
K1-DRPIN	Conversion - Disable Indexes on Production Tables This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object. Limitation: the indexes on the batch run history and other batch operation-related tables can not be disabled • If no specific target is populated, the process disables indexes on all converted tables in Production schema
K1-SDSIN	Conversion - Disable Indexes on Staging Tables This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object. Limitation: the indexes on the batch run history and other batch operation-related tables can not be disabled • If no specific target is populated, the process disables indexes on all converted tables in Staging schema
K1-DRICMS	Conversion - Disable Customer Modification Indexes This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the process disables indexes on all conversion-eligible tables in Customer Modification schema
K1-RIUSP	Conversion - Rebuild Indexes and Update Statistics in Production This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the process rebuilds indexes and updates statistics on all converted tables in Production schema • Specify the sampling size (percentage) for statistics gathering. If not specified, the system will use default dbms_stats.auto_sample_size. • Specify whether you wish to rebuild indexes, to gather table statistics or both. It is recommended to rebuild the indexes and update statistics right after the data upload.

Copyright © 2026, Oracle and/or its affiliates.

Batch Control	Description
K1-RIUSS	Conversion - Rebuild Indexes and Update Statistics in Staging This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the process rebuilds indexes and updates statistics on all converted tables in Staging schema • Specify the sampling size (percentage) for statistics gathering. If not specified, the system will use default dbms_stats.auto_sample_size • Specify whether you wish to rebuild indexes, to gather table statistics or both It is recommended to rebuild the indexes and update statistics right after the data upload.
K1-RUSCM	Conversion - Update Customer Modification Statistics This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the process rebuilds indexes and updates statistics on all conversion-eligible tables in Customer Modification schema • Specify the sampling size (percentage) for statistics gathering. If not specified, the system will use default dbms_stats.auto_sample_size • Specify whether you wish to rebuild indexes, to gather table statistics or both It is recommended to rebuild the indexes and update statistics right after the data upload.
K1-CLNTB	Conversion - Truncate Tables in Production This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object. Limitation: the sequences, the batch run history and other batch operation-related tables can not be truncated • If no specific target is populated, the truncates all converted tables in Production schema
K1-SCLTB	Conversion - Truncate Tables in Staging This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object. Limitation: the sequences, the batch run history and other batch operation-related tables can not be truncated • If no specific target is populated, the truncates all converted tables in Staging schema
K1-CLNCM	Conversion - Truncate Customer Modification Tables This process can be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the truncates all conversion-eligible tables in Customer Modification schema
K1-CLNRT	Conversion â€” Truncate XML Resolution Tables This process is allowed to run only in the Staging schema and may be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the truncates all XML Resolution tables in Staging schema

Copyright © 2026, Oracle and/or its affiliates.

Batch Control	Description
K1-CLNKY	Conversion - Truncate Key Reference Tables This process is allowed to run only in the Staging schema and may be used in two modes: • Populate Table or Maintenance Object batch parameter to process specific object • If no specific target is populated, the truncates all Key Reference tables in Staging schema

- Configuring Data Load Batch Controls for Conversion Project

Configuring Data Load Batch Controls for Conversion Project

The generic batch process K1-CNVLD performs the load of the input data file(s) into a target table or maintenance object, specified as one of the batch parameters.

Consider creating individual batch controls per object (table or maintenance object).

It allows leverage the parallel processing capacity of the system; the data load processes for all objects can be submitted near-simultaneously, thus minimizing the time needed for the legacy data upload, which is only an initial step in the overall data conversion process.

Use batch control K1-CNVLD for rehearsal load batch run for various tables and/or maintenance objects and determine the optimal load strategy:

- Whether the data should be extracted and loaded as single Tables and/or Maintenance Objects
- Whether and how to split the data files and the number of threads for the batch
- Potential log file size and the feasible logging level

Configure data load Batch Controls for each individual Table or Maintenance Object. Pattern the configuration after K1-CNVLD and set the default parameter values for:

- **Input, Output and Archived File Storage Locations**. The location (compartments and buckets) has to be defined in advance in the cloud object storage; batch parameters are referencing Extendable Lookup ***F1-FileStorage*** value(s) corresponding to these locations. The parameter value should be composed as **file-storage:*//***<Extendable Lookup Value>/<object storage bucket name>, for example: *file-storage://OS-SHARED/CONV-Input*
- Target **Table** or **Maintenance Object** Either one of these two parameters must be populated.
- **File Extension**. When specifying the **file extension**, include all the extensions available. For example. if the file name is ***XXX.csv.gz,*** enter parameter value ***csv.gz***
- **Log Level.** Specify the value *LOG* to force SQL Loader to produce the most detailed data upload process log.
- **Retain Input Option**. This parameter controls whether the original input data files should be left 'as is' at the input data location or purged from the object storage or moved to the archived data location. When the input data is archived the timestamp is appended to the original file name.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Note: if the batch process was not able to upload the input data file, this file remains at the input data location.

- **Max Number of Upload Errors**.

  The value of this parameter pertains to the desired errors threshold for the SQL Loader. The load process halts after the specified number of records in error is reached. The SQL Loader log contains a message SKIPPED=NNN where NNN marks the position of the last record in error in the input data file. The process may then be resumed from this position if the batch is submitted with the ***skip*** parameter populated with the value of SKIPPED from the log.

Default **Thread Count** depends on the type of the uploaded table. Regular tables can be uploaded in a single or multiple threads. Key tables must be uploaded in a single thread

Input Data Files

This section provides information on inputting data files for data conversion.

- Overview
- Input Data for a Staging Table
- Input Data for Maintenance Object
- Limitations for Input Data

Overview

This section provides information on the requirements and details for file upload, loading table, maintenance object, CLOB, layout, data formatting, and so on related to inputting data files for data conversion.

- File Creation and Upload
- Loading Table or Maintenance Object
- Multiple Data Files
- Loading CLOB Data
- File Layout and Data Formatting
- Defining Custom Data Delimiters and Enclosing Characters

File Creation and Upload

The extract data may be uploaded in both compressed and decompressed form.

Supported compressed formats include zip and gzip. The files with extension **.gz** and **.zip** will be automatically decompressed by the system.

> **Note**
>
> For the further details on supported compressed formats please refer to the Oracle Utilities Application Framework documentation.

Copyright © 2026, Oracle and/or its affiliates.

File Creation

Use Conversion Task query to retrieve conversion task(s) for table(s) or maintenance object(s) that you are planning to convert. Review input data specifications. Create the data extract text file, using field delimiters, enclosing characters and data formatting according to the specifications.

If the files were created under Windows operating system, it is recommended to remove the carriage return character prior to compression (not applicable for secondary files with CLOB data).

File Compression with gzip

Use gzip utility to compress the file.

- For Windows operating system, download and install gzip utility for Windows. Run the following:

```
# Navigate to the gzip folder
cd C:\gzip-1.3.12-1-bin\bin
# Run gzip.
# New file will be created in the same directory as the original the input file
gzip -k <full path to the input data file>
# Sample command for the file TABLE_NAME.txt located under
# C/myDataDirectory/:
gzip â€“k C/myDataDirectory/TABLE_NAME.txt
```

- For Unix/Linux operating systems, run the following command:

```
gzip < <inputFile name> > <outputFile name with .gz suffix>
# Sample command for the file TABLE_NAME.txt
gzip < TABLE_NAME.txt > TABLE_NAME.txt.gz
```

Loading Table or Maintenance Object

The conversion data upload supports two types of the extract:

- Data extract that contains the data for a single target staging table.

  In this case, the upload process inserts records into a single staging table. The input data file consists of similar records, each represents a row in the target table.

- Data extract that contains the data for the group of target staging tables that represent a Maintenance Object.

  In this case, the upload process populates all the tables that belong to a maintenance object. The input data file contains multiple types of records that are inserted into various tables.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If the data is uploaded for a Maintenance Object, each record has to be prefixed with the table name that is used as record type indicator. This requirement is also mentioned in the input file specification

- The application stores the large volumes of data in partitioned tables. If the Maintenance Object contains partitioned tables, the data should be uploaded in a certain order:
  - During the data upload, the primary table in the Maintenance Object should be loaded first, then the indexes should be rebuilt, followed by the data upload into the child tables

Multiple Data Files

The large volume of the converted data may require the extract to be split into multiple parts.

In this case the multi-part extract for a target staging Table or Maintenance Object is loaded with a multi-threaded batch run.

Sample scenario:

10M of the Person records are being converted. The extract file is split into 10 files, PERSON1, PERSON2 PERSON3 etc., each file contains 1M records. All 10 files are uploaded to the input file location.

Batch process 'Load Person data' is submitted with 5 threads; each thread picks up 2 files and uploads the data into staging tables.

Loading CLOB Data

The CLOB data can be loaded in two ways:

- Extracted as part of the main data file. This method is suitable for the relatively small CLOB data size. Refer to Limitations for more details.
- Extracted into a separate file. This method is suitable for larger CLOB data sizes and also for large volume tables or maintenance objects. In this scenario, the secondary file has to be uploaded at the same time as the primary data file.

> **Note**
>
> When loading CLOB data as a secondary file, a separate file is created for each CLOB field in the. It means that if the table 'XXX' contains CLOB fields 'clob1Field1' and 'clobField2', the system would expect to process files XXX, XXX_clobField1_CLOB and XXX_clobField2_CLOB. See also Notes on Secondary Data Files

- Notes on Secondary Data Files (CLOB Data)

Notes on Secondary Data Files (CLOB Data)

Secondary data file is loaded simultaneously with the primary data file. The CLOB data extract should contain exactly the same number of records as a primary file.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> When splitting the extract into multiple data files, make sure that the numbers of extracted records in the primary and secondary files are matching.
>
> It is applicable for both table-level and maintenance-object level load.

Sample Scenario:

Table CI_PER includes CLOB column C1_PER_DATA_AREA. The CLOB field is used to store customer's resume.

The legacy table contain 10K records and the CLOB data is available for some of the records

The primary data file, CI_PREM.csv contains 10K lines, one line per record

The secondary data file, CI_PREM_CLOB, contains 10K records too. The records with the empty CLOB are represented by CLOB delimiter.

Primary File – Regular Data Fields	Secondary File - CLOB
12345678,John,Doe,.....	John's resume <endclob>
45165609,Smith,Mary,.....	Mary Smith resume<endclob>
33336733,Brand,Brent,.....	<endclob>
06737482,Sunshine,Julie,.....	Julie Sunshine resume<endclob>

Splitting single table data extract with CLOB

The following example illustrates how to split the single table large volume extract correctly if the CLOB data is supplied in the secondary file:

Assuming the table has 10K records, split into two equal parts. The following files should be created:

- Primary File 1 with 5K records
- Secondary File 1 with 5K CLOB entries
- Primary File 2 with 5K records
- Secondary File 2 with 5K CLOB entries

Splitting maintenance object data extract with CLOB

The following example illustrates how to split the maintenance object large volume extract correctly if the CLOB data is supplied in the secondary file:

Assuming the maintenance object has two tables, one of the tables includes CLOB column and the primary table has 10K records. The data supposed to be split into two equal parts. The following files should be created:

- Primary File 1 with 5K records for the primary table and corresponding records for the child table
- Secondary File 1 with CLOB entries corresponding to the table in the Primary File 1
- Primary File 2 with 5K records for the primary table and corresponding records for the child table

Copyright © 2026, Oracle and/or its affiliates.

- Secondary File 2 with CLOB entries corresponding to the table in the Primary File 2

> **Note**
>
> For Maintenance Object-level load consider supplying CLOB data in the primary file, to avoid complicated logic of data splitting.
>
> Refer to CLOB Data - XML for limitations concerning XML CLOB data

File Layout and Data Formatting

The input data specifications file for each Table or Maintenance Object that are subject to conversion are stored as an attachment linked to the corresponding conversion tasks. The Conversion Artifact Generator creates conversion task for each table and/or maintenance object.

Specifications are generated based on the metadata and the conversion configurations defined on Conversion Task Type and Conversion Master Configuration. Configurations control delimiters and enclosing characters and define CLOB data processing rules.

The data extract file is expected to contain one record per each target table row. The data field order in the record has to be exactly the same as it is listed in the specification file.

The specifications contain:

- Data delimiters and expected secondary data file names
- Field-by-field data formatting rules for

  data types and size, Date, DateTime and Time formatting
- Special notes on CLOB fields

The fields in the record are expected to be separated by a delimiter character (or string).

For the not-nullable columns with no data, a single space enclosed in the enclosing character (or string) has to be supplied, for example " "

The CLOB data in the main record has to be enclosed in the CLOB Delimiter string, for example *<clobend>some clob data<clobend>*

The CLOB records in the secondary data file has to be separated by CLOB Delimiter string followed by the new line sign, defined as the CLOB Line Separator. IMPORTANT! the last entry in the CLOB data file has to end with the new line, too

- If the data extract is created on Linux, use Line Feed to separate CLOB records and make sure that there is no space after CLOB Delimiter string
- If the data extract is created on Windows, use Line Feed followed by Carriage Return.

Enclosing character (or string) can also be used to encapsulate data that includes a field delimiter, for example *"Hello, World"*

Defining Custom Data Delimiters and Enclosing Characters

The default configurations are delivered with the base product.

Copyright © 2026, Oracle and/or its affiliates.

Your entire legacy data or a specific table, or the data extract mechanism may require use of a different data delimiter and/or enclosing characters. To enable alternative delimiters, perform the following steps:

- Define new data delimiter string, enclosing string, CLOB delimiter string and/or CLOB Line Separator using the corresponding Extendable Lookups
- Configure Conversion Task Type using newly created delimiters
- Amend Conversion Master Configuration, setting default (for all tables or maintenance objects) or override (for specific table or maintenance Object) instructions.
- Regenerate Conversion Artifacts

Now you can create data extract according to the newly generated specifications.

Input Data for a Staging Table

The extract for a single table contains delimited data records. Depending on the conversion configuration, the CLOB data should be supplied either inline or in a separate, secondary file.

Input Data File Names

Input data file names has to follow the rules described in this chapter. The names are case-sensitive.

File Type	File Name
Single data file per table, no CLOB	File name equal target table name, such as CI_PREM
Single data file per table, **single** CLOB column in the table, CLOB data in secondary file	Primary file name equal target table name, such as CI_PREM Secondary file name is composed as target table name concatenated with '_CLOB', such as CI_PREM_CLOB
Single data file per table, **multiple** CLOB columns in the table, CLOB data in secondary file	Primary file name equal target table name, such as CI_PREM **For each CLOB column** being uploaded, the secondary file name is composed as target table name concatenated with CLOB column name concatenated with '_CLOB', such as CI_PREM_COL1_CLOB, CI_PREM_COL2_CLOB
Multiple data files per table, no CLOB	File name is composed as target table name concatenated with file number, such as CI_PREM1, CI_PREM2
Multiple data files per table, CLOB data in secondary file	Primary file name is composed as target table name concatenated with numeric file number, such as CI_PREM1, CI_PREM2, and so on. Secondary file name is composed as target table name concatenated with '_CLOB' and file number, such as CI_PREM_CLOB1, CI_PREM_CLOB2, and so on.

Copyright © 2026, Oracle and/or its affiliates.

File Type	File Name
Multiple data files per table, **multiple** CLOB columns in the table, CLOB data in secondary file	Primary file name is composed as target table name concatenated with numeric file number, such as CI_PREM1, CI_PREM2, and so on. **For each CLOB column** being uploaded, the secondary file name is composed as target table name concatenated with CLOB column name concatenated with '_CLOB' and file number, such as CI_PREM_COL1_CLOB1, CI_PREM_COL1_CLOB2, CI_PREM_COL2_CLOB1, CI_PREM_COL2_CLOB2, and so on.

Input Data for Maintenance Object

The extract for a maintenance object contains delimited data records for all tables included in the maintenance object. Depending on the conversion configuration, the CLOB data should be supplied either inline or in a separate, secondary files, one file per table containing CLOB. Refer to Notes on Secondary Data Files (CLOB Data) for limitations concerning XML CLOB data and more details.

Input Data File Names

Input data file names has to follow the rules described in this chapter. The names are case-sensitive.

File names for Maintenance Object contain Maintenance Object Code. If the code includes spaces or special characters, it should be replaced with '_', for example:

For actual MO Code: SP/MTR HIST, in the file name, use SP_MTR_HST

File Type	File Name
Single data file per Maintenance Object, no CLOB	File name equal target maintenance object name, such as PREMISE
Single data file per Maintenance Object, **single** CLOB column in the table, CLOB data in secondary file	Primary file name equal maintenance object name, such as PREMISE Secondary files name composed as maintenance object name concatenated with table name concatenated with '_CLOB'. For example, if PREMISE's CI_PREM table contains CLOB, the secondary file name is: PREMISE_CI_PREM_CLOB
Single data file per Maintenance Object, **multiple** CLOB columns in the table, CLOB data in secondary file	Primary file name equal maintenance object name, such as PREMISE **For each CLOB column** being uploaded, the secondary files name composed as maintenance object name concatenated with table name concatenated with CLOB column name concatenated with '_CLOB'. For example, if PREMISE's CI_PREM table contains two CLOB columns COL1 and COL2 , the secondary file names are: PREMISE_CI_PREM_COL1_CLOB, PREMISE_CI_PREM_COL2_CLOB

Copyright © 2026, Oracle and/or its affiliates.

File Type	File Name
Multiple data file per Maintenance Object, no CLOB	File name is composed as target maintenance object name concatenated with file number, such as PREMISE1, PREMISE 2 etc
Multiple data file per Maintenance Object, single CLOB column in the table, CLOB data in secondary file	Primary file name is composed as target maintenance object name concatenated with file number, such as PREMISE1, PREMISE 2 etc Secondary files name composed as maintenance object name concatenated with table name concatenated with '_CLOB' concatenated with file number. For example, if PREMISE's CI_PREM table contains CLOB, the secondary file names are: PREMISE_CI_PREM_CLOB1, PREMISE_CI_PREM_CLOB2, etc
Multiple data file per Maintenance Object, **multiple** CLOB columns in the table, CLOB data in secondary file	Primary file name is composed as target maintenance object name concatenated with file number, such as PREMISE1, PREMISE 2 etc **For each CLOB column** being uploaded, the secondary files name composed as maintenance object name concatenated with table name concatenated with column name concatenated with '_CLOB' concatenated with file number. For example, if PREMISE's CI_PREM table contains two CLOB columns COL1 and COL2 , the secondary file names are: PREMISE_CI_PREM_COL1_CLOB1, PREMISE_CI_PREM_COL1_CLOB2, PREMISE_CI_PREM_COL2_CLOB1, PREMISE_CI_PREM_COL2_CLOB2 etc

Limitations for Input Data

Key Tables

Due to technical limitations, Key tables cannot be loaded in multi-threaded mode. If you decide to create input data files using the Maintenance Object method, consider the following:

- Create data extract(s) for a Maintenance Object data, but exclude the Key table(s) and run data upload in multi-threaded batches
- Create separate extract for the Key table(s) only and upload them in single threaded batches.

Duplicate Records

Duplicate records are not rejected during the upload. This may result in the index corruption and other issues in the target table(a).

The default SQL Loader data upload method configured in the system is Direct Path. Among the advantages of a Direct Path method are higher performance and more efficient resources utilization. Constraints are disabled during Direct Path load and as a result the duplicate PK records are not rejected.

There are two approaches to address the issue

- Clean up the duplicate records from the legacy data extract BEFORE the upload

Copyright © 2026, Oracle and/or its affiliates.

- Customise the default configuration and switch to the Conventional Path load method.
  - **Create custom Control File Header**: Duplicate Managed Content K1-SQLLoaderControlFileHeader .and modify to use Conventional Path Load (Consult SQL Loader documentation for more detailed information).
  - **Modify Conversion Instructions** (Conversion Task Type): specify SQL Loader Control File Header created above
  - **Regenerate Conversion Artifacts**

CLOB Data Size

The maximum size of the CLOB data included in the main data file is 10K. If converted CLOB data size is expected to be larger than 10K, create secondary data files.

CLOB Data - XML

The XML data formatted using new line characters cannot be uploaded as part of the primary data file. If your CLOB data includes formatted XML, you should create secondary data file(s) for CLOB columns.

Add an Annotation

Use annotation annotate to add a new annotation to an object.

Syntax

```
annotation annotate
-type <object-type>
-name <object-name>
-label <annotation-label>
-value <annotation-value>
```

Parameters

Parameter	Required	Description
-type <object-type>	Yes	The type of object being annotated. For example, TABLE or TABLE COLUMN.
-name <object-name>	Yes	The object name. For a table, use the table name. For a table column, use TABLENAME.COLUMNNAME.
-label <annotation-label>	Yes	The annotation label. For example, DESCRIPTION.
-value <annotation-value>	Yes	The annotation text stored under the label.

One object can have multiple annotations using different labels.

Copyright © 2026, Oracle and/or its affiliates.

Example

```
annotation annotate -type 'TABLE COLUMN' -name SHOTS.PEAK_BALL_SPEED_KMH -
label DESCRIPTION -value 'Maximum ball speed in kilometers per hour recorded
after the shot was taken'
```

This adds a DESCRIPTION annotation to the PEAK_BALL_SPEED_KMH column in the SHOTS table.

- Input and Output File Location
- Understanding Load Data Process
- Understanding the Conversion Orchestration Process

Input and Output File Location

The following locations has to be defined in order to support legacy data upload:

- File location for input data files upload
- File location for SQL Loader output files and also for archived input data files

See Object Storage chapter for more details on how to define the file location.

Understanding Load Data Process

The setup of the batch controls that is necessary to support data conversion and legacy data extract upload is described in Data Load Batch Controls .

The following sections explain the process of legacy data extract upload with SQL loader.

- Load Data Batch Run Parameters
- Multi-Threading
- Load Outcome â€“ Log, Bad and Rejected Files
- Interrupted Load
- Tables Cleanup and Index Maintenance
- Load Performance Tuning

Load Data Batch Run Parameters

The data upload batch is processing single target object â€“ Table or Maintenance Object. The data extract may be supplied in one or multiple files, created and named according to the Input File instructions for a Staging Table and Maintenance Object .

The process is multi-threaded and optimized for the parallel load.

Using the batch parameters you can control:

- Level of logging
- Data extract retention
- Resume the interrupted load
- Maximum number of load errors

Copyright © 2026, Oracle and/or its affiliates.

Multi-Threading

The process is threading by dividing the multiple data files between the threads. Each thread in turn, is processing its files one by one.

The exception is Key Tables. They are index-organized tables and have to be loaded in the single thread, due to the SQL Loader restrictions.

Load Outcome â€“ Log, Bad and Rejected Files

SQL Loader output files are available for download after each run . Refer to Input and Output File Location for details. To ensure file name uniqueness, the output file names are concatenated with the current timestamp.

- **Log file** contains the information about the run, including number of record processed, errors encountered and other useful information. The level of logging is controlled by the batch parameter ***log*** .
- **Bad** and **Rejected** files contain the records that were rejected by either the SQL Loader or the database. If the errors are not extensive and could be fixed manually, these files can be edited, renamed and used as an input again.

Interrupted Load

The data load process can be re-started. Once SQL Loader reached the maximum number of errors allowed for the run, it records the position of the last record in error in the log. The restarted load begins pulling the data from the file after skipping certain number of records.

In order to continue processing interrupted load, perform the following steps:

- Retrieve the log file. Find statement '*Specify SKIP=* ***n*** *when continuing the load .'* in the log file.
- Examine the log file and determine whether the problems with the data are easily amendable. Retrieve .bad and .rejected files from the same location where SQL Loader log files are found, review the problem and decide whether the entire extract has to be corrected or the upload should continue forward.
- Re-upload the input data file to the server
- Submit the batch once again, this time specifying the ***n*** as a ***skip*** batch parameter

Simillar approach can be utilised to recover from the partial data upload. Note that in order to provide an additional safeguard for your effort and allow recovery it is recommended to create the data extract with records ordered by the primary key. This technique will allow you to determine the portion of the remainder of the un-uploaded data and make decision on the subsequent actions. If you are uploading large volumes of data and the interruption happened toward the end of the upload process it could be beneficial to complete the upload rather than to cleanup and start over.

Consider the following scenarios:

- Data Upload batch process ended abnormally due to an unrecoverable event such as software malfunction. In this case neither SQL loader nor the batch process are able to end gracefully and report the number of records processed.
- Data Upload batch process encountered a legitimate error and the batch thread and the entire batch run is now in error status.

Copyright © 2026, Oracle and/or its affiliates.

- The SQL Loader process ended with fatal error that prevented it to log the "skipped" option properly and it is not found anywherein the SQL Loader log

If you decied to proceed with recovery, perform the following steps:

- Query the table and determine the primary key of the last record that was sucessfully uploaded - this would be possible if the data in the input file was ordered
- Then determine the position of this record in the data file
- Finaly, submit the batch once again and use the ***skip*** batch parameter to resume the load from this position

Tables Cleanup and Index Maintenance

The SQL Loader runs in parallel mode in order to maximize performance. Therefore the target tables are not emptied prior to the data insertion and must be done explicitly, by running corresponding batch jobs.

Indexes are disabled during the data upload and then need to be re-built afterwards. The product provides batch processes that support index disabling and re-building indexes and gathering table statistics.

Most of the larger volume tables in the application are partitioned. The partitioned indexes cannot be disabled implicitly by the data upload process and should be disabled implicitly before running the upload.

If your are migrating an existing on-premise Oracle Enterprise Utilities customer to the cloud, the migration requirements may include the data in the custom tables. On cloud, these tables reside in the Customer Modification schema. The product provides the dedicated batch controls to operate on the Customer Modification schema.

- Use batch control ***K1-SCLTB*** to truncate tables in **Staging** area and batch control ***K1-CLNTB*** to truncate tables in **Production**. Use batch control ***K1-CLNCM*** to truncate tables in Customer Modification schema.
- Use batch control ***K1-SDSIN*** to disable indexes in **Staging** area and batch control ***K1-DRPIN*** to disable indexes in **Production**. Use batch control ***K1-DRICM*** to disable indexes on tables in the Customer Modification schema.
- Use batch control ***K1-RIUSS*** to rebuild indexes and/or update table statistics in Staging and ***K1-RIUSP*** to perform the same in **Production**. Use batch control ***K1-RUSCM*** rebuild indexes and/or update statistics on tables Customer Modification schema.
- Use batch control ***K1-CLNKY*** to truncate **Key Reference** tables in **Staging** area
- Use batch control ***K1-CLNRT*** to truncate **XML Resolution** tables in Staging Area
- Use batch process ***K1-SDSTG*** to disable Triggers in **Staging** and batch control ***K1-PDSTG*** to disable triggers in **Production**
- Use batch process ***K1-SENTG*** to enable Triggers in **Staging** and batch control ***K1-PENTG*** to enable triggers in **Production**

Supported scenarios include:

- **Truncate Specific Table or Maintenance Object**: In order to truncate the specific table, submit the corresponding batch job, specifying the `table` parameter. In order to truncate the data stored in a specific Maintenance Object, submit the corresponding batch job, specifying the `maintenanceObject` parameter. The process will also disable indexes in the truncated tables.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If the truncated table's metadata defines a Key table, the Key table gets truncated too.

- **Truncate all Converted Tables**: In order to truncate all converted tables run the corresponding batch job without specifying either the `table` or `maintenanceObject` parameters. The process will disable indexes and truncate all tables marked for conversion in the metadata.
- **Truncate Key Reference Tables or XML Resolution Tables for Specific Table or Maintenance Object**: In order to truncate Key Reference table linked to a staging table, submit the corresponding batch job, specifying the `table` parameter. In order to truncate Key Reference tables for a specific Maintenance Object, submit the corresponding batch job, specifying the `maintenanceObject` parameter.
- **Truncate all Key Reference Tables or XML Resolution Tables**: Submit the corresponding batch job without specifying either the `table` or `maintenanceObject` parameters to truncate all Key Reference tables.
- **Disable Indexes for Specific Table or Maintenance Object**: In order to disable indexes for the specific table, submit the corresponding batch job, specifying the `table` parameter. In order to disable indexes for the specific Maintenance Object's tables, submit the corresponding batch job, specifying the `maintenanceObject` parameter.
- **Disable Indexes for all converted Tables**: In order to disable indexes on all converted tables run the corresponding batch job without specifying either the `table` or `maintenanceObject` parameters. The process will disable indexes and truncate all tables marked for conversion in the metadata.

> **Note**
>
> You should not use conversion batch processes to truncate and/or alter indexes on the batch and batch job stream-related tables. Attempt to cleanup the batch job history or reset sequences may render the system un-operational.

Load Performance Tuning

The data specifics â€“ volumes, structure and other aspects â€“ may justify customizing the default configurations for all or some tables.

The SQL Loader is processing data according to the Control File. The fragment that contains general load parameters is stored as Managed Content that is referenced on the Conversion Task Type.

You can create new Managed Content, configure the Conversion Task Type and specify the new settings on Conversion Master Configuration, for all or specific Tables or Maintenance Objects.

Understanding the Conversion Orchestration Process

The following sections provide information on general aspects of conversion orchestration.

Enabling Conversion

Copyright © 2026, Oracle and/or its affiliates.

Conversion activities are possible as long as conversion is enabled in the environment. The authorized Conversion Administrator may run the corresponding batch job to enable conversion.

Switching between Staging and Production Schemas

In the environment enabled for conversion, the online application is running against the database schema that contains synonyms pointing to either Staging or Production tables.

The switching is possible only while Conversion is Enabled

Navigate to **Admin > Conversion Support > Switch Schema** to switch the synonyms, .

The current schema information is displayed on the sidebar zone when Conversion is enabled in the environment.

> **Note**
>
> The operation fails if there are batch processes currently in progress. Should you receive the error message while attempting to switch synonyms, please review the running batches and wait until its all completed before repeating the attempt.

Preparing for Conversion

The preparation steps include evaluating initial conversion configurations provided by the product, customizing the configurations if needed, and finally, generating conversion artifacts.

Most of the preparation should be done when the environment is running against the Production schema, except for job streams for conversion processes that are scheduled and, published when the schema is switched to Staging.

Conversion Development

The creation of the legacy data extract and rehearsal of the data load and subsequent conversion data processing is done while the environment is running against the Staging schema.

Consider creating and scheduling the job stream for the sequence of the batch processes for both data load and following validation, key generation and insertion.

Uploading Data

SQL Loader implicitly disables the indexes in the non-partitioned tables before the upload. In the partitioned tables the indexes needs to be explicitly disabled by the batch process prior to the upload. Once the data upload is completed the indexes have to be rebuilt.

Upload has to be done in a certain order if loading single tables that belong to a Maintenance Object whose primary table is partitioned. The child tables within such Maintenance Objects contain Foreign Key constraints to the primary table's Primary Key. The primary table has to be uploaded first. The indexes should be rebuilt right after upload. The subsequent tables should be uploaded according to the Maintenance Object table's hierarchy (parent first, child next)

You may combine the table truncation, data upload and the index maintenance and statistic updates into a batch stream and create a dedicated batch job stream for each converted Table or Maintenance Object.

Conversion Run

For the mock-up, or dress rehearsal or the actual go-live conversion run you may choose to amend data load batch controls for tables/maintenance objects to improve performance:

Copyright © 2026, Oracle and/or its affiliates.

- Reduce the logging level - set ***log*** batch parameter to NOLOG
- Do not retain input data - set ***retaininput*** batch parameter to PURGE

Disabling Conversion

After conversion is completed, the various activities such as table truncation and index maintenance should not be allowed.

Upon conversion project completion, switch the schema to Production and request that the authorized Conversion Administrator run the corresponding batch job to disable Conversion in the environment.

Enabling Incremental Conversion

Legacy data conversion may be done in stages. After the first chunk is converted and the system begins running in production, you may need to convert the next portion(s) of the data. This orchestration macro-scenario is called *incremental conversion*; it imposes certain limits and restrictions on the conversion activities and it has to be approved by the management.

If the incremental conversion has been approved, request that the authorized Conversion Administrator run the corresponding batch job to enable the incremental conversion in the environment.

Security Setup for Conversion

The services associated with data conversion are combined into the following user groups:

- **Conversion Administrators** includes the services linked to the most sensitive database operations: enable/disable conversion and switching database synonyms between production and staging schema
- **Conversion Development** includes the services associated with conversion-related configurations
- **Conversion Operations** provides access to services associated with data load batch processes. This group could be extended to include services associated with specific table(s) or maintenance object data loads

These user groups are included in the base product. Your implementation may chose to use it as is or create a different setup.

Conversion Reconciliation Reports

Your cloud service subscription includes online database querying capabilities via Analytics Publisher and Database Actions. These can be used to create and run data reports against both production and staging schema tables. Contact your Security Administrator for the access information.

Batch Scheduler for Cloud Implementations

This chapter provides information and requirements on batch scheduler in support of Oracle Utilities Cloud implementations.

- SaaS Batch Scheduler Overview

Copyright © 2026, Oracle and/or its affiliates.

- Scheduler Batch Stream Definitions
- Batch Scheduler Batch Control
- Scheduler Batch Stream Operations

SaaS Batch Scheduler Overview

SaaS Batch Scheduler is a feature in Oracle Utilities Cloud Service Foundation that provides a SaaS batch scheduler engine and user interfaces. It facilitates customers and implementers to define, manage and schedule stream of batch jobs to run at periodic intervals using a user friendly interface. The SaaS batch scheduler engine is responsible for scheduling and processing the stream of batch jobs. It has a processing loop that runs every X seconds(configured by default at 10 seconds) to perform these operations. In addition, users can monitor the progress of the streams, each of the steps and also perform required exception handling. The SaaS batch scheduler engine processes the stream of batch jobs per scheduled time, within that minute.

SaaS Batch Scheduler feature is supported by the following system entities:

- Scheduler Batch Stream Definition â€“ a Business Object based on the Batch Job Stream Definition maintenance object
- Batch Scheduler Batch Control â€“ a Business Object based on the Scheduler Program maintenance object

Scheduler Batch Stream Definitions

This section provides information on Scheduler Batch Stream Definitions.

- Defining a Scheduler Batch Stream Definition
- Activating a Scheduler Batch Stream Definition
- Updating an Active Scheduler Batch Stream Definition
- Inactivating a Scheduler Batch Stream Definition
- Canceling a Scheduler Batch Stream Definition
- Deleting a Scheduler Batch Stream Definition
- Migrating Scheduler Batch Stream Definitions
- Tips For Setting Up Scheduler Batch Stream Definitions
- System Override Date Support

Defining a Scheduler Batch Stream Definition

In order to define a Scheduler Batch Stream Definition, from the **Admin** menu, select **Batch Operations**, select **Scheduler Batch Stream Definition**, and select **Add**.

A Scheduler Batch Stream Definition includes specifying the batch jobs and the order in which they should be run as "Stream Steps", the user to use to run these batch jobs and a "Schedule" to state when and how often the batch job stream should run. Batch jobs can be setup to run in sequence or in parallel fashion or a combination of both.

Copyright © 2026, Oracle and/or its affiliates.

Business Date: A Scheduler Batch Stream Definition can be optionally configured to run on a particular business date. When a business date is specified, each of the batch jobs in the stream run with the business date set. The business date can be either a specific business date or a variable business date. For example, business date set to run a day before current date. This ensures every time the stream runs the batch jobs in the stream run with current date -1.

Run On Activate: A Scheduler Batch Stream Definition can also be optionally configured to run as soon as it's activated.

Start Schedule Date/Time: It can optionally be configured to specify schedule to be effective in the future by setting a date/time to start schedule. If the start schedule date/time is not provided then the schedule on the Scheduler Batch Stream is effective as of current date.

The batch job to run for each stream step can be either specified directly or via a "Batch Scheduler Batch Control". A Batch Scheduler Batch Control enables setting custom batch parameters on a Batch Control. When a batch job is submitted for a stream step that has Batch Scheduler Batch Control specified on it, the custom batch parameters are used on the submitted batch job. Refer to Configuring a New Batch Scheduler Batch Control for more details.

A Stream step includes specifying the following details

- Step Name: the name of the step
- Batch Control: the batch control to run for that step.
- Thread Count: the number of threads to use to run this step's batch control
- Batch Scheduler Batch Control: the batch scheduler batch control to use for that step. Either a batch control or batch scheduler batch control can be specified but not both
- Step Conditions: specifies when the current step should run. It includes the following details
  - Step Name: the step that should have run prior to current step
  - Step Status: the status the prior step should be in when its finished
  - Step Condition: indicates how (And/Or) prior step should combine with next subsequent step conditions. For example, if step C should execute after step B and A have ended, then step C's has two step conditions 1)A Ended And 2)B Ended.

> **Note**
>
> There can be stream configurations where a step is specified and no steps run after the specified step runs. This is not a common scenario and a warning is logged on the Log tab to adjust stream configuration, if needed.

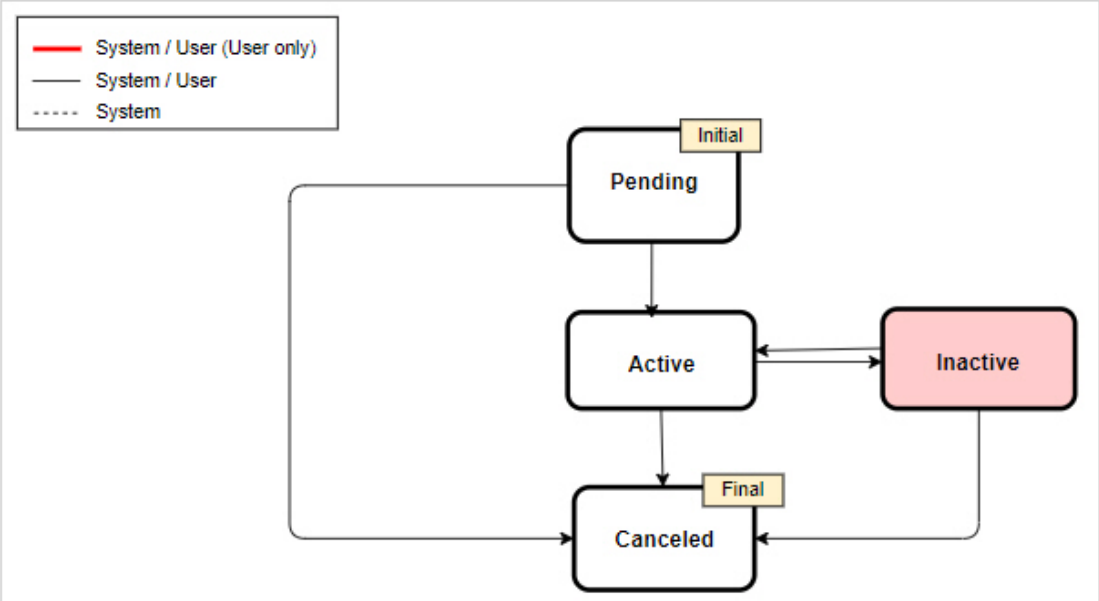
A Scheduler Batch Stream Definition's schedule can be specified using various frequencies.

- Daily, By Minutes: run every "x" minutes every day except on specified excluded days
- Daily, By Time: run at certain times every day except on specified excluded days
- Monthly, By Month Day Number: run on a specific day of the month, at specified time
- Monthly, By Week Days: run on days of a specific week in a month, at specified time
- Weekly: run every "x" weeks on specific days, at specified time

Copyright © 2026, Oracle and/or its affiliates.

- Yearly, By Month Day Number: run on a day of the month, at given time in specified months
- Yearly, By Week Days: run on days of a specific week, at given time in specified months
- Custom: run on a specific date at specified time

A Scheduler Batch Stream Definition can be setup to have level of service algorithms. Following three level of service algorithm types are supported.



- Stream Run has failed.
- Scheduler Batch Stream not started X minutes.
- Scheduler Batch Stream Job Ran Too long (Relative Run).

A Scheduler Batch Stream Definition can also be created without defining a schedule. When activated, it remains activated without a schedule and can be used for any manual runs.

There are custom ways in which a scheduler batch stream definition can be setup. This involves creating a Batch Scheduler Batch Control. Refer to Tips For Setting Up Batch Job Stream Definitions and Batch Scheduler Batch Control for more information.

Activating a Scheduler Batch Stream Definition

Once the Scheduler Batch Stream Definition is ready, it can be activated in the SaaS batch Scheduler to run at periodic intervals by transitioning the Scheduler Batch Stream Definition to Active state. An activated Scheduler Batch Stream Definition is called a Scheduler Batch Stream. A Scheduler Batch Stream runs based on the schedule defined on it.

By default, every batch job in a Scheduler Batch Stream Definition is internally setup to run in such a way that if that batch job fails the Scheduler Batch Stream run stops execution. User then has an option to fix the issue and re-start the stream.

Updating an Active Scheduler Batch Stream Definition

Copyright © 2026, Oracle and/or its affiliates.

A Scheduler Batch Stream Definition can be changed while in Active state. While active, any changes made to the Scheduler Batch Stream Definition are reflected on the next Scheduler Batch Stream run.

Changes to a Scheduler Batch Stream Definition can be made by editing it or using the edit options in the Scheduler Batch Stream Definition steps tab.

Inactivating a Scheduler Batch Stream Definition

A Scheduler Batch Stream Definition can be stopped from running further by inactivating it. Once inactivated, the SaaS batch scheduler stops scheduling and processing the scheduler batch stream definition. This is useful in situations where the stream needs to stop running temporarily for a brief period of time.

A Scheduler Batch Stream Definition can be re-activated back for scheduling and running in the future.

Canceling a Scheduler Batch Stream Definition

A Scheduler Batch Stream Definition can be canceled so that it no longer runs. If a scheduler batch stream run is ongoing when the scheduler batch stream definition is canceled, a warning is used. Canceling a scheduler batch stream definition has no impact on that currently ongoing run. User has the option to continue with the cancelation of the scheduler batch stream definition and let the scheduler batch stream run or navigate to the scheduler batch streams operations portal to cancel the currently ongoing run and then cancel the scheduler batch stream definition. Canceled scheduler batch stream definitions are allowed to be deleted.

Deleting a Scheduler Batch Stream Definition

A Scheduler Batch Stream Definition can be deleted in Pending, Inactive and Canceled states. In case of deleting an Inactive or a Canceled scheduler batch stream definition, respective scheduler batch stream runs are also deleted.

Migrating Scheduler Batch Stream Definitions

Scheduler Batch Stream Definitions can be migrated to other environments using the Content Migration Assistant (CMA) process or the Process Automation Tool.

Scheduler Batch Stream Definitions and Batch Scheduler Batch Controls are added in the target environment in the same status as the source environment. That is active scheduler batch stream definitions are added as active.

A Scheduler Batch Stream Definition should be marked as Inactive in source environment before migrating to target environment if it should not run as soon as it's migrated.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If a Scheduler Batch Stream is already scheduled in target environment and has next scheduled run date/time populated and the migration from source environment results in the stream having a different schedule, the new schedule will not be picked up by SaaS batch scheduler until the next run happens on the previously scheduled time. In order for the new schedule to take effect immediately, the scheduling details of the stream definition can be edited which resets the next scheduled run date/time so SaaS batch scheduler can re-determine next scheduled run date/time per new schedule.

Tips For Setting Up Scheduler Batch Stream Definitions

Configuring scheduler batch stream definitions to avoid open-ended stream issue

The scheduler batch stream definitions should always be configured such that the stream "ends" only once all the steps in the stream are completed either by configuring it on the "end of stream" step condition or by defining the inter-dependencies between the steps. This ensures the scheduler batch stream run execution does not stop in the middle of the stream.

Transferring batch job stream definitions to SaaS batch scheduler

Customers that are upgrading from prior cloud releases using Oracle Scheduler are recommended to plan transfer and migration of existing batch job streams definitions to SaaS Batch Scheduler. The recommended steps are:

- (Optional Step) Migrate existing batch job stream definitions from production environment to any pre-prod environment.
- In any pre-prod environment, use the transfer option to move the existing batch job stream definition to scheduler batch stream definition (new object for SaaS Batch Scheduler).
- Perform thorough testing of newly created scheduler batch stream definitions.
- Before migrating to the target environments, the batch job stream definitions in the target environment should be canceled(if needed) and deleted.
- Migrate the newly created scheduler batch stream definitions by using Content Migration Assistant (CMA) to production. Migration Plans for scheduler batch stream definitions are available for review.

Jobs that run past midnight must have same business date as other jobs in a stream

In situations where a scheduler batch stream runs too long and has some jobs run past midnight, all jobs in the scheduler batch stream can be set to run with same business date. Set the business date option value on the scheduler batch stream definition to 'SYSDATE' and the scheduler engine processes all the steps in the scheduler batch stream with same date when the scheduler batch stream started.

How to split a big stream into multiple smaller stream

If the Scheduler Batch Stream Definition is too long with many jobs to run, it can be split into multiple smaller streams such that one stream runs after the other. This can be done using a new batch control K1-RNSBS (Run Scheduler Batch Stream). Create a Batch Scheduler Batch Control for every sub stream, specify the batch control as K1-RNSBS, batch parameter name as the sub stream name. Use this Batch Scheduler Batch Control as a last step on the previous stream before it ends so that as soon as the previous stream's steps are completed, the last step will initiate the new sub stream. For example, if you have a stream with jobs A,B,C,B,E,F,G,H. Split the stream into stream 1 with A,B,C,D and stream 2 with E,F,G,H.

Copyright © 2026, Oracle and/or its affiliates.

Create a Batch Scheduler Batch Control with batch control K1-RNSBS, batch parameter name as stream 2. On stream 1 after step D, define a new step that invokes the created Batch Scheduler Batch Control. Note that there are no dependencies between sub-streams. That is each sub stream would be kicked off by the new batch control to run on it's own and the stream that called the sub stream does not wait for it to finish. So such configuration is to be used with only those steps that run in parallel.

> **Note**
>
> Sub-streams follow the main stream's schedule. Schedule on a sub-stream is generally not supported.

How to configure scheduler batch stream definitions to run only on OUAF working calendar dates

To setup Scheduler Batch Stream Definition to run only on working days, use the batch control K1-CWCEL. Create a Batch Scheduler Batch Control with this batch control, batch parameter Work Calendar set to required work calendar, Verify that **Run On Business Day** is set to true. Use this Batch Scheduler Batch Control as the first step to run on the stream. Define the stream to end if this step fails. Define the stream's subsequent step to execute if this step succeeds. When the stream runs on a scheduled day, the first step checks if the day falls on a working day as per the work calendar. If the day is not a working day then the stream ends execution ensuring stream runs only on desired dates.

Scheduler batch stream definitions that check existence of a file

In situations where a scheduler batch stream definition needs to check if a file has been uploaded/created by another process before it can continue with rest of it's processing, a special batch program K1-OSCFE is available. A stream step can be introduced referring to this new batch program with parameter specifying which object storage bucket to check the file in and also status to return if the file does not exist. This stream step can be added right before the step that has dependency on checking the existence of the file and continue processing or not.

Handling scheduler batch stream definitions inter-dependencies

In situations where a scheduler batch stream should not run when another scheduler batch stream is running, the inter-dependencies between such scheduler batch stream definitions can be configured by using a special batch program K1-CKCCR. Following steps are needed to setup such configuration.

- The new batch program accepts two parameters script name and script data. Write a CM script that checks whether a dependent job stream is running. If it's running, then the script should terminate with an error.
- On the scheduler batch stream that needs to be paused/hold if another job stream is running, add a new stream step as the first step of the job stream. Use the new batch program on the first step(by setting the CM script as the input parameter) or create a batch scheduler batch control if the batch control is to be used across many job streams with different CM service scripts as input parameters. Set the dependent job stream name as the script data parameter.
- Update the "End Of Stream" step condition such that if first step has failed, end the stream. This ensures the scheduler batch stream does not run if the other dependent scheduler batch stream is already running.

Copyright © 2026, Oracle and/or its affiliates.

- Update the step(s) intended to execute after the first step, the step condition that if first step succeeded only then these steps should continue.

> **Note**
>
> The special batch program is not restricted to only these situations. It can be used in many custom scenarios by writing the corresponding CM script that terminates if a desired situation is met.

System Override Date Support

This section provides information on system override date support.

A System Date can be overridden at either system level or user level or both. SaaS Batch Scheduler supports the system date override at system level only. The scheduler batch streams are scheduled and processed including submitting batch jobs on the stream steps per system date override. Any online operations performed by user on the scheduler batch stream operations portal such as skip, pause, cancel etc are also processed per system date override.

> **Note**
>
> When system date is overridden, scheduler batch stream definitions that are already scheduled and have next scheduled date set on them do not automatically get the new scheduled date per the overridden system date. This means the next run would be per the current date/time. The overridden system date reflects on the subsequent runs after the scheduler batch stream runs once. If the system override date needs to take effect immediately, the stream's schedule can be updated. This reset/blanks out the next scheduled run so it gets determined immediately per system overridden date.

Batch Scheduler Batch Control

This section provides information on using batch scheduler batch controls.

- Configuring a New Batch Scheduler Batch Control

Configuring a New Batch Scheduler Batch Control

In order to configure a new Batch Scheduler Batch Control, from the **Admin** menu, select **Batch Operations**, and select **Batch Scheduler Batch Control**. Use the **Batch Scheduler Batch Control** portal to search for and view existing batch scheduler batch controls.

A Batch Scheduler Batch Control is an entity that holds details of a batch control. Typically a scheduler batch stream definition is defined with batch control specified directly on it. In this case the batch parameters on the batch control are used in batch job submissions. A Batch Scheduler Batch Control can be created when batch parameters need to be customized different from the default batch parameters. The Batch Scheduler Batch Control can then be used on the Scheduler Batch Stream Definition. Only active batch scheduler batch controls can be used on the Scheduler Batch Stream Definition.

Copyright © 2026, Oracle and/or its affiliates.

Scheduler Batch Stream Operations

The **Scheduler Batch Stream Operations** portal provides an overview of scheduler batch streams that are currently running or suspended or completed within the last week.

To navigate to Scheduler Batch Streams Operations portal, from the **Admin** menu, select **Batch Operations**, and select **Scheduler Batch Stream Operations**.

By default the Running Search By option is displayed where streams that are running can be searched. Broadcast any of the stream run for more information on status of each of its steps.

Two more Search By options are available to search the scheduler batch streams â€" 1. Suspended 2. Completed

Running Search By Option: This option displays Scheduler Batch Stream runs that are In Progress, Stopping, Pausing or Canceling statuses. Refer to Monitoring A Running Scheduler Batch Stream for more information.

Suspended Search By Option: This option displays Scheduler Batch Stream runs that are Failed, Stopped or Paused statuses. Refer to Monitoring A Suspended Scheduler Batch Stream for more information.

Completed Search By Option: This option displays Scheduler Batch Stream runs that are Ended or Canceled statuses. Refer to Monitoring A Completed Scheduler Batch Stream for more information

- Monitoring a Running Scheduler Batch Stream
- Monitoring a Suspended Scheduler Batch Stream
- Viewing a Completed Scheduler Batch Stream
- Handling Exceptions

Monitoring a Running Scheduler Batch Stream

A Scheduler Batch Stream is considered Running if it is one of the following statuses.

- In Progress
- Stopping
- Pausing
- Canceling
- Ending

You can monitor the progress of a running Scheduler Batch Stream by broadcasting it from the Running search by option search results. The broadcasted zone **View Stream Steps** shows progress of the stream such as what steps have already completed and their status, what is the currently running step(s) along with steps that have not yet started. You can monitor the progress of the stream by refreshing the page or by configuring the page to refresh automatically. To configure automatic page refresh, refer to the **User Portal Preferences** for this portal.

The **View Streams Steps** zone also has information on when the step started and completed, the duration the step ran for and the option to view the batch job run. Clicking on the **View** button displays the batch run details of the batch job.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> A stream is set to Ending status if stream is In Progress and the End Of Stream step has ended. This means some of the steps are still either in In Progress or Submitted status. An Ending stream is set to Ended status once no more steps are In Progress or Submitted status.

Stream Operations

When performing operations on a scheduler batch stream, the operation is not immediately processed real-time. User can only make a request for a **desired** operation. SaaS Batch Scheduler processes these requests and updates scheduler batch stream run accordingly.

Following operations are allowed on the Running scheduler batch streams.

- *Cancel:* A scheduler batch stream run can be canceled while in In Progress or Pausing state. When this operation is performed, scheduler batch stream is set to Canceling status. SaaS Batch Scheduler processes these requests and submits a cancellation request to cancel the underlying batch job. Once the underlying batch job is canceled, the scheduler batch stream is set to Canceled status. A Canceled scheduler batch stream is removed from this Running streams list and is displayed on the Completed streams list.
- *Stop:* A scheduler batch stream run can be stopped while in In Progress state. When this operation is performed, scheduler batch stream is set to Stopping status. SaaS Batch Scheduler processes these requests and submits a cancellation request to cancel the underlying batch job. Once the underlying batch job is canceled, the scheduler batch stream is set to Stopped status. A Stopped scheduler batch stream is removed from this Running streams list and is displayed on the Suspended streams list

  > **Note**
  >
  > Note the difference between canceling a scheduler batch stream and stopping a scheduler batch stream. Canceling a scheduler batch stream cancels the steps in progress and cancels the scheduler batch stream so rest of the stream steps do not run permanently. Stopping a scheduler batch stream stops/cancels the stream steps that are In Progress and stops the stream execution temporarily. A stopped stream can be re-started from the Suspended Streams list on the Scheduler Batch Streams Operations Suspended Search By Option. Re-starting a stopped stream re-starts the steps that were stopped and submits the batch jobs associated with those steps to continue rest of the processing of the scheduler batch stream.

- *Pause:* A scheduler batch stream can be paused while In Progress state. The scheduler batch stream is set to Pausing status. SaaS Batch Scheduler processes these requests and pauses the scheduler batch stream once stream steps that are In Progress have completed. While the steps are In Progress, the scheduler batch stream is set to Pausing status. Once steps are complete, the scheduler batch stream is set to Paused status. If the stream steps that are In Progress are the last set of steps to be processed, then there are no steps remaining to pause the scheduler batch stream. Scheduler batch stream is not Paused and completes processing.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Note the difference between stopping a scheduler batch stream and pausing a scheduler batch stream. Stopping a scheduler batch stream cancels the steps that are in progress and stops the stream execution temporarily. Pausing a scheduler batch stream, the steps In Progress continue execution and complete and stream is paused after that. Rest of the stream execution is on hold temporarily.

- *Interrupt:* An interrupt operation is used when the scheduler batch stream is stuck in In Progress state for long period of time and is not progressing. When used, the interrupt operation cancels the steps that are currently In Progress and re-submits the batch jobs on those steps so that the rest of the steps in the scheduler batch stream can be processed.

Stream Step Operations:

- *Skip:* A stream step(s) can be skipped by using the skip multi-action button on this zone. Only steps that are in "Not Submitted" state can be skipped.

The stream steps can be in one of the following states:

- Not Submitted
-  Submitted
-  In Progress
-  Ended
-  Skipped

Monitoring a Suspended Scheduler Batch Stream

A Scheduler Batch Stream is considered suspended if it's stopped running temporarily. A Scheduler Batch Stream is considered Suspended if it is one of the following statuses.

- Failed
- Stopped
- Paused

You can monitor the progress of a suspended Scheduler Batch Stream by broadcasting it from the Suspended search by option search results. The broadcasted zone **View Stream Steps** shows progress of the stream such as what steps have already completed and their status, what is the currently running step(s) along with steps that have not yet started. You can monitor the progress of the stream by refreshing the page or by configuring the page to refresh automatically. To configure automatic page refresh, refer to the **User Portal Preferences** for this portal.

The **View Stream Steps** zone also has information on when the step started and completed, the duration the step ran for and the option to view the batch job run. Clicking on the **View** button displays the batch run details of the batch job.

Stream Operations

Copyright © 2026, Oracle and/or its affiliates.

When performing operations on a scheduler batch stream, the operation is not immediately processed real-time. User can only make a request for a **desired** operation. SaaS Batch Scheduler processes these requests and updates scheduler batch stream run accordingly.

Following operations are allowed on the Running scheduler batch streams.

- *Resume:* A scheduler batch stream run can be resumed from Paused state. When this operation is performed, scheduler batch stream is set to In Progress status. SaaS Batch Scheduler processes these requests and starts processing the rest of the steps in the scheduler batch stream. A resumed scheduler batch stream is removed from this Suspended streams list and is displayed on the Running streams list.
- *Restart Stream:* A scheduler batch stream run can be restarted while in Failed or Stopped state. When this operation is performed, scheduler batch stream is set to In Progress status. SaaS Batch Scheduler processes these requests and starts processing the rest of the steps starting with Failed or Stopped steps. A restarted scheduler batch stream is removed from this Suspended streams list and is displayed on the Running streams list
- *Cancel:* A scheduler batch stream run can be canceled while in any one of the Suspended states. When this operation is performed, scheduler batch stream is set to Canceling status. SaaS Batch Scheduler processes these requests and in case of Failed scheduler batch stream, submits a cancellation request to cancel the underlying batch job. Once the underlying batch job is canceled, the scheduler batch stream is set to Canceled status. A Canceled scheduler batch stream is removed from this Running streams list and is displayed on the Completed streams list.

Stream Step Operations:

- Skip: A stream step(s) can be skipped by using the skip multi-action button on this zone. Only steps that are in "Not Submitted" state can be skipped.

The stream steps can be in one of the following states:

- Not Submitted
-  Submitted
-  Ended
-  Failed
-  Stopped
-  Skipped

Viewing a Completed Scheduler Batch Stream

A Scheduler Batch Stream is considered Completed if it is one of the following statuses.

- Ended
- Canceled

You can view completed Scheduler Batch Stream by broadcasting it from the Completed search by option search results. The broadcasted zone **View Stream Steps** shows status of the stream such as what steps have already completed and their status, what is the currently

Copyright © 2026, Oracle and/or its affiliates.

running step(s) along with steps that have not yet started. You can monitor the progress of the stream by refreshing the page or by configuring the page to refresh automatically. To configure automatic page refresh, refer to the **User Portal Preferences** for this portal.

The **View Stream Steps** zone also has information on when the step started and completed, the duration the step ran for and the option to view the batch job run. Clicking on the **View** button displays the batch run details of the batch job.

The stream steps can be in one of the following states:

- Not Submitted
-  Submitted
-  Ended
-  Failed
-  Skipped
-  Canceled

Handling Exceptions

Errors in Scheduler Batch Stream

A batch job submitted as part of a Scheduler Batch Stream can run into error with one of its threads being in error. It could be because of business scenario or environment issue etc. In such a case, the corresponding Scheduler Batch Stream stops execution and its step ends in failed state. The cause for the failure is noted on the Additional Details column on the stream step. You can fix the issue and restart the stream via the multi-select **Restart Stream** option on the scheduler batch stream operations completed query option. Restarting a stream will result in the Scheduler Batch Stream continuing execution from the step that failed and finish through to end.

> **Note**
>
> Once a Scheduler Batch Stream fails, its future scheduled runs no longer execute until the failed run is addressed.

Scheduler Batch Stream stuck in running status

A Scheduler Batch Stream can be stuck in Running status as one of its steps is in running status for too long. In this situation there are various options.

Cancelling a scheduler batch stream: The corresponding batch job submission is stuck in pending status as the thread pool name set on the batch control is invalid. In such case, the running Scheduler Batch Stream can be cancelled via the multi-select **Cancel** option. The thread pool name can then be set to a valid value and the Scheduler Batch Stream can be submitted manually via the **Run Manually** option on the Scheduler Batch Stream Definition or wait until it's scheduled to run next.

Copyright © 2026, Oracle and/or its affiliates.

Interrupting a scheduler batch stream: The corresponding batch job submission is stuck in started status while the respective batch run or batch threads have ended. In this case, the running scheduler batch stream can be interrupted via the multi-select **Interrupt** option. This sets the scheduler batch stream and respective steps in the "Failed" state. The **Restart Stream** multi-select option can then be used to re-start the stream to continue execution from the step that failed and complete processing of stream.

Batch Queues Overview

Batch Queues is a new portal where users can view the status and progress of various batch jobs in the system. The portal provides visibility for users into what batch jobs are queued or running on existing thread pools DEFAULT and NOCACHE.

Users can view each of the batch job's details and broadcast them to view list of threads, their status and records details.

The list of batch jobs can be filtered by status, thread pool and batch control to view desired batch jobs.

Batch Alerts

This chapter provides information and requirements on batch alerts in support of Oracle Utilities Cloud implementations.

- Batch Alerts Overview
- Alerting On A Batch Job Stream
- Alerting On A Batch Job

Batch Alerts Overview

Batch Alerts provide alerting and monitoring mechanisms for batch and batch job streams. Alerts are raised when desired batch jobs or batch job streams do not perform as expected.

Currently there are few level of service algorithms on batch controls to indicate how the corresponding batch jobs are doing.

New level of service algorithms are now introduced on the batch controls.

In addition, level of service algorithms are introduced on batch job streams to determine overall health of batch job streams.

New installation options health check algorithms are introduced for health component batch and batch job stream. Each health component's health check algorithm will invoke their level of service algorithms and return the overall results

Overall results from health check algorithms are displayed on the health check portal for monitoring purposes to view overall health of the system.

Copyright © 2026, Oracle and/or its affiliates.

To receive alerts on overall health of the system, use the alert probe - bash script external utility that probes the system and sends email notifications to configurable set of email addresses.

The alert probe can be run on windows or linux machines. Alerts can be customized for errors and warnings. A paging alert is sent in case of errors. A non-paging alert is sent in case of warnings.

The frequency at which alerts are raised is configurable.

> **Note**
>
> The alert probe is provided on an use-as-is basis, no support is provided for it.

Alerting On A Batch Job Stream

To receive alerts on an active batch job stream, edit the batch job stream and add the desired level of service algorithm on it.

> **Note**
>
> Only algorithm types are delivered for Batch job stream level of service algorithms. A corresponding algorithm must be created before it can be added onto the batch job stream

Following level of services are currently supported on batch job streams

- Batch Job Stream has not started within 'X' minutes
- Batch Job Stream has failed
- Batch Job Stream ran too long (relative run)

Alerting On A Batch Job

Additional level of services are included on batch job that will be part of alerting mechanism

- Batch Job has processed low number of records
- Batch Job throughput is too low
- Batch Job ran too long (relative run)
- Batch Job has not started within 'X' minutes

ILM Dashboard for Cloud Implementations

This chapter provides information on ILM Dashboard in support of Oracle Utilities Cloud implementations.

- ILM Dashboard Overview

Copyright © 2026, Oracle and/or its affiliates.

- ILM Dashboard - Main Tab
- ILM Dashboard - Partitions Tab
- ILM Dashboard - Drop A Partition

ILM Dashboard Overview

ILM Dashboard is a feature that provides an all-in-one portal to view Information Lifecycle Management (ILM) configurations and manage ILM tasks in one place. ILM Dashboard has two tabs - Main tab and Partitions tab.

Main tab displays information on current ILM configuration, if any, current retention period of maintenance objects and status of ILM batch processes

Partitions tab displays information on current partition data in the system for all maintenance objects including the sub-partition data.

ILM Dashboard - Main Tab

The ILM Dashboard - Main tab has information on current ILM configurations, retention period on maintenance objects and ILM batch processes current status.

ILM Configuration: Displays the current ILM configuration in the system as well as the default retention period for all ILM eligible maintenance objects.

Retention Period Overridden Maintenance Objects: Displays the list of ILM eligible maintenance objects where the retention period is overridden and their current retention period.

ILM Batch Jobs Status: Displays the list of ILM Batch Controls and their latest batch job/run details. ILM Batch Controls that never ran even once are displayed first followed by the ones that ran in descending order of their last run date/time.

ILM Batch Runs: Displays the batch runs for the ILM batch control that was broadcasted on the "ILM Batch Jobs Status" zone. The batch runs are displayed sorted by end date/time with recently ended ones displayed first. Each run's first three batch parameter values are displayed on it's run. Customers can navigate to respective batch job submission page to view list of all parameters and their values.

ILM Dashboard - Partitions Tab

The ILM Dashboard - Partitions tab displays information on current partitions in the system for all maintenance objects that are ILM enabled.

Maintenance Objects: Displays a drop down with list of maintenance objects that are ILM enabled. Selecting a maintenance object displays the maintenance object along with it's partition information such as all partitions Total Size (In GB) and Total Records Based On Last Stats. If no maintenance object is selected, all maintenance objects are displayed along with their partition information.

Checking the PMAX partitions with data displays only those maintenance objects and their PMAX partitions information that have data in the PMAX partitions. If a maintenance object and PMAX partitions with data is selected, only the PMAX partitions information of the PMAX partitions that have data in it are displayed for the selected maintenance object.

Copyright © 2026, Oracle and/or its affiliates.

Partitions: Displays list of partitions and their details for the selected maintenance object. The partitions are sorted by partition name latest month first. By default, the last twelve months and Pmax partition are displayed by default. User can further search for historical partitions using the filter options upto last four years.

For each partition, it's Compression Type is displayed. Compression Type for each displays "Refer Sub-partition" if the partition does not have compression but one of the sub-partitions does.

For a maintenance object, at any given time, the oldest partition can be requested to be dropped via the "Drop Partition" button. A new "Partition Drop Request" object is then created for this request to go through the approval process. Refer to Dropping A Partition for more information on request to drop partitions and it's approval process.

Sub-partitions: Displays list of sub-partitions and their details for the selected partition. The sub-partitions are sorted by sub-partition name latest month first.

Partition Drop Requests: Displays list of partition drop requests along with it's current status and applicable actions for the current user. Only displayed if there are partition drop request records. Displays partition drop requests for the selected maintenance object, if none is selected then all partition drop requests for all maintenance objects are displayed.

By default, only partition drop requests in Pending and Error status are displayed. For partition drop requests in other statuses, user can use the filter options. Refer to Dropping A Partition for additional information.

ILM Dashboard - Drop A Partition

The ILM Dashboard - Partitions tab displays information on current partitions in the system for all Maintenance Objects that are ILM enabled.

For a Maintenance Object, at any given time, the oldest partition of the primary table can be requested to be dropped via the "Drop Partition" button by a **Requester** user. A new "Partition Drop Request" object is then created for this request in Pending status and a To Do is created for an Approver user so the request goes through the approval process.

Requesters

A user must be setup as a Requester user in order to drop a primary table's oldest partition for a selected Maintenance Object at any given point. Please refer to Administrative User Guide for more information on how to setup these users.

> **Note**
>
> A pre-requisite exists for dropping a primary table's oldest partitions with data. The crawler Batch Control associated with the Maintenance Object must be run first prior to requesting the partition drop, so that relevant data is appropriately marked for the partition to be dropped.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> When oldest partition of the primary table for a maintenance object is requested to dropped, the oldest partitions of child tables for that maintenance object are also dropped. This is based on the referenced partitions setup for the maintenance object. If the maintenance object does not have referenced partitions setup, then only the primary table's oldest partition is dropped.

The "Partition Drop Request" object is initially in Pending status and displayed to **Approver** users in the "Partition Drop Requests" zone.

Approvers

A user must be setup as an Approver user for them to approve any Partition Drop Requests.Please refer to Administrative User Guide for more information on how to setup these users.

Viewing Drop Partition Requests

Only the Requester or Approver can view Drop Partition Requests based on their access. By default, only Pending or Error Drop Partition Requests are displayed. User can use the filter critera option to display all Drop Partition Requests or search for ones with different statuses. Depending on the user's access, the available and applicable actions are displayed to the user.

When the Approver views list of Partition Drop Requests, they have the option of either approving or rejecting the request.

Approving a request results in Partition Drop Request in In Progress status and completing the To Do previously created for that Approver. A batch job submission for Batch Control K1-ILMDR (ILM Automation - Drop Partition) is also initiated to drop the requested partition. Once the partition is successfully dropped, the Partition Drop Request transitions to Completed final status. Otherwise, if there are any errors, the Partition Drop Request transitions to Error status.

Rejecting a request requires specifying a reason as to why the request was rejected. Possible reasons for rejecting a request are 1. Approver determines that partition that is requested to drop is required and so it should not be dropped. 2. Incorrect request to drop a partition was made where Requester accidentally requested wrong partition to be dropped. Once the Approver rejects the request, the Partition Drop Request transitions to Rejected final status.

When the Partition Drop Request is in Error status, the Requester has the option to re-try the request again or cancel the request. In the case of re-try option, Requester can review the errors, take any necessary steps needed and and re-try the Partition Drop Request again. For example, if the pre-requisite step was not taken prior to requesting a partition drop, the data in the partition will not be marked for dropping. In this case, an error would be generated when the partition with that data is requested to be dropped. Requester can review the error to confirm the reason and run the crawler Batch Control associated with the Maintenance Object to mark partition data to be dropped. Once it is complete, Requester can re-try the Partition Drop Request again.

A Partition Drop Request in Pending status can be canceled by the Requester user if desired. A Requester user can also cancel the Partition Drop Request that is in Error status if they wish to not re-try the request.

Recommendations

It is recommended that dropping partitions is tested thoroughly in non-production environments first before performing the same operation in a production environment.

Tips

Copyright © 2026, Oracle and/or its affiliates.

- Once a partition is dropped, the data is also removed from the database and there is no way to restore the data back into the environment. It is imperative that customers review the partition and the respective data before requesting and approving the Partition Drop Request.
- Customers can optionally choose to raise an SR(Service Request) to request a database copy prior to dropping a partition

Oracle Cloud Infrastructure Identity and Access Management Integration

This chapter provides information about integration with Oracle Cloud Infrastructure Identity and Access Management for Oracle Utilities cloud services.

> **Note**
>
> This section does not apply to all implementations. Contact your system administrator to confirm if your implementation includes Oracle Utilities Cloud Service Foundation and Oracle Cloud Infrastructure Identity and Access Management (IAM) integration.

- Identity and Access Management Integration Overview
- Configuring Identity and Access Management Integration

Identity and Access Management Integration Overview

Oracle Cloud Infrastructure Identity and Access Management (IAM) with Identity Domains provides identity and access management functionality for the Oracle Utilities cloud services and supports single sign on (SSO) and identity federation capabilities.

It protects both online and webservices API access to the Oracle Utilities cloud service. Refer to the Detailed Oracle Cloud Services Administration guide for the instructions on how to configure and manage online and API access and maintain users, groups, application roles and integration OAuth clients.

In IAM, an identity domain is provided with each service subscription. Once provisioned, the identity domain is administered exclusively by the client.

Security administrator uses identity domains to manage application users, who are given access to a one or multiple application environment(s). The security administrator may also assign another user to an administrative role in the identity domain and delegate user management privileges.

Newly created users receive an account activation email from IAM, and must reset their password.

The integration with IAM supports Just-In-Time User Provisioning.

When a user attempts to access the utility application URL, the user is redirected to an identity domain for authentication. Once the user is successfully authenticated, they are redirected back to the application and the authentication token is evaluated and validated. The system then checks if the user already exists in the application, and if not, it triggers the Just-In-Time User Provisioning logic that creates and activates the new user.

Copyright © 2026, Oracle and/or its affiliates.

The **F1-IDMUser** business object is used for creation of new user records sourced from the external identity management integrations.

For the integration with Oracle Cloud Infrastructure Identity and Access Management, the algorithm is defined on the **F1-IDMUser** business object to determine the Template User whose information should be copied to the newly created user.

- Just In Time User Provisioning

Just In Time User Provisioning

Just-In-Time User Provisioning is a process of creating a new user record upon first successful login. The implementation may follow either one of the main approaches:

- **Just-In-Time with Coarse-Grained User Authorization** allows security administrator to immediately begin working on the authorization and access setup, while other ("business") users might wait until the proper access and authorization is configured for them in the application.
- **Just-In-Time with Fine-Grained User Authorization** provides both security administrator and the business user with instant access to the appropriate application functionality.
- Coarse-Grained User Authorization (Default)
- Fine-Grained User Authorization

Coarse-Grained User Authorization (Default)

With course-grained user authorization, Just-In-Time Provisioning creates users with two authorization levels:

- **Security and Access Administrator.**
  - **Users with an administrative role in the identity domain** are provisioned using a **Security Administrator Template User**. The user gains the access to all transactions and services related to application security and user authorization setup
- **Authenticated User**
  - **Users with no administrative role(s) in the identity domain** are provisioned using a **Minimum Access Template User**. The user gains access to *My Preferences* page only. The security and access administrator completes the authorization and access setup manually.

No additional configuration effort is needed if your implementation chose to follow this approach. The scope of the actual security access for both Security Administrator and Authenticated User is customizable. Refer to Override Default Access for more information.

Fine-Grained User Authorization

With fine-grained user authorization,Just-In-Time Provisioning creates users with multiple authorization levels, according to their Identity Domain's Group membership and based on utility application configuration:

- **Security and Access Administrator**
  - **Users with an administrative role in the identity domain** are provisioned using a **Security Administrator Template User**. The user gains the access to all transactions and services related to application security and user authorization setup

Copyright © 2026, Oracle and/or its affiliates.

- **Business/Administrative Users** with access to a specific business and/or administrative functions in the application
  - **Users that are members of a Group in the identity domain** are provisioned using a **Template User mapped to this Group**. The user gains access to the application according to the Template User's setup.
- **Authenticated User**
  - **Users with no administrative role(s) in identity domain** and **no membership in any of the identity domain's Groups** are provisioned using the **Minimum Access Template User**. The user gains access to *My Preferences* page only. The security and access administrator completes the authorization and access setup manually.

The mapping between identity domain's Groups and Template Users is stored in theIdentity and Access Management Integration Configuration.

Configuring Identity and Access Management Integration

The integration configuration in the utility application has to be done in conjunction with the corresponding setup in the Identity and Access Management system.

- Configuring Just In Time User Provisioning
- Customizing the Integration

Configuring Just In Time User Provisioning

In order to configure user authorization for Just in Time Provisioning, perform the following steps:

- Create User Groups that represent most typical business and/or administrative roles in the application
- Create Template Users that represent typical access level for major business and/or administrative functions
- Request your customer's identity domain Administrator to create Groups in IAM with Identity Domains that will correspond to the Template Users create above
- Setup the mapping between the identity domain's Groups and Template Users using Identity and Access Management Integration Configuration
- Template Users and User Groups
- Identity and Access Management Integration Configuration

Template Users and User Groups

- Define User Group(s) that represent the major business and/or administrative responsibilities in the application
- Define Template User(s) that represent the typical level of access to the application functionality

Identity and Access Management Integration Configuration

Copyright © 2026, Oracle and/or its affiliates.

The Identity and Access Management Integration Configuration master configuration stores the definitions related to the integration with Oracle Cloud Infrastructure Identity and Access Management.

For Just-In-Time User Provisioning, configure the **User Provision Rules**:

- Map the Groups defined in the identity domain to the Template Users defined in the application.

Customizing the Integration

The product is delivered with out-of-the-box support for Just in Time User Provisioning with Coarse-Grained Authorization. Possible customization scopes are:

- Customize the default access level for Coarse-Grained Authorization. See Override Default Access Level for details.
- Configure the Just in Time User Provisioning with Fine-Grained Authorization.
- Override Default Access Level
- Override Logic to Determine Template User

Override Default Access Level

Both Security Administrator and Minimum Access Template Users are specified as parameters for the K1-IDCSUSRTM algorithm .

To override the default access level:

- Create new Template Users and setup user groups for default administrative access
- Create new Template Users and setup user groups for default minimum access

Create a new version of the K1-IDCSUSRTM algorithm and specify the Template Users created above as the algorithm's parameters

Override Logic to Determine Template User

The algorithm that determines the Template User is implemented as a pre-processing algorithm that determines the Template User on the **F1-IDMUser.** business object.

To override the logic used to determine the template user:

- Create a custom algorithm type and algorithm and use custom logic to determine the Template User for provisioning.
- Deactivate the existing product algorithm and specify the custom algorithm instead. Note that the algorithm that determines the Template User should be plugged before the algorithm that populates the data from the Template User.

Oracle Cloud Object Storage

Oracle Cloud Object Storage (Object Storage) is a part of Oracle Cloud Infrastructure Storage Services.

Copyright © 2026, Oracle and/or its affiliates.

Oracle Cloud Object Storage can be accessed and managed using Oracle Cloud Infrastructure Console or programmatically using Command Line Interface (CLI), REST APIs or Java. The Object Storage that is used by the system is owned and managed by customers.

Oracle Utilities Cloud Services use Object Storage as the file storage location for all file related integrations. Batch processes that need to read or write files as input will access Object Storage.

The system requires some configuration in order to allow it to connect to the Object Storage and have access to the files that need to be processed by it. The following chapter describes the required configuration in order to connect to Object Storage as well as provides information on how to reference files in Object Storage in batch processes.

Please refer to Oracle Cloud Infrastructure documentation for more information on Object Storage.

- File Storage Configuration for Object Storage
- Referencing Files on Object Storage

File Storage Configuration for Object Storage

In order for the system to connect to Object Storage a File Storage Extendable Lookup has to be created with the following information:

- The Oracle Cloud Infrastructure tenancy details, which can be obtained from the Oracle Cloud Infrastructure Console(available to customers who purchased Object Storage).
- The API Key that is used by the system to connect to that Object Storage.

Refer to product documentation on "File Storage" for more details.

> **Note**
>
> - Each File Storage Location configuration refers to a combination of Object Storage Tenancy, Compartment and User ID.Since customers can choose to create many Compartments in their Object Storage, access to each such Compartment will require a separate File Storage configuration.
> - It is also recommended that each File Location configuration will reference a **different** Cloud Infrastructure User ID.This can limit, for example, the system's access to production files from a non-production environment.
> - API Keys are managed using Key Rings. Key Rings can be shared between File Storage Extendable Lookups but the Keys in these Key Rings cannot be shared across system environments. For example, keys generated for the Development environment **cannot** be used for the Testing or Production environments.Refer to the following topics in the Framework Administrative User Guide:
>
>   **External File Storage**, **Key Rings**.

Referencing Files on Object Storage

Access to files is typically required in Batch processes. Some batch processes include direct reference to the files they need to process (for input or output) while some processes rely on

additional configuration (for example, the Content Migration Assistant (CMA) Import and Export processes that rely on the CMA Master Configuration Settings).

Direct Reference

Reference to Object Storage can be used anywhere that a file location is allowed. The format is:

file-storage://<File Location>/<Bucket>/<Filename.ext>

- <File-Location>: The File Storage Extendable Lookup value that is defined for that file.It should include all the details the system needs to access the Object Storage location for that file.
- <Bucket>: The equivalent of a Folder in the Oracle Cloud Object Storage.Since the folder structure in Object Storage is flat, Buckets cannot include other Buckets and therefore only one Bucket can be noted here.

CMA Master Configuration

CMA Master Configuration includes the location of files for export and import processing:

- Import Folder: should reference a file location for an Object Storage Bucket(i.e. just the file location without the a file name, for example: "file-storage://CMALocation/CMA-Files"), "CMALocation" is the File Location Extendable Lookup name.
- Export Folder: should reference a file location for an Object Storage Bucket (uch as "file-storage://CMALocation/CMA-Files").

> **Note**
>
> In order to take advantage of the automation of migration of configuration data from one system environment to another via the Process Automation Tool, the Import and Export directories have to point to the same location!

Conversion Data Upload Processes

The batch process that loads customer data files into the cloud (K1-CNVLD) using SQL Loader has two parameters that describes where to get the input data files and where to store the output files:

- inputFileStorage: should reference a file location for an Object Storage Bucket (such as "file-storage://CONVLocation/Input"), "CONVLocation" is the File Location Extendable Lookup name.
- outputFileStorage: should reference a file location for an Object Storage Bucket (such as file-storage://CONVLocation/Output).

Maintaining Customer Code

The system supports a process to import custom Java code to be deployed in the cloud under certain use cases.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Refer to the Cloud Services Implementation Guide for information about how to use this functionality.

The Customer Code portal allows you to review the status of the lifecycle of the process to import code and allows you to review errors that may have been received.

To view a customer code record, navigate using **Admin**, then **Implementation Tools**, then **Customer Code**. You are brought to a query portal with options for searching for customer code. Once a record has been selected, you are brought to the maintenance portal to view and maintain the selected record.
