- Service Point Category: Meter

```
servicePointConnected=false disconnectLocation=D1SR deviceInstalledAtSP=false
specificFieldTask=D1-ConnSPAtSrceAndInstMtr spTypeCategory=D1MT
```

For additional information, refer to the D1-CRSPACT Algorithm Type.

Update Device (D1-UPDDVC)

Algorithms of this type determine if an activity needs to be created to update the device based on the state of the service point and device installed at the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created.

- **Error if SP Not Connected or no Device Installed (Default is Yes)**: Indicates if the algorithm should return an error if the service point is not connected or if a device is not currently installed. Valid values are "Yes" and "Con" (continue)
- **SP State and Activity BO to Create**: Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. These parameters use the following mnemonic to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the value of this mnemonic, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values in include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.

Copyright © 2026, Oracle and/or its affiliates.

Mnemonic	Description
alternativeFieldTask	Specifies an alternative Field Task Type to use when creating a service order field activity in the event that the device does not support the command indicated by the "activityBOToCreate" mnemonic. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the activity business object to create. A value of 'skip' will continue the evaluation of the algorithm's next parameter

For example, the following parameter configuration would create a "Turn On Meter" service order field activity given the following conditions:

- Installation Status: Manual Off
- Service Point Category: Meter

```
installEventStatusOverride=ManualOff specificFieldTask=D1-TurnOnMeter
spTypeCategory=D1MT
```

Other parameters used by algorithms of this type include:

- **Field Activity BO**: Specifies the activity business object to instantiate if the algorithm creates a field task type (see above parameter).
- **XPath of Activity Element controlling Activity creation**: Defines an element within the activity business object schema that can be used to control whether or not this algorithm should create an activity. For example, to specify that the value of the "Connect New Device" flag be used to determine whether or not the algorithm should create an activity, this parameter could be set to "connectNewDevice".
- **Element value indication that Activity creation should not proceed**: Specifies a value for the element defined in the "XPath of Activity Element controlling Activity creation" parameter that would indicate that the algorithm should not create an activity. Valid values are based on the element defined for the "XPath of Activity Element controlling Activity creation" parameter. For example, to specify that an activity should not be created if the "Connect New Device" flag is set to "Do Not Connect / Turn On", this parameter should be set to "D1NC" (from the D1_CONNECT_NEW_DEVICE_FLG lookup).

For additional information, refer to the D1-UPDDVC Algorithm Type.

Remote Turn Off Turn On (D1-REMONOFF)

Algorithms of this type remotely turn a device off and on for a Back to Back service request. Algorithms of this type use the following parameters:

- **Device Incompatibility Detected Activity BO**: Specifies the activity business object the algorithm will look for. If the algorithm finds an activity of this business object, the algorithm terminates.
- **Remote Connect BO**: Specifies the activity business object to instantiate when creating a remote connect command.
- **Remote Disconnect BO**: Specifies the activity business object to instantiate when creating a remote disconnect command.
- **Installation Event Status Override for Connect**: The override status to which the Installation Event Status is set after performing a remote connect command.

Copyright © 2026, Oracle and/or its affiliates.

- **Installation Event Status Override for Disconnect**: The override status to which the Installation Event Status is set after performing a remote disconnect command.

For additional information, refer to the D1-REMONOFF Algorithm Type.

Check for Measurement (D1-CHKMSMT)

Algorithms of this type determine if measurements exist on activity's service point as of the service date/time. If no measurement is found, algorithms of this type create an activity to either obtain or wait for a measurement. The specific type of activity is based on the type and configuration of the device and service point. Algorithms of this type use the following parameters:

- **Activity BO To Wait For Measurement:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a measurement for the service point.
- **Activity BO For Field Read**: Specifies the field activity business object to instantiate when the algorithm logic indicates it should request a meter reading from the field.
- **Specific Field Task**: Specifies the field task type when creating a service order field activity for a meter reading from the field.
- **Activity BO To Wait For Scheduled Read**: Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a scheduled read for the service point.
- **Activity BO For On Demand Read - Scalar**: Specifies the activity business object to instantiate when the algorithm logic indicates it should issue an on-demand read (scalar) smart meter command.
- **Start Range for Normal Measurement Condition**: The start of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **End Range for Normal Measurement Condition**: The end of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **Minimum Range for bottom Measurement condition**: The minimum measurement condition used when searching for measurements for the service point. Used only when no measurements are found in the "normal" range defined by the "Start/End Range Normal Measurement Condition" parameters.

The following parameters on the orchestration activity type are also used by algorithms of this type when searching for measurements for the service point:

- **Look for Measurement within the Day**: Limits the search to the reference date (the service date).
- **Minimum and Maximum Offset Number of Days**: Numbers of days added to /subtracted from the reference date to expand the search period.

For additional information, refer to the D1-CHKMSMT Algorithm Type.

Algorithm Types and Orchestration Activity Business Objects

Each of the orchestration activity business objects uses a different set of these algorithm types. The table below lists which of these algorithm types are defined for each of the service order orchestration activity business objects.

Copyright © 2026, Oracle and/or its affiliates.

	Enable Service	Disable Service	Cut for Non-Payment	Reconnect for Payment	Meter Exchange	Back-to-Back
Customer-Device Compatibility Check	X					X
Connect Only If Previously Connected					X	
Create Specific Activity	X					
Create Meter Exchange Field Activity					X	
Update Device	X	X	X	X	X	X
Remote Turn Off Turn On						X
Decommission Removed Meter					X	
Check For Measurement:	X	X	X			X

Cancel / Update Orchestration - Algorithm Types

Enter algorithms on the "Cancel Specific Activity" and "Update Specific Activity" states attempt to cancel or update a specific child activity. These algorithms are based on the following algorithm types.

- **Cancel Specific Activity**: Algorithms of this type cancel the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.
- **Update Specific Activity**: Algorithms of this type update the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.

Algorithm Type	Algorithm(s)
Cancel Specific Activity (D1-CANSPACT)	Cancel Specific Activity (D1-CANSPACT)
Update Specific Activity (D1-UPDSPAC)	Update Specific Activity (D1-UPDSPAC)

Use the Algorithm Type and Algorithm portals to view additional details about these algorithms.

Understanding Service Order Field Activity Types

Service order activity types must be configured for each type of service order activity.

Service order activity types are assigned to the following Activity Type Categories:

Service Order Activity	Activity Type Category
Back-to-Back	Service Request Orchestration

Copyright © 2026, Oracle and/or its affiliates.

Cancel Orchestration	Orchestration Maintenance
Cut Service for Non-Payment	Request Orchestration
Disable Service	Request Orchestration
Enable Service	Request Orchestration
Exchange Meter	Request Orchestration
Reconnect Service for Payment	Request Orchestration
Update Orchestration	Orchestration Maintenance

Refer to Understanding Activity Types for more information about activity types.

Configuring Service Order Activity Types

You use the **SOM Activity Type** portal is to view and maintain service order activity types.

Refer to Understanding Activity Types for more information.

You can access the portal by selecting **Admin**, **Communication**, **SOM Activity Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order activity types as well as service order activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List**: This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type**: This zone provides information about the selected Activity Type
- **Field Task By Device Condition**: This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Update Device (D1-UPDDVC) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition**: This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the “.Create Specific Activity (D1-CRSPACT) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order activity types supported by Service Order Management:

Service Order Activity	Activity Type (Business Object)
Enable Service	Enable Service (D1–EnableServiceType)
Disable Service	Disable Service (D1–DisableServiceType)
Cut Service for Non-Payment	Cut Service for Non-Payment (D1-CutServiceForNonPaymentType)
Reconnect Service for Payment	Reconnect for Payment (D1–ReconnectForPaymentType)
Meter Exchange	Exchange Meter (D1–ExchangeMeterType)
Back-to-Back Service	Back-to-Back Service (D1–BackToBackServiceType)
Cancel Orchestration	Cancel Orchestration (D1–CancelOrchestrationType)
Update Orchestration	Update Orchestration (D1–UpdateOrchestrationType)

The demonstration database contains examples of each of these service order activity types.

Setting Up Service Order Field Activities

Understanding Service Order Field Activities

This section describes service order field activities and how they communicate with field work management systems.

Service order field activities are activities that involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.

Service order field activities send messages to a field work system, which in turn assigns them to crews to be completed in the field.

Field Activity Information

All service order field activities are based on the Field Activity (D1-FieldActivity) business object, and include the following user-accessible information:

- **Status**: The current status of the service order field activity.
- **Service Date/Time**: The date and time the service order field activity was created.
- **Service Point**: The service point associated with the service order field activity.
- **Field Task Type**: The field task type for the service order field activity. This defines the type of task and other processing details regarding how Service Order Management processes the service order field activity. See Field Task Types for more details about field task types.
- **Recipient**: The field work system service provider to which the service order field activity is sent for scheduling and assignment.
- **Device ID**: The device related to the service order field activity (if applicable).
- **Request Information**: Details of the service order request, including requester and external system information.
- **Contact Details (or Customer Information)**: Contact details for the customer associated with the service order request.
- **Address Information**: The address of the service point associated with the service order field activity.

The field activity business object also contains other information that is populated by algorithms and scripts as the service order field activity is processed by the system.

How Do Service Order Field Activities Work?

At a high level, service order field activities work as follows:

Create Field Activity

A service order orchestration activity creates a service order field activity based on the current state of the service point/meter/item.

Retrieve Required Data

The service order field activity uses a set of pre-processing algorithms to derive and populate data needed by the activity, such as the device, service point, address, effective date, and others.

Copyright © 2026, Oracle and/or its affiliates.

Request Appointment (Optional)

If the service order field activity task type specifies that field tasks of this type require an appointment, the service order field activity checks for available appointment slots in the field work system and sends a notification to the appointment handling system.

Create Outbound Communication

The service order field activity creates an outbound communication to send the service order field activity to the field work system. The outbound communication gathers the information required by the field work system before being sent. This information is retrieved by a set of processing scripts defined on the field task type.

Receive Inbound Communication

When the service order field activity has been completed, the field work system sends an inbound communication back to Service Order Management.

Inbound communications can contain Field Activity Remarks (entered by field resources when they perform and complete their field work. If the Field Activity Remarks reference completion events, they are executed.

The inbound communications create completion events as defined on the field task type. If the service order field activity was successfully completed, it creates the "Completion Events When Successful" completion events. If the service order field activity was canceled, it creates the "Completion Events When Canceled" completion events.

Execute Completion Events

After receiving the inbound communication, a service order field activity algorithm transitions any active completion events into their executed state.

Complete Processing

The service order field activity completes its processing by doing the following:

- Updating the parent orchestration activity
- Sending a success response to the requester
- Transitioning the parent orchestration activity to the next state in its lifecycle
- Sending a service order field activity completion outbound communication to subscribing systems.

Service Order Field Activity Processing

This section outlines how service order field activities are processed.

Pre-Processing, Validation, and Post-Processing Algorithms

When service order field activities are first instantiated, a set of pre-processing algorithms populate and derive information needed for the activity, such as the activity type, service point, device, address, effective date, and other information.

Validation algorithms validate this information when first retrieved and when updated.

When service order field activities are completed, a post-processing algorithm populates the activity end date/time.

Copyright © 2026, Oracle and/or its affiliates.

Service Order Field Activity Lifecycle

As a service order field activity moves through its lifecycle, it triggers various business processes based on the type of service order field activity. The table below outlines the lifecycle for the Field Activity (D1-FieldActivity) business object.

State	Description
Pending	The initial state for service order field activities. An Enter algorithm sends an acknowledgement to the requesting system. The activity is transitioned to the next state via a monitor process.
Validate	Enter algorithms perform the following: Validate Activity Type (and transition to error if invalid) Derive and validate service order field activity recipient Validate duplicate and conflict service order field activities Derive and validate service order field activity service point Derive and validate service order field activity device Validate address constituents Check for any existing cut service restrictions The activity is transitioned to the next state via a monitor process.
Validation Error	If the business object fails any of the validations in the Pending state, it enters this state. Enter algorithms perform the following: Create a To Do based on specified To Do Type and To Do Role Set the "Allow Child to Transition Parent Activity" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed. Activities in this state can be corrected and retried.
Waiting to Request	If a service order field activity has a future effective date, it remains in this state until the effective date is reached. A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time). An Enter algorithm sets the "Allow Child to Transition Parent Activity Based On Effective Date" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Waiting for Appointment	If the service order field activity passes its validations and the effective date has been reached, the activity enters this state. Enter algorithms perform the following: Evaluate if an appointment is required for field tasks of this type. If not, the activity transitions to the "Communication in Progress" state. Create a To Do if an appointment is necessary but the system is not able to send an appointment request. Set the "Allow Child to Transition Parent Activity" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed. Send a notification to the appointment handling system. Monitor algorithms perform the following: Verify if an appointment has been supplied. Send a notification to the appointment handling system. The activity is transitioned to the next state via a monitor process. See Waiting for Appointment for more information about this state.
Communication in Progress	Service order field activities enter this state following the "Waiting for Appointment" or "Retry" states. Enter algorithms perform the following: Create an outbound communication for the service order field activity (see Communication in Progress for more information). Set the "Allow Child to Transition Parent Activity" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed. Monitor algorithms perform the following: Check for existing child communications. Check that the activity hasn’t timed out.
Discarded	Activities discarded in other states enter this state. Enter algorithms perform the following: Cancel outstanding outbound communications. Cancel outstanding completion events. Populate the cancel reason. Send a failure notification to the requesting system. Transition the parent activity to the "Activity Error" state (see Service Order Orchestration Activity Lifecycle for more information). Check if a Cancel Orchestration activity is required.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Communication Error	If an outbound or inbound communication an Error state, the service order field activity enters this state. Monitor algorithms perform the following: Check that the activity hasn’t timed out. Enter algorithms perform the following: Create a To Do based on specified To Do Type and To Do Role. Set the "Allow Child to Transition Parent Activity" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed. Activities in this state can be corrected and retried.
Retry	When a service order field activity is retried after correction of an error condition, it enters this state. Enter algorithms perform the following: Check to determine if there are associated outbound communications in progress. Cancel any outstanding outbound communications.
Execute Completion Events	After an inbound communication is received, it enters this state. Enter algorithms perform the following: Executes completion events defined on the field task type (these completion events were initially created by the inbound communication). Evaluates the "Field Activity Completed" flag on the service order field activity. If this is set to "No", the service order field activity is transitioned to the "Canceled In Field" state. The activity is transitioned to the next state via a monitor process. See Execute Completion Events for more information about this state.
Completion Event Error	If an error occurs during completion event processing, the service order field activity enters this state. Monitor algorithms perform the following: Check that the activity hasn’t timed out. Enter algorithms perform the following: Create a To Do based on specified To Do Type and To Do Role. Set the "Allow Child to Transition Parent Activity" flag to “yes”. This allows the service order field activity to transition the parent orchestration activity if needed. Activities in this state can be corrected and retried.
Completed	Service order field activities enter this state when all completion events have successfully completed. Enter algorithms perform the following: Update the parent orchestration activity. Send a success response to the requester. Transition the parent orchestration activity to the next state in its lifecycle. Send a service order field activity completion outbound communication to subscribing systems.

Copyright © 2026, Oracle and/or its affiliates.

State	Description
Canceled in Field	If the "Field Activity Completed" flag on the field activity is set to "No", the service order field activity enter this state. Enter algorithms perform the following: Send a failed response to the requester. Transition the parent orchestration activity to the "Activity Error" state. Create a To Do to notify users that the service order field activity has been canceled.

Waiting for Appointment

When a service order field activity enters the "Wait for Appointment" state, it first determines if an appointment is necessary for the service order field activity. If not, the activity moves on to the "Communication in Progress" state (see below).

If an appointment request cannot be sent for some reason, the service order field activity creates a To Do item to alert a user to attempt to manually request an appointment. Otherwise, the service order field activity sends an outbound message to the field work system requesting an appointment. based on the appropriate processing role defined on the."Send Notification to Appointment Handling System - Enter" algorithm.

Processing Role	Outbound Communication Business Object
Appointment Response (default) Used if: An appointment is required and needs to be scheduled Appointment has been set	Send Appointment Response Outbound Message (D1-SendApptRespOutboundMsg) Note: An outbound message must be created based on this business object.

The response from the field work system can be received by creating an Inbound Web Service that references the "Book selected appointment to Field Activity" (D1-BookAppt) service script.

While in this state, monitor algorithms verify if an appointment has been supplied and send notifications to the field work system.

Communication in Progress

Service order field activity communications are records of messages sent between Service Order Management and an external field work system. Communications can flow both outbound and inbound.

See Service Order Field Activity Communication for more information about service order field activity communication.

Manually Completing Service Order Field Activities

Service order field activities in the "Communication in Progress" state can be manually completed or canceled by clicking **Complete** in the **Record Actions** section of the **Activity** zone. This opens the **Field Activity Manual Completion** page where the user can enter appropriate details to manually complete the field activity (such as completion information, service point information, device information, and so on). When submitted, this page creates an inbound communication and transitions the field activity to the next state as appropriate.

Copyright © 2026, Oracle and/or its affiliates.

Note: Implementations can define custom service scripts for each field task type in the **Manual FA Completion Controls** section on the Field Task Type extendable lookup to customize the sections displayed on the **Field Activity Manual Completion** page.

Execute Completion Events

After receiving the inbound communication, the service order field activity enters the "Execute Completion Events" state.

The inbound communication will have previously created completion events for the service order field activity, based on those defined on the field task type or those referenced by field activity remarks. These creation events begin in the "Pending" state.

An Enter algorithm transitions completion events associated with the service order field activity into their "Executed" state.

Service Order Field Activity Communication

This section outlines how service order field activities communicate with field work systems.

When a service order field activity enters the "Communication in Progress" state, it sends an outbound communication to the field work system, and waits for an inbound communication response.

See **Understanding the Service Order Field Activity Communication Process** below for more information about the role of communications in the service order field activity communication process.

Outbound Communications

Outbound Communications represent messages sent from Service Order Management to. an external field work system Outbound communications use the following types of objects:

Outbound Communication Business Objects

An outbound communication business object exists for each type of message to be sent to an external system. For service order field activities, the following base package outbound communication objects can be used.

Type of Outbound Communication	Outbound Communication Business Object
Initial service order field activity outbound communication	Field Activity Outbound Communication (D1-FieldActivityOBComm)
Modify outbound communication Used to send an update to a service order field activity previously sent to the field work system.	Field Activity Outbound Communication (D1-ActivityModifyOBComm)

Outbound Message Types

A outbound message type must also be created for each type of message to be sent to an external system. Again, this is based on the types of messages the system is designed to accept. For service order field activities, the following outbound message types are needed:

Copyright © 2026, Oracle and/or its affiliates.

Type of Outbound Communication	Outbound Message Type
Initial Service Order Field Activity Message	Field Activity Outbound Message
Modify Existing Service Order Field Activity	Modify Field Activity Outbound Message

Refer to the Oracle Utilities Application Framework documentation for more information about outbound message types.

External Systems

You must also create an External System for each external system to which Service Order Management will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch, XAI, or Real-time)
- Message Sender (if Processing Method is set to Real-time or XAI)
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

To continue the example above, you might create the following external system:

External Application		
Outbound Message Type	**Processing Method**	**Batch Control**
Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)
Modify Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)

Refer to the Oracle Utilities Application Framework documentation for more information about external systems.

Inbound Communications

Inbound Communications represent messages sent from an external field work system to Service Order Management. Inbound communications are typically sent in response to a service order field activity. Inbound communications use the following types of objects:

Inbound Communication Business Objects

An inbound communication business object must be created for each type of message to be received from an external system. For service order field activities, the following base package inbound communication object can be used.

Inbound Communication Business Object
Field Activity Inbound Communication (D1-FieldActivityIBComm)

Inbound Web Service

Copyright © 2026, Oracle and/or its affiliates.

You must also create an Inbound Web Service for each type of message to be received from an external system. Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send. To continue the example above, you might create the following inbound web services:

Inbound Web Service	Schema (Inbound Communication Business Object)
Field Activity Inbound Communication	Field Activity Inbound Communication D1-FieldActivityIBComm

Refer to the Oracle Utilities Application Framework documentation for more information about Inbound Web Services.

Field Activity Remarks

Inbound communications can contain activity remarks, which represent notes entered by the field worker as they perform and complete their field work. These can be solely informational, or can reference completion events via the "Remark Processing" section of the Field Activity Remark Type extendable lookup. This allows information sent with the inbound communication to initiate business processing if necessary.

Completion events specified on this extendable lookup are created by the inbound communication, and then executed when the service order field activity enters the "Execute Completion Events" state.

Understanding the Service Order Field Activity Communication Process

This section provides an overview of the communication process that takes place when a service order field activity is initiated. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used by Service Order Management

Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Base Package Objects
1.	An orchestration activity creates a service order field activity as part of its processing. A service order field activity business object is instantiated for the command.	Field Activity Business Object: Field Activity (D1-FieldActivity)
2.	When the service order field activity enters the Communication in Progress tate, it creates an outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
3.	A Enter algorithm on the "Awaiting Response" state of the outbound communication retrieves information needed by the outbound message to be sent to the field work system based on processing scripts specified on the field task type.	Enter Algorithm: Populate Send Detail for Field Activity (D1-POPSNDDTL)

Copyright © 2026, Oracle and/or its affiliates.

Step	Process	Base Package Objects
4.	A Enter algorithm on the "Awaiting Response" state of the outbound communication creates an outbound message.	Enter Algorithm: Create Outbound Message (D1-COUTMSG) Note: An outbound message type for this message is not included in the base package.
5.	The outbound message is sent to middleware components via an External System and Batch Control. Middleware components utilize Business Process Execution Language (BPEL).	External System: MWM Batch Control: Sync Request Monitor (F1-SYNRQ)
6.	The middleware converts the outbound message from SOM format into the format used by the field work system, and sends the message to the field work system.	
7.	When the field work system sends a response, the middleware receives the response message from the field work system, and converts it from the format used by the field work system to SOM format and invokes an Inbound Web Service.	Inbound Web Service: D1-FieldActivityIBComm
8.	The Inbound Web Service picks up the message, and creates a corresponding inbound communication. The specific type of inbound communication business object created is determined by the Inbound Web Service.	Inbound Web Service: D1-FieldActivityIBComm Inbound Communication Business Object: Field Activity Inbound Communication (D1-FieldActivityIBComm)
9.	The inbound communication identifies the parent outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
10.	The inbound communication creates the completion events defined on the field activity field task type (Successful or Canceled, as appropriate) in the "Pending" state. If the inbound communication contains field activity remarks, it also executes any field activity remark completion events.	Inbound Communication Business Object: Field Activity Inbound Communication D1-FieldActivityIBComm
11.	The inbound communication updates the outbound communication. This update is performed by an Enter algorithm on the “Completed” Status of the inbound communication business object’s lifecycle.	Inbound Communication Business Object: Field Activity Inbound Communication D1-FieldActivityIBComm Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)

Copyright © 2026, Oracle and/or its affiliates.

Step	Process	Base Package Objects
12.	The outbound communication updates the “Completion Flag” and the original service order field activity business object. This update is performed by an Enter algorithm on the “Completed” Status of the outbound communication business object’s lifecycle.	Outbound Communication BO: Initiate Connect Disconnect (D3-InitiateConnectDisconnect) Field Activity Business Object: Field Activity (D1-FieldActivity)

Unrelated Pickup Orders

When field work crews are out performing field work, it’s possible that they will encounter other work unrelated to their current task that needs to be done. This type of work can be as simple as trimming a tree whose branches are too close to power lines, or the replacement of a meter for a different customer or service point. These types of task are referred to as "unrelated pickup activities." Crews can either work the field activity or leave it to be assigned to another crew at a later date.

When the crew creates an unrelated pickup activity in the field work system, it is sent to Service Order Management, and a corresponding service order field activity is created in the system.

Unrelated pickup activities can be created via one of the following Inbound Web Services:

- Field Activity Asynchronous Req Inbound (D1-FARequestAsynchronous)
- Field Activity Synchronous Req Inbound (D1-FARequestSynchronous)

Once created, the are processed like any other service order field activity. If the pickup activity was completed in the field before being sent to Service Order Management, it will quickly move through its lifecycle (as now further action is needed) until it reaches the "Completed" state.

Retrieving Service Point Information

If the unrelated pickup activity is customer-related it will require service point information to be created. This information can be queried by the field work crew via the "Field Work Service Point Query" (D1-FieldWorkSPQuery) Inbound web service.

This service uses set of service point criteria to allow the field crew to search for a service based upon either service point or device information. The service returns a list of service points that is configurable in length. If the number of results is larger than the configured maximum length the service indicates that additional records exist and the crew can request another set of results allowing them to identify the proper service point to associate to the activity.

There are times when an unrelated pick-up activity is identified but the field crew is out-of-coverage (i.e. no network connection) and they will not be able to immediately verify service point information. In this type of situation, the crew can input the service point criteria fields and create the activity, which, when imported into Service Order Management, will attempt to identify the service point based upon the information provided. If the service point can be uniquely identified everything should operate as normal. If the service point cannot be uniquely identified then the service order field activity is set to the error state.

Setting Up Service Order Field Activity Types

- Understanding Service Order Field Activity Types
- Configuring Service Order Field Activity Types

Understanding Service Order Field Activity Types

A single service order field activity type must be configured to support communication with external field work systems such as Oracle Utilities Module Workforce Management. Service order activity types are assigned to the “Field Activity” Activity Type Category.

Refer to Understanding Activity Types for more information about activity types.

Service Order Field Activity Types and Divisions

Service order field activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the**Miscellaneous** tab of the **User** portal.

See Understanding Divisions for more information about divisions.

Configuring Service Order Field Activity Types

You use the **SOM Activity Type** portal is to view and maintain service order field activity types.

Refer to Understanding Activity Types for more information.

You can access the portal by selecting **Admin**, **Communication**, **SOM Activity Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order field activity types as well as service order field activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List**: This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types

Copyright © 2026, Oracle and/or its affiliates.

that have yet to be configured. Broadcast a record to display the details of the selected record.

- **Activity Type**: This zone provides information about the selected Activity Type
- **Field Task By Device Condition**: This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Update Device (D1-UPDDVC) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition**: This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the “Create Specific Activity (D1-CRSPACT) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order field activity type supported by Service Order Management:

Field Activity	Activity Type (Business Object)
Field Activity	Field Activity (D1–FieldActivityType)

The demonstration database contains examples of each of these service order activity types.

Configuring Service Order Field Activity Reschedule Reasons

The Reschedule Reason (D1-RescheduleReasonLookup) extendable lookup can be used to define reasons for rescheduling field activities. Reschedule reasons are captured on field activities, as well as their parent service order activity and an update orchestration activity.

Use the following steps to define service order field activity reschedule reasons:

Copyright © 2026, Oracle and/or its affiliates.

1. Select **Admin**, **General**, **Extendable Lookup** to access the **Extendable Lookup Query** portal.
2. Enter “D1-RescheduleReasonLookup” in the **Business Object** field (or enter “Reschedule Reason” in the **Description** field) and click **Search**.
3. Click the “Reschedule Reason” link in the **Description** column of the search results.
4. Click **Add**, and enter the following details for the reschedule reason (fields not listed below are optional):
    - **Reschedule Reason**: A code used to designate the reschedule reason.
    - **Status**: The status of the reschedule reason.
    - **Description**: A description of the reschedule reason. This is what will appear in **Reschedule Reason** drop-down list on the service order field activity.
5. Click **Save**.

Field Task Types

- Understanding Field Task Types
- Configuring Field Task Types

Understanding Field Task Types

A service order field activity’s field task type defines details about the type of task to be performed and how the system will process the activity.

Field Task Type Information

Field task types are values for the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup. Each field task type value includes the following information:

- **Routing**: Indicates if field tasks of this type can only be performed at a service point. Valid values are "SP Required" and "Pass-Through".
- **Appointment Option**: Indicates if an appointment (via a mobile workforce application) is required or applicable to field tasks of this type. Valid values are "Not Applicable", "Optional", and "Required".
- **Completion Events When Successful**: One or more completion events that are executed upon successful completion of field tasks of this type.
- **Completion Events When Canceled**: One or more completion events that are executed upon cancellation of field tasks of this type.
- **Duplicate Task Type Information**: Defines processing rules for handling potential duplicate field tasks, including:
    - **Allow Duplicates**: Specifies whether or not duplicate field tasks are allowed
    - **Duplicate Threshold**: A number of hours used to determine if a newly instantiated field task type should be considered a duplicate.
    - **Field Task Types**: A list of one or more field task types that are considered to be duplicates of the field task type
- **Conflict Task Type Information**: Defines processing rules for handling potentially conflicting field tasks, including:

Copyright © 2026, Oracle and/or its affiliates.

- **Allow Conflicts**: Specifies whether or not conflicting field tasks are allowed
- **Conflict Threshold**: A number of hours used to determine if a newly instantiated field task type should be considered a conflict.
- **Field Task Types**: A list of one or more field task types that are considered to conflict with the field task type

- **Processing Scripts**: Defines one or more processing scripts to extract supplemental information needed by the mobile workforce application to schedule field tasks of this

Configuring Field Task Types

Field task types are configured using the extendable lookup portal.

You can access the extendable lookup portal from the **Admin > General > Extendable Lookup**.

Use the **Extendable Lookup Search** zone to search for and select the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup.

The following zones may appear as part of the portal's **Main** tab page:

- **Extendable Lookup List:** This zone displays a list of values for the Field Task Type extendable lookup.
- **Extendable Lookup List:** This zone provides information about the selected value.

Service Order Management Configuration

The following table outlines the field task types that must be configured to support each of the service order activity types supported by Service Order Management:

Service Order Activity	Field Task Types
Enable Service — Meters	Connect SP at Source: D1-ConnectSPAtSource Connect SP at Meter: D1-ConnectSPAtMeter Connect SP at Source and Turn On: D1-ConnectSPAtSourceAndTurnOn Connect SP at Meter and Turn On: D1-ConnectSPAtMeterAndTurnOn Connect SP at Source and Install Meter: D1-ConnSPAtSrceAndInstMtr Connect SP at Meter and Install Meter: D1-ConnSPAtMtrAndInstMtr Install Meter: D1-InstallMeter Turn On Meter: D1-TurnOnMeter

Reconnect Service for Payment — Items	Item - Reconnect for Payment: D1-ReconnectItemForPayment
Meter Exchange	Exchange Meter: D1-ExchangeMeter
Item Exchange	Exchange Device: D1-ExchangeDevice
Back-to-Back — Meters	Read Meter: D1-ReadMeter

Defining Credit & Collections Options

> **Note**
>
> The functionality described in this section is meant to handle the collection of unpaid balances. If your organization practices open-item accounting and collects on unpaid bills, you will not use this functionality. Rather, you will use the functionality described under Defining Overdue Processing Options.

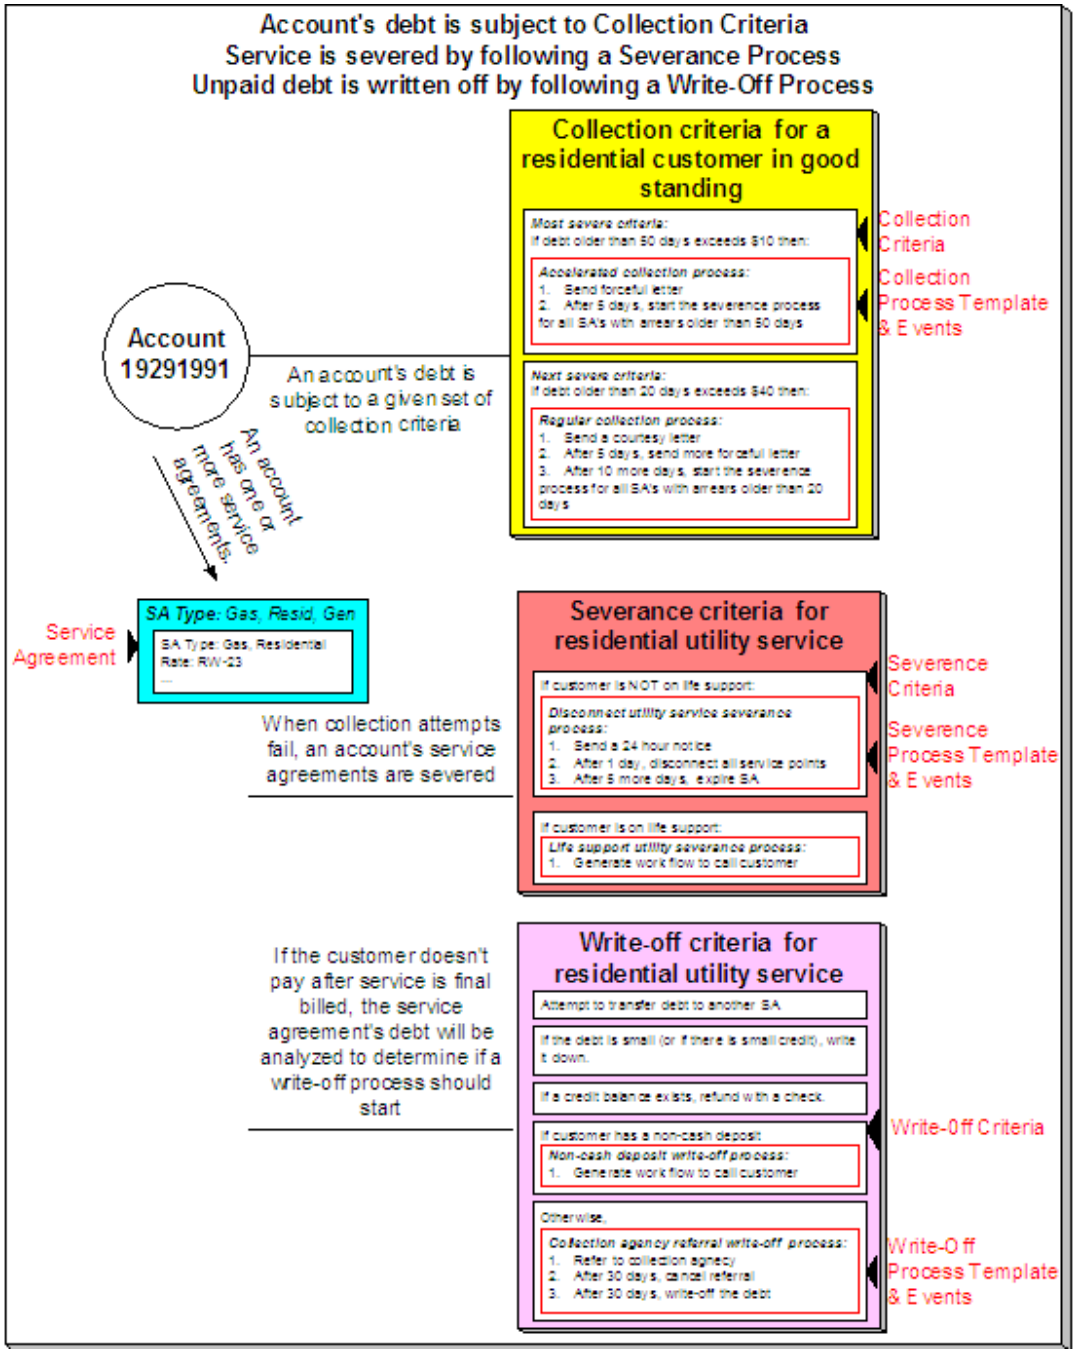
The system periodically monitors how much your customers owe to ensure they haven't violated your collection criteria. When a violation is detected, the system generates the appropriate responses (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). This section describes how to set up the tables that control your credit & collections processing.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> Setting up the credit & collections control tables is as challenging as your organization's collection rules. If you have simple rules then your setup process will be straightforward. If your collection rules are complicated (e.g., they differ based on the type of customer, the type of debt, the age of debt, the type of service, etc.), then your setup process will be more challenging.

- The Big Picture Of Credit & Collections
- Creating Collection, Severance & Write-Off Procedures
- How To

The Big Picture Of Credit & Collections



This section provides an overview of important C&C concepts with which you should be familiar before you set up your C&C control tables.

- Collection Criteria versus Severance Criteria Versus Write Off Criteria
- The C&C Monitors
- The Big Picture Of Collection Processes
- The Big Picture Of Collection Events
- The Big Picture Of Severance Process Cancellation
- The Big Picture Of Severance Events
- The Big Picture Of Write Off Processing
- The Big Picture Of Write-off Events
- Calendar Versus Work Days
- The Big Picture Of Payment Arrangements and Pay Plans

Collection Criteria versus Severance Criteria Versus Write Off Criteria

The following diagram introduces important concepts related to the C&C processes:

Copyright © 2026, Oracle and/or its affiliates.

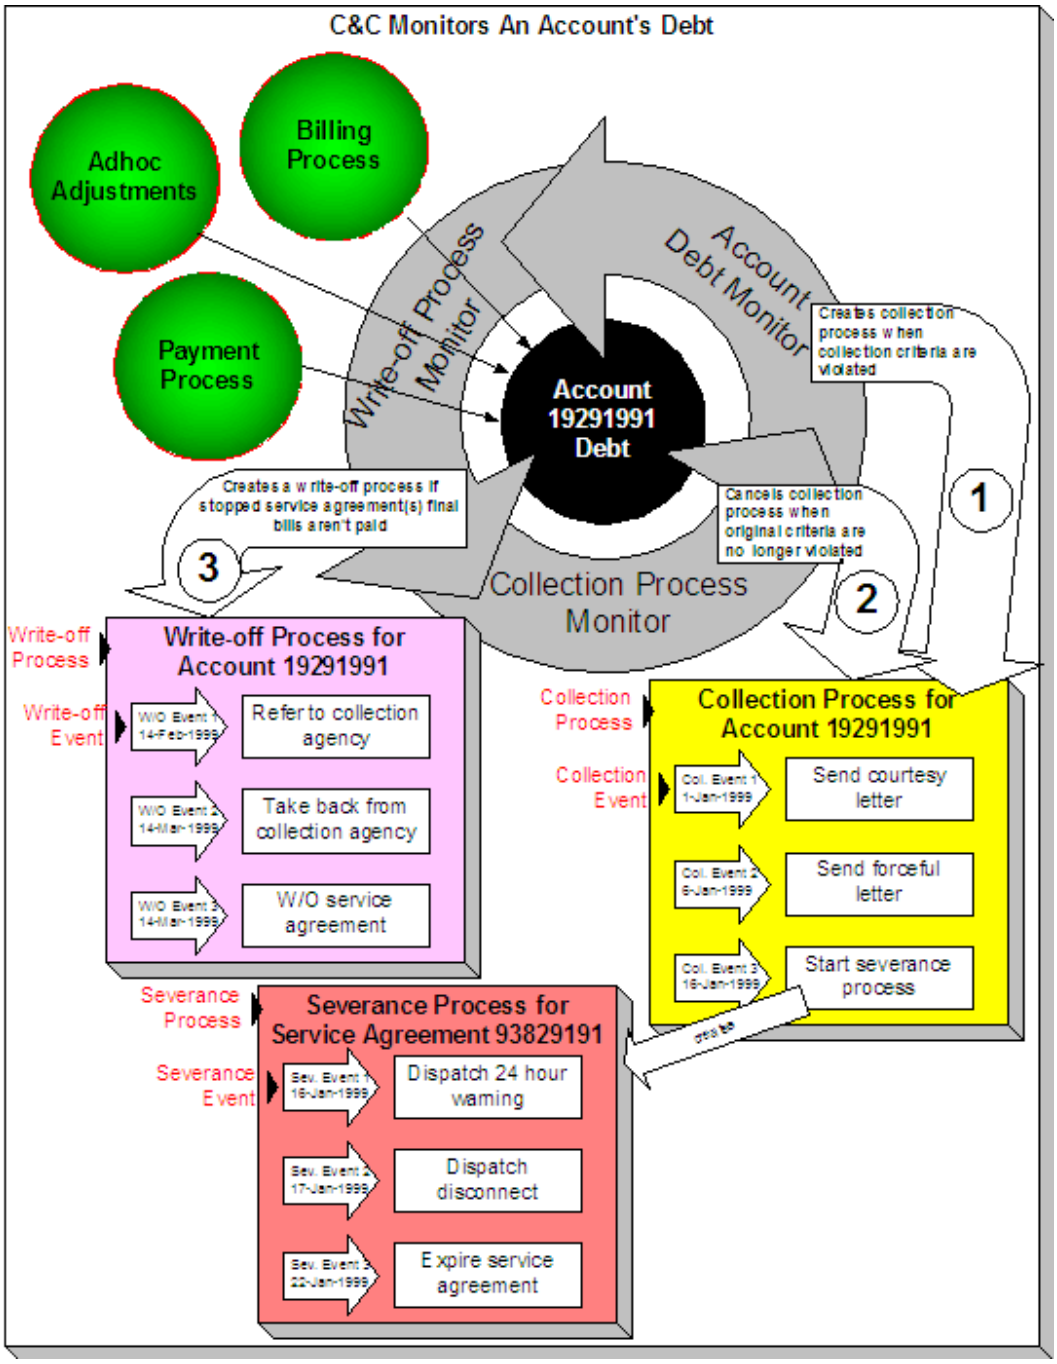
There are many important concepts illustrated above:

An account's debt comes from its service agreements	An account's debt is managed at the service agreement level, i.e., the system keeps track of how much a customer owes in respect of each service agreement. In order to determine an account's balance, the system must add up the debt on each of the account's service agreements.
Collection criteria define intolerable debt	Collection criteria are control data that define intolerable debt. Most criteria are defined using a combination of number of days in arrears and a dollar amount.

Copyright © 2026, Oracle and/or its affiliates.

Collection criteria may be compared to an account's total debt or to subsets of debt	If your organization has simple collection procedures, you will probably target collection criteria at an account's total debt. However, you have the option of segregating an account's debt into debt classes and targeting the collection criteria at each class. For more information about debt classes, see Different Collection Criteria For Different Customers And Different Debt.
Collection criteria also define what to do when the level of intolerable debt is exceeded	When you define collection criteria, you also define how the system should respond if an account violates your criteria. These collection events are defined in respect of a "collection process template".
There are usually several collection events that take place when criteria are violated	A collection process template usually has several collection events. Each event is meant to prod the customer to pay. The initial collection events are typically letters. If payment is not received after several such attempts, the last collection event typically starts a severance process for each service agreement in arrears.
A severance process template defines how to sever a service agreement	A "severance process template" defines how to sever a given type of service agreement. A severance process template usually contains several severance events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received.
Severance criteria define how to sever service agreements	Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer (or premise). For example, you may have a different severance process if the customer has life support equipment.
After a service agreement is severed, it will be final billed	When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.

Copyright © 2026, Oracle and/or its affiliates.



If a customer doesn't pay their final bill, the account's debt will be analyzed to determine if the system can reduce the debt to zero using a variety of mechanisms	The system will look at an account's finaled debt on its next scheduled credit review date (typically a few days after the bill's due date). The system will attempt to reduce the service agreement's debt to zero using all of the following methods: • If the account has active service agreements, it will transfer the finaled debt to an active service agreement. – If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit). * If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).
If a customer's finaled debt cannot be reduced via any of the previous methods, the system creates a write-off process	A write-off process contains one or more write-off events. These events can generate a letter, send a To Do entry to a CSR, send a referral to a collection agency, etc. When you set up the system, you define the type of write-off process to use for every collection class / write-off debt class combination. In addition, you can also indicate when the type of write-off process should differ depending on some attribute of the customer (or premise). For example, you may have a different write-off process if the customer has a non-cash deposit.
The last write-off event typically causes the debt to be written off	Ultimately, if the write-off events fail, the debt will have to be written off. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life and will have to be paid off if the customer ever returns.

> **Note**
>
> **Checkpoint.** At this point, you should be familiar with the concept that an account's debt is compared to user-defined collection criteria. If the account violates the criteria, a series of events will ensue that prod the customer to pay. If the customer doesn't respond, every service agreement in arrears will be severed (i.e., disconnected). If lack of service doesn't inspire payment, the service agreement will be expired and a write-off process will be created to manage the write-off activities.

The C&C Monitors

Copyright © 2026, Oracle and/or its affiliates.

Your collection, severance and write-off criteria described in the previous section exist to support the processes that manage the collection activities. The following diagram illustrates, at a high level, the major processes that manage the collection of overdue debt:

There are many important concepts illustrated above:

Bills, payments and adjustments affect an account's debt	An account's debt is the accumulation of all bills, payments and adjustments.

Copyright © 2026, Oracle and/or its affiliates.

The Account Debt Monitor creates a collection process when an account violates collection criteria	Periodically, a background process referred to as the Account Debt Monitor determines if an account's debt violates your collection criteria. If so, a collection process is created using the violated criteria's collection process template. Refer to When Is An Account's Debt Monitored? for a description of when an account's debt is compared against collection criteria.
A collection process contains one or more collection events	The collection process contains a series of collection events. These events correspond with the collection event types associated with the collection process template. The initial collection events are typically letters. If payment is not received after several such communications, the last collection event typically starts a severance process for each service agreement in arrears.
The Collection Process Monitor cancels a collection process when warranted	The Collection Process Monitor cancels a collection process when its service agreements satisfy your cancellation criteria (e.g., when the service agreements have less than $10 of debt older than 20 days). Refer to How Are Collection Processes Cancelled for more information about the cancellation process.
The last collection event starts one or more severance processes	The last collection event typically starts one or more severance processes. A severance process contains the activities necessary to sever a service agreement. The service agreement(s) that are severed may be all SAs that are associated with the collection process. Alternatively, you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). The algorithm on the collection event that starts severance will control which service agreement(s) are severed. Refer to How To Nominate A Single Service Agreement To Sever for more information.
Each service agreement has its own severance process	Every service agreement that is severed has a severance process. The type of process is dependent on the severance criteria linked to the service agreement's SA type.
A severance process contains one or more severance events	The severance process contains a series of severance events. The events correspond with the severance process template's severance events.

Copyright © 2026, Oracle and/or its affiliates.

The system cancels a severance process when warranted	The system cancels a severance process when its service agreement satisfies your cancellation criteria (note, it is possible to set up the system so that all service agreements in the debt class must satisfy your cancellation criteria before a severance process is cancelled). It's important to note that the cancellation is real time (as opposed to the cancellation of collection processes, which happens in a background process). Refer to How Are Severance Events Canceled? for more information.
The last severance event should expire the service agreement	The last severance event typically expires its service agreement. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).
If you nominate a single SA to sever when multiple SAs are in arrears...	Earlier we indicated that you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). If you do this, you also need a severance event that will sever all other service agreements in the debt class if the severance of the nominated service agreement doesn't inspire payment. A severance event algorithm to do such is supplied with the base package. Refer to How To Nominate A Single Service Agreement To Sever for more information.
The Write-Off Monitor creates a write off process to collect stopped, unpaid debt	The Write-Off Monitor reviews stopped and reactivated service agreements after their closing bill's due date (plus grace period). The Write-Off Monitor attempts to reduce the service agreement's debt to zero using all of the following methods: • If the account has active service agreements, it will transfer the finaled debt to an active service agreement. – If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit). * If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer). If the system is unsuccessful in reducing the account's debt to zero, a write-off process will be created using the appropriate write-off process template. Refer to The Big Picture Of Write Off Processing for more information about the write-off process.

Copyright © 2026, Oracle and/or its affiliates.

A write-off process contains one or more write-off events	The write-off process contains a series of write-off events. These events correspond with the write-off event types associated with the write-off process template. The initial write-off events are typically collection agency referrals and/or letters. If payment is not received as a result of such efforts, the last write-off event typically writes off the customer's debt.
The system cancels a write-off process when warranted	The system cancels a write-off process when its service agreements no longer have debt (i.e., they become closed).
Another write-off process will be created if a closed service agreement ever reactivates	If a service agreement becomes reactivated (e.g., because the final payment bounces), the service agreement will be processed by the Write-Off Monitor and the whole write-off process starts again.

> **Note**
>
> **Checkpoint.** At this point, you should be familiar with the concept that a collection process will be created for an account that violates collection criteria. The collection process consists of a series of events that typically generate letters and / or To Do entries. If the customer doesn't respond, a severance process will be started for one or more service agreements. A severance process consists of a series of events that typically generate letters and/or disconnection field activities. If lack of service doesn't inspire payment, the last severance event expires the service agreement (and a final bill will be scheduled when the last service agreement is expired). If the customer doesn't pay the final bill, a write-off process will be created for each type of unpaid debt. The write-off process consists of a series of events that ultimately result in the write-off of the customer's debt. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life (because the write-off service agreement is linked to the account) and will have to be paid off if the customer ever returns.

The Big Picture Of Collection Processes

The topics in this section describe how collection processes are created and cancelled.

> **NOT_SUPPORTED**
>
> For more information refer to The Lifecycle Of A Collection Process And Its Events.

- How Does The Account Debt Monitor Work?
- How Are Collection Processes Cancelled?

Copyright © 2026, Oracle and/or its affiliates.

How Does The Account Debt Monitor Work?

This section describes how the Account Debt Monitor uses your collection criteria and collection process templates to collect overdue debt.

- Different Collection Criteria For Different Customers And Different Debt
- Override Conditions
- When Is An Account's Debt Monitored?
- How Is An Account's Debt Monitored?
- What Happens When A Collection Process Is Started?
- Experimenting With Alternative Collection Process Templates

Different Collection Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different collection criteria for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different regulator-imposed criteria applied to each state's debt. You differentiate your debt in respect of the collection process via the **CIS division code on each customer's account**.
- You probably have different collection criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different collection criteria for different classes of debt. For example, if a single customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have the freedom to apply stricter criteria to the unregulated debt. You differentiate your debt in respect of the collection process via a **debt class code on the customers' service agreements** (note: the debt class is actually defined on the service agreement's SA type).
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

Given the above, you should understand that different collection criteria will exist for every combination of CIS division, collection class, debt class, and currency code. If you're confused, consider the following matrix (where we assume you have a single currency and division and therefore avoid the third and fourth dimensions):

SA's Debt Class	Account's Collection Class: Commercial Customer	Account's Collection Class: Residential Customer

Copyright © 2026, Oracle and/or its affiliates.

Regulated	N/A - there is no regulated, commercial customer debt.	Highest Priority: If > $5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > $25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > $10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > $1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > $10 in arrears by more than 25 days, create the normal collection process for residential customers.
Charitable Contribution	Highest Priority: If > $10 in arrears by more than 50 days, create the charitable collection process.	Highest Priority: If > $10 in arrears by more than 50 days, create the charitable collection process.

Also, notice that there can be multiple criteria for each cell in the matrix. What differentiates one collection criteria from another is its priority. The higher priority criteria will be compared first. If the debt meets the criteria, the collection process is initiated and no further comparisons are performed.

NOT_SUPPORTED

For more information about maintaining this matrix, refer to Setting Up Collection Class Controls. For more information about how the system handles an element in this matrix that has multiple criteria, see How Is An Account's Debt Monitored?.

Override Conditions

Warning

Your credit & collection requirements may not require any overrides and therefore this section may not be relevant for your organization.

The matrix presented in the previous section showed:

- You can have different collection criteria for different categories of debt and customers.
- When a collection criteria is violated, the system generates a specific collection process.

Copyright © 2026, Oracle and/or its affiliates.

This works great for many organizations, but if your organization has other factors that affect either the collection criteria OR the collection process that is initiated when the criteria is violated, you may need to use override collection criteria. For example,

- If you have a different collection process for regulated, residential debt during the winter months, you'll need to use override collection criteria (where the override criteria is "if it's winter").
- If you have different collection criteria for customers with a poor credit score, you'll need to use override collection criteria (where the override criteria is "if the customer's credit rating is poor").

NOT_SUPPORTED

Refer to Designing Your Collection Class Control Overrides for more information.

This section describes how and when the Account Debt Monitor analyzes an account's debt.

When Is An Account's Debt Monitored?

The account debt monitor (ADM) analyzes an account's debt at least every X days, where X is defined on the customer class control associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, an account's debt will also be monitored as follows:

- The ADM looks at an account's debt X days after an account's bill due date (X is defined on the account's customer class in the field Collection Grace Days).
- The ADM looks at an account's debt after a payment is canceled when the cancellation reason indicates NSF (non-sufficient funds).
- The ADM looks at an account's debt after a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to Monitoring Payment Arrangements for more information.
- The ADM looks at an account's debt after a pay plan is broken. Refer to The Pay Plan Monitor for more information.

How Is An Account's Debt Monitored?

Assume the following collection control matrix exists for your organization:

SA's Debt Class	Account's Collection Class: Commercial Customer	Account's Collection Class: Residential Customer

Copyright © 2026, Oracle and/or its affiliates.

Regulated	N/A - there is no regulated, large customer debt	Highest Priority: If > $5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > $25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > $10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > $1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > $10 in arrears by more than 25 days, create the normal collection process for residential customers.

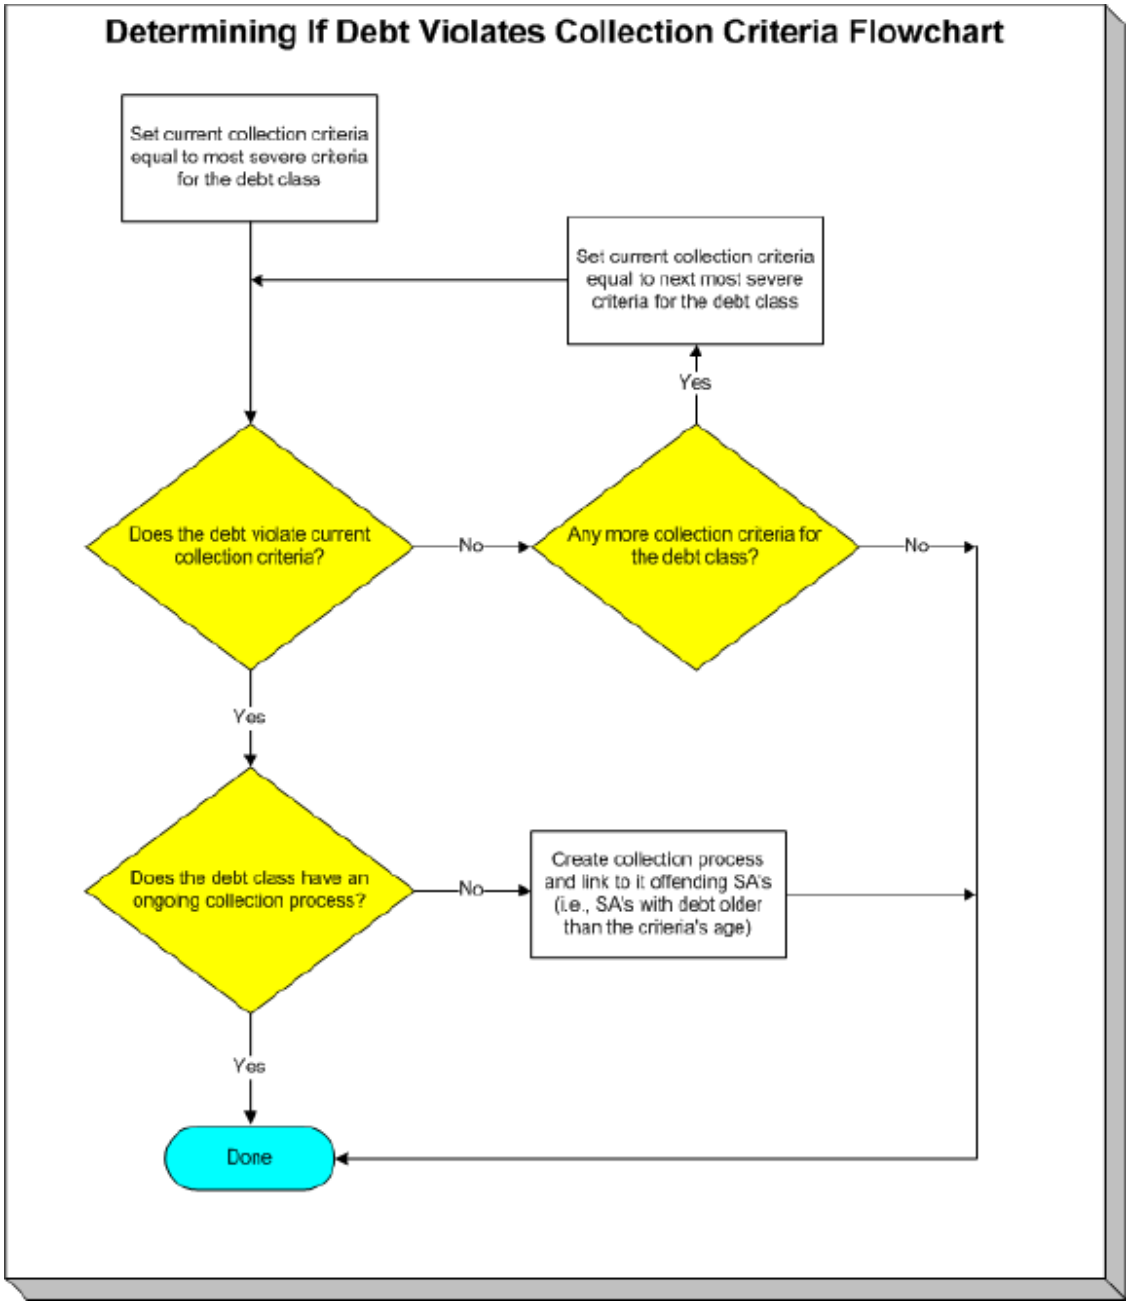
This matrix contains the information used by the Account Debt Monitor.

NOT_SUPPORTED

For more information about the information in this matrix, refer to Different Collection Criteria For Different Customers And Different Debt.

This matrix can be overwhelming when viewed as a whole. So let's consider how to use it for a specific account's debt and things will become clearer.

First, because an account belongs to a unique collection class, we only have to worry about a single column in the matrix when monitoring an account's debt.



Next, we accumulate the total amount of aged debt for each unique debt class associated with the account's service agreements.

Next, we subject the accumulated aged debt to the override aged debt algorithm (plugged in on the debt class). This algorithm can cause aged debt to be reduced. This is an optional algorithm and is only used if you set up pay plans for customers. Refer to How Pay Plans Affect The Account Debt Monitor for more information.

Next, we determine if the debt for the debt class violates the collection criteria in the respective matrix element. If so, we kick off a collection process and link the offending service agreements to it. The logic associated with the determination of whether to kick off a collection process is rather sophisticated. The following flowchart explains the exact details.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Important.** If a service agreement is part of an ongoing severance process, it will NOT be considered by the Account Debt Monitor (it's already being severed). If a service agreement is stopped, closed, or reactivated, it also will NOT be considered by the Account Debt Monitor (it's already severed).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Multiple collection processes may be kicked off.** It's important to be aware that if an account's service agreements reference multiple debt classes, a collection process will be started for each offending debt class.
>
> **One collection process per debt class.** A given debt class for an account may only have one ongoing collection process at any point in time.

What Happens When A Collection Process Is Started?

When you define collection criteria, you must define the collection process template to use if the criteria are violated. The system uses this template to create the account-specific collection process.

Every service agreement that is part of the offending debt class that has debt older than X days will be linked to the collection process (where X is the debt age on the collection criteria).

Also linked to the collection process will be one or more collection events. These events are typically a series of letters meant to prod the customer (you can also create an event that sends a To Do entry to a user to highlight the offensive debt). You define exactly which letters are generated and when they are generated when you set up the events on your collection process templates.

It's important to note that all of the collection events will be created when the collection process is created. Each of these collection events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to Calendar vs Work Days for information that describes how the trigger date is set.

A separate process, Activate Collection Events, is responsible for activating collection events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a severance processes, etc.)

If adequate payments / credits are recorded in the system, the collection process will be cancelled.

> **NOT_SUPPORTED**
>
> For more information about collection process templates, see Setting Up Collection Process Templates. For more information about collection events, see The Big Picture Of Collection Events. For more information about how a collection process is cancelled, see How Are Collection Processes Cancelled.

Experimenting With Alternative Collection Process Templates

The system allows you to determine the efficacy of proposed collection process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

Copyright © 2026, Oracle and/or its affiliates.

We'll use an example to explain. Let's assume your prevailing collection process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" collection process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Collection Processing Feature Configuration for every champion template. Each option's value defines:
  - the "champion" collection process template code
  - the "challenger" collection process template code
  - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing collection process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, the Account Debt Monitor will use the challenger template X% of the time rather than the champion template.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination.

How Are Collection Processes Cancelled?

A collection process may be cancelled via the mechanisms described in this section.

- The Collection Process Monitor Can Cancel A Collection Process
- A New Payment Plan Can Cancel A Collection Process
- A User May Cancel A Collection Process At Their Discretion
- Stopping A Service Agreement May Cancel A Collection Process

The Collection Process Monitor Can Cancel A Collection Process

Copyright © 2026, Oracle and/or its affiliates.

The Collection Process Monitor (CPM or C1-CPM)) is a background process that reviews a collection process when the debt associated with one of its service agreements is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

The review performed by the CPM occurs as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the collection process's debt class must be less than a given threshold amount for a collection process to be cancelled. If so, the collection process is cancelled.
- Please be aware that, if a Pay Plan exists for the account and debt class, the customer's debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Please be aware that this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

> **Note**
>
> **The above logic is not "hard coded".** The CPM calls the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm will cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
  - All service agreements that are in arrears in a given debt class are linked to the collection process.
  - The collection event called Start Severance creates a severance process for every service agreement that is in arrears on the collection process (the alternative is to Nominate A Single Service Agreement To Sever).
  - If you use the Start Severance collection event, you would want to remove a service agreement from a collection process when it no longer has intolerable debt (regardless of the state of the debt class's entire debt). You'd want to do this because, if you don't, the system would start a severance process for the paid up service agreement and if it's paid up, you wouldn't want a severance process created for it.
- To "remove" service agreements from a collection process when they no longer have intolerable debt, you should plug-in a Service Agreement-Oriented Cancel Criteria Algorithm on your collection process templates. The CPM will call this algorithm if you've plugged it in.

> **Note**
>
> When all service agreements are "removed" from a collection process, the CPM cancels all pending collection events and cancels the collection process.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> Checking if individual service agreements should be removed from a collection process is optional (meaning that you don't have to plug one in on the collection process template).

A New Payment Plan Can Cancel A Collection Process

Refer to Collection Process / Severance Process Cancellation When A Pay Plan Is Created for the details.

> **Note**
>
> **Real time cancellation.** Please be aware that the system will cancel a collection process real time when a pay plan is created (if the pay plan's scheduled payments are enough to pay-off the customer's outstanding debt).

A User May Cancel A Collection Process At Their Discretion

A user may cancel a collection process at their discretion.

Stopping A Service Agreement May Cancel A Collection Process

The system will "remove" a service agreement from a collection process when it is stopped (i.e., when the service agreement's status becomes Stopped). When the last service agreement is "removed" from the collection process, the collection process will be cancelled.

The Big Picture Of Collection Events

This section describes the various types of collection events and their lifecycle.

- How Are Collection Events Created?
- Types Of Collection Events
- Collection Event Lifecycle
- Collection Event Trigger Date
- How Are Collection Events Completed
- The Last Collection Event Should Kick Off Severance Process(es)
- How Are Collection Events Canceled?

Copyright © 2026, Oracle and/or its affiliates.

How Are Collection Events Created?

Collection events may be created as follows:

- The Account Debt Monitor creates a collection process when an account violates collection criteria. The collection process has one or more collection event(s). The number and type of events is controlled by the collection process template associated with the collection process.
- Collection events are created when a user creates an ad hoc collection process. The number and type of events is controlled by the collection process template defined when the collection process is created.
- An ad hoc collection event may be created and linked to an existing collection process by a user at their discretion.

> **Note**
>
> **Bottom line.** Most collection events are created by the system when it creates a collection process for delinquent accounts. If you need to create an ad hoc collection event, you can either create a collection process whose template contains the desired event OR link the desired event to an existing collection process.

> **NOT_SUPPORTED**
>
> For more information about the creation of events by the Account Debt Monitor refer to What Happens When A Collection Process Is Started?. For more information about creating ad hoc collection processes, refer to Collection Process Maintenance. For more information about creating ad hoc events, refer to Collection Process - Events.

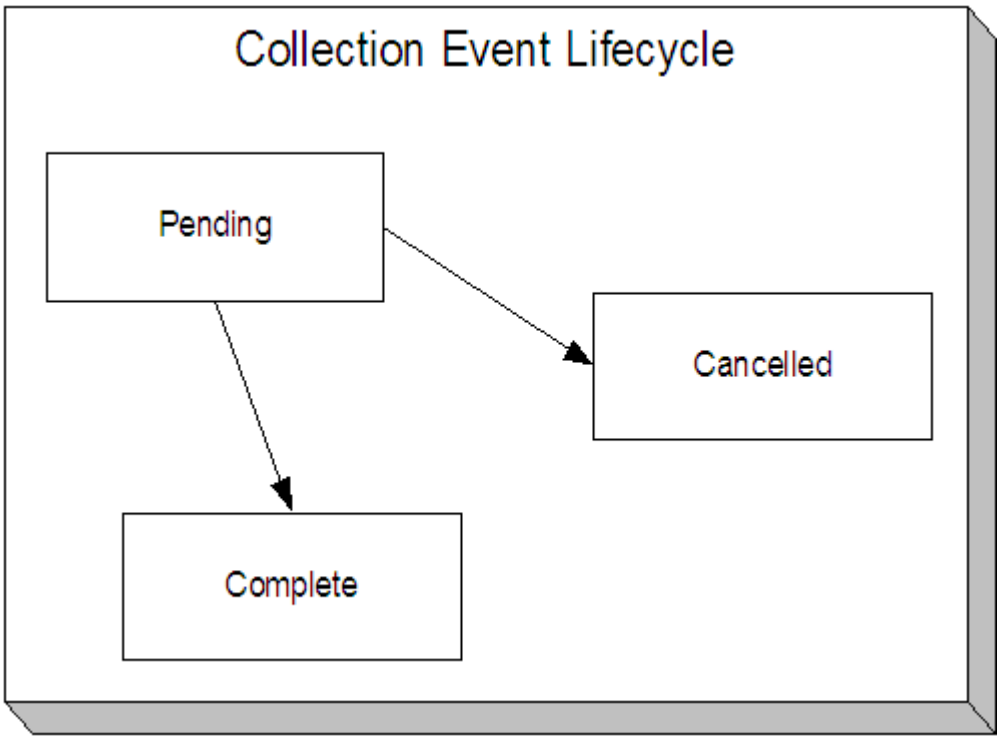
Types Of Collection Events

The following table describes the various types of collection events and what happens when they are completed:

Type Of Collection Event	What Happens In The System
Send Letter	A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced. The type of letter is defined on the customer contact's contact type. The recipient of each letter is defined on Account / Person (those persons marked as **Receiving Notifications**).

Copyright © 2026, Oracle and/or its affiliates.

Create To Do Entry	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the collection event type.
Cancel Budget	Every service agreement linked to the account that is on a budget is "removed" from the budget (i.e., the recurring charge amount for the service agreement is set to zero). In addition, a syncing adjustment is issued to cause each SA's current balance to be set equal to their payoff balance (the adjustment type is defined on the SA's SA type). Also, the Budget Plan field on the Account - Budget page is cleared.
Generic Algorithm	The algorithm defined on the event's event type is executed.
Start Severance Process	A severance process is created for every service agreement linked to the collection process. The type of severance process is defined on the SA type table (every service agreement references an SA type).



NOT_SUPPORTED

Refer to Setting Up Collection Event Types for more information.

Collection Event Lifecycle

The following diagram shows the possible lifecycle of a collection event:

Copyright © 2026, Oracle and/or its affiliates.

Collection events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

NOT_SUPPORTED

For more information about a collection event's trigger date, see Collection Event Trigger Date.

A pending event will be cancelled automatically by the system when the account's debt no longer violates the collection criteria that sparked the event's collection process. A pending event may also be cancelled by a user at their discretion. Refer to How Are Collection Processes Cancelled for more information about how the system will cancel a collection process (and its events).

Collection Event Trigger Date

When a collection event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to Calendar vs. Work Days for more information.

How Are Collection Events Completed

A background process runs periodically (at least daily) that looks for collection events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to Collection Event Activator for more information.

Copyright © 2026, Oracle and/or its affiliates.

The Last Collection Event Should Kick Off Severance Process(es)

The last collection event will typically kick off the severance process for every service agreement linked to the collection process. This will only happen if you set up the collection process template accordingly (i.e., the last event type in the process template is the kind that starts a severance process for every service agreement linked to the collection process).

> **Note**
>
> **Nominating a service agreement to sever.** Many organizations that have multiple services in arrears will NOT sever every service agreement that's in arrears. Rather, they will nominate one service agreement and use it to encourage the customer to pay for the other services. If your organization works this way, then your last collection event should call the Nominate A Service Agreement To Sever Algorithm.

How Are Collection Events Canceled?

Users can cancel a collection event at their discretion. In addition, the system can cancel a collection event when it automatically cancels a collection process. Refer to How Are Collection Processes Cancelled for the details.

The Big Picture Of Severance Process Cancellation

The topics in this section provide high level information about the cancellation of severance processes.

> **NOT_SUPPORTED**
>
> For more information refer to The Lifecycle Of A Severance Process And Its Events.

- How Are Severance Processes Cancelled?
- What Happens When A Severance Process Is Cancelled?

How Are Severance Processes Cancelled?

A severance process may be cancelled via the mechanisms described in this section.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to What Happens When A Severance Process Is Cancelled? for what happens when a severance process is cancelled.

- The Freezing Of Certain Financial Transactions Can Cancel A Severance Process
- A New Payment Plan Can Cancel A Severance Process
- A User May Cancel A Severance Process At Their Discretion
- Stopping A Service Agreement Will Cancel A Severance Process

The Freezing Of Certain Financial Transactions Can Cancel A Severance Process

Note

The system will only cancel a severance process if its severance process template indicates that **Auto Cancel** is allowed. Typically, this switch is set on all severance process templates except for the odd ones that are used to reconnect service.

The system reviews a severance process real-time whenever its service agreement's debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

Note

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no background process that monitors severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered.

The review takes place as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the severance process's debt class must be less than or equal to a given threshold amount for a severance process to be cancelled. If so, the severance process is cancelled.
- Please be aware that, if a Pay Plan exists for the account and debt class, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it

Copyright © 2026, Oracle and/or its affiliates.

is compared to the threshold amount. Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

> **Note**
>
> **The above logic is not "hard coded".** The system calls the Severance Process Cancel Criteria Algorithm defined on the debt class that is associated with the severance process. This algorithm cancels a severance process if the sum of ALL service agreements in the debt class have debt less than or equal to a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
  - The collection event called Start Severance creates a severance process for every service agreement that is in arrears. Note: you would only use this type of collection event if you do not Nominate A Single Service Agreement To Sever.
  - If you use the Start Severance collection event, then you would want to cancel a severance process when its service agreement no longer has intolerable debt (regardless of the state of the debt class's entire debt).
- To cancel a severance process when its related service agreement no longer has intolerable debt, you should plug-in a Cancel Criteria Algorithm on your severance process templates. The system will call this algorithm if you've plugged it in.

> **Note**
>
> **Manual Creation**. A user can create a severance process for an account that does not qualify to be on severance according to the cancel criteria algorithm. For example, perhaps your cancel criteria algorithm cancels a severance process when the account's debt falls below a threshold amount. A user can create a severance process for an account whose debt is already below this threshold. Because cancellation is real time, there is no action that will cause this severance process to be canceled. When a manual severance process is created, the system executes the appropriate cancellation criteria algorithm. If the algorithm indicates that the system would have canceled this severance process, a warning is issued.

A New Payment Plan Can Cancel A Severance Process

Refer to Collection Process / Severance Process Cancellation When A Pay Plan Is Created for the details.

> **Note**
>
> **Real time cancellation.** Please be aware that the system will cancel a severance process real time when a pay plan is created that pays off enough debt.

Copyright © 2026, Oracle and/or its affiliates.

A User May Cancel A Severance Process At Their Discretion

A user may cancel a severance process at their discretion.

Stopping A Service Agreement Will Cancel A Severance Process

The system will cancel a severance process if its service agreement is stopped (i.e., when the service agreement's status becomes Stopped).

What Happens When A Severance Process Is Cancelled?

The following takes place when a severance process is canceled by the system:

- The system cancels all pending severance events and deactivates the severance process.
- If there are any field activities linked to the severance process, an optional plug-in spot defined on the installation record allows you to plug in an algorithm to cancel these field activities.
  - The base package Severance Process Cancellation Algorithm will cancel all pending field activities that were created as a result of the severance process that are not linked to a dispatched field order.
- If there are any pending field activities left associated with the severance process, it is marked to trigger the creation of a To Do entry to highlight that field activities exist for a canceled severance process. (This happens if you have not plugged in an algorithm to perform the cancellation or if the algorithm detected a condition that prevented cancellation.) To create the To Do entry, you must run the background process TD-SPRO.
- There is an optional plug-in spot defined on the severance process' template. If an algorithm is plugged-in, it is called. The base package algorithm will create a reconnect process if there are completed field activities for a cut for nonpayment severance event associated with the severance process. Refer to Severance Post Cancellation Algorithm for more information about this algorithm.

The Big Picture Of Severance Events

This section describes the various types of severance events and their lifecycle:

- How Are Severance Events Created?
- Types Of Severance Events
- Field Events Versus Office Events
- Severance Event Lifecycle
- Severance Event Dependencies and Trigger Date
- Field Events And Their Activities
- Severance Event Activation & Completion
- How Are Severance Events Canceled?

Copyright © 2026, Oracle and/or its affiliates.

How Are Severance Events Created?

Severance events may be created as follows:

- The process that completes (i.e., executes) collection events creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The number and type of events is controlled by the severance process template associated with the severance process. Refer to The Collection Event Activator for more information about this process.
- Severance events will be created when a user creates an ad hoc severance process. The number and type of severance events is controlled by the severance process template associated with the severance process.
- An ad hoc severance event may be created and linked to an existing severance process by a user at their discretion.

> **Note**
>
> **Bottom line.** Most severance events are created by the system when it creates a severance process for delinquent service agreements. If you need to create an ad hoc severance event, you can either create a severance process whose template contains the desired event OR link the desired event to an existing severance process.

> **NOT_SUPPORTED**
>
> For more information about creating ad hoc severance processes and events, refer to How To Perform Common Severance Process Functions.

Types Of Severance Events

The following table describes the various types of severance events and what happens when they are completed:

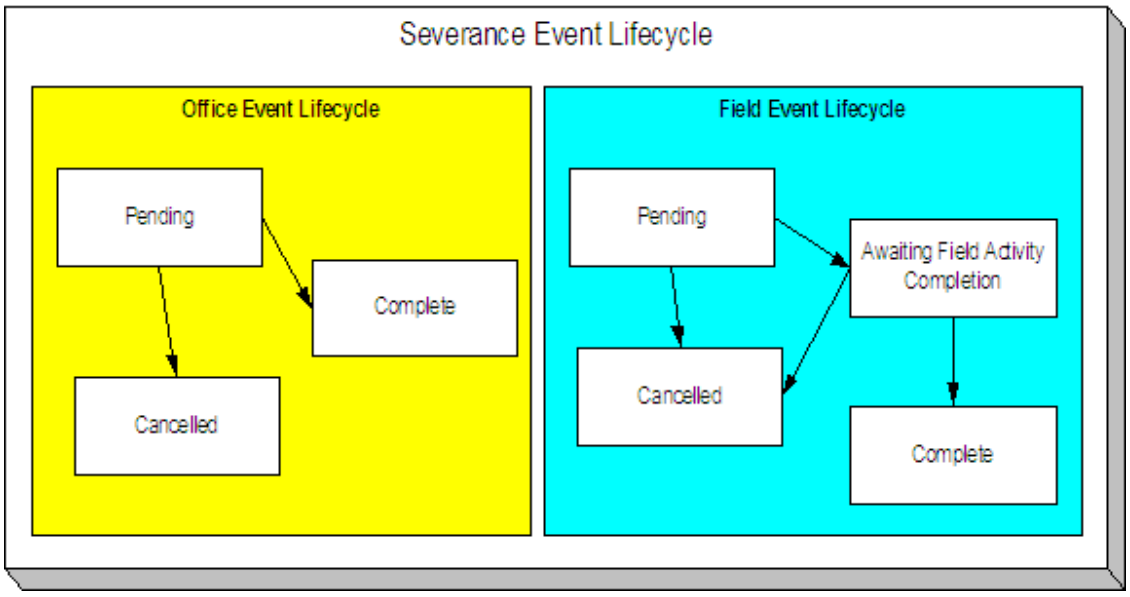
Type Of Severance Event	What Happens In The System
Send Letter	A customer contact is created for every financially responsible person linked to the service agreement's account. It is the customer contact that causes a letter to be produced. The type of letter is defined on the customer contact's contact type. The recipient of each letter is defined on Account / Person (those persons marked as **Receiving Notifications**).
Create To Do Entry	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.

Copyright © 2026, Oracle and/or its affiliates.

Create Field Activities	A field activity is created for each service point associated with the service agreement being severed. The type of activity is defined on the service point's SP type's field activity type profile.
Generic Algorithm	The algorithm defined on the event's event type is executed.
Expire Service Agreement	The service agreement is expired and, if earlier severance events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point.
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the collection event type.

NOT_SUPPORTED

Refer to Setting Up Severance Event Types for more information.



Field Events Versus Office Events

Severance events are considered either field or office events. Office events are just like collection events in that they don't involve any type of field activity in their completion. Field events, however, are not like collection events because they create one or more field activities. These activities cause these events to have a different lifecycle. Refer to Severance Event Lifecycle for more information.

Severance Event Lifecycle

The following diagram shows the possible lifecycle of a severance event:

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the lifecycle of severance events of the office variety:

- Office events are initially created in the pending state.
- A pending office event becomes complete when the system sees that its trigger date is on or before the current date. At this time, the system executes the event's activity (e.g., create a letter, create To Do entry).

NOT_SUPPORTED

For more information about a severance event's trigger date, see Severance Event Dependencies & Trigger Date.

- A pending office event will be cancelled automatically by the system when the debt associated with the severance process's service agreement is sufficiently reduced. A pending office event may also be cancelled by a user at their discretion. Refer to How Are Severance Processes Cancelled for more information about how the system will cancel a severance process (and its events).

The following points explain the lifecycle of severance events of the field variety:

- Field events are initially created in the pending state.
- A pending field event becomes awaiting field activity completion when the system sees that its trigger date is on or before the current date. At this time, the system creates the field activities associated with the given event (e.g., disconnection warning, disconnect for nonpayment, etc.).

NOT_SUPPORTED

For more information about a severance event's trigger date, refer to Severance Event Dependencies & Trigger Date. For more information about the field activities that are created for a field severance event, refer to Field Events And Their Activities.

Copyright © 2026, Oracle and/or its affiliates.

- An awaiting field activity completion field event becomes complete when the system sees that its field activities are all complete or cancelled.
- A pending field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits. A pending field event may also be cancelled by a user at their discretion.
- An awaiting field activity completion field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits if the field activity has not been dispatched (refer to Designing Your Reconnection Procedures for information on how the system handles the situation if the field activity is completed or dispatched). An awaiting field activity completion event may also be cancelled by a user at their discretion.

Severance Event Dependencies and Trigger Date

When a severance event is created by the system, its trigger date cannot be set. This is because, unlike collection events, the trigger date on severance events can only be set when ALL of the preceding severance events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a standard severance process and its events:

Event Number	Severance Event	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Preceding Events
10	Field activity - Disconnect for non-payment warning	N/A - first event	0
20	Field activity - Disconnect for non-payment	10	2
30	Create To Do entry	20	0
40	Send letter to customer	20	0
50	Expire service agreement	20	10

This severance process is meant to execute as follows:

- On the first day, generate a 48-hour warning of impending disconnection. This is a field event as most organizations deliver this warning in person.
- After 2 days (i.e., 48 hours) have passed, create a field activity to disconnect for non-payment.
- When this is completed, generate a To Do entry to let a CSR know about the cutoff. Also, send a letter to the customer.
- If after 10 days from the cutoff, we still don't have payment, expire the service agreement.

As can be seen from the above example, the later events are dependent on the completion of the field activities in the earlier events. This means that when you set up a severance event, you must indicate the events on which it depends (and the number of days after their completion that the event should be triggered).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** The system sets the trigger date on severance events when it detects that all of its dependent events are complete (this is the responsibility of the SED background process). Refer to Calendar vs Work Days for a description of your choices in respect of how the trigger date is calculated.

Field Events And Their Activities

When the system is told to start a severance event that creates field activities (e.g., disconnect for non-payment), it will generate a field activity for every service point linked to the service agreement.

The question is, where does it get the field activity type associated with the field activities? The answer is explained below:

- Every service point has an SP type.
- Every SP type references a field activity type profile.
- A field activity type profile contains a matrix defining activity types to generate under various situations. Some of these situations are those associated with severance.

> **NOT_SUPPORTED**
>
> For more information, refer to Setting Up Field Activity Type Profiles.

Severance Event Activation & Completion

A background process runs periodically (at least daily) that looks for severance events with a trigger date on or before the current date. This process executes the activity associated with each event. If the event is an office event, the event then becomes complete. If the event is a field event, the event becomes "awaiting field activity completion" until the field activities are complete. At this time, the severance event is completed. Refer to Severance Event Activator for more information.

How Are Severance Events Canceled?

Users can cancel a severance event at their discretion. In addition, the system can cancel a severance event when it automatically cancels a severance process. Refer to How Are Severance Processes Cancelled for the details.

The Big Picture Of Write Off Processing

Copyright © 2026, Oracle and/or its affiliates.

Before you financially write-off debt, most companies go to some effort to collect the past due funds. You control exactly what happens by setting up the various write-off control tables. The topics in this section provide background information that will help you understand how the information in these control tables is used.

- How Is Debt Financially Written-Off?
- The Ramifications of Write Offs in the General Ledger
- Automated versus Manual Write Offs
- How Does The Write-Off Monitor Work?
- How Does A Write-Off Process Get Cancelled?
- How Do Collection Agency Referrals Work?

How Is Debt Financially Written-Off?

Before debt can be written-off, a write-off service agreement must exist for the account. Why? Because when you write-off a normal service agreement's debt, you are actually transferring its debt to a write-off service agreement.

A write-off service agreement is just like other service agreements in that:

- It holds debt.
- When a payment is received, the service agreement's debt is reduced.

Debt is transferred to a write-off service agreement (WO SA) from the customer's uncollectable service agreements (SAs). The following points highlight important characteristics about the uncollectable SAs and the WO SA:

- The WO SA and the uncollectable SAs should be linked to the same account (note: this isn't a strict rule, it just makes sense because an account's written off funds should be linked to the account).
- Debt may be transferred to a WO SA from any type of service agreement regardless of debt class, i.e., a WO SA can contain debt that originated in any debt class.
- When you transfer debt from the uncollectable SAs to the WO SA, the debt is removed from the uncollectable SAs (and their status becomes closed - assuming their balance becomes zero).
- If you use the system's automated write-off processing, the system will create WO SAs for you. The system's automated write-off processing can write-off revenue in a different manner than is used to write-off liabilities. Refer to The Ramifications of Write Offs in the General Ledger for more information.
- WO SAs are immune from the account debt monitor (assuming their debt class is marked as not being subject to collection activities).
- WO SAs are not billed (assuming their SA type is marked as being not billable).
- WO SAs start their life with a non-zero payoff and current balances (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose uncollectable debt necessitated the creation of the WO SA.
- If the customer pays off the write-off debt, the WO SA remains active in case you ever need to write-off debt in the future. If you don't like the WO SA remaining active after it's paid off, you can indicate on the WO SA's SA Type that it is a "one time charge", this will cause the WO SA to be automatically closed when it's paid off.

Copyright © 2026, Oracle and/or its affiliates.

- You can transfer additional uncollectable debt to the WO SA.

> **Note**
>
> **Bankruptcy write-offs.** If you have to write-off debt because a customer declares bankruptcy, everything stated above is true. The only thing you have to do is use a different SA type for bankruptcy write-offs as compared to "normal" write-offs. On the bankruptcy write-off SA type, simply leave the payment segment type blank - this way the system will never distribute a payment to the bankrupt debt (because bankrupt debt is legally uncollectable).

The Ramifications of Write Offs in the General Ledger

> **Warning**
>
> If you practice cash accounting, refer to Cash Accounting and Write-Offs.

When you write-off unpaid debt, you shouldn't book it all to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you typically want to:

- Book the written off revenue to a write-off expense account, and
- Reduce the liabilities (you don't owe the liability if you don't get paid).

Consider the following example of a simple electric service agreement with two financial transactions:

Event	GL Accounting
Customer is billed	A/R 1000 Revenue <900> State Tax Payable - Taxing State - California <80> City Tax Payable - Taxing City - San Francisco <20>
Customer is levied a late payment charge	A/R 50 Late Payment Revenue <50>

After these two financial transactions are booked, the customer has debt of $1050. Of this $1,050; $950 is revenue and $100 is liability (money you owe the taxing authorities).

If the customer doesn't pay, you will eventually have to write-off this debt. Most organizations would issue the following types of financial transactions to do this:

Event	GL Accounting

Copyright © 2026, Oracle and/or its affiliates.

Write-off the bill	Write-off Expense 900 State Tax Payable - Taxing State - California 80 City Tax Payable - Taxing City - San Francisco 20 A/R <1000>
Write-off the late payment charge	Write-off Expense 50 A/R <50>

Notice in the above transactions, the two separate revenue accounts are written off by booking to an expense account. However, the liability accounts are reversed. Why is revenue treated differently from liabilities at write-off time? There's a good reason for it (if you're an accountant), for the time being, just accept that this is how it works.

And finally, we need to worry about what happens if the customer eventually pays off their written off debt. If this happens, most organizations would pay off the write-off first, and, if there was still money left, they'd reimburse the taxing authorities. If we assume the customer pays off the entire written off debt, the following financial transactions would be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900 Write-off Expense <900>
Reinstate the liabilities	Cash 100 State Tax Payable - Taxing State - California <80> City Tax Payable - Taxing City - San Francisco <20>

While the reinstatement of liabilities at payment time is possible in the system, the ramifications of doing such make this approach impracticable (the ramifications are a) if the check bounces, we would not be able to reduce the liabilities, and b) if there was a partial payment of the liabilities, the remaining unpaid amount could get written down). Therefore, when a write-off is paid the following financial transactions should be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900 Write-off Expense <900>
Reinstate the liabilities	Cash 100 Reinstated liabilities <100>

Notice that rather than reinstating the individual liabilities, we simply reinstate all liabilities into a single account. This means your accountants will have to distribute this money to the appropriate liabilities manually.

So, how do we achieve the above in the system? This explanation is a little complicated, but it'll make sense if you keep the above financial transactions in mind:

- First of all, you'll need two different SA types - one to hold the written off revenue and another to hold the reduced liabilities.
  - On the SA type that holds written off revenue, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference your Write-off Expense account.

Copyright © 2026, Oracle and/or its affiliates.

- On the SA type that holds the reduced liabilities, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference a the "reinstated liabilities" GL account.

Next, you need to understand how the system's standard write-off logic works:

- The system accumulates the distribution codes from GL details associated with recent financial transactions linked to the service agreement being written-off.
- When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement(s). The number and type of service agreements to which the bad debt is transferred is defined on the distribution codes. Refer to Setting Up Distribution Codes for how to define the type of write-off service agreement associated with a distribution code. In our example, we'd need the two SA types described above - one for the revenue accounts, the other for the liability accounts.
- At write-off time, for those distribution codes associated with revenue, the system will create a transfer adjustment from the normal service agreement to the write-off revenue service agreement. This will reduce (credit) the receivable on the normal service agreement and increase (debit) the expense account defined on the write-off revenue service agreement.
- However, if we do the above for the distribution codes associated with liabilities, we have a problem. The problem is a bit hard to explain unless you understand tax accounting, but it basically comes down to this - if we simply transfer the portion of the receivable balance associated with the liabilities to the write-off liability SA, we will always be debiting the distribution code defined on the SA type. This isn't correct because we really want to debit the liability account (and reference the characteristic type and value from the original credit) when we reduce the liability. So how do we do this? For those distribution codes associated with liabilities, you need to indicate that you want to override the distribution code on the "transfer to" side of the transfer adjustment with the distribution code / characteristic type / characteristic value that was originally booked. Refer to Setting Up Distribution Codes for how to indicate you want to override the distribution code at write-off time. If you do the above, then at write-off time the transfer adjustment will reduce (credit) the receivable on the normal service agreement and increase (debit) the original liability accounts from the original financial transactions.

If you followed the above, you'll see that we now have everything debited and credited appropriately. And, if a payment materializes for the written off debt, we will simply debit cash and credit the distribution code on the respective SA (either Write Off Expense or Reinstated Liabilities).

> **Note**
>
> **Batch and real-time write-offs may use the above processing.** The above logic is executed real time when a user writes off debt using the write-off transaction (assuming the base package write off algorithm is plugged into the account's customer class). The above logic is executed in batch when a write-off event that references a Write Off Using Distribution Codes event type is executed. Write-off events are described in detail below.

Copyright © 2026, Oracle and/or its affiliates.

Automated versus Manual Write Offs

The system will automatically create write-off SAs and transfer uncollectable debt to them during the automated write-off processing described below.

If necessary, you can write-off debt outside of the automated write-off process using either of the following methods:

- You can transfer bad debt from any service agreement to a write-off service agreement using a transfer adjustment.
- You can use the write-off transaction to write-off debt real-time. When this transaction is used, the system executes the logic embedded in the Write Off Method algorithm that's plugged in on the account's customer class.

How Does The Write-Off Monitor Work?

This section describes how the Write Off Monitor uses your write-off criteria and write-off process templates to collect overdue debt.

- Different Write-Off Criteria For Different Customers And Different Debt
- When Is Debt Monitored For Write Off Purposes?
- Attempt To Close The SA Before Creating A Write Off Process
- What Happens When A Write-Off Process Is Started?

Different Write-Off Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different write-off criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different write-off criteria for different classes of debt. For example, if a customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have control over how to write-off unregulated debt. You differentiate your debt in respect of the collection process via a write-off **debt class on the customers' service agreements** (note the write-off debt class is actually defined on the SA type and every service agreement has a SA type).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Write Off Debt Class vs. Regular Debt Class.** It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt.

Given the above, you should understand that different write-off criteria will exist for every combination of collection class and write-off debt class. If you're confused, then consider the following matrix:

SA's Write-Off Debt Class	**Account's Collection Class: Commercial Customer**	**Account's Collection Class: Residential Customer**
Regulated	N/A - there is no regulated, commercial customer debt.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. If the debt is <= $-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for regulated debt.

Copyright © 2026, Oracle and/or its affiliates.

Unregulated	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt / credit is < $10 and > $-10, write down the debt using a write-down adjustment. If the debt / credit is <= $-10, create an A/P adjustment to refund the credit to the customer. If debt still remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process. Otherwise, create the default write-off process for unregulated commercial debt.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. If the debt is <= $-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for unregulated residential debt.

Notice that each cell in the matrix has the same pattern:

- The system first attempts to reduce the SA's current and payoff balances to zero using the following methods (assuming you have set up the write-off control appropriately):
  - Sync the current balance with the payoff balance. If the SA's payoff balance is zero, this will cause the current balance to become zero and therefore close the SA.
  - If there's a debit balance, transfer the debt to any pending start or active SA in the same write-off debt class.
  - If there's a credit balance, transfer the debt to any non-closed / non-cancelled SA in the same write-off debt class
  - If the remaining debit / credit balance is within a user-defined tolerance (this is defined on the respective algorithm on the write-off control), create an adjustment to write-down the small balance.
  - If a credit balance remains, create an A/P adjustment to refund the balance with a check (the adjustment type is defined on the respective algorithm on the write-off control).
- All of the above points will cause the SA to close. If debt remains, the system starts some type of write-off process. The type of process is dependent on the respective criteria. What differentiates one write-off criteria from another is its priority. The higher priority criteria will be compared first. If the customer / debt meets the criteria, the write-off process is initiated; no further comparisons are performed.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about maintaining this matrix, refer to Setting Up Write-off Control.

When Is Debt Monitored For Write Off Purposes?

The write-off monitor only reviews a service agreement when the following conditions are true:

- The service agreement is stopped and reactivated.
- If the service agreement is a "billable charge" SA (as identified on its SA type), all of its billable charges must appear on a bill segment AND the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is not a "billable charge" SA AND it is billable (as identified on its SA type), the SA must have a closing bill segment (i.e., it must be final billed) and the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is a sub SA, its master SA must abide by the above conditions.
- If the service agreement is not billable, it is possible that adjustments, which affect the SA's debt, exist. The write-off monitor will only review a non-billable SA if all FTs for this SA that have been marked to include on a bill have been swept onto a bill and the bill for any of these FTs has a bill due date plus grace period on or before the business date.

Note

Postponing write-off processing. You can prevent the write-off process from processing an eligible service agreement by populating the account's C&C Postpone Date with a future date.

Attempt To Close The SA Before Creating A Write Off Process

Before the write-off monitor creates a write-off process for a stopped and reactivated service agreement, it attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finaled debt to a pending start or active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Plug-in algorithms do the work.** Algorithms that are plugged-in on the write-off control responsible for managing the service agreement's debt actually perform the above effort. You can customize these algorithms to behave exactly how your collections staff desires.

If the algorithms responsible for the above effort are successful in reducing the service agreement's debt to zero, then the service agreement closes and will not be subject to write-off processing. If the above algorithms don't result in the service agreement's debt being reduced to zero, a write-off process will be started (as describe below).

What Happens When A Write-Off Process Is Started?

When you define write-off criteria, you must define the write-off process template to use if the criteria are violated. The system uses this template to create the account-specific write-off process.

Every stopped or reactivated service agreement that is part of the offending write-off debt class will be linked to the write-off process.

Also linked to the write-off process will be one or more write-off events. These events are meant to prod the customer. You define the types of events and when they are generated when you set up your write-off process templates.

It's important to note that all of the write-off events will be created when the write-off process is created. Each of these write-off events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to Calendar vs Work Days for a description of how the trigger date is calculated.

A separate process, Activate Write-off events, is responsible for activating write-off events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do to an operator, refer debt to a collection agency, etc.)

> **Note**
>
> **Multiple write-off processes may be kicked off.** It's important to be aware that if an account's service agreements reference multiple write off debt classes, a write-off process will be started for each offending write off debt class that has stopped or reactivated service agreements.

> **NOT_SUPPORTED**
>
> For more information about write-off process templates, see Setting Up Write Off Process Templates. For more information about write-off events, see The Big Picture Of Write-off Events. For more information about how a write-off process is cancelled, see How Does A Write-Off Process Get Cancelled?.

Copyright © 2026, Oracle and/or its affiliates.

How Does A Write-Off Process Get Cancelled?

The system "removes" a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process. When the write-off process is deactivated, all collection agency referrals associated with the write-off process are cancelled.

> **Note**
>
> **Removing closed service agreements from a write-off process.** Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

How Do Collection Agency Referrals Work?

The following points describe how collection agency referrals work.

- A write-off process has one or more events. One type of event causes overdue debt to be referred to a collection agency.
- When a referral write-off event is activated, the system marks the event for processing by the event's Collection Agency Referral Algorithm (refer to Setting Up Write Off Event Types for more information).
- The next time the Collection Agency Referral process executes (the frequency is dependent on your background process schedule), it will refer the process' debt to a collection agency. The specific agency to which the debt is referred is controlled by the event type's Collection Agency Referral Algorithm. The sample algorithm supplied with the system simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must write your own algorithm.
- Regardless of the manner in which a collection agency is selected for an account's debt, the referral involves the creation of a collection agency referral history record. Refer to Collection Referral for more information.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that, in turn, triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to Setting Up Collection Agencies for more information.
- If the collection agency is successful in obtaining the funds, simply add a payment. If the payment causes the SA's balance to become zero, the system will automatically close the service agreement. When the system closes a service agreement, it is "removed" from the write-off process. When a write-off process no longer contains active service agreements, the system cancels the write-off process. When a write off process is cancelled, all collection agency referrals are automatically cancelled.
- Collection agency referrals get cancelled by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).

Copyright © 2026, Oracle and/or its affiliates.

- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you design your write-off process to generate a collection agency cancellation X days after the referral. Refer to Setting Up Write Off Process Templates for how to do this. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).

> **NOT_SUPPORTED**
>
> When you enable the Control Central alert algorithm, C1-COLL-REF, an alert displays when an account has an active collection agency referral. This algorithm is plugged-in on the installation record.

The Big Picture Of Write-off Events

This section describes the various types of write-off events and their lifecycle.

- How Are Write-off Events Created?
- Types Of Write-off Events
- Write-off Event Lifecycle
- Write-off Event Trigger Date
- How Are Write-off Events Completed
- The Last Write-off Event Should Write Off All Debt Associated With All SAs
- How Are Write-off Events Canceled?

How Are Write-off Events Created?

Write-off events may be created as follows:

- The Write-Off Monitor creates a write-off process when an account has unpaid, final billed service agreements. The write-off process has one or more write-off event(s). Refer to How Does The Write-Off Monitor Work? for more information about how the system creates write-off processes and their events.
- Write-off events are created when an operator creates an ad hoc write-off process. The number and type of events is controlled by the write-off process template defined when the write-off process is created.
- An ad hoc write-off event may be created and linked to an existing write-off process by an operator at their discretion.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** Most write-off events are created by the system when it creates a write-off process for unpaid, finaled service agreements. If you need to create an ad hoc write-off event, you can either create a write-off process using a template that contains the desired event OR link the desired event to an existing write-off process.

> **NOT_SUPPORTED**
>
> For more information about creating ad hoc write-off processes and events, refer to How To Perform Common Write-off Maintenance Functions.

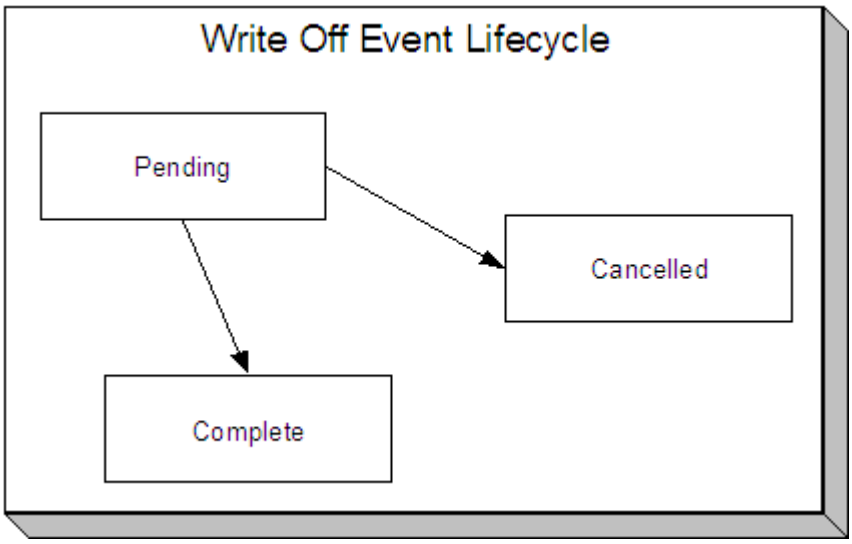
Types Of Write-off Events

The following table describes the various types of write-off events and what happens when they are completed:

Type Of Write-off Event	What Happens In The System
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the write-off event type.
Cancel Agency Referral	All collection agency referrals associated with the write-off process will be cancelled.
Refer to Agency	The debt associated with the SAs linked to the write-off process will be referred to a collection agency.
Send Letter	A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced. The type of letter is defined on the customer contact type control table. The recipient of each letter is defined on Account / Person (those persons marked as **Receiving Notifications**).
Send To Do	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.

Copyright © 2026, Oracle and/or its affiliates.

Write Off using Distrib Code	This type of event is used to write-off bad debt in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. You'd use this method for example if you want to write-off revenue differently than you write-off liabilities. The system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement. The type of service agreements to which the debt is transferred is defined on the distribution codes.
Write Off using SA Type	The service agreements linked to the process will be written-off by transferring their debt to a new or existing write-off service agreement. Note: the SA type of the write-off service agreement is defined on the algorithm defined on events of this type.
Generic Algorithm	The system calls the algorithm defined on the write-off event type. This type of event is used when what you need to do isn't handled by one of the above event types.



NOT_SUPPORTED

Refer to Setting Up Write Off Event Types for more information.

Write-off Event Lifecycle

The following diagram shows the possible lifecycle of a write-off event:

Copyright © 2026, Oracle and/or its affiliates.

Write-off events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

NOT_SUPPORTED

For more information about a write-off event's trigger date, see Write-off Event Trigger Date.

A pending event will be cancelled automatically by the system when the service agreements linked to the process are all closed (i.e., they no longer have debt - either because it was paid or transferred to a write-off service agreement). A pending event may be cancelled by an operator at their discretion.

Write-off Event Trigger Date

When a write-off event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to Calendar vs. Work Days for more information.

How Are Write-off Events Completed

A background process runs periodically (at least daily) that looks for write-off events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to Write Off Event Activator for more information.

The Last Write-off Event Should Write Off All Debt Associated With All SAs

The last write-off event will typically transfer all debt from the service agreement's linked to the process to a write off service agreement (linked to the account). This will only happen if you set up the write-off process template accordingly (i.e., the last event in the write-off process

Copyright © 2026, Oracle and/or its affiliates.

template is the kind that writes off debt for every service agreement linked to the write-off process).

How Are Write-off Events Canceled?

The system removes a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). Be aware that any type of financial event could cause an SA's balance to fall to zero (e.g., the creation of an adjustment, the application or cancellation of a payment, the cancellation of a bill, ...). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process.

> **Note**
>
> **Real time cancellation.** Unlike collection processes, the system cancels write-off processes real time when the service agreement becomes closed (i.e., there is no background process that monitors write-off processes).

Besides the automated cancellation process, an operator may cancel a write-off event at will.

> **Note**
>
> **Removing closed service agreements from a write-off process.** Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

Calendar Versus Work Days

When you set up your collection, severance and write-off process templates, you supply information that controls how the system determines the trigger date of each event in the related process. There are two different mechanisms for doing this:

- When you set up your severance process templates, you must define the number of days between each event. For example, the second event (send cutoff warning) may need to be triggered 7 days after the first event (send reminder letter).
- When you set up your collection and write-off process templates, you must define the number of days after the start of the process when each event should be triggered. For example, the second event (send cutoff warning) may need to be triggered 7 days after the start of the collection process.

The system uses this information in conjunction with the account's division's work calendar when it allocates a trigger date to the various collection, severance, and write-off events in your processes. The system offers you the following choices in respect of how it calculates an event's trigger date:

- You can indicate that the trigger date should be set to the next possible workday. For example, if you indicate that the second event is triggered 7 days after the first event, the system will add 7 days to the first event's completion date. It then checks if this is a

Copyright © 2026, Oracle and/or its affiliates.

workday (and not a holiday), if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.

- You can indicate that the trigger date should be calculated by counting workdays. For example, if you indicate that the second event is triggered 7 days after the first event, the system will count 7 workdays (using the account's division's work calendar), and set the trigger date accordingly.

You must define which of the above methods is used in the following processes:

- Account Debt Monitor (ADM). Refer to The Account Debt Monitor for more information.
- Collection Event Trigger (CET). Refer to The Collection Event Activator for more information.
- Severance Event Set Trigger Date (SED). Refer to Set Trigger Date for more information.
- Write-off Monitor (WPM). Refer to The Write Off Monitor for more information.

The Big Picture Of Payment Arrangements and Pay Plans

The topics in this section describe two different mechanisms that allow a customer to payoff overdue debt in installments.

- The Big Picture Of Payment Arrangement Requests
- The Big Picture Of Pay Arrangements
- The Big Picture Of Pay Plans
- Setting Up Pay Plan Control Tables

The Big Picture Of Payment Arrangement Requests

A Payment Arrangement Request is used to manage the process of starting a payment arrangement. It is a step-by-step process that can include:

- Checking the account’s eligibility for payment arrangement
- Capturing the terms of the payment arrangement such as the included service agreements, down payment amount, number of installments and installment amount
- Evaluating whether or not the payment arrangement request requires approval
- User approval / rejection of the payment arrangement request
- Monitoring for the down payment, if applicable
- Creating the payment arrangement service agreement

The topics in this section describe how payment arrangement requests work.

- Lifecycle Of A Payment Arrangement Request
- Payment Arrangement Eligibility
- Payment Arrangement Request Approval
- Payment Arrangement Down Payments
- Setting Up Payment Arrangement Request Control Tables
- Automatically Cancelling Inactive Payment Arrangement Requests

Copyright © 2026, Oracle and/or its affiliates.

Lifecycle Of A Payment Arrangement Request

The base product provides a Payment Arrangement Request (**C1–PARequest**) business object that supports the functions needed to create a payment arrangement. Its lifecycle allows for managing and monitoring of the preqrequisites of a payment arrangement:

- The first step in the payment arrangement request process is typically to check that the account is eligible for a payment arrangement. One or more eligibility criteria are executed and an overall assessment is made on the results, to determine the account's eligibility/ ineligibility. The request goes into the **Eligibility Checked** state. The results are shown on the user interface, for the user to determine the next step.
  - If the account is ineligible for a payment arrangement, the request process ends. The payment arrangement request goes into the **Denied** state.
  - If the account is eligible, the process can proceed with setting up the terms of the payment arrangement. The agreed upon terms are submitted and the request proceeds to the next step. If there are no prerequisites (approvals, down payment etc,), the request can automatically go to the **Granted** state, where the payment arrangement service agreement is created
- A payment arrangement request may be subject to prior approval if it meets certain criteria — e.g. the payment arrangement amount exceeds a threshold amount. The payment arrangement request goes into the **Approval In Progress** state, where an authorized user will need to review the request and **Approve** or **Reject** it accordingly.
  - If the user approves the request, the request will proceed to the next step — i.e. either another prerequisite (such as a down payment) or granting the request.
  - If the user rejects the request, the request will automatically go to the **Denied** state.
- If a down payment must be paid prior to starting the payment arrangement, the request will stay in the **Waiting for Down Payment** state until the payment is received or until the down payment due date.
  - If the down payment is paid (i.e. according to implementation-specific criteria for considering it paid), the payment arrangement request goes into the **Granted** state, where the payment arrangement service agreement is created. The account's SA balances to include in the payment arrangement are recalculated, based on the actual down payment that was received.
  - On the other hand, if the down payment is not received or is received but insufficient, the payment arrangement request goes into the **Unpaid Down Payment** state.
- A payment arrangement in a **Waiting for Down Payment** or **Approval In Progress** state can be **Withdrawn**. This is for cases where a customer decides to not proceed with the payment arrangement.
- Any issues encountered during the recalculation of the SA balances or during the creation of the payment arrangement service agreement can put the request into the **Error** state.

Refer to the Payment Arrangement Request business object, for more details on these lifecycle rules.

Payment Arrangement Eligibility

An account's eligibility for payment arrangement is typically checked at the start of the request process. Based on the results of these eligibility checks, a user can determine whether or not the payment arrangement request can proceed.

Copyright © 2026, Oracle and/or its affiliates.

Since the eligibility rules can vary across implementations, the base product provides plug-in spots on the Payment Arrangement Request Type (**C1–PARequestType**) business object for eligibility checking:

- The **PA Request Type – Eligibility Criteria** algorithm spot is responsible for checking specific conditions or activity on the account, to determine payment arrangement eligibility. Algorithms of this type commonly return a simple Pass/Fail result. The base product supplies a sample algorithm that checks the account's past broken payment arrangements.
- The **PA Request Type — Criteria Assessment** algorithm spot is responsible for taking the results of the execution of **PA Request Type – Eligibility Criteria** algorithms and determining the overall result, which is whether or not the account is eligible for payment arrangement. The base product supplies two sample algorithms for this spot:
  - One algorithm type checks for at least one Fail result from the **PA Request Type – Eligibility Criteria** algorithms and if it finds one, returns an *Ineligible* result
  - Another algorithm type simply returns an *Eligible* result. This is for implementations that do not need **PA Request Type – Eligibility Criteria** algorithms. This default algorithm would be the only algorithm to plug in.

.

Payment Arrangement Request Approval

A payment arrangement request may require prior approval, based on the terms specified on the request. For instance, if the total payment arrangement amount exceeds a set threshold amount, the request may have to be routed to another user for approval. That user will need to review the request and Approve or Reject accordingly.

Since the approval requirements are implementation-specific, the base product provides a **PA Request Type — Determine Approval Requirement** plug-in spot on the Payment Arrangement Request Type (**C1–PARequestType**) business object. Algorithms of this type return an indicator of whether or not approval is needed. If the algorithm indicates that approval is needed, the payment arrangement request will go into the **Approval In Progress** state until a user reviews and approves/rejects the request.

Your implementation must configure an algorithm with your specific approval criteria. The base product does not currently supply an algorithm type for this spot.

Payment Arrangement Down Payments

A down payment may be required/applicable as a prerequisite for starting the payment arrangement.

A setting on the Payment Arrangement Request Type controls whether down payments are required/optional/not applicable. If down payments are required or optional, the payment arrangement request type defines the down payment options, which are percentages of the total payment arrangement amount or a flat amount.

The down payment due date is calculated based on settings in the Payment Arrangement Request Type – e.g. number of days till due.

The down payment is monitored for the actual payment:

- If the down payment is paid, the request is granted. The SA balances are recalculated based on the down payment amount that was paid and the payment arrangement service agreement is created.

Copyright © 2026, Oracle and/or its affiliates.

- If the down payment is unpaid or is insufficient (based on the implementation's rules), the request is denied and the payment arrangement service agreement will not be created.

Refer to the Payment Arrangement Request Type (**C1–PARequestType**) business object for more details on down payment option configuration and to the Payment Arrangement Request (**C1–PARequest**) business object, to see the monitor algorithm that checks if the down payment was made.

Setting Up Payment Arrangement Request Control Tables

This section describes the control tables needed to set up payment arrangement requests.

- Setting Up Payment Arrangement Request Types
- Setting Up Payment Arrangement Request Reasons
- Setting Up Payment Arrangement Request Status Reasons

Setting Up Payment Arrangement Request Types

A payment arrangement request type defines properties that control how a request for payment arrangement is processed.

Refer to The Big Picture Of Payment Arrangement Requests for an overview of payment arrangement request functionality.

To maintain payment arrangement request types, open **Admin**, and then **Credit & Collection**, and then **Payment Arrangement Request Type**, and then **Search**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information on the fields.

Setting Up Payment Arrangement Request Reasons

A payment arrangement request can capture the specific reason why a customer is asking to go on a payment arrangement. This reason is optional if using the base-owned Payment Arrangement Request (**C1–PARequest**) business object and the Payment Arrangement Request Process Flow Type (**C1-PAREQUEST**) on your Payment Arrangement Request Types.

To use Payment Arrangement Request Reasons, configure your specific values on the **C1-PARequestReasonLookup** extendable lookup. No base values are supplied for this lookup.

Setting Up Payment Arrangement Request Status Reasons

The Payment Arrangement Request (**C1–PARequest**) base business object provides the option to specify the reason for the request going into the **Denied** or **Canceled** state.

A few base-owned status reasons are supplied. To add other reasons for payment arrangement request cancellation/denial, go to the Status Reason portal and update the **C1–PARequest** business object's status reasons for the Denied and Canceled states.

Copyright © 2026, Oracle and/or its affiliates.

Automatically Cancelling Inactive Payment Arrangement Requests

The system is delivered with a batch process, Cancel Inactive PA Requests (C1-ACPAR), that can be used to cancel payment arrangement requests that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the Plug-in Driven Background Processes framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the payment arrangement request. Adjust the batch parameters according to your custom logic, if needed.

The Big Picture Of Pay Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

> **Note**
>
> **Nomenclature.** Some people refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the customer's bill only contains charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

- Creating Payment Arrangements
- Installment, Payoff and Current Amounts
- Monitoring Payment Arrangements

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed.
- When a payment is received, the service agreement's debt is reduced.
- If the service agreement becomes delinquent, a collection process is initiated to collect the overdue debt.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent service agreements (SAs) at the inception of the payment arrangement.

When you transfer delinquent debt from the delinquent SAs to the PA SA, the debt is removed from the delinquent SAs. If you transfer all debt from the delinquent SAs, the customer will no

Copyright © 2026, Oracle and/or its affiliates.

longer be in arrears in a given debt class (and if the customer is no longer in arrears, active collection and severance processes will be cancelled).

> **Note**
>
> **Use the Payment Arrangement Request Transaction.** You could do the above functions by adding a new service agreement and creating transfer adjustments. However, this is tedious. Rather, use the Payment Arrangement Request process. This process is recommend when requests for payment arrangements require eligibility checking and other prerequisites such as down payments and approvals. When a payment arrangement request is granted, it creates the PA SA, transfers debt to it, and sets up the installment amount.
>
> You can also create the payment arrangement service agreement directly using the Payment Arrangement transaction if you don't require any prior eligibility checks, down payments or approvals. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

> **Warning**
>
> If you do not understand the difference between payoff balance and current balance, refer to Current Amount versus Payoff Amount.

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, neither the original service agreements nor the PA SA have delinquent debt. If the customer neglects to pay their payment arrangement, the PA SA will fall into arrears and a collection process will ensue. If the customer neglects to pay their previously delinquent SAs, they will again fall into arrears and a collection process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes $500 on their electric and water service agreements and they want to pay this off in 10 installments, you'd set up the installment amount to be $50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their normal service agreements, you can transfer additional delinquent debt to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off $500 with 10 installments of $50 would have an initial payoff balance of $500 and a current balance of $0. After the first bill, the PA SA would still have a

Copyright © 2026, Oracle and/or its affiliates.

payoff balance of $500, but its current balance would be $50. When the customer pays, the PA SA's payoff balance would fall to $450 and its current balance would return to $0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff $1,000 of debt in $10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed ($50 for new debt and $10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays $60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Monitoring Payment Arrangements

The PA SA should belong to its own debt class (let's call it Payment Arrangement Debt) so that you can have stricter collection criteria for payment arrangement debt (as compared to normal SAs). Because there will be a new debt class, there will be a unique collection class control (CCC) for payment arrangements. This CCC will have debt criteria associated with payment arrangement debt. If these criteria are violated, we will kick off a collection process that should have 1 collection event - Start Severance.

The severance process template for PA SAs will have 1 severance event that calls the Break Payment Arrangement Event algorithm. This algorithm does the following:

- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement (identified by the XFER adjustment type on the PA SA's SA type). When these are cancelled, the original arrearage will be reinstated under the original SAs - this debt should be rather old by this point.
- Syncs up current balance with payoff balance on the PA SA.

Copyright © 2026, Oracle and/or its affiliates.

- Makes the PA SA pending stop (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the account's debt using the standard distribution algorithm. Because the payment arrangement debt that was reinstated should be rather old, it should get relieved first. This relief will occur via transfer adjustments from the PA SA to the original SAs.
- If there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), the debt will be transferred back to one of the SAs from which the arrangement was originally created.
- Inserts a characteristic under the PA SA to indicate that it has been broken (we need this for the account debt monitor (ADM) a few steps down).
- Inserts a row on the account debt monitor trigger. This trigger will cause the account to be reviewed by the ADM the next time it runs.

> **Note**
>
> **The PA SA must final bill before it closes.** The PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the ADM next runs, it will analyze the account's reinstated debt. We recommend creating a new override collection criteria for the normal debt class that will return a value of true if the account has a closed payment arrangement that has been broken in the last X days (where X is a parameter of the override collection criteria's algorithm). If this algorithm returns a true, kick off a unique collection process template (that has nasty events). A sample algorithm of this type is supplied in the base package - COLL COND PA.

To complete this discussion, we have to worry about the situation when the final bill of a payment arrangement goes unpaid. In this situation, the payment arrangement is stopped and will therefore not be processed by the ADM. In this case, the write off monitor will process the PA SA after its final bill's due date and a write-off process will start. This write off process will have a single event that calls the Break Payment Arrangement algorithm (described above). After the FT's are issued in this event, the SA will close (because it's been final billed and its balance will go to zero).

The Big Picture Of Pay Plans

A pay plan (PP) is an agreement with a customer to make payments on specific dates. Pay plans differ from payment arrangements in that pay plans have user-defined scheduled payment dates, which are independent from the customer's billing dates. In other words, payment arrangements appear on the customer's bills, pay plan scheduled payments do not.

If a customer is in arrears and you want to receive payments on specific dates (as opposed to with the customer's regular bills), you would set up a pay plan and define the dates on which you expect the payments.

The topics in this section describe how pay plans work.

- A Pay Plan Has One Or More Scheduled Payments
- Automatic Payments Can Be Created On The Scheduled Payment Dates

- Collection Process / Severance Process Cancellation
- Interesting Pay Plan Facts

A Pay Plan Has One Or More Scheduled Payments

When you create a pay plan for an account, you must define the number of scheduled payments and their respective amounts. There is no limit to the number of scheduled payments that may be set up under a pay plan.

Automatic Payments Can Be Created On The Scheduled Payment Dates

The system will create automatic payments on a pay plan's scheduled payment dates if:

- The account is set up for automatic payment (as described under How To Set Up A Customer To Pay Automatically), and
- The payment method defined on the pay plan indicates automatic payment is being used

The background process called PPAPAY is responsible for creating these automatic payments. It does this by calling the automatic payment creation algorithm plugged in on the installation record.

> **Note**
>
> If the **Autopay Creation Option** on the installation record is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process (APAYDSFR) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to Automatic Payment Dates for more information on how this date is calculated). Refer to Automatic Payments for more information.

A Pay Plan Insulates Overdue Debt From The Account Debt Monitor

A pay plan's scheduled payments are used by the account debt monitor as "pseudo payments" that relieve the account's debt before it is subjected to the collection criteria (refer to How Does The Account Debt Monitor Work for more information about collection criteria).

It's important to understand that a pay plan only insulates the account's debt that belongs to the pay plan's debt class. Therefore, if a customer has debt that belongs to two debt classes

Copyright © 2026, Oracle and/or its affiliates.

(e.g., normal debt and 3 rd party pass through debt), you would need to set up a separate pay plan for each debt class (assuming both types of debt are covered by a pay plan). Refer to Different Collection Criteria For Different Customers and Different Debt for more information about debt classes.

A Pay Plan Must Reference A Pay Plan Type

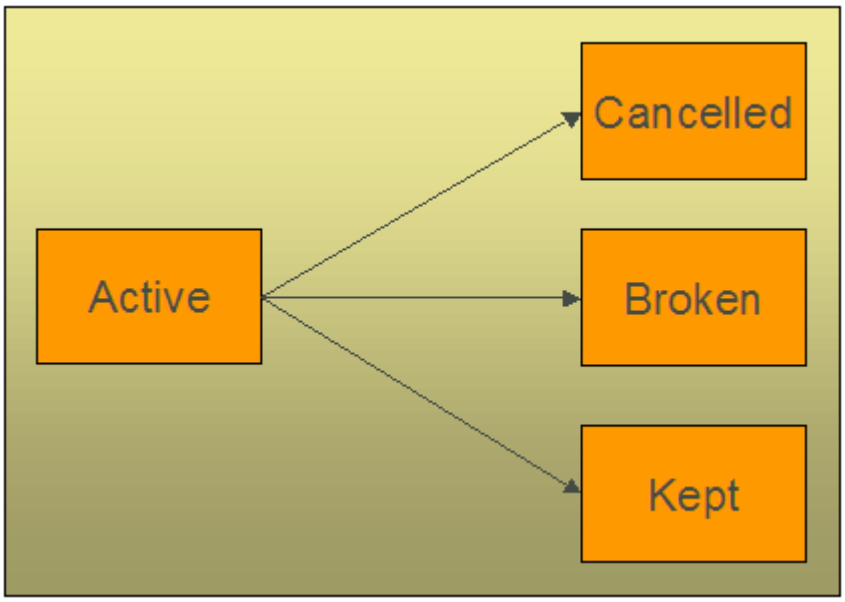
When you create a pay plan, you must define its pay plan type. The pay plan type controls the following functions:

- The debt class whose debt is insulated by the pay plan.
- The type of algorithm (if any) that is executed when the pay plan is broken. You might use such an algorithm to affect the customer's credit rating when the pay plan is broken.

A Pay Plan May Reference A Third-Party Payor

In addition to referencing the account whose debt is insulated by the pay plan, the pay plan must also reference the account that is responsible for making the payments. We refer to this second account as the pay plan's "payor".

While the payor's account is typically the same as the account whose debt is insulated by the pay plan, you can indicate a third-party payor (e.g., a social service agency) is responsible for making the pay plan's scheduled payments.



If your organization allows third-party payors, you can define each on the third-party payor control table. This control table exists to simplify the data-entry effort when you create a pay plan (as it defines the account associated with the third-party payor).

> **Note**
>
> If a pay plan does not reference a third-party payor, any non-third-party payor (i.e., any account that is not defined in the third-party payor control table) can make payments on behalf of the customer. If a pay plan references a third-party payor, only payments made by the third party on behalf of the customer are counted towards the fulfillment of the pay plan.

The Lifecycle Of A Pay Plan

The following diagram shows the possible lifecycle of a pay plan:

Copyright © 2026, Oracle and/or its affiliates.

The following points explain this lifecycle:

- Pay plans are initially created in the active state. Active pay plans are monitored for compliance by The Pay Plan Monitor.
- A pay plan may be cancelled as follows:
  - A user can cancel a pay plan at will.
  - When a SA is stopped AND there are no other active SAs in the same debt class, all **Active** pay plans associated with the account and debt class will be will be **Canceled** .
  - The activation of a collection event that calls the "cancel pay plan" algorithm will cancel all active pay plans associated with the collection process's debt class. You may want to use such a collection event if your organization cancels active pay plans when new debt causes a collection process to kick-off. Note, the base package algorithm that performs this function will not cancel the pay plan if it's associated with a 3rd party payor.
- The Pay Plan Monitor causes active pay plans to become broken if sufficient payments have not been made to satisfy the pay plan's scheduled payments.
- The Pay Plan Monitor causes active pay plans to become kept when it detects that sufficient payments have been made to satisfy the pay plan's scheduled payments.

Highlighting The Existence Of Broken / Kept / Active and Denied Pay Plans

You can define on the installation record plug-in algorithms that format alert messages. (Refer to Installation Options - Algorithms for additional information.) We recommend that you take advantage of the following algorithms to highlight pay plans:

- Highlight pay plans in a given status. This algorithm is used to highlight pay plans in a given state (broken, kept, cancelled) that were started within the last X days.
- Highlight customer contacts of a given type. This algorithm would be used to highlight customer contacts of a given type that were created within the last X days. This would be useful if you create a specific type of customer contact when you deny a pay plan. Some utilities do this to prevent customers from shopping around.

Copyright © 2026, Oracle and/or its affiliates.

In addition, you can define account-specific alerts to highlight customers that should never be allowed to have a pay plan (for whatever reason).

A Pay Plan Must Reference A Payment Method

When you create a pay plan, you must define how the customer will make the payments be referencing a payment method. Examples of payment methods include: In Person , Wire Transfer, By Post, Express Mail, etc.

The payment method is more than just documentation as it defines the number of grace days the customer has to make the pay plan's scheduled payments. For example, if you set up the payment method control table to indicate that payments made By Post have 3 grace days, then the customer has up to 3 days after each scheduled payment date to make the payment. If payment is not received by the scheduled payment date plus the grace days, the pay plan will be marked as broken (and the ADM will be triggered).

The Pay Plan Monitor

NOT_SUPPORTED

Please understand the concepts described in The Lifecycle Of A Pay Plan and The Tendering Account May Differ From The Account Whose Debt Is Relieved before reading this section.

The Pay Plan Monitor background process (referred to as PPM) is responsible for monitoring active payment plans. This process can cause a pay plan (PP) to become kept or broken (or being left as active).

Note

When is a pay plan marked as broken / kept? It's important to understand that only the PPM can cause a pay plan to become kept or broken. This means that if a customer makes a payment that satisfies a pay plan, the pay plan will only be marked as kept when the pay plan monitor next runs. Analogously, if a payment is cancelled, nothing will happen to an active pay plan until the PPM next runs. When the PPM next runs, it will see that the scheduled payment was not kept and it will break the pay plan and schedule the ADM to be executed. When the ADM next executes, it will create a collection process (because the customer's debt will no longer be insulated by the pay plan's scheduled payments).

NSF Cancellations After A Pay Plan Is Kept. If a payment is cancelled due to non-sufficient funds (NSF) after a pay plan is marked as kept, the pay plan will remain kept. But keep in mind that the pay plan's account is scheduled for review by the ADM when a payment is cancelled due to NSF. When the ADM reviews the account's debt, it will no longer have an active pay plan to insulate it and the account's debt will likely trigger a new collection process. Refer to How Pay Plans Affect The Account Debt Monitor for more information.

Copyright © 2026, Oracle and/or its affiliates.

The following points describe, at a high level, how the PPM monitors a pay plan (PP) for compliance.

- The system selects all frozen, non-cancelled payment segments associated with the PP's account and debt class where:
  - The payment date is after the start date of the pay plan, and
  - The payment's pay event has at least one tender that references the pay plan's payor.
- The system logically reduces / removes past and current scheduled payments (starting with the earliest scheduled payment) until the total amount of payment segments is exhausted (or there are no more historical / current scheduled payments).

> **Note**
>
> **Paying pay plans in advance.** Scheduled payments with a future date are not logically removed / reduced. This means that if a customer makes advance payments on a pay plan, it will not be marked as kept until all scheduled payment dates are in the past.

- If all scheduled payments have been logically removed, the pay plan is marked as kept.
- If there exist scheduled payments where the pay date + grace days (grace days are defined on the pay plan's payment method) is before the current date (i.e., a payment doesn't exist for a scheduled payment):
  - The pay plan is marked as broken.
  - The PP's break algorithm (if any) is called (note, for European / Australian pay plans, there are scenarios where the break algorithm can cause the pay plan to become unbroken - when there aren't at least two missed, historical scheduled payments).
  - An ADM trigger is stored for the PP's account. This will cause the account to be reviewed by the ADM the next time it runs. And because the pay plan is broken, its scheduled payments will no longer insulate the account's arrearage.

> **Important**
>
> It's important that you schedule the PPM to run before the ADM so that it can break unpaid payment plans prior to the ADM subjecting the account's debt to collection criteria. Refer to How Pay Plans Affect The ADM for more information.

How Pay Plans Affect The Account Debt Monitor

As described under A Pay Plan Insulates Overdue Debt From The Account Debt Monitor, a pay plan's scheduled payments insulate an account's debt from the ADM. This section describes how this is accomplished.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> You should understand the concepts in How Does The Account Debt Monitor Work and The Tendering Account May Differ From The Account Whose Debt Is Relieved before reading the following.

> **Note**
>
> **The ADM will be triggered when a pay plan is broken.** Refer to The Pay Plan Monitor for an explanation of how the ADM is triggered when a pay plan is broken.

Before the ADM subjects an account's debt to the collection criteria, it calls the debt's debt class's Override Arrears Algorithm (this is an optional plug-in spot on Debt Class). This algorithm is passed the debt class's aged debt and manipulates it as follows:

- First, a list of all past, present and future scheduled payments associated with the account and debt class's active pay plans is constructed.
  - If multiple payors are encountered (because the customer has multiple pay plans and these have different payors), a separate list of scheduled payments is maintained for each payor.
- Next, for each payor, retrieve the total amount of frozen, non-cancelled payment segments made on behalf of the pay plan's account and debt class.
  - Select all frozen, non-cancelled payment segments associated with the pay plan's account and debt class whose pay date is >= pay plan's start date and the pay segment's event has at least one tendering account associated with the pay plan's payor.
- Next, logically reduce / remove past and current scheduled payments (starting with the earliest scheduled payment) until the payor's payment amount is exhausted (or there are no more historical / current scheduled payments). Future scheduled payments cannot be remove / reduced.
- Finally, reduce the passed in aged debt with any unpaid scheduled payments.

> **Note**
>
> **This logic is not "hard coded".** Rather, the mechanism used to use a pay plan's scheduled payments to reduce debt is defined in an algorithm defined on the pay plan's debt class. The contents in this section describe how a base package algorithm works. Because it's an algorithm, you can introduce whatever logic you please.

The following is an example of how pay plans affect aged debt.

Date	Event	SA's Arrears	SA's Balances	Scheduled Payments

Copyright © 2026, Oracle and/or its affiliates.

Prior to creation of the PP 1/18/2000		$1,000 - 90 days old $1,600 - 60 days old $1,900 - 30 days old	Current: $4,500 Payoff: $4,500	
1/18/2000	Pay Plan created. The $4,500 in future scheduled payments offsets the existing $4,500 of aged debt.	$1,000 - 90 days old $1,600 - 60 days old $1,900 - 30 days old **De facto ADM debt: $0**	Current: $4,500 Payoff: $4,500	1/20/2001 $1,500 2/01/2001 $1,500 2/07/2001 $1,500
1/20/2001	The customer pays $1,500. There exists $3,000 of future scheduled payments that offset the arrears	$1,100 - 62 days old $1,900 - 32 days old **De facto ADM debt: $0**	Current: $3,000 Payoff: $3,000	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
1/20/2001	ADM runs. The $3000 in future scheduled payments offsets the Current Balance of $3000, so CC events not created.	$1,100 - 62 days old $1,900 - 32 days old **De facto ADM debt: $0**	Current: $3,000 Payoff: $3,000	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
1/24/2001	A new bill is created for $400	$1,100 - 62 days old $1,900 - 32 days old $400 - 1 day old **De facto ADM debt: $400 - 1 day old**	Current: $3,400 Payoff: $3,400	1/20/2001 $1,500 "Paid" 2/01/2001 $1,500 Future 2/07/2001 $1,500 Future
2/2/2001	Pay Plan Monitor runs. PP marked as Broken because the 2/1/2001 scheduled payment has not been paid (assuming no grace period on the pay plan's payment method)	$1,100 - 74 days old $1,900 - 44 days old $400 - 8 days old	Current: $3,400 Payoff: $3,400	1/20/2001 $1,500 "Paid" **2/01/2001 $1,500 "Late"** 2/07/2001 $1,500 Future

Copyright © 2026, Oracle and/or its affiliates.

2/2/2001	ADM runs. There are no active pay plans and therefore there is nothing to insulate the customer's debt. Therefore the aged debt will be subjected to the collection criteria and an appropriate collection process will be created.	$1,100 - 74 days old $1,900 - 44 days old $400 - 8 days old **De facto ADM debt is the same as above (i.e., rather old)**	Current: $3,400 Payoff: $3,400	**Pay plan is broken and therefore its scheduled payments cannot be used.**

Collection Process / Severance Process Cancellation

When a pay plan (PP) is created, the system determines if it can cancel active collection and severance processes associated with the pay plan's account and debt class. It does this because a pay plan's scheduled payments act as "pseudo payments" that relieve the account's debt (temporarily). The following points describe how this works:

- The system attempts to cancel collection processes by calling the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm is meant to cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see How Pay Plans Affect The Account Debt Monitor for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.
- It attempts to cancel severance processes by calling the Severance Process Cancel Criteria Algorithm defined on the debt class that is associated with the severance process. This algorithm is meant to cancel a severance process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see How Pay Plans Affect The Account Debt Monitor for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

If collection / severance processes still exist for the account / debt class associated with the pay plan, a warning is issued.

Interesting Pay Plan Facts

The following points describe a variety of interesting facts about pay plans (PP):

- An account may have many active pay plans. However, only 1 pay plan may be active for a given account / debt class / payor at any point in time.
- The existence of a pay plan has no impact on payment distribution.

Copyright © 2026, Oracle and/or its affiliates.

- When a SA is stopped, if the SA's debt class has an active PP AND there are no other active SAs in the same debt class, the PP will be cancelled
  - The cancel reason will be "cancelled by system" (as opposed to "cancelled by user")
- If necessary, different collection / severance processes can be triggered if a broken PP is detected (via the override algorithms on CCC and write-off control - we do NOT provide such algorithms).

Setting Up Pay Plan Control Tables

This section describes the control tables needed to set up pay plans.

- Setting Up Pay Plan Types
- Setting Up Payment Methods
- Setting Up Third Party Payors

Setting Up Pay Plan Types

Pay plan types control what is done by a given pay plan. Open **Admin**, and then **Credit & Collection**, and then **Pay Plan Type** to define your pay plan types.

> **NOT_SUPPORTED**
>
> For more information refer to The Big Picture Of Pay Plans for more information.

Description of Page

To modify a pay plan type, simply move to a field and change its value. To add a new pay plan type, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Plan Type The name of the pay plan type.

Description A meaningful description of the pay plan type.

Broken Algorithm This algorithm is called when a pay plan is broken. Refer to The Pay Plan Monitor for more information about how pay plans are broken.

If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that breaks a pay plan.

Debt Class The debt class covered by pay plans of this type. Refer to Setting Up Debt Classes for more information.

Setting Up Payment Methods

Payment methods are used to describe how a customer intends to make their pay plan's scheduled payments. Open **Admin**, and then **Credit & Collection**, and then **Pay Method** to define your payment methods.

Copyright © 2026, Oracle and/or its affiliates.

> **NOT_SUPPORTED**
>
> For more information refer to A Pay Plan Must Reference A Payment Method for more information.

Description of Page

To modify a pay method, simply move to a field and change its value. To add a new pay method, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Method The name of the payment method.

Description A meaningful description of the payment method.

Grace Days The number of days added to the scheduled payment date. The ADM will consider the pay plan to be broken if payment is not made by the scheduled date plus the grace days.

Auto Pay If the pay method is marked as being for **Auto Pay**, the PPAPAY background process will automatically create an automatic payment on the pay plan's scheduled payment dates IF the account has been set up for automatic payment.

Setting Up Third Party Payors

Pay plans support optional third-party payors. Open **Admin**, and then **Credit & Collection**, and then **Third Party Payor** to define your third-party payors.

> **Note**
>
> A third-party payor refers to an account. You must set up the account before you can create a third-party payor.

> **NOT_SUPPORTED**
>
> Refer to A Pay Plan May Reference A 3rd Party Payor for more information.

Description of Page

The following fields display for each third party payor:

Third Party Payor Provide a meaning id for the third-party payor that can be easily recognized when setting up a pay plan.

Description A meaningful description of the payor.

Account ID The account that is used for this payor. It is this account that is tracked as the "payee" of any payments made towards a third party payor's pay plan.

Active Check this box if the payor is currently available to participate in pay plans.

Creating Collection, Severance & Write-Off Procedures

Your collection procedures define how your organization collects overdue debt. Your severance procedures define how your organization severs service agreements when collection attempts fail. Your write-off procedures define how your organization writes off finaled debt. In this section, we describe how to set up the data that controls these procedures.

NOT_SUPPORTED

For more information about collection, severance and write-off procedures, see The Big Picture Of Credit & Collections (C&C).

Warning

There are innumerable ways to design your collection, severance and write-off procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production collection, severance and write-off procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

- Designing Your Collection Procedures
- Setting Up Collection Procedures
- Designing Your Severance Procedures
- Designing Your Reconnection Procedures
- Setting Up Severance Procedures
- Designing Your Write-Off Procedures
- Setting Up Write-Off Procedures
- Setting Up Feature Configuration

Designing Your Collection Procedures

The design of your collection procedures is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the collection process control tables.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about how the information in this matrix is used to monitor your customers' debt, refer to Different Collection Criteria For Different Customers And Different Debt.

- Designing Your Debt Classes
- Designing Your Collection Classes
- Designing Collection Class Controls
- Designing Your Collection Class Control Overrides
- Designing Collection Process Templates & Collection Event Types
- Defining Cancellation Process Auto Cancellation Criteria

Designing Your Debt Classes

Multiple debt classes are needed when you have different collection procedures for different types of service agreements. If all service agreement debt is collected the same way, then you'll have just one debt class (call it Generic). However, if you're like many organizations, you will have multiple debt classes. The following points will help you understand why:

- If you have both regulated and unregulated service, you probably have different debt classes for each type of service. Why? Because your local regulators control how you collect and cutoff overdue, regulated debt. For unregulated debt, your organization controls how overdue debt is collected.
- If your customers make charitable donations, you will have a charitable contribution debt class. Why? Because you probably send a different type of letter when the customer falls into arrears on their charitable contributions. You also can't cut off their water service if they don't make their charitable contributions.
- If you levy deposits, you will probably have a deposit debt class. Why? Because you probably respond differently if the customer doesn't pay their deposit (e.g., you may decide to cut off their electric service until the deposit is paid).
- If you allow customers to make payments on Non-Billed Budgets, you will probably have a Non-Billed Budget debt class. Why? Because you probably respond differently if the customer doesn't pay their Non-Billed Budget (e.g., you may decide to expire the Non-Billed Budget but not affect their other service since the Non-Billed Budget is a way for customers to prepay for upcoming bills).
- If you write-off uncollectable debt, you will need another debt class for write-off service agreements. Why? Because when you write-off debt in the system, you transfer the uncollectable debt from the original service agreement(s) to a write-off service agreement. The write-off service agreement holds this debt forever (or until it is paid). You need to use a different debt class for the write-off service agreements because they aren't subject to collection criteria.
- If you use the system to charge your organization's company usage, you'll need another debt class (we refer to it as the "N/A" debt class below). Why? Because all service agreements must have a debt class, even those that will never have debt.

SA's Debt Class	Account's Collection Class	Account's Collection Class

Copyright © 2026, Oracle and/or its affiliates.

Regulated
Unregulated
Charitable Contribution
Deposit
Non-Billed Budget
Write Off
N/A

Designing Your Collection Classes

Multiple collection classes are needed when any debt class has different collection rules depending on the type of customer. If all customers within all debt classes are collected the same way, then you'll just have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

Consider unregulated debt. For commercial/industrial customers, you probably don't worry until they owe you more than, say, $100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, $5 after 20 days. In this situation, you will have at least two collection classes: one for large customers, the other for residential customers.

In our example, we are assuming you have two collection classes: Residential and Commercial/Industrial.

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Charitable Contribution		
Regulated		
Unregulated		
Write Off		
Company Usage		

Designing Collection Class Controls

At this point we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Each cell should have a "collection class control" that defines its collection criteria and what to do if the criteria are violated. If a cell doesn't have a collection class control, this means you don't have any debt associated with that combination of collection class and debt class. So, we'll mark each cell without debt with "N/A".

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A

Copyright © 2026, Oracle and/or its affiliates.

Deposit		
Write Off		
N/A		

Next, we'll mark each cell for debt classes whose debt isn't collectable (i.e., the write-off and N/A debt classes).

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off	N/A	N/A
N/A	N/A	N/A

> **Note**
>
> If the Account Debt Monitor encounters debt associated with a non-existent collection class control, it will issue an error.

Determining the collection criteria in each remaining cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For charitable debt, if the customer is more than $0 in arrears by more than 20 days, kick off the "charity reminder" collection process. We'll talk more about this collection process later.
- For regulated / residential debt, if the customer is more than $15 in arrears by more than 20 days, kick off the Normal Regulated collection process. We'll talk more about this collection process later.
- For unregulated / residential debt, if the customer is more than $5 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For unregulated / commercial-industrial debt we have multiple criteria:
  - Highest priority. If the customer is more than $10,000 in arrears by more than 20 days, kick off the Large Overdue Debt collection process. We'll talk more about this collection process later.
  - Lower priority. If the customer is more than $100 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For deposit debt (regardless of collection class) we have multiple criteria:
  - Highest priority. If the customer is more than $5 in arrears by more than 50 days, kick off the Deposit Severely Overdue collection process. We'll talk more about this collection process later.

Copyright © 2026, Oracle and/or its affiliates.

- Lower priority. If the customer is more than $15 in arrears by more than 20 days, kick off the Deposit collection process. We'll talk more about this collection process later.

Given the above, our matrix will look as follows:

SA's Debt Class	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
Charitable Contribution	If > $0 is older than 20 days, start Charity Reminder collection process.	N/A
Regulated	If > $15 is older than 20 days, start Normal Regulated collection process.	N/A
Unregulated	If > $5 is older than 20 days, start Normal Unregulated collection process.	Highest priority: If > $10,000 is older than 20 days, start Large Overdue Debt collection process. Lower priority: If > $100 is older than 20 days, start Normal Unregulated collection process.
Deposit	Highest priority: If > $5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > $15 is older than 20 days, start Deposit collection process.	Highest priority: If > $5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > $15 is older than 20 days, start Deposit collection process.
Write Off	N/A	N/A
N/A	N/A	N/A

Designing Your Collection Class Control Overrides

> **Warning**
>
> Your collection needs may not require any overrides for your collection class control matrix and therefore this section may not be relevant.

The following matrix will help you design your collection class overrides. When the matrix is complete, you're ready to set up the collection class control tables.

Notice that the matrix has two dimensions: one is dependent on collection condition algorithms; the other is dependent on the collection class controls designed in the previous section. Collection condition algorithms are confusing. Think of them as optional conditions that, if met, will subject the collection class control's debt to different collection criteria.

Each cell in the matrix contains the collection criteria that will be applied to the account's debt when the collection condition is met (i.e., the same type of criteria - dollars and days and collection process - are defined in each cell).

Copyright © 2026, Oracle and/or its affiliates.

We label the first collection condition as the Default. The collection criteria associated with this column will be used to analyze an account's debt when none of the other conditions applies. We'll start by indicating the Default collection criteria (this was defined in the previous section).

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

If a different collection process OR criteria should be used when other conditions are met, you should indicate such by defining the collection criteria in the cell. For example, if we assume that all unregulated residential debt has a different collection process when the account's credit score is less than the threshold credit rating on the installation record or the account’s CIS Division, our matrix will look as follows:

SA's Debt Class	Account's Collection Class: Default	Account's Collection Class: Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	Override: If Credit Rating is lower than the credit rating threshold: If > $5 is older than 15 days, start Risky Unregulated collection process.
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

Once the matrix is complete, you're ready to design your collection process and collection event types.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The collection conditions are limited by your imagination (and business requirements).** We have provided the collection conditions you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors. For example, if you have different collection criteria that apply during winter months, you should add a new collection condition (called Winter Season). Or if you have different criteria based on years of service, you could have another condition.
>
> **New collection conditions may require programming.** See How To Add A New Algorithm for more information.

Designing Collection Process Templates & Collection Event Types

The following table shows the collection process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Collection Process Template	Collection Event Template	Triggered X Days From Start Of Collection Process
Charitable Contribution Reminder	Charity courtesy reminder letter	0
	Start severance	15
Normal Regulated	Regulated courtesy reminder letter	0
	Regulated second notice letter	10
	Start severance	15
Large Overdue Debt	Large debt courtesy reminder letter	0
	To Do for large overdue debt	3
	Large debt second notice letter	10
	Start severance	15
Normal Unregulated	Unregulated courtesy reminder letter	0
	Unregulated second notice letter	5
	Start severance	10
Risky Customer Unregulated	Unregulated risky letter	0
	Start severance	5
Deposit	Deposit reminder	0
Deposit Severely Overdue	Create To Do entry	0

If we extract each unique event type from the above table, we end up with the following:

Collection Event Type	Event Type

Copyright © 2026, Oracle and/or its affiliates.

Charity courtesy reminder letter	Send Letter - CHARIT REMIN
Start severance	Start Severance Process
Regulated courtesy reminder letter	Send Letter - REGUL REMIN
Regulated second notice letter	Send Letter - REGUL second
Large debt courtesy reminder	Send Letter - LARGE REMIN
Risky debt courtesy reminder	Send Letter - RISKY REMIN
To Do for large overdue debt	Issue To Do
Large debt second notice letter	Send Letter - LARGE second
Unregulated courtesy reminder letter	Send Letter - UNREG REMIN
Unregulated second notice letter	Send Letter - UNREG second
Deposit reminder	Send Letter - DEPOS REMIN
To Do for deposit severely overdue	Issue To Do

Now you're (almost) ready to set up your collection procedures.

Defining Cancellation Process Auto Cancellation Criteria

The topics in the section How Are Collection Processes Cancelled describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your Debt Classes, and optionally, on your Collection Process Templates.

Setting Up Collection Procedures

In the previous section, Designing Your Collection Procedures, we presented a case study that illustrated a mythical organization's collection procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Collection Event Types
- Setting Up Collection Process Templates
- Setting Up Collection Classes
- Setting Up Debt Classes
- Setting Up Collection Class Controls

Setting Up Collection Event Types

Collection event types control what is done by a given collection event. Open **Admin**, and then **Credit & Collection**, and then **Collection Event Type**, and then **Add** to define your collection event types.

Description of Page

Enter a unique **Collection Event Type** and **Description** for the collection event type.

Copyright © 2026, Oracle and/or its affiliates.

Enter the **Collection Event Type**. Permissible values are: Affect Credit, Rating/Cash-Only, Cancel Budget, Generic Algorithm, Send Letter, Create To Do Entry, Start Severance Process. The following discussion describes the parameters that must be defined for each type of collection event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Credit Rating Points** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Credit Rating Months** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

NOT_SUPPORTED

For more information, refer to Account - Credit Rating.

The Send Letter collection event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

Note

Letter creation is triggered via a customer contact. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the collection event. Refer to Setting Up Letter Templates for more information.

The Cancel Budget collection event type cancel an account's budget plan (if the account is on such a plan). When a budget plan is cancelled, adjustments are issued to synchronize every service agreement's current balance with its payoff balance and each applicable SA's recurring charge amount (i.e., budget amount) is set to zero.

The Generic Algorithm collection event type causes the algorithm defined in the **Collection Event Alg** to be executed. You use this type of algorithm when the standard types of collection events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).

Copyright © 2026, Oracle and/or its affiliates.

- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type of activated.

The Create To Do Entry collection event type causes a To Do entry to be issued. A good example of where this is used is when the collection event requires that the customer be called on the phone. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-CEVT for the type of To Do entry that's created).

The Start Severance Process type will start a severance process for every service agreement linked to the collection process. No parameters are needed for this type of event.

Enter a **Long Description** to fully describe the collection event type.

Setting Up Collection Process Templates

Collection process templates define the collection events that will be executed when a collection criteria rule is violated. Open **Admin**, and then **Credit & Collection**, and then **Collection Process Template**, and then **Add** to define your collection process templates.

Description of Page

Enter a unique **Collection Process Template** and **Description** for the collection process template.

Select a **Cancel Criteria Algorithm** if your organization allows individual service agreements to be "removed" from a collection process regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM. If this algorithm is specified, it is executed by the collection process monitor when it detects that a credit has been applied to a service agreement linked to an active collection process. This algorithm will indicate if the specific service agreement that has been credited no longer has debt that warrants a collection process. Refer to How Are Collection Processes Cancelled for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that "removes" a service agreement from a collection processes if the service agreement's debt so warrants.

The **Response** grid contains an entry for every collection event that will be created when a collection process that references this template is created. The following information must be defined for each event:

Event Sequence controls the order in which the collection event types appear under the collection process template. The sequence number is system-assigned and cannot be changed. If you have to insert a collection event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Collection Event Type Specify the type of collection event to be generated.

Days After Process Creation Specify the number of days after the creation of the collection process that the related collection event will be triggered. Refer to Calendar vs Work Days for a description of how this system uses this information to set the trigger date on the respective collection events.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about collection event types, see Setting Up Collection Event Types. For more information about trigger dates, see Collection Event Trigger Date.

Setting Up Collection Classes

Every account has a collection class. This class is one of several fields that control the collection method applied to the account's debt. Open **Admin**, and then **Credit & Collection**, and then **Collection Class** to define your collection classes.

NOT_SUPPORTED

For more information about collection classes, see Designing Your Collection Classes.

Description of Page

Enter a unique **Collection Class** code and **Description** for each collection class.

Indicate which method is used to monitor the member accounts' unpaid debt:

- If you practice balance-forward accounting for accounts belonging to this collection class, select Collection, Severance & Write-Off. This method of collection is described throughout this chapter.
- If you practice open-item accounting for accounts belonging to this collection class, select Overdue. This method of collection is described under Defining Overdue Processing Options.
- If accounts belonging to this collection class are not subject to either of the above collection methods, select Not Eligible For Collection. Please be aware that these accounts will NOT be reviewed for overdue debt.

Setting Up Debt Classes

Every SA type has a debt class. This class is one of several fields that control the collection criteria applied to the service agreement's debt. Open **Admin**, and then **Credit & Collection**, and then **Debt Class**, and then **Add** to define your debt classes.

NOT_SUPPORTED

For more information about debt classes, see Designing Your Debt Classes.

Description of Page

Enter a unique **Debt Class** and **Description** for the debt class.

Copyright © 2026, Oracle and/or its affiliates.

Turn on **Eligible for Collection** if service agreements belonging to this debt class have their debt monitored by the collection process. This should only be turned off if this debt cannot be collected, e.g., write-off debt.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to an arbitrary number as only one algorithm for each system event is allowed in this case.

> **Warning**
>
> These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
Collection Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a collection process can be canceled, and if so, it cancels it. Refer to How Are Collection Processes Cancelled for more information.
Severance Process Cancellation	Required if debt class is eligible for collection	This algorithm determines if a severance process can be canceled, and if so, it cancels it. Refer to How Are Severance Processes Cancelled for more information.

Copyright © 2026, Oracle and/or its affiliates.

Override Arrears Due to Pay Plan	Required if you use Pay Plans	This algorithm is called to temporarily override a customer's arrears using a pay plan's scheduled payments when the system looks at an account's debt from a credit & collections perspective (i.e., the ADM calls this algorithm before it subjects a customer's debt to the collection criteria and when a pay plan is created). It does not actually change any data, but overlays the current arrears with the pay plan scheduled payments. This algorithm is also called by the above algorithms when a pay plan is created in order to evaluate if the scheduled payments actually cover the arrears (if so, the collection / severance processes are cancelled). It is also called periodically by the ADM in order to establish if the current state of the pay plan still covers the arrears. Refer to How Pay Plans Affect The Account Debt Monitor.

Setting Up Collection Class Controls

The topics in this section describe the windows on which you set up your collection class control information.

> **Warning**
>
> The information in this page is what controls how the system analyzes your customer's debt. The flexibility of this control information provides you with almost unlimited options. This is very powerful, but it requires careful analysis. Refer to Designing Your Collection Procedures **for more information**.

- Collection Class Control - Main Information
- Collection Class Control - Debt Criteria

Collection Class Control - Main Information

The information on this transaction defines the conditions that will be checked by the Account Debt Monitor when it checks if an account has violated your debt criteria.

Copyright © 2026, Oracle and/or its affiliates.

Open **Admin**, and then **Credit & Collection**, and then **Collection Class Control**, and then **Add** to define this information.

> **NOT_SUPPORTED**
>
> For more information about collection class control, refer to Designing Collection Class Controls.

Description of Page

Enter a unique **Collection Class Control** code and **Description** for the collection class control (CCC).

Enter the **CIS Division** to which the CCC's criteria applies.

Enter the **Collection Class** to which the CCC's criteria applies.

Enter the **Debt Class** to which the CCC's criteria applies.

Enter the **Currency Code** in which the CCC's criteria are denominated.

Use **Long Description** to further describe the CCC.

> **NOT_SUPPORTED**
>
> The information in the following grid is not intuitively obvious. Refer to Designing Collection Class Controls and Designing Your Collection Class Control Overrides for more information.

The grid which follows contains the conditions that are checked by the Account Debt Monitor (ADM) to determine the type of criteria (defined on the next tab) that will be applied against an account's debt. In other words - the ADM will check each condition (from highest to lowest **Priority**). The first condition that returns a value of true will cause the system to compare the account's debt against the debt criteria defined on the next tab.

Multiple conditions may be defined if different conditions result in a different type of debt thresholds (or a different type of collection process). The following fields are required for each condition:

Collection Condition Priority The priority controls the order in which the ADM checks if a collection condition applies (the lower the number, the higher the priority). Higher priorities are checked before lower priorities.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is COLL_CAT_PRIO_FLG.

Condition Algorithm Define the algorithm used to check if an account should be subject to the collection criteria defined on the next tab. If the algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** (defined

Copyright © 2026, Oracle and/or its affiliates.

on the next tab) and start a collection process if the account has debt that violates these criteria.

You must have at least one collection condition; otherwise the system will not have criteria against which to compare the account's debt. This entry should have the lowest priority code and reference the "default" algorithm. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that references the "default" collection condition algorithm type (COLL COND DF).

If you have other conditions that should be checked before the default condition, you must create an entry for each in this grid. Each entry should have a priority consistent with your business requirements (and this priority should be higher than the default condition's priority). In addition, you should reference an algorithm that contains the conditions that will be checked to determine if the account should be subject to the debt criteria (defined on the next tab). The system is supplied with many additional algorithm types. In order to take advantage of them, you will need to create an algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that references one of the collection condition algorithm types.

Where Used

Collection class controls contain the data that controls the Account Debt Monitor. Refer to How Does The Account Debt Monitor Work? for more information.

Collection Class Control - Debt Criteria

The information on this page defines the debt and age thresholds used by the Account Debt Monitor when it checks if an account has violated your acceptable levels of debt. Open **Admin**, and then **Credit & Collection**, and then **Collection Class Control**, and then **Search** and navigate to the **Debt Criteria** page to define this information.

> **Note**
>
> **The information on this page is not intuitively obvious.** Refer to Designing Collection Class Controls and Designing Your Collection Class Control Overrides for more information.

Description of Page

The **Debt Criteria** scroll contains an entry for each collection criteria algorithm defined on the **Main** tab. The following information appears

The **Collection Condition Priority** controls the order in which the Account Debt Monitor (ADM) checks if a collection condition applies. Higher priorities are checked before lower priorities.

The **Condition Algorithm** is called by the ADM to determine which collection criteria should be applied to the account's debt. If this algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** defined below. If the account violates any criteria, a collection process will be started (using the respective **Collection Process Template**).

The grid that follows contains the debt age and amount of debt that must be violated by the account in order for the ADM to create a collection process template. The following fields should be defined:

Copyright © 2026, Oracle and/or its affiliates.

Arrears Priority controls the order in which the arrears criteria will be checked by the Account Debt Monitor (the lower the number, the higher the priority). The first criteria, if any, that is met will cause a collection process to be created (using the **Collection Process Template**).

Collection Process Template If the Account Debt Monitor determines that the account's debt violates the corresponding criteria, it creates a collection process using the specified collection process template.

Arrears Amount When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than "> Number of Days" (the next field) AND the debt exceeds "> Arrears Amount". If so, a collection process is started.

Days When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than **Days** AND the debt exceeds **Arrears Amount**. If so, a collection process is started.

Where Used

Collection class controls contains the data that controls the Account Debt Monitor.

Designing Your Severance Procedures

The following matrix will help you design your severance procedures. When the matrix is complete, you're ready to set up the severance process control tables.

Notice that the matrix has two dimensions: one is dependent on severance criteria algorithms; the other is dependent on the SA type of the service agreement being severed. The number and type of SA types is dependent on how your organization sets up the SA type table (the SA types shown below are characteristic of those used by a simple utility).

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support
Electric Residential		
Electric Commercial		
Gas Residential		
Gas Commercial		
Charitable Contribution		

Once you know the values of each dimension, you fill in each cell with its respective severance events. We've completed the sample matrix with some characteristic events.

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support

Copyright © 2026, Oracle and/or its affiliates.

Electric Residential	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	Create a To Do entry asking a collection rep to call the customer. 5 days later, create a 72-hour warning field activity. 2 days after completion, create a To Do entry telling collection rep of impending life support cutoff. 3 days after completion of warning, create a disconnect service field activity AND generate a To Do entry informing a collection agent of such. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection expire the service agreement.
Electric Commercial	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	N/A
Gas Residential	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.
Gas Commercial	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	N/A
Charitable Contribution	Expire service agreement	Expire service agreement

Copyright © 2026, Oracle and/or its affiliates.

Once the matrix is complete, you determine the severance process templates needed to implement your severance procedures. The following table shows the severance process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Utility severance - default	10	Field activity - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Electric life support residential severance	10	Generate delinquent life support customer To Do entry	N/A - first event	0
	20	Field activity - 72 hour disconnect for non-payment warning	10	5
	30	Generate impending life support cutoff To Do entry to C&C rep	20	2
	40	Field activity - cut for non-payment	20	3
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Just expire severance	10	Expire service agreement	N/A - first event	

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
48-hour warning	Generate Field Activity - Disconnect Warning
72-hour warning	Generate Field Activity - Disconnect Warning
Disconnect for non payment	Generate Field Activity - Cut For Non-Payment
Delinquent life support customer	Create To Do Entry - C&C Rep Role

Copyright © 2026, Oracle and/or its affiliates.

Impending life support cutoff	Create To Do Entry - C&C Rep Role
Service has been disconnected letter	Send Letter - Customer Contact Type is Disconnect Letter
Expire service agreement	Expire Service Agreement

> **Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

Now you're (almost) ready to set up your severance procedures.

- Defining Severance Process Auto Cancellation Criteria

Defining Severance Process Auto Cancellation Criteria

The topics in the section How Are Severance Processes Cancelled describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your Debt Classes, and optionally, on your Severance Process Templates.

Designing Your Reconnection Procedures

If a customer pays for a service agreement after the service has been cut for non-payment AND BEFORE THE SA HAS BEEN EXPIRED, they need to be reconnected. Counter-intuitively, you must set up a severance process to initiate the field activities to reconnect service.

> **Note**
>
> **Why do you use a severance process to reconnect service?** Because a severance process is nothing more than a series of events that take place one after another. Some of the events create field activities, others send letters, others create To Do entries. So, why not use a severance process? You just have to send different letters and perform different field activities.

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> The system will automatically create a reconnection process if a severance process is cancelled as a result of a payment (or other credits). Please note that this will only happen if you plug-in the appropriate post cancellation algorithm on your severance process templates. Refer to What Happens When A Severance Process Is Cancelled? **for more information**.

While you don't define the reconnect procedures for an SA type, we recommend you think about the reconnection steps for each of your SA types that can be disconnected for nonpayment. We've completed the sample matrix with some characteristic events.

SA Type	Steps
Electric Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Electric Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.

Once the matrix is complete, you determine the severance process templates needed to implement your reconnection procedures. Notice each SA type has the same reconnection steps. This means you just need one severance process. The following table shows this severance process template and its events.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Reconnect	10	Field activity - reconnect service	N/A - first event	0
	20	Service has been reconnected letter	10	0

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
Reconnect	Generate Field Activity - Reconnect
Service has been reconnected letter	Send Letter

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

> **Important**
>
> If you want the system to automatically create a reconnection process if a customer pays after they have been cut, you must specify the appropriate post cancellation algorithm on your severance process templates.

And now you're ready to set up your severance (and reconnection) procedures.

Setting Up Severance Procedures

In the previous section, Designing Your Severance Procedures, we presented a case study that illustrated a mythical organization's severance procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Severance Event Types
- Setting Up Severance Process Templates

Setting Up Severance Event Types

Severance event types control what is done by a given severance event. Open **Admin**, and then **Credit & Collection**, and then **Severance Event Type**, and then **Add** to define your severance event types.

> **NOT_SUPPORTED**
>
> For more information refer to Designing Your Severance Procedures.

Description of Page

Enter a unique **Severance Event Type** code and **Description** for the severance event type.

Enter the Severance **Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Send Letter, Generic Algorithm, Create To Do Entry, Create Field Activities, Expire Service Agreement. The following discussion describes the parameters that must be defined for each type of severance event.

Copyright © 2026, Oracle and/or its affiliates.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- account debt monitor.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

The Send Letter severance event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Generic Algorithm severance event type causes the algorithm defined in the **Sev. Event Algorithm** to be executed. You use this type of algorithm when the standard types of severance events won't do what you need done.

The Create To Do Entry severance event type causes a To Do entry to be created. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-SEVT for the type of To Do entry that's created).

The Generate Field Activities severance event type causes one or more field activities to be generated. Enter the following **Parameters** for this type of event:

- Select the **Customer Event** associated with the field activity. Valid values are: Cut For Non-Payment (CNP), Disconnect Warning (Disc Warn), Reconnect for Payment (Reconn), Start Service (Start) , Start/Stop Service (Start/Stop), Stop Service (Stop), Reread (Reread).
- The system uses the **Customer Event** to select the appropriate field activity type(s) from the field activity type profile associated with the service points linked to the service agreement.

> **⚠ Warning**
>
> The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter off) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to Setting Up Field Activity Type Profiles for how to set up the specific disconnect field activity types for your various types of service points.

The Expire Service Agreement severance event type causes the service agreement to be moved to the pending stop state (it also populates the service agreement's stop date). Refer to Finalizing Pending Stops for how the system will eventually stop the service agreement (and then final bill it). There are no parameters for this type of event.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Cut for non-payment field activities are special.** The Expire Service Agreement severance event type also makes any "cut for non-payment" field activities created by earlier severance events available to stop service. Specifically, it changes the linkage type of the field activities from Severance Activity to Stop Activity. You can see a service agreement's service points' field activities and their respective linkage type on Service Agreement - Service Point.

Enter a **Long Description** to fully describe the severance event type.

Setting Up Severance Process Templates

Severance process templates define the severance events that will be executed when a service agreement is severed. Open **Admin**, and then **Credit & Collection**, and then **Severance Process Template**, and then **Add** to define your severance process templates.

Description of Page

Enter a unique **Severance Process Template** and **Description** for the severance process template.

If severance processes of this type should be automatically canceled when the customer pays the collection amount on the severance, turn on **Auto Cancel**. This switch would typically only be turned off for severance processes used to reconnect a cut service because you don't want such a reconnection process to be canceled when a payment is made. Refer to Designing Your Reconnection Procedures for more information.

In addition to turning on the **Auto Cancel** switch, specify a **Cancel Criteria Algorithm** if your organization allows a severance process to be cancelled regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM.

If the **Cancel Criteria Algorithm** is specified, it is executed when a credit is posted to the service agreement associated with a severance process. This algorithm will indicate if the service agreement no longer has debt that warrants a severance process. Refer to How Are Severance Processes Cancelled for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

If you wish to perform any special processes after a severance process is canceled, specify a **Post Cancel Algorithm**. This can be used to start a reconnection in case the severance process was canceled too late to stop the disconnection. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to Setting Up Algorithms). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

When a service agreement is to be severed due to non-payment, the system creates a severance process and links to it one or more severance events based on the **Event Types** entered here. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event:

Copyright © 2026, Oracle and/or its affiliates.

Event Sequence controls the order in which the severance event types appear under the severance process template. The sequence number is system-assigned and cannot be changed. If you have to insert a severance event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Severance Event Type Specify the type of severance event to be generated.

Dependent On Other Events Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. For example, you would turn this switch on for the event that initiates the field activity to disconnect service. Why? Because you only want to disconnect service after the preceding event that warned the client of impending disconnection is complete.

Days After Prev Response Specify the number of days after the completion / cancellation of the dependent events on which the severance event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of days after the creation of the severance process that the related severance event will be triggered. Refer to Severance Event Dependencies and Trigger Date and Calendar vs Work Days for a description of how the system uses this information to set the trigger date on the respective severance events.

When the **Dependent On Other Events** switch is on, use the grid to define the events on which this event is dependent. If multiple events are specified in the grid, all such events must be completed or cancelled before the event will be triggered.

Sequence is system-assigned and cannot be specified or changed.

Dependent On Sequence Specify the sequence number of the severance event on which the above severance event depends.

NOT_SUPPORTED

For more information about severance event types, see Setting Up Severance Event Types. For more information about trigger dates, see Severance Event Dependencies & Trigger Date.

Designing Your Write-Off Procedures

The design of your write-off procedures is relatively straightforward. Simply follow the instructions in the following topics.

- Designing Your Write-Off Debt Classes
- Designing Write-Off Controls
- Designing Write Off Process Templates & Write Off Event Types

Designing Your Write-Off Debt Classes

Multiple write-off debt classes are needed when you have different write-off procedures for different types of service agreements. If all service agreement debt is written-off the same way, then you'll have just one write-off debt class (call it Generic). However, if you're like many

Copyright © 2026, Oracle and/or its affiliates.

organizations, you will have multiple write-off debt classes. The following points will help you understand why:

- If you bill for 3 rd parties, you probably have different write-off debt classes for the 3 rd party service agreements. Why? Because you probably treat 3 rd party uncollectable debt differently from your own debt.
- You will need a separate write-off debt class for service agreements whose debt cannot be written off. Why? Because there is a switch on the write-off debt class control table that controls if service agreements in the write-off debt class are eligible for write-off processing. Given that you will have some service agreements that hold debt that aren't eligible for write-off processing (e.g., service agreements that hold written-off debt and service agreements that overpayments), you will need at least one other write-off debt class.
- If you use the system to calculate charges for your organization's company usage, you'll need another write-off debt class (we refer to it as the "N/A" write-off debt class below). Why? Because all service agreements must have a write-off debt class, even those that will never have debt.

SA's Write-Off Debt Class	**Account's Collection Class**	**Account's Collection Class**
Normal W/O		
N/A		

Designing Write-Off Controls

Set up a matrix using the collection classes you designed when you were designing your collection procedures (Designing Your Collection Procedures).

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**
Normal Write Off		
N/A		

Each cell should have a "write-off control" that defines what to do when the system detects finaled debt that hasn't been paid. This is true even of the "N/A" write-off debt class. Why? Because you may want the system to write-down these stopped SAs when they have a small balance. For example, if you have a write-off service agreement that subsequently receives a partial payment that leaves a small amount owing, you probably want the system to generate a write-down adjustment (so that the write-off service agreement will close). We'll initially fill in the matrix for the "N/A' write-off debt class.

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**
Normal Write Off		

Copyright © 2026, Oracle and/or its affiliates.

N/A	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment.

> **Note**
>
> If the Write Off Monitor encounters debt associated with a non-defined collection class and write-off debt class, it will issue an error.

For each cell that isn't designated as N/A, you need to answer the following questions:

- Are you allowed to transfer debt to other non-closed service agreements linked to the account? If so, you need to define the algorithm used to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- Are you allowed to write-down small amounts of debt (or small credits)? If so, you need to define the algorithm used to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- Should you refund credit balances with a check? If so, you need to define the algorithm to do such. Refer to Setting Up Write-off Control for more information about this algorithm.
- If debt remains after doing the above, how do you write it off (e.g., do you first refer the debt to a collection agency and only write it off after waiting 30 days)?

We'll fill in the above matrix with our assumptions:

SA's Write-Off Debt Class	**Account's Collection Class Residential**	**Account's Collection Class Commercial/Industrial**

Copyright © 2026, Oracle and/or its affiliates.

Normal Write-Off	Attempt to reduce the SA's balance to zero using the following methods: Attempt to transfer debt to another active service agreement linked to the account. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. If the debt is <= $-1, create an A/P adjustment to refund the credit to the customer. If debt remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process. Otherwise, create the default write-off process for residential debt.	Attempt to reduce the SA's balance to zero using the following methods: Attempt to transfer debt to another active service agreement linked to the account. If the debt / credit is < $10 and > $-10, write down the debt using a write-down adjustment. If the debt / credit is <= $-10, create an A/P adjustment to refund the credit to the customer. If debt remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process. Otherwise, create the default write-off process for commercial debt.
N/A	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < $10 and > $-1, write down the debt using a write-down adjustment. Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.

We can now use the information in the above matrix to design the necessary Write Off Process Templates and Write Off Event Types.

Designing Write Off Process Templates & Write Off Event Types

The following table shows the write-off process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Write Off Process Template	Write Off Event Type	Triggered X Days From Start Of Write Off Process
Residential	Refer to collection agency	0
	Letter notifying customer of referral	0
	Cancel collection agency referral	60
	Write off	60

Copyright © 2026, Oracle and/or its affiliates.

Non-Cash Deposit Exists	To Do for non-cash deposit redemption	0
	To Do to highlight unpaid SA(s) still exist (and they will be reconsidered for write-off processing)	10
Commercial	Refer to collection agency	0
	Letter notifying customer of referral	0
	To Do to check up on collection agency's efforts	30
	Cancel collection agency referral	60
	Write off	60

If we extract each unique event type from the above table, we end up with the following:

Write Off Event Type	Event Type
Notification of write-off referral	Send letter - Debt referred to a collection agency
Refer to collection agency	Refer to collection agency
Cancel collection agency referral	Cancel collection agency referral
Write off	Write off
To Do for non-cash deposit redemption	Generate To Do - Redeem non-cash deposit
To Do to highlight unpaid SA(s) still exist	Generate To Do - SA(s) linked to a non-cash deposit remain unpaid (and will be reconsidered for write-off processing)
To Do to check up on collection agency's efforts	Generate To Do - Check up on collection agency's efforts

And now you're ready to set up your write-off procedures.

Setting Up Write-Off Procedures

In the previous section, Designing Your Write-Off Procedures, we presented a case study that illustrated a mythical organization's write off procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

- Setting Up Write Off Debt Classes
- Setting Up Write Off Event Types
- Setting Up Write Off Process Templates
- Setting Up Write Off Control
- Setting Up Collection Agencies

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Write Off Debt Classes

Every SA type has a write-off debt class. This class is one of several fields that control the write off criteria applied to the service agreement's debt. Select **Admin**, and then **Credit & Collection**, and then **Write Off Debt Class** to define your debt classes.

> **NOT_SUPPORTED**
>
> For more information about debt classes, see Designing Your Write-Off Debt Classes.

Panel controls

To modify a write-off debt class, simply move to a field and change its value. To add a new write-off debt class, click + to insert a row, then fill in the information for each field. The following fields display:

Write Off Debt Class Code The unique identifier of the write off debt class.

Eligible for Write Off Indicates if service agreements belonging to this write off debt class are eligible for write-off processing. This should only be turned off if this debt cannot be written off, e.g., write off debt.

Description The description of the write off debt class.

Setting Up Write Off Event Types

Write-off event types control what is done by a given write-off event. Select **Admin**, and then **Credit & Collection**, and then **Write Off Event Type**, and then **Add** to define your write-off event types.

Description of Page

Enter a unique **Write Off Event Type** code and **Description** for the write-off event type.

Select the **Write Off Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Cancel Agency Referral, Generic Algorithm, Refer to Agency, Send Letter, Create To Do Entry, Write Off using Distrib Code, and Write Off using SA Type. The following discussion describes the parameters that must be defined for each type of write-off event.

The Affect Credit Rating/Cash-Only write-off event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Affect Credit Rating By** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account’s CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account’s CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Affect Cash-Only Score By** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the

Copyright © 2026, Oracle and/or its affiliates.

cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

> **NOT_SUPPORTED**
>
> For more information, refer to Account - Credit Rating.

The Cancel Agency Referral event type will cancel previous collection agency referrals. No parameters are needed for this type of event.

The Generic Algorithm write-off event type causes the algorithm defined in the **Generic Algorithm** to be executed. You use this type of algorithm when the standard types of write off events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type are activated.

The Refer to Agency event type will refer the debt associated with the process' SAs to a collection agency. You must supply the **Agency Selection Algorithm** that is used to determine the collection agency associated with the referral. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines the collection agency to which bad debt should be referred.

> **Note**
>
> **Letters.** You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the write off event type. Refer to Setting Up Letter Templates for more information.

The Send Letter write-off event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following parameters for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Create To Do Entry write-off event type causes a To Do entry to be issued. Refer to The Big Picture of To Do Entries for more information about To Do entries (refer to the To Do type TD-WOEVT for the type of To Do entry that's created).

The Write Off using Distrib Code event type causes bad debt to be written off in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. Use this method if, for example, you want to write-off revenue differently than you write-off liabilities. When this type of event is activated, the system accumulates the distribution

Copyright © 2026, Oracle and/or its affiliates.

codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreements. The type of service agreements to which the debt is transferred is defined on the distribution codes. Refer to Setting Up Distribution Codes for more information.

The Write Off using SA Type event type causes all debt associated with the process' SAs to be transferred to a write-off service agreement linked to the account. Enter the following **Parameters** for this type of event:

- **CIS Division / SA Type** is the type of write-off service agreement to which the debt will be transferred. Note well,
  - The system will reuse an existing service agreement if an active SA of this type is already linked to the account; otherwise the system will create a new service agreement of this type.
  - The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on the write-offable SA Type. Refer to SA Type - Main Information for more information.
  - The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write off SA type. Refer to SA Type - Detail for more information.

Enter a **Comment** to fully describe the write-off event type.

Setting Up Write Off Process Templates

Write-off process templates define the write-off events that will be executed when a write-off criteria rule is violated. Select **Admin**, and then **Credit & Collection**, and then **Write Off Process Template**, and then **Add** to define your write-off process templates.

Description of Page

Enter a unique **Write Off Process Template** code and **Description** for the write-off process template.

The rows in the following grid define the events that will be created when a write off process is created using this template. The following fields display:

Event Sequence Controls the order in which the write-off event is executed. The sequence number is system assigned and cannot be changed. If you need to insert a write-off event between two existing events, you must remove the latter events, insert the new event, and then re-enter the removed events.

Write-off Event Type Code Specify the type of write-off event to be generated. The event type's description is displayed adjacent.

Days After Process Creation Specify the number of days after the creation of the write-off process that the related write-off event will be triggered. Refer to Calendar vs Work Days for a description of how this system uses this information to set the trigger date on the respective write-off events.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about write-off event types, see Setting Up Write Off Event Types. For more information about trigger dates, see Write-off Event Trigger Date.

Setting Up Write Off Control

Write-off controls define how the system handles finaled, unpaid debt belonging to a given collection class and write off debt class.

- Write Off Control - Main
- Write Off Control - Criteria

Write Off Control - Main

Select **Admin**, and then **Credit & Collection**, and then **Write Off Control**, and then **Add** to define basic information about a write-off control. After entering basic information, navigate to the **Criteria** tab to define the type of write-off process to start when given criteria are met.

NOT_SUPPORTED

For more information about write-off control, refer to Designing Write-Off Controls.

Panel controls

Enter a **Write Off Control** code and **Description** for the write-off control (WOC).

Enter the **Collection Class** to which the WOC applies.

Enter the **Write Off Debt Class Code** to which the WOC applies.

Enter general **Comments** to further describe the WOC.

Define the **Synch All Algorithm** used by the system to generate adjustments that cause current balance to equal payoff balance on the service agreements to be written off. This type of algorithm is issued before you actually start a write-off process as current balance is meaningless at write-off time (the customer owes you the payoff balance). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that synchronizes current and payoff balances.

Define the **Debt Transfer Algorithm** used by the system when it attempts to transfer the unpaid debt to another active service agreement linked to the stopped SA's account. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that transfers unpaid balances.

Copyright © 2026, Oracle and/or its affiliates.

Define the **Write Down Algorithm** used by the system when it attempts to write-down small debt and/or credit balances. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that writes down small amounts.

Define the **Credit Refund Algorithm** used by the system when it refunds a credit balance to a customer. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that refunds credit balances.

Write Off Control - Criteria

Select **Admin**, and then **Credit & Collection**, and then **Write Off Control**, and then **Search** and navigate to the **Criteria** page to define the type of write-off process to start when given criteria are met.

> **NOT_SUPPORTED**
>
> The following information is not intuitively obvious. Refer to Designing Write-Off Controls for more information.

Panel controls

The information in the grid defines the write-off process to be executed for debt belonging to the previously defined collection class and write off debt class. The type of write-off process may differ depending on some condition. For example, you may have a different write-off process if the customer has a non-cash deposit. You must have at least one entry in this collection otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **Write Off Criteria Algorithm** that references the WO CRIT DFLT the algorithm type.

The following fields display:

Priority controls the order in which the criteria will be checked by the Write Off Monitor (higher priorities are checked before lower priorities). The first criteria algorithm that is met (i.e., returns a value of *True*) will cause the associated write-off process to be initiated.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: Collection Class Control, Severance Criteria, and Write Off Control .

Write Off Criteria Algorithm The Write Off Monitor checks if the condition defined by the W/O Condition Algorithm applies to the account whose debt is being analyzed. If a condition is met, a write-off process is created using the associated write-off process template.

Copyright © 2026, Oracle and/or its affiliates.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines if a customer's bad debt should be processed using the associated **Write Off Process Template**.

> **Important**
>
> You must have at least one entry in this grid otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **W/O Criteria Algorithm** that references the WO CRIT DFLT algorithm type.

Write Off Process Template If the Write Off Monitor determines the condition defined by the w/o condition algorithm applies, a write-off process is created using the associated write-off process template.

Where Used

Write-off controls contain the data that controls the Write Off Monitor. Refer to How Does The Write-Off Monitor Work? for more information.

Setting Up Collection Agencies

You must set up a collection agency for each such organization to which you refer delinquent debt. To define a collection agency, select **Admin**, and then **Credit & Collection**, and then **Collection Agency.**

Description of Page

Enter an easily recognizable **Collection Agency** code and **Description** for each collection agency.

A collection agency must be associated with a Person. Choose the **Person ID** of the organization from the prompt.

> **NOT_SUPPORTED**
>
> Information about how to set up persons is discussed in Maintaining Persons.

Turn on the **Active** switch if the collection agency is actively receiving referrals.

Specify the **Batch Control** that's used to route new and cancelled referrals to the collection agency. The batch control's description is displayed adjacent.

Where Used

Collection agencies get assigned to collection agency referrals when the collection agency referral background process executes. Refer to How Do Collection Agency Referrals Work? for more information.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Feature Configuration

You must set up a Feature Configuration if you use the champion / challenger functionality.

The following describes the various **Option Types** that must be defined:

Champion Template$Challenger Template$Percentage(1-100). You need only set up options of this type if your implementation implements Champion / Challenger functionality. Options of this type are entered in the format ABnnn where A is the collection process template of the champion template, B is the collection process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The collection monitor uses this option to override the champion collection process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

How To

The contents of this section describe how to set up various credit and collections scenarios.

- How Arrears History is Captured
- How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

How Arrears History is Captured

The system captures a history of arrears (amount owed) for accounts under an active collection activity – those with an active collection, severance, or overdue process. The data is maintained from the creation of the process to when it is set to inactive. Currently, there is no user interface to view the history records. Rather, they are stored in the system so they can be retrieved by other processes and APIs.

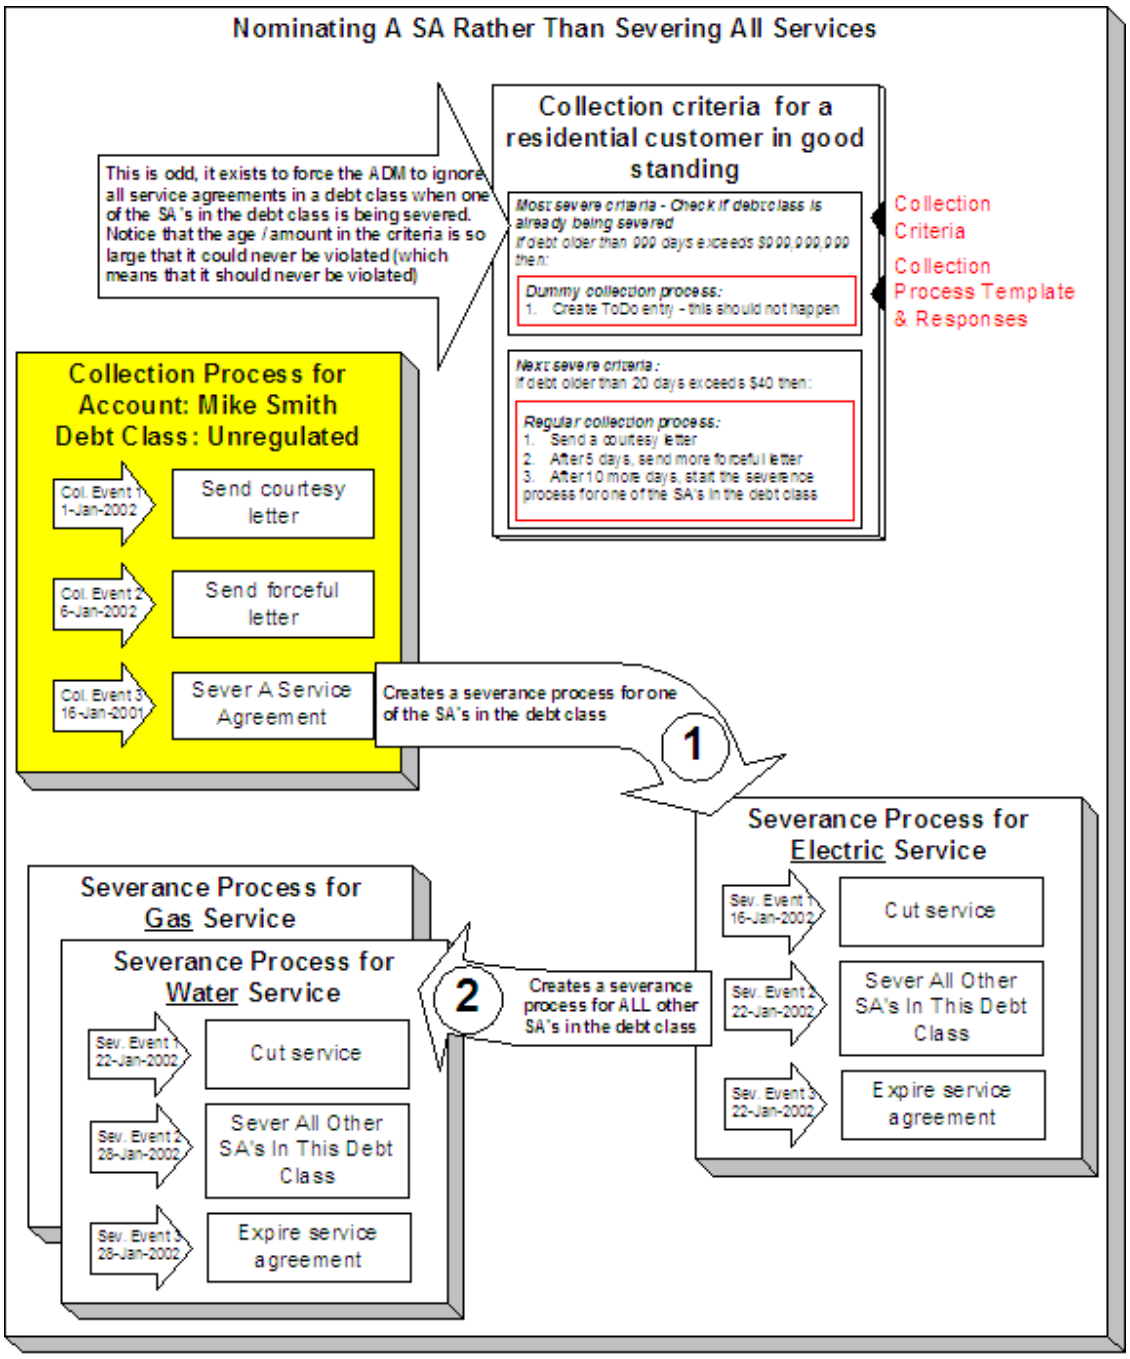
Where is this information captured? The system uses child maintenance objects that extend their parent object to capture this information. Arrears history records are stored in the following tables: Collection Process Arrears History, Collection Process SA Arrears History, Severance Process Arrears History and Overdue Process Arrears History. Arrears history is stored on the Collection Process SA Arrears History table when the system is configured to use service agreement-oriented cancel criteria. Refer to How Are Collection Processes Cancelled and How Are Severance Processes Cancelled for more information on debt class or service agreement-oriented cancel criteria configurations.

Why is this information captured? One reason is because it's difficult to derive real-time. The system relies on plug-in spots to know if a collection activity can be canceled. These plug-in spots calculate the amount owed under a collection activity, sometimes adjust that amount by promised future payments, and compare that amount to a threshold that is configured as an algorithm parameter. So, outside of the system processes that call these plug-in spots, it is difficult for an API or query to replicate the logic. Therefore, the system captures the information from the plug-in spot drivers – the programs that call the plug-ins. The drivers are base programs and will work with algorithms delivered with the system or your custom algorithms; just make sure they are populating the output elements for the plug-in spot.

Copyright © 2026, Oracle and/or its affiliates.

The above explains the technical aspect of this, but why or how can this data be used? One reason is to allow inquiries across many accounts belonging to the same person or business. Consider a large entity such as a local government with hundreds or even thousands of accounts and the desire to know how much debt is under collection at any moment. Aside from being difficult to replicate the logic that derives these amounts, that query could be a timely one to perform.

The most recent amount owed and related information should meet the business needs for cases like the one described above. However, instead of keeping a current snapshot of amount owed for each process, the system creates a record upon process creation and a new record each time there is a change in the amount owed or other data captured. One reason for this is to have the data to analyze the payment patterns for debt under collection. Is the debt paid in one lump sum or in small amounts? Is it paid close to the process creation or days or weeks later? Are customers paying the full amount owed or just enough to get below the threshold to cancel collection activity? This data makes these types of analytics possible.



What data is being stored? The key information is the amount still owed for the collection activity, the cancelation threshold amount, and the amount owed before being adjusted by future payments. Refer to How Pay Plans Affect The Account Debt Monitor for more information about how pay plans affect the amount owed. The system is also able to determine if debt class or service agreement-oriented cancel criteria configurations are used based on which plug-in spots are being used and this information is captured. This is important in knowing how to use and interpret the data. Refer to the system metadata for these tables to see exactly what data is captured.

What system processes call the plug-in spots responsible for capturing the arrears history? These plug-in spots are called when the processes that collect on debt are created. They are called in a special mode that does the calculations but doesn't take any action. This is to capture the initial record. These plug-in spots are also called by the processes that monitor ongoing collection of debt, some updates to these processes, and by system events such as payments or other credit financial transactions.

How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

Some organizations that offer multiple services do not sever all services when the customer falls into arrears. Rather, they nominate a single service agreement to sever in the hopes that the lack of service will cause the customer to remit payment. The following diagram illustrates the control tables values required to implement this type of requirement.

Copyright © 2026, Oracle and/or its affiliates.

The following important concepts are illustrated above:

- The collection process's last event does NOT sever all services. Rather, it calls an algorithm that selects a single service to sever. A base package algorithm allows you to define the primary service to sever and a secondary service to sever (if the customer does not have the primary service). If you sold electricity and gas, you would probably define the primary service as electricity and the secondary as gas (because electricity is easier to cutoff than gas).
- The severance process that is started for the primary service cuts service. If the customer doesn't remit what is owed, the second severance event calls an algorithm that severs all other service agreements in the debt class.

Copyright © 2026, Oracle and/or its affiliates.

- Because you are nominating a single service to sever, you must set up a special value in collection class control to force the ADM to ignore all service agreements in a debt class when one of the SAs in the debt class is being severed. Notice that the age / amount in the criteria is so large that it could never be violated.
- In addition, because the entire debt class must no longer be in arrears to stop the collection and severance processes, you must plug-in the appropriate collection process and severance process cancellation criteria on the debt class. Refer to How Are Collection Processes Cancelled and How Are Severance Processes Cancelled for more information about how these algorithms are used. Also note, you do not need service agreement cancellation criteria defined on your collection process templates and severance process templates (because cancellation is controlled at the debt class level).

Defining Asset Options

> **Note**
>
> The asset management functionality described in this section is available with the following products:
>
> - Oracle Utilities Advanced Meter Solution (C2M-AMS)
> - Oracle Utilities Customer to Meter (C2M)
> - Oracle Utilities Customer Cloud Service (CCS)
> - Oracle Utilities Meter Data Management (MDM)
> - Oracle Utilities Meter Solution Cloud Service (MSCS)

Asset Activity Types

- Understanding Asset Activity Types
- Defining Asset Activity Types

Understanding Asset Activity Types

Copyright © 2026, Oracle and/or its affiliates.

Activity types define the main attributes broad range of activities, such as maintenance, repairs, inspections, field work etc. The base package includes an asset activity type business object (W1-SOMActivityType) that should be used when created asset activity types.

Activity types are defined by:

- **Activity Business Object**: The business object used for asset activities of this type
- **Activity Schedule Information**: Default scheduling information for asset activities of this type, including Activation Lead Days, Work Lead Days, and Activity Disposition.
- **Attachments**: One or more attachments associated with asset activities of this type, such as procedures or checklists.
- **Exception Handling**: Details regarding exception handling for asset activities of this type, including default To Do Type, To Do Role, and retry options.
- **Completion Event Types**: One or more completion event types associated with asset activities of this type. See Understanding Completion Event Types for more information.
- **Object To Create**: The service history type to be created by asset activities of this type. Service history records are created by Create Activity Type's Service History completion events.

Refer to Defining Asset Activity Types for more information about setting up asset types.

> **Note**
>
> Asset activity types are created by the system when field task types are created in Service Order Management.

Defining Asset Activity Types

You use the **Activity Type** portal to display and maintain asset activity types.

Refer to Understanding Asset Activity Types for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Activity Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type**: This zone displays basic information about the activity type.
- **Attachments**: This zone attachments associated with the activity type.

Asset Completion Event Types

- Understanding Asset Completion Event Types
- Defining Asset Completion Event Types

Understanding Asset Completion Event Types

Copyright © 2026, Oracle and/or its affiliates.

Asset completion event types are used to define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.

Asset completion event types are referenced on activity types to indicate which completion events should be included as part of the lifecycle of activities of that type. For example, this affects when service history is created for an activity, and the disposition of the assets on an activity as the activity is processed. Asset completion events can be configured as optional or required for activities of different types.

Asset completion event types are defined by:

- **Completion Event Business Object**: The business object used for asset completion events of this type
- **Identifiers**: One or more identifiers that can be used to characterize asset completion events of this type
- **Inbound Communication**: Information used to create asset completion events of this type using information defined within an inbound communication business object, or within its raw message
- **UI Payload Create Data Mover**: XPath statements executed when creating asset completion events of this type online. These statements are used to populate elements within the payload from the completion event business object.

Refer to Defining Completion Event Types for more information about setting up completion event types.

Defining Asset Completion Event Types

You use the **Completion Event Type** portal to display and maintain asset completion event types.

Refer to Understanding Asset Completion Event Types for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Completion Event Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Completion Event Type** : This zone provides information about the selected completion event type, including as inbound communications and attachments.
- **Unlink Activity Types**: This zone enables the removal of an activity type from the completion event type. To remove an activity type select the activity type(s) to remove and click **Remove**. The selected activity types will no longer appear in the **Unlink Activity Types** zone.
- **Link Activity Types**: This zone enables adding an activity type to the completion event type. To link an activity type:
    1. Enter search criteria n the **Activity Type Description** field and click **Search**. The zone will display a list of activity types matching your search criteria.
    2. Select the activity type(s) to add and click **Link**. The selected activity types will now appear in the **Unlink Activity Types** zone.

Copyright © 2026, Oracle and/or its affiliates.

Asset Inbound Communication Types

- Understanding Asset Inbound Communication Types
- Defining Asset Inbound Communication Types

Understanding Asset Inbound Communication Types

Asset inbound communication types define the information required for the system to receive messages from external systems. These typically hold value mappings of the inbound communication elements to an xpath element in the completion message.

Asset inbound communication types are defined by:

- **Inbound Communication Business Object**: The business object used for asset inbound communications of this type
- **Exception Handling**: Details regarding exception handling for asset inbound communications of this type, including default To Do Type, To Do Role, and retry options.
- **Message Validation**: Source elements within the inbound communication business object or raw message used for validation of asset inbound communications of this type
- **Communication Data Mapping**: Information used to populate communication business object elements from information within the communication's raw message
- **Attachment Suppression**: Substitution text used in place of large data attachments in the completion event list on the inbound communication. Used when messages received from an external system contain attachment data that are very large.

Refer to Defining Asset Inbound Communication Types for more information about setting up asset inbound communication types.

Defining Asset Inbound Communication Types

You use the **Communication Type** portal to display and maintain asset inbound communication types.

Refer to Understanding Asset Inbound Communication Types for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Inbound Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List**: This zone lists all asset inbound communication type records. Broadcast a record to display the details of the selected record.
- **Communication Type**: This zone provides information about the selected communication type, such as attachment suppression, communication data mapping, message validation and exception handling.

Asset Types

Copyright © 2026, Oracle and/or its affiliates.

- Understanding Asset Types
- Defining Asset Types

Understanding Asset Types

Asset types define the attributes for assets and components of a certain type including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.

Asset types are defined by:

- **Component Relationship**: A flag that indicates if components can be installed on assets or components of this type
- **Asset Business Object**: The business object used for assets or components based on this asset type
- **Valid Location Types**: A list of location types where assets or components of this type can be located
- **Valid Attached To Asset Types**: A list of valid asset types where components of this type can be attached (applicable to components only)
- **Valid Service History Types**: A list of valid service history types that can apply for assets or components of this type

Refer to Defining Asset Types for more information about setting up asset types.

Asset Classes

Assets are defined by classes, each of which is based on a specific business object, and determines the type of asset: an asset or a component.

The table below lists the asset classes and the business object for each.

Asset Class	Business Object
Asset	W1-AssetType (Operational Device Asset Type)
Component	W1-ComponentType (Operational Device Component Type)

Defining Asset Types

You use the **Asset Type** portal to display and maintain asset types.

Refer to Understanding Asset Types for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Type** : This zone provides information about the asset type.
- **Asset Type Statistics**: This zone displays statistics for the asset type.

Copyright © 2026, Oracle and/or its affiliates.

Service History Questions

- Understanding Service History Questions
- Defining Service History Questions

Understanding Service History Questions

Service History Questions are used to guide workers through corrective and preventive inspection processes as part of an asset's service history.

Service history questions are associated to a service history type which is then associated to an asset type.

During a corrective or inspection process, workers can be guided through a series of questions assessing the condition of the asset. The answers can be "weighted", which when calculated, gives an overall score as to the condition of the asset. The calculation is generally a sum (answer points * question weight), but can vary depending on the service history type. The total inspection points are then normalized to an overall grade or score. The condition rating and confidence rating are also calculated and the asset is updated with the appropriate values.

A service history question's answers can be defined as check boxes, multiple choice, or free-form text.

Refer to Defining Service History Questions for more information about defining service history questions.

Defining Service History Questions

You use the **Service History Question** portal to display and maintain Service History questions.

Refer to Understanding Service History Questions for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Question**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Question**: This zone provides information about the question.
- **Service History List**: This zone displays a list of service history types that reference the question.

Service History Types

- Understanding Service History Types
- Defining Service History Types

Copyright © 2026, Oracle and/or its affiliates.

Understanding Service History Types

Service history types define the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.

Service history types are defined by the following:

- **Service History Business Object**: The business object used to create service history records of this type.
- **Category**: The category to which service history records of this type belong. The base package includes the following categories:
  - Downtime
  - Failure
  - Inspection
  - Maintenance
  - Repair
- **Subclass**: The specific subclass of the service history type, based on the **Service History Business Object**. Oracle Utilities Customer To Meter supports two subclasses of service history types:
  - Operational Device Service History
  - Questionnaire Service History

  Each service history type subclass includes other specific configuration information, outlined below.

Operational Device Service History Types

Operational Device Service history types are also defined by the following:

- **Service Schedules**: One or more template work orders and time intervals that should be used to schedule work order generation for service history records of this type

Questionnaire Service History Types

Questionnaire Service history types are also defined by the following:

- **Follow-up Actions**: One or more actions intended as “follow-up” actions for service histories of the service history type, such as work orders or work order activities, users can configure those follow-up actions on the service history type. Note that if a regulatory compliance requirement is associated with a follow-up action, a compliance type must be specified. For example, a Service History Type of “Grade 2 Gas Leak”, might include a follow-up action of “Recheck” which could be configured with a “30 day” Compliance Type and a follow-up action of “Repair” which could be configured with a “1 year” Compliance Type.
- **Stop Processing Service History Type**: One or more service history types that should stop the processing of **Follow-ip Actions**. For example, certain problem that needs follow up actions was reported. Then another service history, which indicates the problem has been fixed or its severity has changed, is recorded. Businesses might want to stop/cancel the follow up actions based on the original problem/severity.
- **Questions**: A list of one or more questions used to guide inspection of an asset. Questions are defined in the **Questions** portal.

Copyright © 2026, Oracle and/or its affiliates.

Defining Service History Types

You use the **Service History Type** portal to display and maintain service history types.

Refer to Understanding Service History Types for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service History Type**: This zone provides information about the service history type.
- **Questionnaire Tree**: This zone displays the service history types' questionnaire, based on the questions defined for the service history type. Applicable for Questionnaire service history types only.
- **Unlink Asset Types**: This zone lists the asset types currently linked to the service history type. To unlink one or more asset types, check the corresponding checkboxes and click **Remove**.
- **Link Asset Types**: This zone is used to search for and link asset types to the service history type. To link new asset types,
  1. Enter search criteria in the **Asset Type Description** field.
  2. Click **Search**.
  3. Select the asset types to link by checking the corresponding checkboxes.
  4. Click **Link**.

Configuration Types

- Understanding Configuration Types
- Defining Configuration Types

Understanding Configuration Types

Configuration types define the information required for various asset configurations with other assets, components, firmware, and other data.

Configurations are referenced on specifications which are then referenced on assets and components to indicate the best way that these entities can work with the other entities that they are connected to in the field.

Configuration types are defined by the following:

- **Configuration Class**: The class for configurations of this type
- **Configuration Category**: The category of configurations of this type
- **Configuration Business Object**: The business object used for configurations of this type

Copyright © 2026, Oracle and/or its affiliates.

Configuration Classes

In general configuration classes define the types of connections that are being configured. Each configuration class is based on a specific business object, which is the business object used for configurations of each class and type.

The table below lists the configuration classes and the business object for each.

Configuration Class	Business Object
Single Asset	W1-SingleAssetConfig (Single Asset Configuration)
Asset/Component	W1-AssetCompConfig (Asset/Component Configuration)
Asset to Asset	W1-AssetToAssetCompConfig (Asset to Asset/Component Configuration)
Asset/Component to Asset	W1-AssetCompToAssetConfig (Asset/Component to Asset Configuration)
Asset to Asset/Component	W1-AssetToAssetConfig (Asset to Asset Configuration)
Asset/Component to Asset/ Component	W1-AssetCompToAssetCompConfig (Asset/Component to Asset/ Component Config)

Defining Configuration Types

You use the **Configuration Type** portal to display and maintain configuration types.

Refer to Understanding Configuration Types for more information.

You can access the portal by selecting **Admin**,, then **Asset Management**, then **Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Type List**: This zone lists all configuration type records. Broadcast a record to display the details of the selected record.
- **Configuration Type** : This zone provides information about the selected configuration type.

Configurations

- Understanding Configurations
- Defining Configurations

Understanding Configurations

Configurations document and manage valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.

Configurations are defined by the following:

- **Configuration Type**: The configuration type upon which the configuration is based

Copyright © 2026, Oracle and/or its affiliates.

- **Status**: The current status of the configuration
- **Configuration Detail**: Specific information related to the configuration such as the assets and components involved, the firmware, characteristics, identifiers and other important information

Defining Configurations

You use the **Configuration** portal to display and maintain configurations.

Refer to Understanding Configurations for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration**: This zone provides information about the selected configuration.
- **Configuration Attachments**: This zone lists any attachments defined for the configuration.

Configuration Reports

- Understanding Configuration Reports
- Defining Configuration Reports

Understanding Configuration Reports

Configuration reports provide a summary of any currently installed configurations.

These reports show whether the configuration in an installation is valid or invalid, the identifiers and values being used, and display all of the assets/components and other elements that make up the installed configuration.

Configuration reports are defined by the following:

- **Reporting Mode**: The mode in which the report is run (One Time or Recurring)
- **Status**: The current status of the report (Pending or Submitted)
- **Report Criteria**: Specific information used to establish the filter criteria when generating the report, such as the assets and components involved, the firmware, characteristics, identifiers and other important information.
- **Report Result**: Specific information for each configuration, including the number of configurations, the assets and components involved, and the specifications and firmware versions of each. If the configuration is invalid, the **Configuration** column is blank in the report results. Users can navigate to specific valid configurations to review and edit the setup as needed. In addition, users can generate a work order to correct, reconfigure, or otherwise maintain any of the configurations by clicking **Generate Activity**.

Copyright © 2026, Oracle and/or its affiliates.

Base Package Configuration Reports

The base package includes a number of configuration reports, each based on one of the support configuration classes (see Understanding Configuration Types.

The table below lists the configuration reports and the business object for each.

Configuration Report	Business Object
Single Asset Configuration Report	W1-SingleAssetCfgRpt
Asset/Component Configuration Report	W1-AssetCompCfgRpt
Asset to Asset Configuration Report	W1-AssetToAssetCfgRpt
Asset/Component to Asset Configuration Report	W1-AssetCompToAssetCfgRpt
Asset to Asset/Component Configuration Report	W1-AssetToAssetCompCfgRpt
Asset/Component to Asset/Component Configuration Report	W1-AssetCompToAssetCompCfgRpt

Defining Configuration Reports

You use the **Configuration Report** portal to display and maintain configuration reports.

Refer to Understanding Configuration Reports for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration Report**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Report**: This zone provides information about the selected configuration report.

Defining Location Options

Understanding Asset Location Types

Asset location types define the details of locations of a certain type where assets or components can be installed. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.

Asset location types are defined by the following:

- **Class**: The general class for asset locations of this type, such as commercial or residential, a shop or warehouse, etc.
- **Location Business Object**: The business object used for asset locations of this type
- **Number of Assets Allowed**: A flag that indicates whether or not asset locations of this type can accommodate a single or multiple assets
- **Service Type**: The type of service (electric, water, etc.) that asset locations of this type support
- **Allow Related Work Locations**: A flag that indicates whether asset locations of this type should be allowed to be connected to a work location
- **Valid Parent Location/Organization Types**: One or more valid parent locations and parent organizations that can be referenced on asset locations of this type. Used primarily for reporting.
- **Valid Communicate-To Location Types**: One or more asset location types to which asset locations of this type can communicate. The **Tree View** tab of any asset or location will display other related assets with a visual indication of their relationship.

> **Note**
>
> Asset location types are used to define locations where assets and components are installed. Locations where assets that are out of service are stored and maintained are defined via Out of Service locations and Out of Service location types.

> **Note**
>
> In Oracle Utilities Customer To Meter, asset location types are maintained via Merged Maintenance.

Defining Asset Location Types

You use the **Asset Location Type** portal is used to display and maintain asset location types.

Refer to Understanding Asset Location Types for more information.

You can access the portal by selecting **Admin**, **Location**, then **Asset Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Location Type List**: This zone lists all asset location type records. Broadcast a record to display the details of the selected record.

Copyright © 2026, Oracle and/or its affiliates.

- **Asset Location Type**: This zone provides information about the selected asset location type.

> **Note**
>
> In Oracle Utilities Customer To Meter, asset location types are maintained via Merged Maintenance.

Organization Types

- Understanding Organization Types
- Defining Organization Types

Understanding Organization Types

Organization types define the main attributes for organizations of a certain type.

Organization types are defined by the following:

- **Class**: The general class organization. Parent organizations have a class of “Parent”.
- **Organization Business Object**: The business object used for organizations of this type
- **Valid Parent Organization Types**: One or more valid parent organizations that can be referenced on organizations of this type. Used primarily for reporting.

Defining Organization Types

You use the **Organization Type** portal is used to display and maintain organization types.

Refer to Understanding Organization Types for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization Type List**: This zone lists all organization type records. Broadcast a record to display the details of the selected record.
- **Organization Type**: This zone provides information about the selected organization type.

Organizations

- Understanding Organizations
- Defining Organizations

Understanding Organizations

Organizations are used for categorization and reporting for locations.

Copyright © 2026, Oracle and/or its affiliates.

For example, your reporting may include a hierarchy that groups locations by a structure of parent and child organizations.

Organizations are defined by the following:

- **Organization Type**: The organization's type. Understanding Organization Types for more information.
- **Organization Disposition**: The current status of the organization (Active or Inactive)
- **Parent Organization**: The parent organization, if applicable.
- **Main Contact**: A contact for the organization

Defining Organizations

You use the **Organization** portal to display and maintain organizations.

Refer to Understanding Organizations for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization**: This zone provides information about the organization.
- **Child Locations / Organizations**: This zone lists any child locations and/or organizations for the current organization.

Out of Service Location Types

- Understanding Out of Service Location Types
- Defining Out of Service Location Types

Understanding Out of Service Location Types

Out of service location types define attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.

Out of service location types are defined by the following:

- **Class**: The general class (storeroom, meter shop, etc.) of out of service locations of this type
- **Location Business Object**: The business object used for out of service locations of this type
- **Valid Parent Location/Organization Types**: One or more valid parent locations and parent organizations that can be referenced on out of service locations of this type. Used primarily for reporting.

Defining Out of Service Location Types

Copyright © 2026, Oracle and/or its affiliates.

You use the **Out of Service Type** portal is used to display and maintain out of service location types.

Refer to Understanding Out of Service Location Types for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location Type List**: This zone lists all out of service location type records. Broadcast a record to display the details of the selected record.
- **Out of Service Location Type**: This zone provides information about the selected out of service location type.

Out of Service Locations

- Understanding Out of Service Locations
- Defining Out of Service Locations

Understanding Out of Service Locations

Out of service locations are physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as “In Repair” or “Pending Disposition” the asset location is typically moved to an out of service location.

Out of service locations are defined by the following

- **Location Type**: The out of service location’s type. See Understanding Out of Service Location Types for more information.
- **Location Disposition**: The current status of the out of service location (Active or Inactive)
- **Parent Location/Organization**: The out of service locations’ parent location or organization (if applicable)
- **External ID**: An ID used to identify the out of service location in external systems
- **Address Information**: The physical address of the out of service location
- **Contacts**: The primary contact for the out of service location. See About Contacts and Maintaining Contacts for more information about creating and maintaining contacts used with out of service locations.
- **Field Information**: Additional information about the physical location, such as GPS coordinates

Defining Out of Service Locations

You use the **Out of Service Location** portal to display and maintain out of service locations.

Refer to Understanding Out of Service Locations for more information.

Copyright © 2026, Oracle and/or its affiliates.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location**: This zone provides information about the out of service location.
- **Current Activities**: This zone provides a summary of the activities that are currently associated to the location.
- **Asset Summary**: This zone provided statistics about the number of assets, by asset type, that are currently associated with the location.
- **Owned Attachments**: This zone lists attachments owned by the location.
- **Referenced Attachments**: This zone lists attachments related to the location.

> **Note**
>
> See About Contacts and Maintaining Contacts for more information about creating and maintaining contacts used with out of service locations.

Defining Device Options

Command Sets

- Understanding Command Sets
- Configuring Command Sets

Understanding Command Sets

Command sets are used to define a group of commands that are not eligible for a particular device. For instance, if Commission or Decommission commands should be considered ineligible for a particular device model, a command set that references the Device Commission and Device Commission business objects could be created and associated with that device model.

Command sets are specified for individual device models via the Manufacturer portal.

Individual devices of a particular model can be configured to override ineligibility if needed.

Configuring Command Sets

This portal is used to display and maintain a Command Set.

Refer to Understanding Command Sets for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Command Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Command Set List:** This zone lists all Command Set records. Broadcast a record to display the details of the selected record.
- **Command Set:** This zone provides information about the selected Command Set.

Head End Systems

- Understanding Head End Systems
- Understanding Processing Methods
- Understanding SGG Adapter Configuration
- Configuring Head End Systems

Understanding Head End Systems

Head end systems are systems that collect measurement data and meter events for eventual submission to the application. Many devices can communicate to the application through a single head-end system, but a utility may have numerous head-end systems through which they communicate with devices.

Head end systems utilize processing methods that specify the type of initial measurement data and device events to create for devices (and their related measuring components) based on measuring component type. Head end systems also utilize processing methods that specify how smart meter commands are processed.

Refer to Understanding Processing Methods for more information about processing methods.

Head End Systems Impact Data Import and Export

Head end systems are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each head end system can be associated to an external system which is used to define the messages that can be sent to that service provider and how each message is sent.

Understanding Processing Methods

Copyright © 2026, Oracle and/or its affiliates.

Head end systems, external applications, and market participants can have one or more associated processing methods that define the format or means by which it receives or sends data from or to the application, such as bill determinants, interval data, or meter events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and usage transactions. Processing methods can also be used to define the information an external system wishes to subscribe to receive from our application.

At the lowest level processing methods are used to identify an outbound message type, business object, batch control, or message category and number.

Each processing method is comprised of a business object that defines what is being mapped as well as how it should be mapped.

Important Processing Method System Events

The actual logic to determine the appropriate output for a given head end system, external application, or market participant and processing role for a processing method is executed by the following system event:

- **Determine Processing Method(s)**: is a business object algorithm system event that takes in a head end system, external application, or market participant, a processing role, and a list of relevant input data aka related object (e.g. a measuring component, device, etc). For the head end system or external application and the input data it will analyze the selection criteria to determine the appropriate output.

How Processing Methods Work

Processing methods perform two basic tasks:

- They define the criteria for selecting the appropriate output. This can be as simple as providing a single object in return without qualification or in more involved situations it could support determining the appropriate return object based on characteristics of the data being processed. This is accomplished through the data structure defined on the processing method business object.
- They evaluate the criteria for selecting the appropriate output given a specific head end system, external application, or market participant. This is accomplished through the Determine Processing Method system event on the processing method business object.

Each processing method business object can be associated to one or more processing roles. This is done by adding the Applicable Processing Role business object option. It is these processing roles that actually create the association between a head end system, external application, or market participant, the processing method, and the functional event that is being executed. For example, when initial measurement data is processed through the IMD Seeder the processing role Initial Measurement Creation is used to identify the processing method "How to Create MC Related Information" which maps a particular measuring component type to the appropriate initial measurement business object to be used for processing.

When system logic requires the results of a processing method the service Determine Service Providers and Methods is used. This service is available to call via Java or from within scripting through the business service of the same name. It can be called in one of two ways:

With a head end system, external application, or market participant: identifies the appropriate output for a single head end system, external application, or market participant being processed for the input processing role and related objects

Without a head end system, external application, or market participant: used to identify subscribing sysems. This will provide a list of any head end system, external application, or

Copyright © 2026, Oracle and/or its affiliates.

market participant that has the input processing role and an appropriate output given the related objects.

Processing Methods Available

There are the following processing methods provided by the base package:

Name	Details	Business Object
How to Create OB COMM/Send OB Message	Identifies Message Number/ Category, Business Object, Outbound Message Type and allows for an override by a device type.	D1-HowToCreateActivityOBComm
How to Create MC Related Information	Identifies a business object and allows for an override by measuring component type.	D1-HowToCreateMCInformation
How to Process Device Event Related Info	Identifies a business object, outbound message type, and batch control by device event category allowing for an override by device event type.	D1-HowToProcDvcEvtsInformation
How to Process Device Related Information	Identifies a business object and allows for an override by device type.	D1-HowToProcessDeviceInfo
How to Send Activity Related Information	Identifies a batch control and business object by activity type and allows for an override by device type.	D1-HowToSendActInformation
How to Send Activity Related O\B Messages	Identifies an outbound message type, message category, and message number and allows for override by activity type.	D1-HowToSendActivityResponse
How To Create US Related Information	Identifies a business object and allows for override by usage subscription type.	D2-HowToCreateUSInformation
How To Send US Related Information	Identifies a batch control, business object, and outbound message type and allows for override by usage subscription type.	D2-HowToSendUSInformation
How to Process Service Point Related Info	Identifies a business object and allows for override by service point type.	D1-HowToProcSPRelatedInfo
How to Send Field Activity Related Info	Identifies a outbound message type and allows for an override by field task type.	D1-HowToSendFARelatedInfo
How to Send Field Activity Remark Info	Identifies an outbound message type for an activity remark type.	D1-HowToSendActivityRemarkInfo
How to Translate External Value	Identifies a business object and allows for override by identifier.	D1-HowToTranslateExternalValue
How to Request Customer Notification	Identifies a list of outbound message types.	D1-HowToRequestCustomerNotific

Copyright © 2026, Oracle and/or its affiliates.

How to Process Business Flag Related Info	Identifies an outbound message type and allows for an override by business flag type.	D1-HowToProcessBusinessFlagInf

Understanding SGG Adapter Configuration

This section describes how to use a head end system's SGG Adapter Configuration portal.

You can use the SGG Adapter Configuration portal to view configuration information and access configuration components for an SGG adapter head end system.

Note: This portal displays configuration information for head-end systems that reference an SGG Adapter Configuration Sheet extendable lookup..

To use the configuration information portal for an SGG adapter head end system:

Select **Admin > Device > Head End System**.

In the Head End system List zone, click the Broadcast icon for the head-end system you wish to view.

Click the SGG Adapter Configuration tab to view the configuration information.

The SGG Adapter Configuration portal contains the following zones:

- **SGG Adapter Configuration Tracker**: This zone displays the configuration details of the adapter, as defined by the SGG Adapter Configuration Sheet extendable lookup referenced on the head end system. The configuration details include:

The components required for usage and event processing and command processing. To view more details about the components, you can click the component name to go to the business object for the component. For example, you can click the business object "SSN - Connect or Disconnect" to go to the business object portal for the SSN - Connect or Disconnect business object.

Status messages describing the configuration status of components. The following table lists the status messages that may be displayed and the possible actions you can take:

If the status message is...	You can...
Set up this processing method	Click the processing role to set up the processing method.
This processing method has been configured	Click the processing role to view the configured processing method.
Update your processing method with a communication BO	Click the status message to set up the processing method.
Update your external system / outbound message type with an Message sender	Click the status message to go to the external system.
Update your processing method with an outbound message type	Click the status message to set up the processing method.
Add a value to get started	Click the status message to go to the extendable lookup.
Values Existing: (number)	Click the status message to go to the extendable lookup.
Add a communication type	Click the status message to go to the communication type portal.

Copyright © 2026, Oracle and/or its affiliates.

Add a device event type	Click the status message to go to the device event type business object for the communication type. This message appears only for Echelon type adapters.
Master Configuration has been added	Click the status message to view the Master Configuration portal.
Add Master Configuration for this adapter	Click the status message to view the Master Configuration portal.

Upload Statistics Aggregators: This zone lists the IMD Upload Statistics Aggregator measuring components associated with the head-end system.

Configuring Head End Systems

This portal is used to display and maintain Head End Systems.

Refer to Understanding Head-End Systems for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Head End System**.

The following zones may appear as part of the portal's **Main** tab page:

- **Head End System List:** This zone lists all Head End System records. Broadcast a record to display the details of the selected record.
- **Head End System:** This zone provides information about the selected Head End System.
- **Processing Method List:** This zone provides the list of processing methods defined for the Head End System.
- **Translation Methods List:** This zone provides the list of translation methods defined for the Head End System.
- **Inbound BOs Send By Service Provider:** This zone lists inbound Business Objects that are sent by this Head End System. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current Head End System.

Measuring Component Types

- Understanding Measuring Component Types
- Configuring Measuring Component Types

Understanding Measuring Component Types

Measuring component types define the most important properties of a measuring component.

Measuring component types define what a measuring component measures (KWH, temperature, etc.), how regularly it measures it, and whether it should be connected to a physical device, or if it's used as a scratchpad measuring component or an aggregator measuring component. Measuring component types also specify how the measuring component's final measurements should be stored, how the measuring component's user-defined values should be calculated, and specific rules governing validation, editing, and estimation (VEE) for measuring components of the type. In addition, measuring component

Copyright © 2026, Oracle and/or its affiliates.

types define display properties and valid attribute values for measuring components belonging to the type.

The following configurable items are available for most measuring component types:

- **Anchor Time**: A time used to define the start and end time of the business day for purposes of processing measurement data and usage transactions for measuring components of this type. Applicable only to dynamic aggregation measuring component types, standalone measuring component types, and profile measuring component types.
- **Initial Load IMD Ordering (Fallback)**: A flag that indicates if incoming initial measurements for measuring components of this type should be processed using Measuring Component Ordering. This is used most often in the case of daily scalar measuring components for which data is occasionally sent to the system out of order, but can also be used to ensure that "check channels" are processed before related channels. Applicable only to measuring component types used with Direct Measurement Processing (see Direct Measurement Processing and Measuring Component Ordering for more information).
- **Value Identifiers**: These store the values of UOM, TOU, and SQI that identify the measured amounts for measuring components of this type. Value identifiers specify the quantities stored on the measurement records for measuring components of this type. Please refer to the Measuring Component Type Value Identifiers topic later in this section for more information.
- **Valid VEE Groups**: These define the VEE groups considered valid for measuring components of this type. Each group supplied here will be available to be selected on measuring components of this type and act as an override to the Fallback VEE Groups.
- **Fallback VEE Groups**: These define default VEE groups for a specific VEE Group Role that can be used with all measuring components of this type. This alleviates the need to specify the same VEE groups on multiple measuring components of the same type. Changes made to these groups will automatically apply to all measuring components of this type unless they have specified their own VEE groups for that particular VEE Group Role. Each VEE group is designated a VEE group role that indicates when and how the VEE group is used (for initial load, manual override, estimation, etc.).
- **Enable ML Based Validation (Fallback)**: A flag that indicate (Yes or No) if initial measurements for measuring components of this type will be processed through a machine learning scoring model. IF set to "Yes", VEE processing for initial load data will only be used when data fails machine learning normalcy checks. See Machine Learning Anomaly Scoring for more information.
- **Anomaly Score Threshold (Fallback)**: The anomaly score threshold for measuring components of this type. This overrides the value set in the MDM Master Configuration. This field is only visible when the **Enable ML based Validation (Fallback)** flag is set to "Yes". See Machine Learning Anomaly Scoring for more information.
- **Eligible Profile Factors (interval only)**: These define the profile factors that are considered to be eligible for interval measuring components of this type. One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a profile factor is required.
- **Valid Profile Factors for Conversion from Scalar to Interval (scalar only)**: These define the profile factors that are considered to be eligible for scalar measuring components of this type when converting scalar measurements to interval measurements. These profile factors are used to produce a curve of interval data from a scalar value. Without one of these factors defined scalar to interval conversion will use a flat line method (i.e. evenly divide the scalar value across the intervals). One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a conversion profile factor is required.

Copyright © 2026, Oracle and/or its affiliates.

- **Valid Scratchpad Measuring Component Types**: These define the scratchpad measuring component types considered valid for measuring components of this type.
- **Related Statistics Measuring Component Types**: These define the measuring component types that will be used to store statistical information about the historical usage of measuring components of this type. Please refer to Configuring Measuring Component Statistics for more information on how this list is used.
- **Display Properties**: Defines how measurement data for measuring components of this type is displayed, including:
  - *Display Configuration*: Details related to how measurements are displayed, including the 360 chart rendering method, number of hours of data to display, the maximum days to search for measurements, the default TOU map used, the TOU by Day Profile factor used, and default measurement condition.
  - *Event Bar Profiles*: The event bar profiles used when displaying measurement data for measuring components of this type. Event bar profiles are defined as values for the 360 View Event Bar Profile extendable lookup.
  - *Final Values Overlay Profiles*: The final values overlay profiles used when displaying measurement data for measuring components of this type. Final values overlay profiles are defined as values for the Final Values Overlay Profile extendable lookup.
  - *Measurement Conditions Not Shown on Chart*: The measurement conditions that should be omitted from rendering onto 360 Degree charts. Measurements whose conditions match these values will be rendered as gaps. For example, many 360 Degree charts use the condition "No Read - System" to represent the lack of a measurement, by adding this condition to this list it a gap will be rendered instead of a line with a 0 quantity measurement and a condition of "No Read - System".

When creating a measuring component type the following options are available:

Name	Details	Business Object
Interval Channel Type - Physical	Provides the configuration for a physical interval channel (including interval size). This is recommended for measuring components that measure consumptive usage in interval sizes up to 1 hour.	D1-IntervalChannelTypePhysical
Interval Channel Type - Scratchpad	Provides the configuration for a scratchpad interval measuring component.	D1-IntervalChannelTypeScratchp
Interval Channel Type - Physical Subtractive	Provides the configuration for a physical subtractive interval channel. In addition to standard interval configuration (including interval size) it also provides additional subtractive specific configuration (e.g. rollover validation, estimate reevaluation, etc). This is recommended for measuring components that measure subtractive usage in interval sizes up to 1 hour.	D1-IntrvlChanTypPhysSubtractiv

Copyright © 2026, Oracle and/or its affiliates.

Interval Channel Type - External	Provide the configuration for interval measuring components that measure data not typically stored in the system, such as Amps. Incoming data for external measuring components of this type can be filtered or passed through to other systems, preventing errors generated by incoming data for measuring components that don't exist. Filtering of data for external measuring components is configured via the **IMD Handling** flag.	D1-IntervalChannelTypeExternal
Register Type	Provides the configuration for a physical register that is manually read (e.g. rollover validation). These can be either consumptive or subtractive but are expected to be read infrequently (e.g. once a month).	D1-RegisterTypePhysical
Auto-Read Register Type	Provides the configuration for a physical register that is automatically read. In addition to the standard register configuration (e.g. rollover validation) it also provides details around the schedule of expected readings (e.g. first daily measurement time and expected hours between measurements). These can either be consumptive or subtractive but are expected to be read frequently (e.g. at least once per day). Note: these measuring component types can also be used to model interval data that is received with a large interval size (24 hours and larger).	D1-AutoReadRegisterType

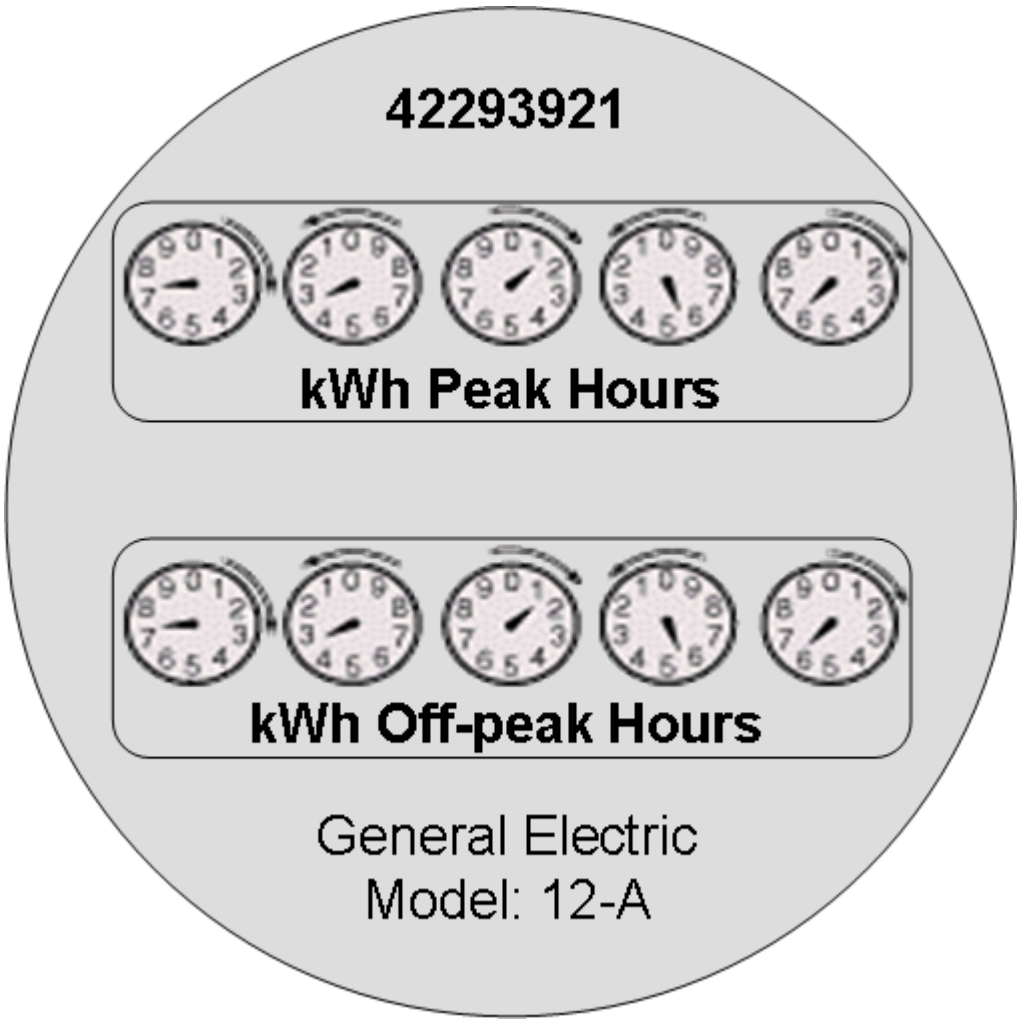
Copyright © 2026, Oracle and/or its affiliates.

Scalar Channel Type - External	Provide the configuration for scalar measuring components that measure data not typically stored in the system. Incoming data for external measuring components of this type can be filtered or passed through to other systems, preventing errors generated by incoming data for measuring components that don't exist. Filtering of data for external measuring components is configured via the **IMD Handling** flag.	D1-ScalarChannelTypeExternal
Aggregator Type	Provides the configuration for an aggregation measurement.	D2-AggregatorType

> **Note**
>
> For “interval” data with an interval size greater than one hour, use the D1-AutoRegisterReadType measuring component type business object and the D1-RegisterAutoRead measuring component business object. This business object is well suited to daily and sub-daily readings. Using an interval data business object can result in measurement date problems during daylights saving time.

Refer to Configuring an Out-of-the-box Aggregation for more information about aggregation configuration

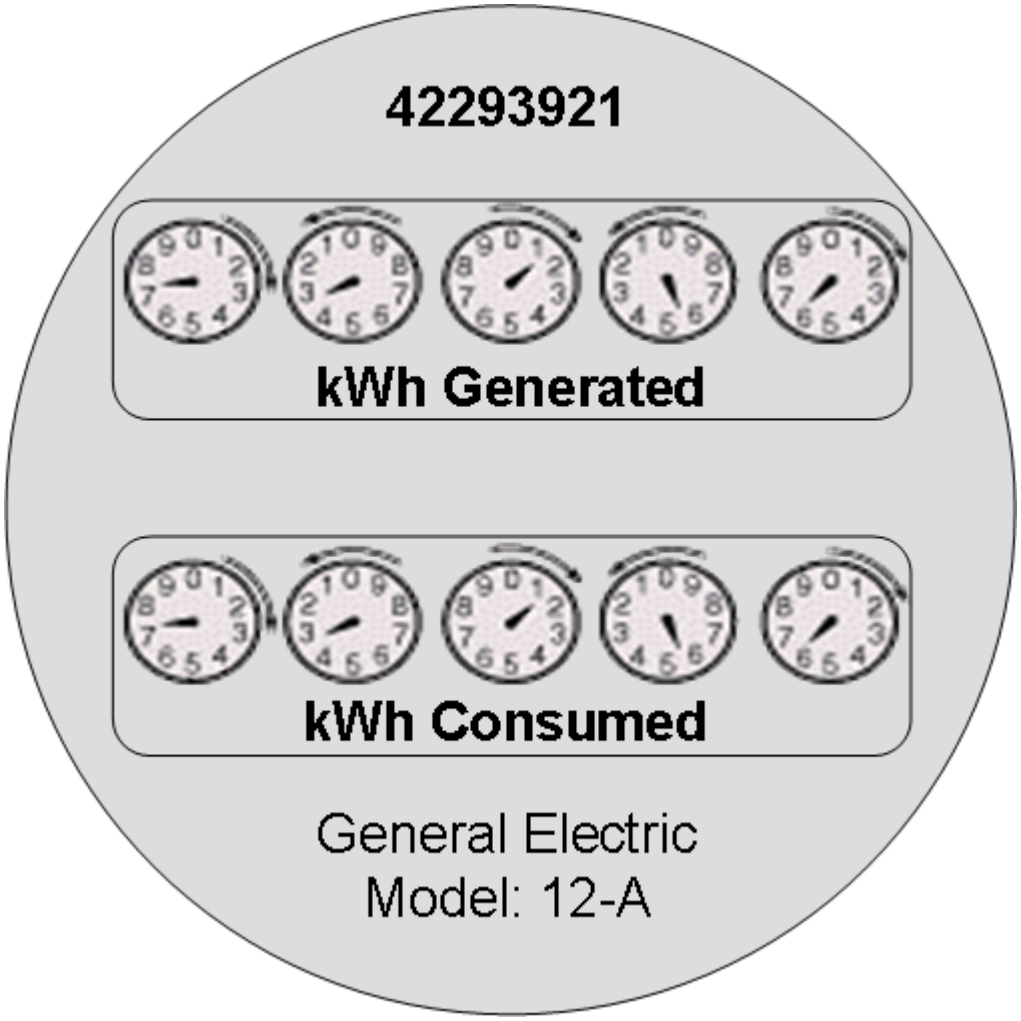
Measuring Component Type Value Identifiers



Measuring components are configured to measure specific types of quantities this is defined by the list of value identifiers on the measuring component type. Up to eleven value identifiers can be specified. The primary measured quantity should be identified using the Value Identifier Type of Measurement. An additional ten derived values can be computed based on the primary measurement, these are identified with the Value Identifier Type of Value 01 through Value 10. Each value identifier is constructed of:

- **Unit of Measure**: The unit of measure for the quantity being recorded. Examples include kilo-watt hours (kWh), kilo-watts (kW), therms, cubic feet (CCF), temperature (Fahrenheit or Celsius), etc. Refer to Understanding Units of Measure for more information.
- **Time of Use**: Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc. Refer to Understanding Time of Use for more information.
- **Service Quantity Identifiers**: Used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Generally, SQI is only used when multiple measuring components measure the same thing, but in different ways. A meter that measures both generation KWH and consumption KWH could use SQIs to differentiate between the two. Refer to Understanding Service Quantity Identifiers for more information.

Copyright © 2026, Oracle and/or its affiliates.



- **Value Derivation Algorithm**: Unlike UOM, TOU, and SQI this is not used in the identification of what is measured but rather is used to calculate a derived value based on the primary measurement. An algorithm from the list should be selected that contains the appropriate logic for calculating the derived value. This is applicable for those value identifiers with a Value Identifier Type of Value 01 through Value 10. More information on how derived values are calculated can be found in the Important Measuring Component Type System Events topic in this chapter. For more functional information about derived values please refer to About Final Measurements.

The combination of UOM, TOU and SQI define what a measuring component measures. TOU and SQI are optional, but UOM must be defined for all value identifiers. For example, consider a meter (as illustrated in the image below) with two measuring components, both measuring the same unit of measure (kWh), but each measuring component measures consumption in different time of use (TOU) periods (peak and off-peak).

Another example might be a meter that records both generated KWH and consumed KWH. This meter would be configured to measure both UOM and SQI.

Copyright © 2026, Oracle and/or its affiliates.

A measurement is recorded each time a measuring component is read. This means that for a meter with two measuring components that is read once a month, two measurements, one for each measuring component, would be recorded each month.

Important Measuring Component Type System Events

The measuring component type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Calculate Interval Consumption**: receives the interval list and performs any necessary calculations on that interval data to compute consumption. Since interval data is already received as consumption data algorithms for this system event are typically limited to application of the appropriate multipliers. Refer to the algorithm type Calculate Interval Consumption (D1-IN-CNSUMP) as an example.
- **Calculate Scalar Consumption**: receives information about the scalar reading and calculates the consumption as appropriate. Algorithms for this event typically support calculating the consumption using a stop and start reading or backing into a reading using consumption and a start reading. Much like the interval counterpart it will apply the appropriate multipliers. Refer to algorithm type Calculate Scalar Consumption (D1-SC-CNSUMP) as an example.
- **Calculate Subtractive Interval Consumption**: receives the interval list and supporting information (e.g. the start reading for the first interval) and either calculates the consumption by subtracting the interval's reading from the prior interval's reading or

Copyright © 2026, Oracle and/or its affiliates.

calculates the reading by adding the current interval's consumption to the prior interval's reading. Refer to algorithm type Calculate Subtractive Interval Consumption (D1-SIN-CNSUM) as an example.

- **Condition Mapping**: receives the details of a single subtractive interval along with the details for its start reading and computes the applicable final condition and reading condition. This is leveraged solely for subtractive interval measuring component types. Refer to algorithm type Subtractive Interval - Condition Mapping (D1-SIN-CNMAP) as an example.

These system events are typically called from within initial measurement processing during the initial stages of the initial measurement lifecycle (e.g. the Pre VEE status of most initial measurement business objects).

In addition to the measuring component type business object algorithms there is an additional system event provided on measuring component type itself:

- **Value Derivation**: receives details of an initial measurement and an associated final measurement. Using these inputs it can compute a value derived either from the primary measurement or one of the other derived values. Refer to algorithm type Derive a quantity using a formula (D1-DERIVAQTY) as an example.

Important Measuring Component System Events

The measuring component business object that is associated to a given measuring component type supports a special system event that is used in the periodic estimation process:

- **Periodic Estimation**: this system event will scan the measuring component's final measurement history to identify missing measurements and create either a To Do, or an estimation initial measurement, or both. More detail about this system event can be found by visiting the following algorithm types: Refer to algorithm type Create Interval IMD and To Do Based Upon Install History (D1-CIITBIH) and Auto-Read Scalar Periodic Estimation (D1-ARSPE) as an example.

Measuring Component Business Object Options

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below are a list of business object options that are defined on the device business object and their impact on system processing:

- **Estimation Initial Measurement Data BO**: Is used to identify the appropriate estimation IMD to create.
- **Manual Override IMD BO**: Is used to identify the appropriate manual override IMD to create.
- **System IMD BO**: Is used to identify the appropriate system IMD to create.
- **Measuring Component Consumption Function**: identifies a function that can be executed from any compatible measuring component 360 Degree zone. Each measuring component can support 0 to many of these functions.
- **Interval Initial Measurement Function**: identifies a function that can be executed from any compatible initial measurement zone. Each measuring component can support 0 to many of these functions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Configuring Measuring Component Types

This portal is used to display and maintain a Measuring Component.

Refer to Understanding Measuring Component Types for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Type:** This zone provides information about the selected Measuring Component Type.

Measuring Component Comparison Types

- Understanding Measuring Component Comparison Types
- Configuring Measuring Component Comparison Types

Understanding Measuring Component Comparison Types

Measuring component comparison types define the details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated. For example, measuring component comparison types can be used on measuring components that store weather data so that comparisons can be made based on temperature. These are used when performing “proxy day” estimations, allowing the application to search for days that are similar to historical data (for instance, the same date from the previous month or previous year) to use as the basis for estimation.

Measuring component comparison types use the following parameters:

- A specific metric to be calculated to enable data comparisons. The “Calculate Comparison Coefficient - Pearson Correlation Coefficient” algorithm, included with the base package can be used to calculate a coefficient based on the linear correlation between two data sets (specifically between weather data stored on a measuring component and on the comparison object).
- The specific object to be compared. This can be either the same measuring component (to compare against historical data for the same measuring component), or a factor profile (to compare against profile data).
- The date range for the comparison period, including the start of the comparison period (current date, same date last year, or both), the time each day through which the comparison will be calculated, and the number of days prior to and after the start date that will be compared with the comparison object.
- Average Difference Eligibility: An average value either above or below the average for the current date that will be eligible for comparison. For example, assume the current date’s average is 75, and the prior day’s average is 72. If the Average Difference Eligibility is set to 3 then the prior day value of 72 will be eligible for comparison to the current day average of 75.
- The maximum number of resulting calculations that should be stored as measuring component comparable periods.

Copyright © 2026, Oracle and/or its affiliates.

- A template that defines which days are considered like each day of the week (for example, weekdays are like other weekdays, weekend days are like other weekend days). This template is defined as a record for the “Like Day Eligibility Template” extendable lookup.
- Work calendars used to determine if specific data should be compared to other weekend days or to the same date in prior years, and which dates, if any, should be excluded from historical data used for comparison.

Configuring Measuring Component Comparison Types

Refer to Understanding Measuring Component Comparison Types for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component Comparison Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Comparison Type List**: This zone lists all measuring component comparison type records. Broadcast a record to display the details of the selected record.
- **Measuring Component Comparison Type**: This zone displays details for the selected measuring component comparison type.

Device Configuration Types

- Understanding Device Configuration Types
- Configuring Device Configuration Types

Understanding Device Configuration Types

Device Configuration types define the measurements a given device can record. It should be noted that the device configuration type itself does not specify this information but rather the device configuration type will identify the valid list of measuring component types that can be referenced associated to a device.

When creating a new device configuration type there are the following options:

Name	Details	Business Object
Device Configuration Type	This represents configurations for physical meters and communication components. It identifies a list of valid measuring components types.	D1-DeviceConfigurationType
Item Configuration Type	This represents badged items that are installed at a particular service point. Given the nature of items there are no measuring component types associated to this type.	D1-ItemConfigurationType

Refer to Configuring Consumption Synchronization for more information on how a device configuration type can be set up to synchronize consumption between two related channels of measurement data.

Copyright © 2026, Oracle and/or its affiliates.

Configuring Device Configuration Types

This portal is used to display and maintain a Device Configuration Type.

Refer to Understanding Device Configuration Types for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Configuration Type List:** This zone lists all Device Configuration Type records. Broadcast a record to display the details of the selected record.
- **Device Configuration Type:** This zone provides information about the selected Device Configuration Type.

Device Types

- Understanding Device Types
- Configuring Device Types

Understanding Device Types

Device types define information about a class of devices, including properties that apply to all devices of a type. Properties defined for a device type can be overridden for an individual device

Specifically, device types provide information about:

- How a device can be configured by defining the valid list of device configuration types
- How a device communicates by defining a fallback head end system and a list of valid head end systems.
- How a device records measurement data through the fallback incoming data shift which plays an important role in daylight savings processing. Refer to Daylight Savings Time Support for more information.
- The consumption profile of an item: the unit of measure consumed and method of calculation (profile or straight line)
- Whether the device is attached to a service point or meter (used with items and device communication equipment)
- Characteristics common to all devices of this type (defined in the **Device Type Characteristics** zone).

When creating a new device type there are the following options:

Name	Details	Business Object

Copyright © 2026, Oracle and/or its affiliates.

Smart Meter Device Type	These devices measure consumption for a given service point, support remote commands, and remote collection of measurement and event data. These devices are associated to a head end system.	D1-SmartMeterType
Manual Meter Device Type	These devices measure consumption for a given service point but require a visit to the service point to collect the measurement data. They are not associated to head end systems.	D1-ManualMeterType
Item Device Type	These devices represent various items that consume consumption at a constant rate which are not directly metered. As consumption is calculated rather than measured so there is no need for an association to a head end system. Devices of this type can either be created individually for "badged" items or can be listed directly on a service point for "unbadged items." These devices may also be configured as equipment that can be attached to a service point.	D1-ItemType
Communications Component Device Type	These devices provide remote collection of consumption data measured by a manual meter on which they are installed. These devices are associated to a head end system.	D1-CommunicationCompMeterType
Device Communication Equipment Type	These devices provide remote collection of consumption data measured by a manual meter to which they are attached. Devices of this sort are sometimes referred to as Encoding Receiver/Transmitter (ERT) modules, or communication modules. These devices are associated to a head end system.	D1-DvcCommEquipmentType

Device Business Object Options Drive Functionality

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below is a list of business object options that are defined on the device business object and their impact on system processing:

Copyright © 2026, Oracle and/or its affiliates.

- **Device Category**: This defines the type of device and correlates to the core device types that are supported (i.e. smart meter, AMR meter, manual meter, item, or communication component). This value is used by smart meter commands, service order management, and other system processes to make processing decisions.
- **Install Event BO**: This identifies the appropriate install event business object to use when this device is being installed at a service point. Refer to About Install Events for more information about install events.
- **Valid Command Request BO**: This identifies the commands that are valid for any device of this type. This option can be repeated for as many commands as the device supports. Note: the combination of the device and service provider (aka head end) define the true list of available commands by device.
- More detail about these options can be found by visiting a device business object and inspecting the business object options.

Device Type - Service Quantity

For "badged" and "unbadged" items consumption is not directly measured. Instead, for each item type, the average daily consumption amount is provided. The commodity represented by the daily consumption amount is defined by the item type's unit of measure.

The average daily consumption amount can be effective dated over time to support changes in the consumption profile. This is used in conjunction with the item's calculation method to derive the consumed amount per interval.

Refer to Multiple Time Zone Support for additional information on how device type service quantities are impacted by multiple time zones.

Valid Device Characteristic Types

The **Valid Device Characteristic Types** zone lists the valid characteristic types that may be instantiated on devices of this type. Characteristics of these types are maintained using the **Device Characteristics** zone in the **Device** portal.

Configuring Device Types

This portal is used to display and maintain a Device Type.

Refer to Understanding Device Types for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Type List:** This zone lists all Device Type records. Broadcast a record to display the details of the selected record.
- **Device Type:** This zone provides information about the selected Device Type.
- **Device Type Service Quantity:** This zone displays the list of effective dated service quantities supported by the selected Device Type. This applies only to Items.
- **Device Type Characteristics**: This zone lists characteristics common to all devices of this type.
- **Valid Device Characteristic Types**: This zone lists the valid characteristic types that may be instantiated on devices of the device type. To add or edit valid characteristic types, click **Edit**.

Service Point Types

- Understanding Service Point Types
- Configuring Service Point Types

Understanding Service Point Types

Service point types define a specific type of point at which service is delivered.

Specifically, service point types define how the application manages many aspects of the service point's behavior. A service point type may have one or more valid device types defined that limit the types of devices that can be installed at service points of this type.

Service point types are defined by the following:

- **Service Point Business Object**: the business object used by service points of this type
- **Service Point Category**: the types of devices that can be installed at service points of this type. Valid values include:
  - **Meter**: Indicates that a single meter can be installed at service points of this type.
  - **Item**: Indicates that a single "badged" item can be installed at service points of this type.
  - **Multi-Item**: Indicates that one or more "unbadged" items can be installed at service points of this type.
- **Divisions**: one or more divisions associated with service points of this type.
- **Valid Device Types**: the device types considered valid for service points of this type.
- **Valid Field Task Types**: the field task types considered valid for service points of this type. The field task types available when creating field activities can be based on the field task

Copyright © 2026, Oracle and/or its affiliates.

types listed here via the **Restrict Field Task Type by Service Point Type** option on the Service Order Management Master Configuration.

- **Usage Snapshot Configuration**: the configuration(s) to be used to take weekly or monthly usage snapshot(s)
- **Unreported Usage Snapshot Configuration**: the configuration(s) to be used to take weekly or monthly unreported usage snapshot(s)

Configuring Service Point Types

You use the Service Point Type portal to view and maintain service point types.

Refer to Understanding Service Point Types for more information.

You can access the portal by selecting **Admin**, **Geographic**, **Service Point Type**.

> **Note**
>
> If the **Control By CIS Division** setting on the **Main** tab on the **Installation Options** portal is set to "Yes", this zone displays only unsecured service point types as well service point types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Type List:** This zone lists all service point type records. Broadcast a record to display the details of the selected record.
- **Service Point Type:** This zone provides information about the selected service point type.
- **Valid SP Characteristic Types**: This zone lists the valid characteristic types that may be instantiated on service points of the service point type. To add or edit valid characteristic types, click **Edit**.

  > **Note**
  >
  > Only characteristics types defined for both the “Service Point — MDM” **and** “Service Point — CCB” characteristic entities can be selected in this zone.

- **Valid Field Task Types**: This zone lists the field task types considered valid for the selected service point type. To add or edit valid field task types, click **Edit**.
- **Valid SA Types**: This zones lists the service agreement types considered valid for the selected service point type. To add valid service agreement types, click **Add** in the zone title bar. To edit, delete, or copy a listed service agreement type, select the service agreement type from the list and click **Edit**, **Delete**, or **Copy** as appropriate.
- **Valid Disconnect Location**: This zone lists disconnection locations considered valid for the selected service point type.

> **Note**
>
> In Oracle Utilities Customer To Meter, Service Point Types are maintained via Merged Maintenance.

Service Point Quantity Types

- Understanding Service Point Quantity Types
- Configuring Service Point Quantity Types

Understanding Service Point Quantity Types

Service point quantity types define types of quantities that can be stored for a service point. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, service point quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Service quantity types use the following parameters:

- The service type (electric, gas, water, etc.) for service point quantities of this type
- Quantity identifiers related to the current service point quantity type (used to provide shorthand descriptions of the various types of values measured by service point quantities of this type)

Configuring Service Point Quantity Types

Refer to Understanding Service Point Quantity Types for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Service Point Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Quantity Type List**: This zone lists all service point quantity type records. Broadcast a record to display the details of the selected record.
- **Service Point Quantity Type**: This zone displays details for the selected service point quantity type.

Divisions

- Understanding Divisions

Understanding Divisions

Divisions are used to delineate between different operating companies within a large conglomerate of utilities.

Divisions can have one or more characteristics defined.

Divisions can be defined on several other objects and entities in the system, including:

Copyright © 2026, Oracle and/or its affiliates.

- Service Point
- Service Order Activities (Request Orchestration activities)
- Service Order Field Activities
- Usage Subscription/Usage Subscription Type
- Usage Calculation Group
- Settlement Calculation Group
- Aggregation Group
- Data Source
- Market Product Type
- Market Product Set

Divisions can be associated with individual users on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

Entity Groups

- Understanding Entity Groups
- Entity Groups

Understanding Entity Groups

Entity Groups are used to define groups of entities, such as devices (including meters or items, as well as controllable devices used with Customer Program Management Cloud Service and Customer Program Management) or service points.

An entity can belong to more than one group if they have different Group Categories. For example, a controllable device associated with a specific program and rate could belong to a group category based on the specific program as well as a group category based on the specific rate.

Entity group processing uses dynamic SQL queries to identify entities that belong to a entity group. These dynamic queries are based on configuration of the Group Category (which defines Template SQL that contains tokens) and Criteria Values (which define specific values for the tokens in the Template SQL). These queries are used by "Eligible <Entity>s for this Group" zones that identify entities eligible for but not currently assigned to a group, as well as <Entity> Group Evaluation batch processes (see **Batch Processing** in **Configuring Entity Groups** for more information).

Entity Groups are defined by the following:

- **Status**: The current status of the entity group
- **Group Category**: The category to which the entity group belongs. Group categories are defined using the Entity Group Category (D1-EntityGrpCodeCategoryLookup) extendable lookup. See below for more information.
- **Group Deactivation Option**: A flag that defines what happens to the relationship (captured in the Device Entity Group or Service Point Entity Group table, as appropriate) between the group and entities belonging to the group if or when the group is deactivated. Options include "Expire" and "Do not Expire".

Copyright © 2026, Oracle and/or its affiliates.

- **Group Assignment Option**: A flag indicating the manner in which groups are assigned to entities. Options include System (via batch process), User (manually), System and User (either).
- **Criteria Value**: One or more criteria values used for selecting entities for the group, based on a Criteria Source and Criteria Value.
  - **Criteria Source**: Defines the source for criteria used for selecting entities for the group (such as a Specification, Rate, or Program). Criteria sources are defined using the Entity Group Criteria Source (D1-EntityGrpCriteriaSrcLookup) extendable lookup. See below for more information.
  - **Criteria Value**: Defines specific values for the criteria that are used when selecting entities for the group. For instance, values for a **Criteria Source** of "Rate" could be rates defined in an extendable lookup.

System Data

Entity Groups are based on the following system data:

Data Type	Description
Maintenance Object	Entity Group (D1-ENTGRP)
Business Object(s)	Entity Group (D1-EntityGroup)

Entity Group Category Extendable Lookup

The Entity Group Category (D1-EntityGrpCodeCategoryLookup) extendable lookup defines categories of entity groups. These are used to define groups of entities (either devices or service points) that share the criteria and template SQL for identifying and retrieving entities but that may have different criteria values. For example, two device entity groups, "Device Group A" and "Device Group B" can reference the same "Specification and Rate" category, which uses Specification and Rate Schedule criteria to identify and retrieve devices (devices in group A are those with a unique combination of Specification and Rate Schedule, while those in group B have a different unique Specification and Rate combination). The category also defines template SQL that uses the "Specification" and "Rate" criteria when identifying and retrieving devices. The Entity Group Category Template SQL contains tokens, and an Entity Groups Criteria Values define specific values for the tokens in the Template SQL.

Values for this extendable lookup are defined by the following:

- **Status**: The current status of the entity group category.
- **Target Maintenance Object**: The maintenance object of the entities that belong to entity groups of this category. Valid options include Device (D1-DEVICE) or Service Point - MDM (D1-SP).
- **Criteria Option**: Flag that indicates whether or not the criteria source along with the SQL template and SQL builder algorithm will be recorded for the entity group in this category. Valid values are "Applicable" and "Not Applicable".
- **Template SQL**: The template SQL used to identify and retrieve entities for entity groups of this category. Applicable only when Criteria Option is set to "Applicable".
- **Entity Group Algorithm**: An algorithm that executes the template SQL, inserting the criteria values from the entity group, to identify and retrieve entities for entity groups of this category.
- **Criteria Sources**: The criteria sources used by the template SQL when identifying and retrieving entities for entity groups of this category. Criteria sources are defined using the Entity Group Criteria Source (D1-EntityGrpCriteriaSrcLookup) extendable lookup. See

Copyright © 2026, Oracle and/or its affiliates.

below for more information. Applicable only when Criteria Option is set to "Applicable". Each criteria source is defined by the following:

  - **Criteria Source**: The name of the criteria source (from the Entity Group Criteria Source (D1-EntityGrpCriteriaSrcLookup) extendable lookup)
  - **Is Required**: A flag that indicates if a value is required for the criteria source (Required or Optional)
  - **Marker**: The token used in the template SQL for the criteria source and value, in the format of "#xxx". For example, the marker for a Specification criteria source might be "#SPEC".
  - **Condition Operator**: The operator used in `WHERE` clauses in the template SQL to filter data based on the criteria source. Values are defined in the Condition Operator (CONDITION_OPR_FLG) lookup.

The base package includes the "SP Measurement Extract" value for this extendable lookup.

Criteria Source Extendable Lookup

The Entity Group Criteria Source (D1-EntityGrpCriteriaSrcLookup) extendable lookup defines the criteria that can be configured for an entity group. Each value defines a single criteria source, such as Specification, Rate, or Program, as well as how the user will enter criteria values for the criteria source, and the source of criteria values for the criteria source. This configuration is used in the **Criteria Value** section of an Entity Group.

Values for this extendable lookup are defined by the following:

- **Status**: The current status of the entity group criteria source
- **Presentation**: The presentation used for the criteria source. Options include:
  - **Drop down**: The user selects a the criteria value from a drop-down list.
  - **Input Text**: The user enters text.
  - **Input Text with Date Picker**: The user selects a date.
  - **Input Text with Date Time Picker**: The user selects a date and time.
- **Value Source**: The source of values for the criteria source. Options include:
  - **Characteristic Type (Pre-Defined)**: Values are from a list of pre-defined values for a characteristic type
  - **Extendable Lookup**: Values are from an extendable lookup
  - **Service Script**: Values are retrieved by a service script
  - **Standard Lookup**: Values are from a standard lookup
- **Value Retriever**: The specific value source used for the criteria source, based on the Value Source. For example, if the Value Source is "Standard Lookup", this would be the lookup code.

Example: A "Rate" criteria source where values are derived from the Customer Rate Schedule (D2-CCBRateScheduleLookup) extendable lookup could be defined as follows:

- **Criteria Source**: Rate
- **Description**: Rate
- **Status**: Active
- **Presentation**: Drop down
- **Value Source**: Extendable Lookup

Copyright © 2026, Oracle and/or its affiliates.

- **Value Retriever**: D2-CCBRateScheduleLookup

Entity Groups

You use the **Entity Group** portal to display and maintain entity groups.

Refer to Understanding Entity Groups for more information.

You can access the portal by selecting **Admin**, select **General**, then select **Entity Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Entity Group**: This zone displays basic information about entity group.
- **Eligible Devices for this Group**: This zone shows a list of devices that are eligible for assignment to this entity group. The list is based on the **Template SQL** on the **Group Category** with the **Criteria Values** applied. To assign one or more devices to the group, select the devices and click **Assign**. Applicable only for "Device" entity groups.
- **Devices in this Group**: This zone shows a list of devices that have been assigned to this entity group. To delete the relationship between the device and the entity group, select the device and click **Delete**. To expire the relationship between the device and the entity group, select the device and click **Expire**. Applicable only for "Device" entity groups.
- **Eligible Service Points for this Group**: This zone shows a list of service points that are eligible for assignment to this entity group. The list is built from the **Template SQL** on the **Group Category** with the **Criteria Values** applied. To assign one or more service points to the group, select the service points and click **Assign**. Applicable only for "Service Point" entity groups.
- **Service Points in this Group**: This zone shows a list of service points that have been assigned to this entity group. To delete the relationship between the service point and the entity group, select the device and click **Delete**. To expire the relationship between the service point and the entity group, select the device and click **Expire**. Applicable only for "Service Point" entity groups.
- **Customer Address Search for Grouping**: This zone lists service points that are eligible for assignment to this entity group (and provides search parameters to filter the results). To assign one or more service points to the group, select the service points from the search results and click **Assign**. Applicable only for entity groups with a **Group Category** of "SP Measurement Extract".
- **Service Points**: This zone shows a list of service points that have been assigned to this SP Measurement Extract entity group. To unassign a service point from the entity group, select the device and click **Unassign**. To expire the relationship between the service point and the entity group, select the device and click **Expire**. To create an extract request for the group, click **Add**. Applicable only for entity groups with a **Group Category** of "SP Measurement Extract".

The following zones may appear as part of the portal's **Requests** tab page:

- **Requests**: This zone lists the requests made for the entity group, such as requests for measurement consumption extract. To a request for the entity group, click **Add** in the zone title bar.

Copyright © 2026, Oracle and/or its affiliates.

Batch Processing

The Device Group Evaluation (D1-DGEV) and Service Point Group Evaluation (D1-SPGEV) batch controls are used to identify devices or service points (respectively) that are eligible for a particular group and assigns them to a specified group, or expires relationships between devices or service points (respectively) and a specified group.

Devices or service points that are not currently assigned to an entity group for a specified category will be assigned to an eligible group. Only one group for the category may be assigned. If the device or service point is currently assigned a group for that category, it will be evaluated for eligibility, and if the current group is no longer eligible, the group is expired. If the same device becomes eligible for another group, that group is assigned to the device or service point.

Parameters:

- **Group Code Category**: A group category used to identify eligible entities. Required if the **Mode** is "Evaluate Group Code Category"
- **Group Code**: A group used to identify eligible entities, Required if the **Mode** is "Expire Device Group Code", "Expire Service Point Group Code" or "Evaluate Group Code", and is optional if the **Mode** is "Evaluate Group Code Category".
- **Mode** (Required): The mode by which the process evaluates entities. Options include:
  - **Expire Device Group Code (D1ED)**: Used to expire device entity group relationships for the specified Group Code
  - **Expire Service Point Group Code (D1ES)**: Used to expire service point entity group relationships for the specified Group Code
  - **Evaluate Group Code (D1EG)**: Used to search entities based on Group Code, and assigns eligible devices or service points to the specified Group Code
  - **Evaluate Group Code Category (D1GC)**: Used to search entities based on Group Code Category (and optionally a Group Code). This mode assigns devices or service points eligible for a group of the specified category (and Group Code if provided), and expires relationships between devices or service points and groups of the specified category (and Group Code is provided).

Note that these batch controls are used with groups whose Group Assignment Option is either "System" or "System or User".

Weather Stations

- Understanding Weather Stations
- Weather Stations

Understanding Weather Stations

Weather stations are facilities that measure atmospheric conditions and collect weather data such temperature, humidity, wind speed and direction, and barometric pressure.

Weather stations are defined by the following:

- **Weather Station**; An ID for the weather station.

Copyright © 2026, Oracle and/or its affiliates.

- **Weather Meter**: The weather meter (see below) that captures weather data for the weather station.
- **Status** A flag that indicates if the weather status is Active or Inactive.
- **Geographic Longitude**: The geographic longitude of the location of the weather station.
- **Geographic Latitude**: The geographic latitude of the location of the weather station.
- **External ID**: An ID used for the weather stations in external systems, such as a distributed energy resource management (DERM) system.

Weather Meters

Weather meters are virtual devices used to store weather data for a weather station within the application. Weather meters can have one more interval measuring components, each configured to store a specific type of weather data (temperature, wind speed, humidity, and so on).

Weather meters are defined by the following:

- **Device Type**: The device type for the weather meter. This should be based on the Weather Meter Type (D1-WeatherMeterType) business object.
- **Status**: The current status of the weather meter (Active or Inactive)
- **Serial Number**: An identifier for the weather meter. This is based on the ID of the Weather Station.

Like other devices, weather meters require device types. Device types for weather meters are created based on the Weather Meter Type (D1-WeatherMeterType) business object. In addition, weather meters have related device configurations based on the Device Configuration (D1-DeviceConfiguration) business object, and measuring components based on the Interval Channel (D1-IntervalChannel) business object.

See Creating Weather Metersfor more information about how weather meters are created.

Weather Stations

You use the **Weather Station** portal to display and maintain weather stations.

Refer to Understanding Weather Stations for more information.

You can access the portal by selecting **Admin**, select **Geographic**, then select **Weather Station**.

The following zones may appear as part of the portal's **Main** tab page:

- **Weather Station List**: This zone lists all weather stations defined in the system. Broadcast a record to display the details of the selected record.
- **Weather Station**: This zone displays the selected weather station.
- **Weather Station Characteristics**: This zone displays characteristics for the selected weather station.

Importing Weather Stations

Weather stations can be imported along with other facility and network location data such as transformers, feeders, and substations. Refer to Importing Facility and Network Location Data from a Distributed Energy Resource System for more information.

Copyright © 2026, Oracle and/or its affiliates.

Creating Weather Meters

Weather meters, including device configurations and measuring components, are created automatically when a weather station is created, based on the Device Type selected when creating the weather station.

This process requires the following data be set up prior to creating weather stations.

Measuring Component Type(s)

One or more measuring components used to capture weather data. Each should be defined as follows:

- **Business Object**: Interval Channel Type - Physical (D1-IntervalChannelTypePhysical)
- **Measuring Component Business Object**: Interval Channel (D1-IntervalChannel)
- **Measurement Business Object**: Measurement (D1-Measurement)
- **Service Type**: The service type associated with how weather data stored by measuring components of this type will be used (typically "Electric").
- **Interval /Scalar**: Interval
- **Consumptive/Subtractive**: Consumptive
- **Interval Size**: The size of the intervals for weather data values stored by measuring components of this type, represented as hours:minutes:seconds (HH:MI:SS)
- **Value Identifiers**: One or more value identifiers for the weather data captured by measuring components of this type (Degrees F, Degrees C, and so on).

Device Configuration Type

A device configuration type that defines the types of measuring components to be created for the weather meter. This should be defined as follows:

- **Business Object**: Device Configuration Type (D1-DeviceConfigurationType)
- **Device Configuration Business Object**: Device Configuration (D1-DeviceConfiguration)
- **Service Type**: The service type associated with how weather data stored by devices of this device configuration type will be used (typically "Electric") This must match the service type defined for the measuring component type.
- **Valid Measuring Component Types**: One or more measuring components (defined above) used to capture weather data. Each should be marked as "Required".

Device Type

A device type that defines the type of weather meter to be created. This should be defined as follows:

- **Business Object**: Weather Meter Type (D1-WeatherMeterType)
- **Device Business Object**: Weather Meter (D1-WeatherMeter)
- **Service Type**: The service type associated with how weather data stored by devices of this type will be used (typically "Electric"). This must match the service type defined for the device configuration type and measuring component type.
- **Valid Device Configuration Types**: A device configuration type that defines the measuring component types to be created for the weather meter.
- **Characteristics**: Characteristics that define the type of data stored by the device (such as temperature)

Copyright © 2026, Oracle and/or its affiliates.

Batch Processing

The Map Service Points to corresponding Weather Stations (D1-MAPWS) batch process can be used to map service points (including metered service points) to weather stations when and as needed.

The Initial Data Export D1-WTHRSTN (D1WSTNX) batch process can be used to export weather station data when and as needed.

Use the **Batch Control** portal to view the parameters used by these batch processes.

Importing Weather Data

Weather data can be imported into the system using the Adapter Development Kit (ADK) in the same manner as used for measurement data. When importing weather data, the weather station ID should be used as the Device ID (the Serial Number on Weather Meters is based on the Weather Station ID). In addition, this requires that appropriate Unit of Measure (UOM), Time of Use (TOU), and Service Quantity Identifiers (SQI) values are defined to represent the weather data used in your implementation, and corresponding UOM translation mapping values are defined in the ADK - UOM Code to Standard UOM Mapping (DG-HeadendUOMLookup) extendable lookup.

See About Measurements and Measurement Processing in the *Business User Guide*, and Configuring Payload Processing for more information.

Postal Code Defaults

- Understanding Postal Code Defaults
- Postal Code Defaults

Understanding Postal Code Defaults

Postal Code Defaults are used to define ranges of postal codes associated with a weather station. These are used when mapping service points (including metered service points) to weather stations when the longitude and latitude of the service point is not available.

Postal code defaults are defined by the following:

- **Postal Code From**: The starting point of the range of postal codes for the postal code default.
- **Postal Code To**: The ending point of the range of postal codes for the postal code default.
- **Country**: The country in which the postal code default resides.
- **City**: The city in which the postal code default resides.
- **County**: The county in which the postal code default resides.
- **State**: The state in which the postal code default resides.
- **Version**: The version of the postal code default.
- **Time Zone**: The time zone in which the postal code default resides.
- **Weather Station**: The weather station associated with the postal code default.

Copyright © 2026, Oracle and/or its affiliates.

Postal Code Defaults

You use the Postal Code Default portal to display and maintain postal code defaults.

Refer to Understanding Postal Code Defaults for more information.

You can access the portal by selecting **Admin**, select **Geographic**, then select **Postal Code Default - MDM**.

The following zones may appear as part of the portal's **Main** tab page:

- **Postal Code Default List**: This zone lists all postal code defaults defined in the system. Broadcast a record to display the details of the selected record.
- **Postal Code Default**: This zone displays the selected postal code default.
- **Postal Code Default Characteristics**: This zone displays characteristics for the selected postal code default.

Batch Processing

The Data Export D1_POSTAL_DFLT (D1POSTTX) batch process can be used to export postal code default data when and as needed. Use the **Batch Control** portal to view the parameters used by this batch process.

Measurement Cycles

- Understanding Measurement Cycles
- Configuring Measurement Cycles

Understanding Measurement Cycles

Measurement cycles define the schedule for manual meter reading of devices at Service Points in that cycle. Measurement cycles can have one or more associated routes used to collect measurements.

Measurement cycles can also be configured to define when to create usage transactions for Usage Subscriptions associated to Service Points in the cycle.

Refer to Measurement Cycle Processing for details on features, configuration and implementation.

Configuring Measurement Cycles

This portal is used to display and maintain a Measurement Cycle.

Refer to Understanding Measurement Cycles for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

Copyright © 2026, Oracle and/or its affiliates.

- **Measurement Cycle List**: This zone lists all Measurement Cycle records. Broadcast a record to display the details of the selected record.
- **Measurement Cycle**: This zone provides information about the selected Measurement Cycle.
- **Measurement Cycle Route List**: This zone lists the measurement cycle routes related to the measurement cycle. Click the **Route** link to view details for a measurement cycle route in the **Measurement Cycle Route** portal.
- **Measurement Cycle Schedule List**: This zone lists the measurement cycle schedules related to the current measurement cycle. Click the **Scheduled Selection Date** link to view details for a measurement cycle schedule in the **Measurement Cycle Schedule** portal.

Configuring Measurement Cycle Routes

The Measurement Cycle Route portal is used to maintain individual measurement cycle routes.

You can access the portal by clicking the **Route** for a specific measurement cycle route in the **Measurement Cycle Route List** zone of the **Measurement Cycle** portal. You are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Route**: This zone provides information about the selected Measurement Cycle Route.
- **Measurement Cycle Route Characteristics**: This zone lists characteristics for the selected Measurement Cycle Route.

Measurement Cycle Processing

Measurement cycle processing supports the following processes:

- **Meter Read Download** (for service point meters scheduled to be read for the measurement cycle): This process stages the activity for the extraction and download of the service point and meter information scheduled for reading.
- **Bill Determinant Push** (for subscribing external applications): This process stages usage transactions that calculate usage that will be sent to the subscribing external application. In this case, measurement cycles can be configured to define when to create usage transactions for Usage Subscriptions associated to Service Points in the cycle. Even Service Points whose meters are read automatically may reference measurement cycles. Creating bill determinants (by creating a usage transaction) is performed by an algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object (similar to creating activities as described above).

Measurement cycle processing is managed by the following three batch processes:

- **Create Pending Measurement Cycle Schedule Routes** (D1-CMCS): This batch process creates Schedule Routes for Measurement Cycle Schedules whose schedule selection date is on or before the batch business date. This process is used if routes have the same schedule each month, quarter, and so on. This process simply copies the routes from the Measurement Cycle to the Measurement Cycle Schedule on/after the scheduled selection date.
- **Create Pending SP / Measurement Cycle Schedule Route Records** (D1-CSPSR): This batch process creates a "SP/Measurement Cycle Schedule Route" transaction for every Service Point in the Measurement Cycle Schedule Route that is ready for processing.

Copyright © 2026, Oracle and/or its affiliates.

- **Process Pending SP / Measurement Cycle Schedule Route Records** (D1-PSPSR): This batch process transitions the Pending "SP/Measurement Cycle Schedule Route" transactions to their Complete state. Algorithms can be configured to create "Meter Read Download" activities or usage transactions. These algorithms would be configured as an Enter algorithm on the "Complete" state of the SP/ Measurement Cycle Schedule Route business object (see below).

Measurement processing requires the following configurations:

- **Meter Read Download**: Configure the Create Meter Read Download Activity (D1-CRMRDACT) algorithm on the "Complete" state of the SP / Measurement Cycle Schedule Route (D1-SPMsrmtCycScheduleRoute) business object.
- **Bill Determinant Push**: Configure the Create Usage Transaction (D2-CRUSGTRN) algorithm on the "Complete" state of the SP / Measurement Cycle Schedule Route (D1-SPMsrmtCycScheduleRoute) business object.

Refer to A Description of the Cyclical Meter Read Process in the *Oracle Utilities Customer to Meter Administrative User Guide* for more information on meter read download (available with Customer to Meter and Customer Cloud Service only).

Refer to About Usage Transactions for more information about usage transactions.

Measurement Cycle Schedules

- Understanding Measurement Cycle Schedules
- Configuring Measurement Cycle Schedules

Understanding Measurement Cycle Schedules

Measurement cycle schedules define the dates on which devices are scheduled to be read for a given measurement cycle and the routes used to collect measurements for the measurement cycle.

For a deeper functional understanding, refer to the About Route Management section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycle Schedules

This portal is used to display and maintain a Measurement Cycle Schedule.

Refer to Understanding Measurement Cycle Schedules and Understanding Measurement Cycles for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle Schedule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Schedule Query:** This zone allows you to query for Measurement Cycle Schedules based on Measurement Cycle and select the desired record.
- **Measurement Cycle Schedule:** This zone provides information about the selected Measurement Cycle Schedule.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Metered Premise Options

This section describes tables that must be set up before you can define premises.

- Setting Up Meter Read Instructions
- Setting Up Meter Read Warnings

Setting Up Meter Read Instructions

When you set up a premise you may define instructions to be supplied to the individuals who read the meters located at the premise. To define meter read instruction codes, open **Admin**, and then **Geographic**, and then **Meter Read Instruction.**

Description of Page

Enter a unique **Meter Read Instruction Code** and **Description** for every meter read instruction.

Setting Up Meter Read Warnings

When you set up a premise you may define warnings to be supplied to the individuals who read the meters located at the premise. To define meter read warning codes, open **Admin**, and then **Geographic**, and then **Meter Read Warning.**

Description of Page

Enter a unique **Meter Read Warning** and a **Description** for every meter read warning.

Configuring Cross Installed Meter Processing

Cross installed meters is the term for situations in which meters are deployed at an incorrect customer service point. Consider the following example: Meter A is supposed to be installed at Service Point A and Meter B is supposed to be installed at Service Point B, but Meter B was mistakenly installed at Service Point A, and Meter A was mistakenly installed at Service Point B. This means that both customers will be billed incorrectly (customer at Service Point A will be billed for usage at Service Point B and vice versa) until the system can updated to reflect the correct meter installations.

This process can also be used to issue financial adjustments and/or cancel/rebill any bill segments that are impacted by the change in meters, and create customer contacts related to the changes. See Adjustments and Cancel / Rebill Incorrect Bill Segments for more information about adjustments and rebilling.

The Cross Installed Meters process provides a tool to re-configure the meters through a correction process. When a user initiates the Cross Installed Meters process, the system will update device installation event details (like status, date and time of installation), device configurations, and measuring components with the correct information.

Cross installed meter processing requires the following administrative data:

Copyright © 2026, Oracle and/or its affiliates.

- Customer Contact Class and Type (optional)
- Request Type
- Action Method

Each of these is described in detail below.

See Correcting Cross Installed Meters in the *Business User Guide* for more information about running cross installed meter processing.

Create a Customer Contact Class and Customer Contact Type - Optional

If you want customer contacts created as a result of cross-installed meter processing, you will need to reference a Contact Class and Contact Type. If you want to use a specific contact class and/or contact type, you will need to create these.

See Setting Up Customer Contact Options for more information about creating contact classes and contact types.

Create a Request Type

Each process flow instance has an associated request record, which is based on a specific request type. You must create a request type based on the "Cross Installed Meter Request Type" business object that will be used for cross installed meter processing.

Use the following procedure to create a request type used with cross installed meter processing

1. Select **Admin**, **General**, **Request Type**, **Add**.
2. Select "Cross Installed Meter Request Type" from the **Request Type Business Object** drop-down list on the **Select Business Object** screen and click **OK**.
3. Enter the following on the **Cross Installed Meter Request Type** screen:
    - **Main**:
        - **Request Type**: A code for your request type
        - **Description**: A description of your request type
    - **Crossed Installed Meter Parameters**:
        - **Swap Meters Service Script**: Cross Installed Meter - Swap Meters (this is the script that performs the change to Install Events)
        - **Insight Type**: Cross Installed Meters - Inline (default)
        - * **Field Task Type**: D1-ServiceInvestigation (this defines the Field Task Type for field activities created by clicking the **Investigate** button on the **Swap Meters** panel)
        - **Create Customer Contact**: Indicates if customer contacts should be created as part of the cross installed meter process
        - **Contact Class**: The contact class used for customer contacts created from cross installed meter process flows. Applicable only if **Create Customer Contact** is set to “Yes”.
        - **Contact Type**: The contact type used for customer contacts created from cross installed meter process flows. Applicable only if **Create Customer Contact** is set to “Yes”.
    - **Bill Correction Parameters**:

Copyright © 2026, Oracle and/or its affiliates.

- **Allow Non-Consecutive Periods**: Indicates whether or not selecting non-consecutive bill segments for a service agreement is allowed when correcting bill segments
- **Adjustment Type**: Indicates the type of adjustment used when correcting bill segments
- **Allow Rebill**: Indicates whether or not to cancel/rebill when correcting bill segments
- **Allow Estimates**: Indicates whether or not to allow the use of estimated usage when using cancel/rebill to correct bill segments
- **Billing Option**: Indicates the billing option (Use Cut off Date or Use Schedule) used when using cancel/rebill to correct bill segments
- **Cancel Reason**: Cross Installed Meter (this is the Cancel reason used when using cancel/rebill to correct bill segments)

4. Click **Save**.

See Setting Up Request Types for more information about creating request types.

Create an Action Method

You must also configure an Action Method to associate the base package Cross-Installed Meter Process Flow Type (X1-CROSSEDMETER) with your custom Request Type.

Use the following procedure to create an action method used with cross installed meter processing

1. Select **Admin**, **System**, **Action Method**, **Add**.
2. Select "Cross Installed Meter Action Method" from the **Request Type Business Object** drop-down list on the **Select Business Object** screen and click **OK**.
3. Enter the following on the **Cross Installed Meter Action Method** screen:
   - **Main**:
     - **Action Method**: A code for your action method
     - **Action Method Role**: Cross Installed Meter
     - **Description**: A description of your request type
   - **Default Details**:
     - **Process Flow Type**: Cross Installed Meter (this is provided with the base package)
     - **Request Type**: Cross Installed Meter (the Request Type created above)
     - **To Do Type**: Cross Installed Meter (this is provided with the base package) This defines To Do Type for To Do Entries created by the Create Meter Process Completion Event.
     - **To Do Role**: A To Do Role for To Do Entries created by the Create Meter Process Completion Event.
4. Click **Save**,

See Defining Action Methods for more information about creating Action Method records.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Consumption Estimation Parameters

The system estimates consumption under the following situations:

- At billing time, when "real" consumption cannot be computed due to the lack of a meter read, the system estimates how much the customer used assuming the following conditions are true:
  - The service agreement allows estimation.
  - The rate schedule allows estimation.
  - The bill cycle schedule (if one is being used) allows estimation.
  - The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption). Note that the base product estimation algorithms may attempt to estimate peak registers.
  - The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. But consider what would happen if we estimated a consumptive register, the consumption associated with the next real read will be billed in its entirety.
- When a meter read is added, the system verifies that the resultant consumption is congruous with historical consumption trends (i.e., high / low checks are performed).

This section describes the tables that must be set up to estimate consumption.

Defining Device Measurement Options

- Units of Measure
- Service Quantity Identifiers
- Time of Use
- Service Types

- Processing Timetable Types
- Initial Measurement Data
- Understanding Interval Price Set Types
- Defining Interval Price Set Types
- Understanding IMD Types
- Configuring IMD Types

Units of Measure

- Understanding Units of Measure
- Configuring Units of Measure

Copyright © 2026, Oracle and/or its affiliates.

Understanding Units of Measure

Units of Measure (UOM) identify quantities measured and recorded, such as KWH, KW, cubic feet, degrees Celsius, etc. UOMs are based on a specific service type.

> **Note**
>
> In Oracle Utilities Customer To Meter, Units of Measure are maintained via Merged Maintenance.

Important Unit of Measure System Events

Unit of Measure supports the following business object algorithm system events:

- **Axis Conversion**: this event receives a list of measurements along with a source UOM and interval size and a target UOM and interval size. It should then perform the necessary actions to convert the source UOM and interval size into the target UOM and interval size. Refer to the algorithm Axis Conversion algorithm (D1-AXIS-CONV) as an example.

Configuring Units of Measure

This portal is used to display and maintain a Unit of Measure.

Refer to Understanding Units of Measure for more information.

You can access the portal by selecting **Admin**, then **General**, then **Unit Of Measure**.

The following zones may appear as part of the portal's **Main** tab page...

- **Unit of Measure List:** This zone lists all units of measure. Broadcast a record to display the details of the selected record.
- **Unit of Measure:** This zone provides information about the selected unit of measure.

Service Quantity Identifiers

- Understanding Service Quantity Identifiers
- Configuring Service Quantity Identifiers

Understanding Service Quantity Identifiers

Service Quantity Identifiers (SQI) are used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Some examples include: Generated, Consumed, etc.

SQIs can also be used as a stand-alone representation of a service quantity that is not measured (one that is not properly described as a UOM) within a usage service quantity collection (such as a billing determinant).

Copyright © 2026, Oracle and/or its affiliates.

Configuring Service Quantity Identifiers

This portal is used to display and maintain a Service Quantity Identifier.

Refer to Understanding Service Quantity Identifiers for more information.

You can access the portal by selecting **Admin**, then **Rates**, then **Service Quantity Identifier**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Quantity Identifier List:** This zone lists all Service Quantity Identifiers. Broadcast a record to display the details of the selected record.
- **Service Quantity Identifier:** This zone provides information about the selected Service Quantity Identifier.

> **Note**
>
> In Oracle Utilities Customer To Meter, Service Quantity Identifiers are maintained via Merged Maintenance.

Time of Use

- Understanding Time of Use
- Configuring Time of Use

Understanding Time of Use

Time of Use (TOU) periods are modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc.

> **Note**
>
> In Oracle Utilities Customer To Meter, Time of Use periods are maintained via Merged Maintenance.

Configuring Time of Use

This portal is used to display and maintain a Time of Use.

Refer to Understanding Time of Use for more information.

You can access the portal by selecting **Admin**, then **Rates**, then **Time of Use**.

The following zones may appear as part of the portal's **Main** tab page:

- **Time Of Use List:** This zone lists all Time Of Use records. Broadcast a record to display the details of the selected record.

Copyright © 2026, Oracle and/or its affiliates.

- **Time Of Use:** This zone provides information about the selected Time Of Use.

> **Note**
>
> In Oracle Utilities Customer To Meter, Time of Use periods are maintained via Merged Maintenance.

Service Types

- Understanding Service Types
- Configuring Service Types

Understanding Service Types

Service Types define specific types of service for which usage can be recorded and captured, such as electric, gas, steam, etc.

Configuring Service Types

This portal is used to display and maintain a Service Type.

Refer to Understanding Service Types for more information.

You can access the portal by selecting **Admin**, then **General**, then **Service Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Type List:** This zone lists all Service Type records. Broadcast a record to display the details of the selected record.
- **Service Type:** This zone provides information about the selected Service Type.

> **Note**
>
> In Oracle Utilities Customer To Meter, Service Types are maintained via Merged Maintenance.

Factors

- Understanding Factors
- Configuring Factors

Understanding Factors

Factor are a centrally stored set of values for use in validation rules, bill determinants calculations, and other processes.

Copyright © 2026, Oracle and/or its affiliates.

A factor can have different values depending upon some definable attribute of a system object, such as customer size associated with a service point. Examples of factors can include minimum and maximum thresholds, loss factors, etc. Classes of factors are defined that can have numeric values (as in the above examples), or values pointing to profile measuring components, or VEE groups.

A factor's values are effective-dated values - either a number, a profile measuring component, a temperature profile measuring component, a VEE group, or some custom-defined value - assigned to a factor and associated to the value of some attribute of a system object. For example, consider a service point that can be classified as residential, commercial, or industrial. The tolerance percentage by which a customer's consumption can exceed last month's consumption can be based on the service point category.

For this example, factor values for a single factor called "tolerance percentage" could be:

- Residential - 20%
- Commercial - 10%
- Industrial - 5%.

Configuring Factors

This portal is used to display and maintain Factors and Factor Values.

Refer to Understanding Factors for more information.

Prerequisites: You must define factor characteristic source algorithms, factor characteristic types, and factor characteristic values before you can create a factor. Refer to the Oracle Utilities Application Framework online help for more information about algorithms, characteristic types, and characteristic values.

You can access the portal by selecting **Admin**, then **General**, then **Factor**.

The following zones may appear as part of the portal's **Main** tab page:

- **Factor List:** This zone lists all factor records. Broadcast a record to display the details of the selected record.
- **Factor:** This zone provides information about the selected factor.
- **Factor Char Value and Factor Value List:** This zone lists the characteristic values associated to the factor characteristic. For each characteristic value it will display the related factor values. From this zone you can click the **Factor Value** link to see the factor value in more detail on the **Factor Value** portal.

Processing Timetable Types

- Understanding Processing Timetable Types
- Configuring Processing Timetable Types

Understanding Processing Timetable Types

Processing timetable types define types of schedules that can be referenced by different processes and objects in Oracle Utilities applications such as Oracle Utilities Meter Data Management and Oracle Utilities Market Settlements Management. For example, if a process

Copyright © 2026, Oracle and/or its affiliates.

requires requesting data from an external system on a daily basis, a daily processing timetable type could be used to define the details of this schedule.

Processing timetable types are used by standalone data request measuring components to control the schedule by which requests for data are processed (for example, in a settlement process in which zonal load is requested on a daily basis). They are also used in the attribute data snapshot creation process.

The base package includes two processing timetable type business objects used with specific scheduling patterns:

- **Daily Processing Timetable**: Used for daily schedules
- **Defined Dates Processing Schedule**: Used for schedules that should execute on specific dates.

Parameters used to define processing timetable types include:

- **Execution Frequency Class**: Designates the type of processing timetable, Daily or Defined Dates (based on the business object)
- **Scheduling Information**: Details about how the schedule is executed, including:
  - **Period Cut-Off Time**: The time of day that represents the end of a period. In many instances this will be 12:00 AM. However, for something like a "Gas Day" this might be set to 09:00 AM.
  - **Earliest Execution Time**: Used to prevent records from being processed until after this time each day. This time relates to the processing time.
  - **Lag / Lead**: A flag that indicates whether periods in the past (Lag) or future (Lead) should be processed (applies to Daily schedules only)
  - **Lag Days / Lead Days**: The number of days in the past (Lag) or future (Lead) that should be processed (applies to Daily schedules only)
  - **Restrict Processing by Work Calendar**: Used to restrict processing to only the work days configured in the Work Calendar and will exclude any holidays added to the calendar (applies to Daily schedules only)
- **Workflow Information**: Details about how the processing timetable aligns with process workflows, including warning time and target due time
- **Processing Dates**: A list of specific dates on which the process should be executed (used with Defined Dates Processing Schedule only)

Configuring Processing Timetable Types

Refer to Understanding Processing Timetable Types for more information.

You can access the portal by selecting **Admin**, then **General**, then **Processing Timetable Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Processing Timetable Type List**: This zone lists all processing timetable type records. Broadcast a record to display the details of the selected record.
- **Processing Timetable Type**: This zone displays details for the selected processing timetable type.

Copyright © 2026, Oracle and/or its affiliates.

Initial Measurement Data

- Configuring the Initial Measurement Algorithms
- Configuring Measurement Logging
- Configuring Direct Measurement Processing
- Configuring Machine Learning Anomaly Scoring
- Removing Unwanted Initial Measurements

Configuring the Initial Measurement Algorithms

The behavior of initial measurement data processing can be adjusted by updating parameters in several key algorithms in the initial measurement lifecycle. This includes algorithms on initial measurement business objects used with Legacy Measurement Processing and algorithms on IMD types used by Direct Measurement Processing.

> **Note**
>
> This is not a list of all algorithms and algorithm parameters that can be customized in the initial measurement processing lifecycle. Rather, it is a selection of some of the more impactful parameters.

Initial Measurement Data Seeder Algorithms

- Derive Service Provider and Measuring Component (D1-DER-SPRMC) / Derive Service Provider and Measuring Component Service (D1-DERSPRMCS):
  - Enabling a standalone measuring component search allows initial measurement data to be processed without a device identifier. This is useful when profile or temperature data is loaded through an IMD Seeder or seeder IMD type and a match must be made on measuring component identifiers alone.
  - If measuring component identifiers can be repeated across measuring components for the same device then the error for duplicate measuring components being found can be turned off. This is useful for certain head end systems that will have multiple channels with the same channel identifier. When a duplicate is found the search will fall back on other means for identifier the correct measuring component.
- Perform Date/Time Adjustments and Undercount/Overcount Check (D1-DODTTMADJ) / Perform Date/Time Adjustments and Undercount/Overcount Check Service (D1-DODTTMADS):
  - Undercount validation can be turned off completely or left enabled. When left enabled the automatic filling of gaps can be turned off separately.
  - The overcount check can be turned off.
  - The automatic adjustment of the individual interval date/times to an interval boundary can be turned on.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> If your implementation receives initial measurement data with date/times that do not include an explicit time zone and the devices report date/times in standard time, you may need to add the following configuration:
>
> - Navigate to **Admin**, then **Integration**, then **Message Option**.
> - In the **XAI compliance** option, ensure that the following text is provided: `xsd:strict:dstGapInStandardTime`
>
> This will prevent a date/time reported in standard time that falls on the missing hour of the day Daylight Savings Time is entered from being misinterpreted.

Specific Initial Measurement Data Algorithms

- Normalize measurements (overwrite identical existing Measurements) (D1-NORM-IMD) / Normalize Measurements Service (overwrite identical Measurements) (D1-AUTO-NORS):
  - When the initial measurement data includes measurements that match exactly with the existing final measurements they can either be overwritten or skipped.
  - If logging of changes to final measurements is desired then it must be indicated as such in this algorithm. It is suggested to keep this turned off for high volume initial measurement data such as initial load. See Configuring Measurement Logging for more details.

> **Note**
>
> Refer to Configuring Consumption Synchronization for additional parameters that can be adjusted on specific initial measurement data algorithms.

Configuring Measurement Logging

There are two components to logging changes to final measurements:

- **Initial Measurement Finalization**: the "normalization" algorithm on a particular initial measurement data business object will determine how final measurements are updated. For performance reasons certain types of initial measurement data (e.g. initial load) are delivered with a final measurement update method that will skip any logging. This can be controlled by parameters on the algorithm that implements the algorithm type Normalize Measurements for Initial Measurement Data (D1-NORM-IMD) or Normalize Measurements for Initial Measurement Data Service (D1-NORM-IMDS) algorithm types. Specifically, with Legacy Measurement Processing the "Create Measurement Log on Update (Y/N)" parameter should be set to "N" as creating these logs has a performance impact. For Direct Measurement Processing, the "Create Measurement Audit (Y/N)") parameter should be set to "Y".
- **Measurement Business Object**: there must be an algorithm for the audit system event configured. The base package delivers the algorithm type Add Measurement Log Record (D1-AMSRMTLOG). It is this algorithm that actually records the log entries.

Copyright © 2026, Oracle and/or its affiliates.

Logging User Updates to Manual Initial Measurements

By default, manual edits made by users of these zones are not logged on the Log tab. Logging of manual edits to manual initial measurements can be enabled by adding a logging algorithm on an appropriate lifecycle state of the manual initial measurement business objects. The Log User Transaction (D1-LOGUSRTRN) base package algorithm can be used for this. This Enter algorithm is designed to be defined on the Initial state of the manual initial measurement business objects, but it can also be defined on any (non-transitory) Interim or Final state as well.

To ensure logging of any or all manual edits made to manual initial measurements, this algorithm should be specified on any state in which users will make manual edits. This will most often be the Pending or VEE Ready states, but could also include the Error, Exception, or Finalized states.

> ⚠ **Caution**
>
> When defining this algorithm, the user should exercise caution and determine if previous algorithms in the sequence within the state contain any form of transitioning logic that may inadvertently cause this algorithm to be bypassed.

Configuring Direct Measurement Processing

Direct Measurement Processing is a method of processing incoming initial measurement data designed to reduce the volume of initial measurement records in the database. Rather than create and update initial measurement data records, Direct Measurement Processing creates temporary staging records (in the IMD Control Staging (D1_IMD_CTRL_STAGE) table) and processes initial measurement data in memory and creates final measurements in the Measurement (D1_MSRMT) table. With Direct Measurement Processing, records in the Initial Measurement Data (D1_INIT_MSRMT_DATA) table are created only if an error is encountered during processing (including VEE processing). See Direct Measurement Processing in the *Business User Guide* for more information about Direct Measurement Processing.

Configuring the system for Direct Measurement Processing involves the following:

IMD Types

IMD Types are configuration records used to define how initial measurements are processed using Direct Measurement Processing. IMD Types are defined for specific measuring component types in the the "Initial Measurement Creation" processing method (“How to Create MC Related Information”) for each head end system. See Understanding IMD Types for more information about IMD Types.

Configure Extendable Lookups

Extendable lookups are used with Direct Measurement Processing for payload processing as well as with Measuring Component Filtering.

Payload Processing

To configure Payload Processing for use with Direct Measurement Processing, enable the **Use IMD Type** option on your SGG Payload Processing Configuration extendable lookup values. See Creating SGG Payload Processing Extendable Lookup Values for more information.

Measuring Component Filtering - Pass Through

Copyright © 2026, Oracle and/or its affiliates.

The Head End Status to Condition Map (D1-HeadEndStatusToConditionMap) extendable lookup is used to map head end systems to head end system status code mapping extendable lookups. This allows Direct Measurement Processing to identify which status code mapping extendable lookup to use based on the head end system associated with the incoming measurement (either specified in the measurement or derived from the measuring component).

Configure Head End System Processing Methods

To configure head end systems for use with Direct Measurement Processing, update the "Initial Measurement Creation" processing method (“How to Create MC Related Information”) to specify the IMD Types to use for your measuring component types for each head end system. See Creating Head End Systems for more information.

If your implementation uses "pass through" external measuring components, the appropriate (interval or scalar) pass through IMD type should be specified for each "pass through" external measuring component type.

Batch Processing

Batch processing is used with Direct Measurement Processing for payload processing, Measuring Component Filtering, and Measuring Component Ordering.

Payload Processing

Direct Measurement Processing receives initial measurement payloads via Payload Processing batch processes based on the following templates:

- Payload Processing Monitor Template (D1-PLPRM)
- Payload Processing Monitor Template with Export (D1-PLPSO)

See Creating Payload Processing Batch Controls for more information.

Measuring Component Filtering - Pass Through

When using Measuring Component Filtering, the Extract Passthrough IMDs In Error (D1-EPIMD) batch process can be used to process "Waiting for Extract" records in the Initial Measurement Data (D1_INIT_MSRMT_DATA) table. This batch process uses the following parameters:

- **Maximum IMDs Per File:** When extracting data, a new file will be created when this limit is reached. Note: this limit is applied per thread.
- **Stream Out File Location:** The file location or Object Storage bucket where initial measurement are posted for distribution to external systems. This should be a file path or the Value of the File Location Extendable Lookup value for the appropriate bucket (usage). See Referencing URIs for more information.
- **Stream Out File Name Prefix**: The prefix for files created in the Stream Out File Location. The file format will be <Stream Out File Name Prefix><batch run>_<thread>_<thread count>_<timestamp>{<_file sequence>}.json.gz. If the Stream Out File Location is set then this parameter is required.

Measuring Component Ordering

When using Measuring Component Ordering, the Process IMD Control Stage Data (D1-IMDCS) batch process can be used to process "Ready to Process" records in the IMD Control Staging table. This batch process uses the following parameters:

- **Value to restrict to IMD Control Stage Status**: Designates the status of records to process. When processing Measuring Component Ordering initial measurements, this should be set to "D1RD" ("Ready to Process").

Copyright © 2026, Oracle and/or its affiliates.

- **Enable sequence handling**: Designates (true or false) if initial measurements should be retrieved and ordered for a measuring component in ascending order by date time and create date time. When processing Measuring Component Ordering initial measurements, this should be set to "true".

See Measuring Component Ordering in the *Business User Guide* for more information.

Master Configuration

When using Direct Measurement Processing, the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration must be set to "Yes" in order to run historical extracts. When this is set to "Yes", change data capture information is recorded in the Measurement Extract Request table instead of the General Process table.

Configure Info Exception IMD Header Business Object

If you want Info Exception IMD Header records to be included in Initial Measurement Data Header Export data, the Create Measurement Extract Request for Info Exceptions (D1CMERINFOEX) algorithm must be configured as an "Enter" algorithm on the Finalized state of the Informational Exception Header (D1-InfoExceptionHeader) business object.

Configuring Machine Learning Anomaly Scoring

Machine Learning Anomaly Scoring is a method of processing incoming initial measurement data designed to use Artificial Intelligence and Machine Learning neural network models to recognize "normal" versus anomalous measurement values, and only perform Validation, Editing, and Estimation (VEE) processing for measurements deemed to be anomalous.

Configuring the system for Machine Learning Anomaly Scoring involves the following:

NOTE: Machine Learning Anomaly Scoring relies on machine learning models that must be deployed as part of your cloud service implementation. Please contact your Oracle Customer Success Manager if you wish to use Machine Learning Anomaly Scoring.

Measuring Components and Measuring Component Types

Specific measuring components and/or measuring component types are enabled for Machine Learning Anomaly Scoring using the **Enable ML Based Validation** or **Enable ML Based Validation (Fallback)** flag (respectively).

In addition, the anomaly threshold for those measuring components and measuring component types can be defined using the **Anomaly Score Threshold** or **Anomaly Score Threshold (Fallback)** fields (respectively).

MDM Master Configuration

The Machine Learning Configuring section of the MDM Master Configuration defines how results coming back from machine learning scoring are processed.

- **Exception Type**: specifies the VEE exception to be created when the machine learning anomaly score is higher than the **Anomaly Score Threshold** or when there was an error during the scoring process.
- **Anomaly Score Threshold**: the limit for the anomaly score of any measurement within an initial measurement data. If the anomaly score (the difference between the Pre-VEE measurement value and the machine learning value) for one or more initial measurement data measurements is equal to or higher than this threshold then the initial measurement data will be considered anomalous and will be processed through VEE rules. Any initial

Copyright © 2026, Oracle and/or its affiliates.

measurements where all anomaly scores are below this threshold skip VEE processing and move to finalizing the initial measurement data to the measurement table.
Note that this can be overridden by the **Anomaly Score Threshold** or **Anomaly Score Threshold (Fallback)** fields on specific measuring components or measuring component types (respectively).

Configure Payload Processing Extendable Lookups

To configure Payload Processing for use with Machine Learning Anomaly Scoring, you need to create two types of Payload Processing Extendable Lookup values:

- **Initial Payload Processing**: These are standard SGG Payload Processing Configuration (D1-SGGPayloadProcessing) extendable lookup values. You need to create one of these for each head end system from which you intend to process data using Machine Learning Anomaly Scoring. See Creating SGG Payload Processing Extendable Lookup Values for more information.
- **Machine Learning Payload Processing**: These are values for the SGG ML Payload Processing Configuration (D1-SGGMLPayloadProcessing) extendable lookup. You need to create one of these for each head end system from which you intend to process data using Machine Learning Anomaly Scoring. Values for this extendable lookup include the following:
  - **Payload Handler Class Name**: The Java class name for the processing handler to be used. This should be "com.splwg.d1.domain.sgg.ml.processing.MLResultPayloadHandler".
  - **Head-End System**: The head end system for which the configuration will apply. Select from the drop-down list.
  - **Load All ML Results**: A checkbox that indicates if Post VEE data should be created in the IMD regardless of anomalous status. This should be avoided in production environments as it increases the storage requirement for each Initial Measurement Data record which can lead to slower transaction processing.
  - **Payload Processing Result Type**: The type of payload to which the configuration applies. Machine Learning Anomaly Scoring is only supported for **Initial Measurements** at this time.
  - **Use IMD Type**: A checkbox that indicates if payload processing should use Direct Measurement Processing and IMD Types. See Direct Measurement Processing in the *Business User Guide* for more information.
  - **Dynamic Parameters**: A list of parameter names and values that support additional processing rules associated with Machine Learning Anomaly Scoring. These include:
    - **boStateConditionCode**: Optional value. Specifies the business object State Condition (from the State Condition (F1_STATE_CONDITION_FLG) lookup) that the payload handler will check for in the initial measurement's current state before proceeding with processing of the payload. The base package includes the Waiting for ML (D1WM) State Condition defined for the “Waiting for ML” state on the Initial Load IMD business objects. Specifying this parameter with this value ensures that only initial measurements in the "Waiting for ML" state will be processed. If this parameter and value are set and the initial measurement is in some other state, processing stops and an error is written to the log.

Configure Post-ML VEE Processing (Optional)

You can define VEE Groups that are executed after machine learning processing to compare or adjust the measurement values based on a related measuring component, such as a scalar measuring component defined as the **Consumption Reference Measuring Component** on

Copyright © 2026, Oracle and/or its affiliates.

an interval measuring component. These groups are referred to as "Post-ML" VEE groups, and are defined for the "Post-ML" VEE Role on measuring component types and measuring components.

Post-ML VEE Groups can include only the following VEE Rules:

- Sum Check
- Interval Adjustment From Scalar
- Scalar Calculation from Interval
- Final Measurement Replacement

To configure Post-ML VEE processing you need to do the following:

- Create one or more Post-ML VEE Groups containing one or more of the VEE rules supported for post-ML processing (listed above). Note that Post-ML VEE Groups can NOT reference Execute VEE Group or VEE Group Matrix rules.
- Add the Post-ML VEE Groups to the appropriate measuring component types and/or measuring components in the **Post-ML** VEE role. Note that Post-ML VEE Groups can only be added when machine learning is enabled for the measuring component or measuring component type via the **Enable ML Based Validation** or **Enable ML Based Validation (Fallback)** flag (respectively).

Batch Processing

Batch processing is used with Machine Learning Anomaly Scoring for both initial payload processing as well as processing data returned from the machine learning model. See Creating Payload Processing Batch Controls for more information about creating Payload Processing batch processes.

Initial Payload Processing

Machine Learning Anomaly Scoring receives initial measurement payloads via Payload Processing batch processes based on the following templates:

- Payload Processing Monitor Template with Export (D1-PLPSO)

This is used to send initial measurements to Object Storage for machine learning processing.

Processing Data Returned from the Machine Learning Model

Machine Learning Anomaly Scoring processing data returned from the machine learning model using Payload Processing batch processes based on the following templates:

- SGG ML Payload Processing Monitor Template (D1-PLMLP)

This is used to retrieve measurements following machine learning processing, populate the IMD with machine learning values and the Anomaly Score Threshold, and calculate the Anomaly Score for each measurement value. Batch processes based in this template require an SGG ML Payload Processing Extendable Lookup value.

- Historical Data Extracts
- Machine Learning Comparative Reporting

Historical Data Extracts

When using Machine Learning Anomaly Scoring with interval measurements, the measurement data being processed includes enough historical data for the machine learning models to perform the anomaly scoring calculations, but when using Machine Learning

Copyright © 2026, Oracle and/or its affiliates.

Anomaly Scoring with scalar measurements, there is a chance that the models will not have access to sufficient historical data to perform those calculations.

In this case, you can extract historical data to supplement the cache of historical data used in the anomaly scoring calculations. This process supports extracts of both interval and scalar data.

Required Configuration

Extracting historical data requires that the **Enable ML-Based Validation** flag be set yo "YES" for all measuring component type for which data is to extracted.

Batch Controls

Extract of data and creation of extract files is performed by the Initial Extract for ML Cache (D1-INIML) batch process.

This batch process uses the following parameters:

- **Start Date/Time**: The start date and time of the data extract
- **Number of Days**: The number of days to extract (the process creates a separate file for each day)
- **Interval/Scalar**: Flag indicating which type of data to extract, interval (D1IN) or scalar (D1SC)
- **File Path**: The file path to where the process will post the file so that it can be ingested into the historical data cache used by the machine learning models. Refer to **Referencing URIs** (LINK) in the user documentation for more details.
- **File Limit**: The number of initial measurements to be included in the file (default is 10,000)

This process extracts data for ALL measuring components where the **Enable ML-Based Validation** flag on the Measuring Component Type is set yo "YES".

File Creation and Naming

Because this process can potentially create very large extract files, the files are created with a controllable sizes. Data is extracted in the Adapter Development Kit Native Format, and each file will only contain initial measurements for a single day, and for a default of 10,000 initial measurements. The logic for creating files differs slightly between interval and scalar data:

- Scalar: Each measurement is an initial measurement. For the common scenario there will be one initial measurement per day. However, some customers get scalar data more often per day or some measuring components may have adhoc reading (field or on demand read command based). For those less common scenarios there may be many initial measurements for a single measuring component for a single day.
- Interval: Files contain and initial measurement for each calendar day. Since each initial measurement can contain a variable number of measurements, there will only ever be one initial measurement per measuring component per day.

Extract files are named based on the following syntax:

pre-vee-init-<channel type>-<date being extracted>-<thread number>-<file number>-<batch run>.xml.gz.

where:

- <channel type> is the type of data to extract: interval (D1IN) or scalar (D1SC)

Copyright © 2026, Oracle and/or its affiliates.

- <date being extracted> is the date for the data being extracted, in YYYYMMDDHH24MISS format YYYY = year, MM = month, DD = day, HH= hour, MI= minute, SS = second)
- <thread number> is the thread number that created the file
- <file number>: is the number of the file, in cases where multiple files are created from same batch process run
- <batch run> is the batch number for the process

Machine Learning Comparative Reporting

Machine Learning (ML) Comparative Reporting enables you to compare ML anomaly results with Validation, Editing, and Estimation (VEE) results and other corrective actions. You can use this functionality to evaluate anomaly score thresholds before deployment and to monitor the effectiveness of ML anomaly scoring in production.

Before configuring comparative reporting, configure Machine Learning Anomaly Scoring, including the required machine learning model, payload processing, and batch controls. This includes set up and configuration of Oracle Cloud Object Storage Buckets (see Creating Object Storage Locations for more information).

Machine Learning (ML) Comparative Reporting can be used in two ways:

- **Historical Evaluation** evaluates existing interval measurement data (IMDs) processed using VEE for a selected period.
- **Ongoing Evaluation** captures comparison statistics for ML exceptions created during normal processing.
- Configuring and Running Historical Evaluations
- Configuring and Running Ongoing Evaluations
- Reviewing Comparative Results

Configuring and Running Historical Evaluations

You can use historical evaluations to score existing initial measurement data (IMDs) originally processed using VEE using ML, compare the ML results with original VEE results, and determine an appropriate anomaly score threshold.

This process use batch processes to create and extract historical "verification" data that can be evaluated by ML and then compared to the original VEE data, Another batch process captures the results in a statistics control record, which can be viewed using the **Meter ML and VEE Dashboard** portal.

> **Note**
>
> Historical verification data is used only for coordinating the scoring by the ML model and evaluation. This data does NOT create or update any measurement data.

> **Note**
>
> Historical evaluation should be used in non-production environments (such as DEV or TEST) ONLY.

Copyright © 2026, Oracle and/or its affiliates.

Configuring Historical Evaluations

Configuring historical evaluation involves the following:

Create ML VEE Exception Type

Define a VEE Exception Type that specifies the VEE exception to be created when the machine learning anomaly score is higher than the **Anomaly Score Threshold** or when there was an error during the scoring process when used with historical evaluation. This may be a different VEE exception Type than used for ongoing ML processing. See MDM Master Configuration in Configuring Machine Learning Anomaly Scoring for more information.

Update MDM Master Configuration

Update the **Machine Learning Configuration** section of the MDM Master Configuration as follows:

- **Exception Type**: Specify the ML VEE Exception Type created for ML historical evaluation (above).
- **Anomaly Score Threshold**: 0 (this ensures that the system retains the ML prediction and anomaly score for all IMDs selected for the evaluation)

See MDM Master Configuration in Configuring Machine Learning Anomaly Scoring for more information.

Configure Consumption Extract

Configure a Consumption Extraction Type for each ML model to be tested based on the ML Historical Verification Extract Type (D1-MLVerificationExtractType) business object. This construction extract type is used to define what is going to be scored as well as how VEE results should be interpreted as compared to ML results.

This should include the following attributes that define the model:

- **Interval Scalar**: A flag that indicates whether Interval or Scalar data is to be evaluated. Together with **Measurement Frequency** and **Service Type**, this helps define eligible measuring-component types.
- **Measurement Frequency**: The frequency at which measurements are captured by the measuring component, represented as hours:minutes:seconds (00:00:00). Together with **Interval Scalar** and **Service Type**, this helps define eligible measuring-component types.
  - **For interval data**: This is the interval size.
  - **For scalar data**: This should align with the expected hours between measurements defined on the scalar measuring component type (such as 24:00:00 for daily, 08:00:00 for 3 times per day).
- **Service Type**: The Service Type for the measurement data being evaluated (such as Electric, Gas, and so on). Together with **Interval Scalar** and **Measurement Frequency**, this helps define eligible measuring component types.
- **Service Point Types**: One or more service point types and UOM/TOU/SQI combination eligible for ML verification. These combinations determine which historical measuring components are evaluated.
- **VEE Exception Type Inclusions**: One or more VEE exception types that represent consumption quality issues ML is expected to detect. When this list is populated, any matching exception qualifies the IMD as having a VEE detected issue, regardless of severity. When empty, any non-informational VEE exception qualifies. You should exclude

Copyright © 2026, Oracle and/or its affiliates.

conditions that ML cannot evaluate so as to ensure ML to VEE comparisons remain meaningful.

- **UT Exception Type Inclusions**: One or more Usage Transaction exception types that indicate user intervention for an IMD with a qualifying VEE exception. The process compares the IMD with Usage Transactions for its Usage Subscription whose periods overlap the IMD period. A qualifying exception is interpreted as evidence of user action to resolve the IMD's data quality issue. When the list is populated, any matching exception counts regardless of severity. When empty, any non-informational Usage Transaction exception counts. Include only exception types that represent data quality issues so that comparisons between ML results and inferred user actions remain meaningful.

See About VEE and Understanding Exception Types for more information.

Configure Statistics Control

Configure a Statistic Control for each ML model to be tested based on the ML Historical Verification Control (D1-MLVerificationControl) business object. Snapshots created based on this statistics control compare the results from ML scoring with the previous VEE results, identifying when they agreed/disagreed. The process attempts to include user actions performed on VEE exceptions to determine if VEE exceptions were true issues or false positives.

These statistic controls are defined by the following:

- **Retention Mode**: Defines how to retain data for snapshots created from this statistic control
- **Snapshot Start Date**: The date on which snapshots created from this statistic control start.
  - **Interval Scalar**: A flag that indicates whether Interval or Scalar data is to be evaluated. Together with **Measurement Frequency** and **Service Type**, this helps define eligible measuring-component types.
  - **Measurement Frequency**: The size of the intervals measured by the measuring component, represented as hours:minutes:seconds (00:00:00). Together with **Interval Scalar** and **Service Type**, this helps define eligible measuring-component types.
    - **For interval data**: This is the interval size.
    - **For scalar data**: This should align with the expected hours between measurements defined on the scalar measuring component type (such as 24:00:00 for daily, 08:00:00 for 3 times per day).
  - **Service Type**: The Service Type for the measurement data being evaluated (such as Electric, Gas, and so on). Together with **Interval Scalar** and **Measurement Frequency**, this helps define eligible measuring-component types.
- **ML Threshold Override**: Use to override the **Anomaly Score Threshold** on the Master Configuration if applicable. This is not used with this historical evaluations.
- **Snapshot Business Object**: The business object to use when creating snapshots based on this statistic control. This should be ML Verification Statistics (D1-MLVerificationStatistics)

Configure SGG ML Payload Processing

Configure ML payload processing as described in Configure Payload Processing Extendable Lookups in Configuring Machine Learning Anomaly Scoring to process results returned from the ML model.

Running Historical Evaluations

Running historical evaluations involves the following:

Copyright © 2026, Oracle and/or its affiliates.

Create Historical Evaluation IMDs

Run the following batch processes in sequence to create "historical validation" initial measurement data that can be used for evaluation by running the following batch processes in sequence:

- Generate ML Historical Verification IMDs (`D1-GMLVI`) to select and create IMDs for evaluation. The IMDs are placed in the Waiting for ML state.
- Extract ML Historical Validation IMDs (`D1-EXHVI`) to export the selected IMDs for ML scoring.

Historical Verification IMDs:

- Are created only from "initial load" initial measurements,
- Duplicate the preVEE data which is sent to ML,
- Duplicate the VEE exceptions for statitsics computation
- Link to the original IMD for traceability

ML Processing

The machine learning model scores the data and sends the results to an object storage location (similar to the process used with Machine Learning Anomaly Scoring

Run ML Payload Processing and Analysis

Once the ML scoring results have been returned to object storage, run the following processes in sequence to process the payloads and capture information about the evaluation:

- SGG ML Payload Processing Monitor Template (`D1-PLMLP`) to process the returned ML results.
- IMD Monitor - Waiting for ML IMDs (`D1-IMDML`) to capture evaluation information and move the IMDs to the Analysis in Progress state.

Capture Statistics

Open the Historical Statistics Control, and click **Capture**. When the dialog opens, enter the **Start Date** and the **Number of Days** to process and click **OK**. This creates a historical ML Verification Statistics Snapshot for each requested day using the statistics control's **ML Threshold Override** or the **Anomaly Score Threshold** defined on the MDM Master Configuration.

Process ML Historical Statistics Snapshots

Run the ML Verification Statistic Snapshot Monitor (D1MLVSSM) batch process to calculate daily ML Verification Statistics Snapshots. The process selects ML Historical Validation IMDs based on service type, interval/scalar mode, and frequency, then stores ML, VEE, user comparisons and anomaly-score distributions for dashboard analysis.

Re-evaluating Historical Results

You can make changes to the Consumption Extract Type or Statistics Control to fine tine the results and identify what works best for your implementation.

If you change the VEE Exception Type or Usage Transaction Exception Type configuration in the Consumption Extract Type:

- Run the Transition ML Historical Validation IMDs (`D1-TMHVI`) batch with the Transition Condition parameter set to `"D1RC"`

Copyright © 2026, Oracle and/or its affiliates.

- Run the ML Verification Statistic Snapshot Monitor (D1MLVSSM) batch process again and review the updated results.

If you only change the **ML Threshold Override** on the Statistic Control:

- Perform the **Capture** action again
- Run the ML Verification Statistic Snapshot Monitor (D1MLVSSM) batch process again and review the updated results.

This process can be run in stages:

- Stage1: ML scoring, run once
- Stage 2: Capture statistical inputs, which involves running `D1-TMHVI`), generating new snapshots, and running `D1MLVSSM` to calculate statistics
- Stage 3: Anomaly score evaluation, which involved creating snapshots and running statistics collection to see how the statistics change and to identify the right threshold

Removing Historical Evaluation Data

After completing a historical evaluation, run Transition ML Historical Validation IMDs (`D1-TMHVI`) batch processing with the Transition Condition parameter set to "`D1CN`" to complete the IMDs and remove their IMD control records.

To remove historical evaluation IMDs that were created in error, run the Remove ML Historical Validation IMDs (`D1-RMHVI`). batch process.

> **Note**
>
> Removing historical evaluation data is not mandatory, but if historical verification is being run on large amounts of data over a long period of time removing periods where research is complete help ensures that performance of the various processes does not degrade.

Configuring and Running Ongoing Evaluations

You can use ongoing evaluation to collect comparative reporting statistics during normal ML anomaly scoring processing.

> **Note**
>
> It is not expected that historical and ongoing evaluations would be configured and active for the same time period. Ongoing is intended for tracking live production ML results, whereas historical evaluations are intended for data that has already been processed using VEE.

Configuring Ongoing Evaluation

Configuring ongoing evaluations involves the following:

Create ML VEE Exception Type

Define a VEE Exception Type using the ML Exception with Statistics business object (`D1-MLExceptionWithStats`). This specifies the VEE exception to be created when the machine learning anomaly score is higher than the **Anomaly Score Threshold** or when there was an

Copyright © 2026, Oracle and/or its affiliates.

error during the scoring process when used with ongoing evaluation. See MDM Master Configuration in Configuring Machine Learning Anomaly Scoring for more information.

> **Note**
>
> The ML Exception with Statistics business object (`D1-MLExceptionWithStats`) lifecycle delays capturing of statistics until after the production usage loading batch window so it can be done in off times during the day. The VEE exception itself is what is capturing the key inputs to the statistics calculations

Update MDM Master Configuration

Update the **Machine Learning Configuration** section of the MDM Master Configuration as follows:

- **Exception Type**: Specify the ML VEE Exception Type created for ML ongoing evaluation (above).
- **Anomaly Score Threshold**: The fallback threshold used when a threshold is not defined for the measuring component or measuring component type.

See MDM Master Configuration in Configuring Machine Learning Anomaly Scoring for more information.

Configure Consumption Extract

Configure a Consumption Extraction Type for each ML model to be tested based on the ML Historical Verification Extract Type (D1-MLVerificationExtractType) business object. Extracts created based on this type are used by the VEE Exception to capture the statistic inputs (such as which VEE exceptions to consider).

This should include the following attributes that define the model:

- **Interval Scalar**: A flag that indicates whether Interval or Scalar data is to be evaluated. Together with **Measurement Frequency** and **Service Type**, this helps define eligible measuring-component types.
- **Measurement Frequency**: The frequency at which measurements are captured by the measuring component, represented as hours:minutes:seconds (00:00:00). Together with **Interval Scalar** and **Service Type**, this helps define eligible measuring-component types.
  - **For interval data**: This is the interval size.
  - **For scalar data**: This should align with the expected hours between measurements defined on the scalar measuring component type (such as 24:00:00 for daily, 08:00:00 for 3 times per day).
- **Service Type**: The Service Type for the measurement data being evaluated (such as Electric, Gas, and so on). Together with **Interval Scalar** and **Measurement Frequency**, this helps define eligible measuring-component types.
- **Service Point Types**: One or more service point types and UOM/TOU/SQI combination eligible for ML verification. These combinations determine which historical measuring components are evaluated.
- **VEE Exception Type Inclusions**: One or more VEE exception types that represent consumption quality issues ML is expected to detect. When this list is populated, any matching exception qualifies the IMD as having a VEE detected issue, regardless of severity. When empty, any non-informational VEE exception qualifies. You should exclude

Copyright © 2026, Oracle and/or its affiliates.

conditions that ML cannot evaluate so as to ensure ML to VEE comparisons remain meaningful.

- **UT Exception Type Inclusions**: One or more Usage Transaction exception types that indicate user intervention for an IMD with a qualifying VEE exception. The process compares the IMD with Usage Transactions for its Usage Subscription whose periods overlap the IMD period. A qualifying exception is interpreted as evidence of user action to resolve the IMD's data quality issue. When the list is populated, any matching exception counts regardless of severity. When empty, any non-informational Usage Transaction exception counts. Include only exception types that represent data quality issues so that comparisons between ML results and inferred user actions remain meaningful.

See About VEE and Understanding Exception Types for more information.

Configure Statistics Control

Configure a Statistic Control for each ML model to be tested based on the ML Ongoing Verification Control (D1-MLOngoingVerificationCntrl) business object. This is similar to the statistics control created for historical evaluation, except that it uses the VEE exception as the source of the statistical inputs.

These statistic controls are defined by the following:

- **Snapshot Frequency Hours**: The frequency (in hours) at
- **Retention Mode**: Defines how to retain data for snapshots created from this statistic control
- **Interval Scalar**: A flag that indicates whether Interval or Scalar data is to be evaluated. Together with **Measurement Frequency** and **Service Type**, this helps define eligible measuring-component types.
- **Measurement Frequency**: The size of the intervals measured by the measuring component, represented as hours:minutes:seconds (00:00:00). Together with **Interval Scalar** and **Service Type**, this helps define eligible measuring-component types.
  - **For interval data**: This is the interval size.
  - **For scalar data**: This should align with the expected hours between measurements defined on the scalar measuring component type (such as 24:00:00 for daily, 08:00:00 for 3 times per day).\
- **Service Type**: The Service Type for the measurement data being evaluated (such as Electric, Gas, and so on). Together with **Interval Scalar** and **Measurement Frequency**, this helps define eligible measuring-component types.
- **Snapshot Business Object**: The business object to use when creating snapshots based on this statistic control. This should be ML Verification Statistics (D1-MLVerificationStatistics)

Configure SGG ML Payload Processing

Configure ML payload processing as described in Configure Payload Processing Extendable Lookups in Configuring Machine Learning Anomaly Scoring to process results returned from the ML model.

Running Ongoing Evaluation

Running ongoing evaluations involves the following:

Batch Processing

Schedule the following batch processes to run on a regular basis:

Copyright © 2026, Oracle and/or its affiliates.

-
- Payload Processing Monitor Template with Export (`D1-PLPSO`) to process incoming measurement data and sends it to ML for scoring.
- SGG ML Payload Processing Monitor Template (`D1-PLMLP`) to process the returned ML results
- Process IMD Control Stage Data (`D1-IMDCS`) to process records in the IMD Control table, including:
  - Running appropriate VEE processing based on the ML result for each IMD with measuring component ordering.
  - The results are either IMDs created in error, a header IMDs created for exceptions, or published measurements
  - This is when the VEE exception will be created for ML
- VEE Exception Monitor (`D2-VEEDF`) to transition all pending VEE exceptions and create the appropriate statistic characteristics against the IMD associated to the VEE exception
- Statistics Control Monitor (`F1-STATS`) to create snapshots that are available for review on the Meter ML and VEE Dashboard.

Reviewing Comparative Results

You can use the **Meter ML and VEE Dashboard** to:

- Review anomaly-score distributions.
- Select an anomaly score threshold that provides a manageable number of exceptions for investigation.
- Compare ML exceptions with VEE results.
- Investigate cases where ML identifies an exception that VEE does not identify.
- Drill into individual IMDs to assess whether the selected threshold identifies meaningful issues.

You access this portal by selecting **Main Menu**, then **Dashboards**, and then **Meter ML and VEE Dashboard**. This portal includes the following zones:

- **ML Meter Statistics Snapshots Header**: used to define filters for data analysis
- **ML and VEE Comparison Matrix**: Compares the results of VEE rules against ML model predictions based on the current ML threshold.
- **ML and User Comparison Matrix**: Compares the actions users have taken on IMDs with VEE exceptions against ML model predictions based on the current ML threshold.
- **VEE and User Comparison Matrix**: Compares the actions users have taken on IMDs with VEE exceptions against VEE results.
- **User Actions**: Displays the conclusions drawn from the user's actions
- **Anomaly Score Distribution**: Displays the count of IMDs for a given anomaly score range

Embedded help icons provide additional details for each zone.

Removing Unwanted Initial Measurements

Copyright © 2026, Oracle and/or its affiliates.

Over time, implementations can accumulate unnecessary non-final initial measurements which effectively become "stuck" in the system. Examples of these types of initial measurements include:

- Erroneously imported duplicate initial measurements
- Initial measurements that failed validation and were not corrected or replaced
- Initial measurements that triggered service issue monitors that remain unresolved

These initial measurements can also have related VEE Exceptions, To Do Entries, and Service Issue Monitors that remain "stuck" as well. This unnecessary data can impact overall system performance and should be reviewed and removed from time to time.

The Remove Unwanted Initial Measurements feature can be used to identify and close or delete these unwanted non-final initial measurements and any related VEE exceptions, To Do Entries and service issue monitors. This process is initiated by creating Request records which specify the parameters used to locate the non-final initial measurements to be removed. The request in turn initiates a batch process which identifies non-final measurements and related VEE Exceptions, To Do Entries, and/or Service Issue Monitors.

This functionality uses the following system objects:

Object Type	Object Name	Description
Request Type Business Object	Remove IMDs Request Type (D1-RemoveIMDsType)	Used to define types of initial measurements removal requests. The Remove IMDs Request (D1-RemoveIMDsRequest) request business object (see below) is defined as the "Related Transaction BO" for this business object, meaning that requests created for request types based on this business object use the Remove IMDs Request (D1-RemoveIMDsRequest) request business object.
Batch Control	Remove Non-Final IMDs (D1-RENFI)	Used to identify non-final measurements and related VEE exceptions, To Do Entries and/or Service Issue Monitors (Service Tasks).
Request Business Object	Remove IMDs Request (D1-RemoveIMDsRequest)	Used to create and process initial measurement removal requests.
Fact Business Object	Remove IMD Object Count (D1-RemoveIMDOjbectCount)	Used to capture details of the initial measurements and related objects to be removed.

Remove Unwanted Initial Measurements Request Types

Requests used to remove initial measurements are based on request types which specify the batch control used to identify and remove the initial measurements.

To create request types used with this feature:

1. Select Menu, **Admin**, **General**, **Request Type**, **Add**.

Copyright © 2026, Oracle and/or its affiliates.

2. Select "Remove IMDs Request Type" from the **Request Type Business Object** drop-down list, and click **OK**.
3. Enter the following:
    - **Request Type**: A code for the request type
    - **Description**: A description of the request type
    - **Batch Control**: Search for and select the batch control to be used for requests of this type. The default is Remove Non-Final IMDs (D1-RENFI), but implementations can create custom versions of this batch control.
4. Click **Save**.

Remove Unwanted Initial Measurements Requests

To create an initial measurement removal request:

1. Select **Menu**, **Tools**, **Request**, **Add**.
2. Select the appropriate request from the **Request Type** drop-down list and click **OK**.
3. Enter the **Submission Parameters** for the request. These include:
    - **Mode**: The mode in which the process will be run. Options include:
        - **Preview**: Returns a count of non-final initial measurements and related objects (VEE Exceptions, To Do Entries, and Service Issue Monitors)
        - **Close**: Transitions non-final initial measurements to the "Discarded" state and completes and/or closes related objects. Details regarding the data impacted by "Close" requests are captured and displayed in the **Object Log** zone.
        - **Delete**: Deletes non-final initial measurements any related objects. Details regarding the data impacted by "Delete" requests are captured and displayed in the **Object Log** zone.
    - **Thread Count**: The number of processing threads allocated to the process
    - **IMD Business Object**: Used to restrict the initial measurements processed to those of a specific business object
    - **IMD Status**:Used to restrict the initial measurements processed to those in a specific non-final state, including Pending, Held, Additional Mapping, Mapping Error, VEE Ready, Defer, Error, VEE Complete, Exception, or Force Complete
    - **IMD Create Date/Time From**: Required. The start date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time From** would be "01-01-2023 12:00 AM".
    - **IMD Create Date/Time To**: Required. The end date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time To** would be "01-31-2023 12:00 AM".
    - **Device Configuration**: Used to restrict the initial measurements processed to those related to a specific device configuration.
4. Click **Save**. The request will then open in the **Request** portal.
5. Click **Submit Batch** to process the request.

Initially requests are created in the "Pending" status. When the request is run (by clicking **Submit Batch**), a batch process based on the batch control defined on the request type is executed.

Copyright © 2026, Oracle and/or its affiliates.

- If the batch process errors, the request **Status** is set to the "Batch Error".
- If the batch process completes, the request **Status** is set to the "Completed".

Details of the process are captured in the **Submission Information** section, and the **Object Log** zone.

The **Submission Information** section includes:

- **Batch Submission**: Link to the batch job submission for the batch process. Click the link to navigate to the **Batch Job Submission** portal to view details of the batch process.
- **IMD SDE Extract Through Date/Time**: The date and time through which specialized data extracts have been performed for initial measurements impacted by the process.
- **End of Batch Date/Time**: The date and time when the batch process was completed.

The **Object Log** zone contains table with details regarding the initial measurements and related objects processed, including:

- **Object**: The type of object processed (Initial Measurement Data, Service Task, To Do Entry, or VEE Exception)
- **Specialized Data Extract Occurred**: An indicator as to whether or not ("Yes" or "No") occurred for initial measurement data
- **Count**: The number of objects processed.

Example:

Object	Specialized Data Extract Occurred	Count
Initial Measurement Data	No	434
Initial Measurement Data	Yes	134
Service Task		1
To Do Entry		425
VEE Exception		413

Batch Control

The Remove Non-Final IMDs (D1-RENFI) batch control identifies and closes or deletes unwanted initial measurements and their related objects. When run, this batch process creates a fact (using the Remove IMD Object Count (D1-RemoveIMDObjectCount) business object) that captures details regarding the batch process and the objects being removed during the process. These details are viewed in the **Object Log** zone in the **Request** portal.

Note that the Request ID is a required parameter for this batch control, meaning that this batch control cannot be run on its own. It can be only run from an initial measurement removal request.

Implementations can create specific versions of this batch control for use when removing specific types of data. For instance, an implementation could create a "Preview" version of this batch control, or a version used only with interval initial measurements.

Implementations can alter the processing of this batch control by creating alternate algorithms for each of the System Events used by this batch process. Refer to **Ad-hoc Processes** in the **Plug-in Driven Background Processes** section for more information.

Copyright © 2026, Oracle and/or its affiliates.

Recommendations and Warnings

- We recommend using the **Preview** mode to identify potential initial measurements for removal before processing a request in either the **Close** or **Delete** mode. This allows you to review and verify the data to be removed before closing or deleting it.
- We recommend that access to this feature be limited to system administrators and other power users. Access to this feature can be restricted via the Remove IMDs Request BOAS (D1-RMIMDREQBOAS) application service.

> **Warning**
>
> If used improperly, this feature can inadvertently remove valid operational data (such as initial measurements in "Pending" status awaiting VEE processing). There is no process for "undoing" the removal of initial measurements and related objects using this feature.

Understanding Interval Price Set Types

Interval price set types define properties belonging to a class of interval price sets.

Interval price set types are defined by the following:

- **Service Type**: The service type to which interval price sets and interval prices based on this type will be applied
- **Interval Size**: The size of the intervals for interval prices based on this type, represented as hours:minutes:seconds (HH:MI:SS).
- **UOM**: The unit of measure used to define interval price sets and interval prices based on this type
- **TOU**: The time of use period used to define interval price sets and interval prices based on this type
- **SQI**: The service quantity identifier used to define interval price sets and interval prices based on this type
- **Short-Hand Description**: A short-hand description used for interval price sets of this type

> **Note**
>
> Either a UOM or SQI **must** be defined when creating an interval price set type.

System Data

Interval Price Set Types are based on the following system data:

Data Type	Description
Maintenance Object	Measuring Component Type (D1-MCTYPE)
Business Object(s)	Interval Price Set Type (D1-IntervalPriceType)

Copyright © 2026, Oracle and/or its affiliates.

Defining Interval Price Set Types

You use the **Interval Price Set Type** portal to display and maintain interval price set types.

Refer to **Understanding Interval Price Set Types** for more information./

You can access the portal by selecting **Admin**, select **Interval Price Set**, then select **Interval Price Set Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Interval Price Set Type**: This zone displays basic information about interval price set type.

Understanding IMD Types

IMD Types are configuration records used to define how initial measurements are processed using Direct Measurement Processing.

There are two main categories of IMD types - seeder types (based on the Seeder IMD Type (D1-IMDSeederType) business object) and specific types (based on the Specific IMD Type (D1-IMDType) business object).

- **Seeder IMD types** represents an initial measurement data (IMD) seeder, which serves as the universal input into the system for external callers or for initial measurement payload processing. The main purpose of the seeder IMD type is to determine the most appropriate specific IMD type (such as interval or scalar, or a type used with a particular Smart Grid Gateway adapter) to use for further processing and prepare the input data for that IMD type. Additionally, the seeder IMD type is used to perform critical validation (such as an interval count validation), device and channel identification, mapping of external values (such as Unit of Measure and time zone) to internal values, and time zone conversion for date/time fields.

  Note: There can only be one seeder IMD type active at any one time.

- **Specific IMD types** define the rules for processing a specific initial measurement data (IMD) record. Different specific IMD types contain rules for processing the different types of initial measurement data that can be received. For example, one IMD type defines the rules for processing a scalar measurement from the Landys+Gyr head end system while another IMD Type instance defines the rules for processing an interval initial measurement from the Sensus head end system. There are four types of algorithms supported for specific IMD types: Pre Processing, Pre-VEE, VEE, and Post-VEE. These algorithms are responsible for validating that the measurement has been correctly mapped to the IMD Type (Pre Processing), calculating consumption (Pre-VEE), performing VEE (VEE), writing to the final measurement table (Post-VEE), among other responsibilities.

IMD Types are defined for specific measuring component types in the the "Initial Measurement Creation" processing method (“How to Create MC Related Information”) for each head end system. See Creating Head End Systems for more information.

IMD Types are defined by the following:

- **Initial Measurement Data Seeder**: A flag that indicates (Yes or No) if the IMD type represents a seeder IMD type. There can only be one active IMD type designated as a seeder IMD type at the same time. Seeder IMD types only use Pre-processing Algorithms (see below).

Copyright © 2026, Oracle and/or its affiliates.

- **IMD Business Object**: The business object to use when creating IMDs for the IMD type.
  - For seeder IMD types, this should be "IMD Seeder" (D1-IMDSeeder).
  - For non-seeder IMD types, this should be an initial load IMD business object such as "Initial Load IMD (Interval)" (D1-InitialLoadIMDInterval) or "Initial Load IMD (Scalar)" (D1-InitialLoadIMDScalar).
- **Status**: The status of the IMD type.
- **IMD Information Exception Header BO**: The bunsess to use when creating header records for "Information" exceptions. See VEE Processing and Exceptions with Direct Measurement Processing for more information.
- **Algorithms**: Algorithms used when processing initial measurement data for the IMD type, including:
  - Pre-processing Algorithms
  - Pre-VEE Algorithms
  - VEE Algorithms
  - Post-VEE Algorithms

System Data

IMD Types are based on the following system data:

Data Type	Description
Maintenance Object	Initial Measurement Data Type (D1-IMDTYPE)
Business Object(s)	Specific IMD Type (D1-IMDType)
	Seeder IMD Seeder Type (D1-IMDSeederType)

Base Package IMD Types

The base package includes several pre-defined IMD types that can be used when processing data from different head end systems supported through Smart Grid Gateway Adapters. These IMD types use vendor-specific initial measurement business objects and algorithms when processing data. The table below lists the IMD types provided with the base package.

IMD Type	Description
IMD Seeder Type (D1-IMDSEEDERTYPE)	Used as the seeder, which determines the appropriate specific IMD type to use and to prepare the input data for that IMD type
Interval IMD Type (D1-INT-IMDTYPE)	Used when processing interval data
Interval Passthrough IMD Type D1-INT-PT-IMDTYPE)	Used with "pass through" interval external measuring components to capture errors in pass through interval measurements
Scalar IMD Type (D1-SCA-IMDTYPE)	Used when processing scalar data
Scalar Passthrough IMD Type (D1-INT-SC-IMDTYPE)	Used with "pass through" scalar external measuring components to capture errors in pass through scalar measurements
Landis+Gyr - Interval IMD Type (D3-INT-IMDTYPE)	Used when processing interval data using the Landis+Gyr Adapter
Landis+Gyr - Scalar IMD Type (D3-SCA-IMDTYPE)	Used when processing scalar data using the Landis+Gyr Adapter
MV90 - Interval IMD Type (D5-INT-IMDTYPE)	Used when processing interval data using the MV90 Adapter

Copyright © 2026, Oracle and/or its affiliates.

MV90 - Scalar IMD Type (D5-SCA-IMDTYPE)	Used when processing scalar data using the MV90 Adapter
Sensus - Interval IMD Type (D6-INT-IMDTYPE)	Used when processing interval data using the Sensus Adapter
Sensus - Scalar IMD Type (D6-SCA-IMDTYPE)	Used when processing scalar data using the Sensus Adapter
SSN - Interval IMD Type (D7-INT-IMDTYPE)	Used when processing interval data using the Silver Spring Networks Adapter
SSN - Scalar IMD Type (D7-SCA-IMDTYPE)	Used when processing scalar data using the Silver Spring Networks Adapter
Itron - Interval IMD Type (D8-INT-IMDTYPE)	Used when processing interval data using the Itron Adapter
Itron - Scalar IMD Type (D8-SCA-IMDTYPE)	Used when processing scalar data using the Itron Adapter
ADK - Interval IMD Type (DG-INT-IMDTYPE)	Used when processing interval data using the Adapter Development Kit
ADK - Scalar IMD Type (DG-SCA-IMDTYPE)	Used when processing scalar data using the Adapter Development Kit

Changing and Extending Base Package IMD Types

The base package IMD types can be changed and/or extended by adding new algorithms to one or more of the algorithm areas (Pre-Processing, Pre-VEE, VEE, or Post-Vee).

When adding new algorithms to a base package IMD type, we recommend creating the algorithm logic in a Groovy Library Script that can be called from an IMD type algorithm as well as from an IMD business object algorithm. See Groovy Library Scripts for more information.

Configuring IMD Types

You use the **IMD Type** portal to display and maintain IMD types.

Refer to Understanding IMD Types for more information.

You can access the portal by selecting **Admin**, then **Device**, then **IMD Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **IMD Type List**: This zone lists all division records. Broadcast a record to display the details of the selected record.
- **IMD Type**: This zone provides information about the selected division.

Defining VEE Options

- Exception Types
- VEE Groups
- VEE Rules
- Measuring Component Statistics

Copyright © 2026, Oracle and/or its affiliates.

Exception Types

- Understanding Exception Types
- Configuring Exception Types

Understanding Exception Types

Exception Types define the groupings of exceptions for an IMD based on their functional similarity. This provides a way to define VEE Exceptions in a distinct enough way to understand the root issue that was generated from the VEE Rule.

For a deeper functional understanding of VEE, refer to the About VEE section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Exception Types

This portal is used to display and maintain an Exception Type.

Refer to Understanding Exception Types for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Exception Type List**: displays all of the Exception Types so you can choose the one you want to display in more detail
- **Exception Type**: shows the specific configuration for the selected Exception Type

There are two different options to use when creating an Exception Type:

Name	Details	Business Object
VEE Exception	This will create a "normal" VEE Exception that is attached to an IMD for tracking of conditions triggered in the VEE process.	D1-VEEException
VEE Exception - Monitor Service Point	In addition to tracking the failure in the VEE process, this VEE Exception generates a Service Issue Monitor. This allows for cumulative tracking of VEE Exceptions that can be configured to result in a Service Investigative Order (field work) for the Service Point.	D2-VEEExceptionServiceMonitor

VEE Groups

- Understanding VEE Groups
- Configuring VEE Groups

Copyright © 2026, Oracle and/or its affiliates.

Understanding VEE Groups

VEE groups are collections of VEE Rules that are applied to initial measurement data. During the VEE process, the system executes the VEE Rules defined in each VEE group. The rules within a VEE group are defined in a specific sequence, allowing control over the order in which the rules are executed.

VEE groups can be associated to a specific measuring component, or to a measuring component type (or both). VEE groups associated with a measuring component type are applied to all measuring components of that type, while those associated to a specific measuring component are applied only to that measuring component. VEE groups associated to a measuring component override those assigned to a measuring component type.

VEE groups can also be referenced by the Execute VEE Group VEE Rule.

For a deeper functional understanding of VEE, refer to the About VEE section of the *Oracle Utilities Meter Solution Business User Guide*.

Post-ML VEE Groups

When using Machine Learning Anomaly Scoring, you can define a VEE Group that is executed after the machine learning processing. These are used to execute rules that compare or adjust the measurement values based on a related measuring component. These groups are referred to as "Post-ML" VEE groups, and are defined for the "Post-ML" VEE Role on measuring component types and measuring components.

Post-ML VEE Groups can only include the following VEE Rules configured for Post-ML:

- Sum Check
- Interval Adjustment From Scalar
- Scalar Calculation from Interval
- Final Measurement Replacement

> **Note**
>
> Post ML VEE Groups can NOT reference Execute VEE Group or VEE Group Matrix rules.

Configuring VEE Groups

This portal is used to display and maintain a VEE Group.

Refer to Understanding VEE Groups for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **VEE Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Group**: Defines basic information about VEE group
- **VEE Rules List**: lists the VEE Rules belonging to the group

Copyright © 2026, Oracle and/or its affiliates.

- **Referencing VEE Rules List**: lists the VEE Rules that reference the group
- **Referencing VEE Group Factors List**: lists the VEE group factors that reference the group
- **Referencing Measuring Component Type List**: lists the measuring component types that reference the group
- **Referencing Measuring Component List**: lists the measuring components that reference the group

VEE Rules

- Understanding VEE Rules
- Configuring VEE Rules

Understanding VEE Rules

VEE Rules are standard and custom Validation and Estimation rules that perform checking and/or manipulation of initial measurement data. VEE Rules are created for a specific VEE group. For example, if you were configuring two VEE groups and both included a specific VEE Rule, you would need to create two instances of the VEE Rule, one for each group.

The specific validation and estimation processing performed on initial measurement data is defined in individual VEE Rules, each performing a specific set of targeted logic. The base product contains many VEE Rules you can use in your implementation, but you can also create your own custom VEE Rules.

Some VEE Rules generate VEE Exceptions if the initial measurement data fails the conditions specified for the rule. Other rules override measurements, changing measurement values as dictated by the rule's parameters. Some rules can both create exceptions and override the measurement as part of a single process. By convention, VEE Rules change the Post-VEE quantities of initial measurement data, but VEE Rules can change anything on an initial measurement.

Every VEE Rule has an effective period. Rules will only be applied if the initial measurement's start date is within the rule's effective period. For example, an Interval Spike Check rule with a Start Date of 11/15/2010 will only be applied if the start date of the initial measurement is on or after 11/15/2010.

This allows you to update the specifics of a rule without removing the previous version of the rule. For example, you might change the tolerance of an Interval Spike Check rule from 1.2 to 1.5 as of a certain date. However, for initial measurement data for the period prior to the change, you would want to use the tolerance for the original version of the rule (1.2) instead of the new tolerance (1.5).

On almost every VEE Rule, the failure of the rule results in a VEE Exception and the Exception Type for the failure can be configured on the rule. These Exception Types can also be set to a specific Exception Severity:

- **Information**: Used to highlight minor issues, but not sufficient to cause the initial measurement data to be put into the exception state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues**: Used to report a problem that will prevent the initial measurement data from being finalized. Multiple "issue exceptions" can be created during VEE processing. If at least one

Copyright © 2026, Oracle and/or its affiliates.

issue exists after all rules have been applied, the initial measurement data is transitioned to the exception state

- **Terminate**: Used to report a severe issue that will cause the VEE process to stop and the initial measurement data to be transitioned immediately to the exception state. Only one terminate exception can be issued (as the first one causes VEE processing to stop on an initial measurement data).

For a deeper functional understanding of VEE, refer to the About VEE section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Rules

This portal is used to display and maintain a VEE Rule. Also, a list of the specific out-of-the-box rules is included below the instructions for using the portal.

Refer to Understanding VEE Rules, Understanding VEE Groups, and Understanding Exception Types for more information. For a deeper functional understanding of VEE, refer to the About VEE section of the *Oracle Utilities Meter Solution Business User Guide*.

You can access the portal by selecting **Admin**, then **VEE**, then VEE Rule. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Rule**: this zone displays all of the configuration items specific to this instance of a VEE Rule.
  - Click **Show All Rules** to open the **VEE Rules** List zone, which lists all of the VEE rules in the VEE group to which the current rule belongs.
- **Eligibility Criteria List**: this zone displays any VEE Rule Eligibility Criteria that have been setup. These eligibility criteria determine conditionally whether the VEE Rule should be executed or not. Use the Add button to create a new eligibility criteria for the rule you're viewing.

Validation VEE Rules

Below is a list of the validation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Consecutive Interval Check	Interval	This validation rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data.
Duplicate IMD Check	Interval or Scalar	This rule allows for a duplicate IMD to be flagged.

Copyright © 2026, Oracle and/or its affiliates.

Dynamic Comparison Validation	Interval or Scalar	This powerful, flexible validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Then you define formulas (no programming required) for the comparison of current measurements to these statistics.
Ensure IMD Exists for Sibling MCs	Interval or Scalar	This rule validates that an IMD exists for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.
Final Measurement Replacement	Interval or Scalar	This validation rule allows you to define a variety of configuration options to decide if new data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking.
High/Low Check	Interval or Scalar	This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.
Inactive Measurement Check	Interval or Scalar	This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a Usage Subscription.
Interval Size Validation	Interval	This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.
Interval Spike Check	Interval	This rule checks for spikes within an IMD and generates an exception if one is found.

Copyright © 2026, Oracle and/or its affiliates.

Multiplier Check	Interval or Scalar	This rule validates that the register multiplier supplied with the IMD is equal to the multiplier stored on the measuring component. If not, an exception is created using the register multiplier exception type and severity configured on the rule.
Negative Consumption Check	Interval or Scalar	This rule flags any IMD where the total consumption is negative.
Prolonged Estimation Check	Interval or Scalar	This validation rule creates an alert when a device has been estimated for an extended period of time.
Raise Missing Quantity Exception	Interval	This rule flags any missing interval data.
Sum Check	Interval or Scalar	This rule is used to compare the difference between interval data to scalar data for a period of time, or between a set of TOU scalar reads to a "Sum" scalar reading.
Unit of Measure Check	Interval or Scalar	This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.
Zero Consumption Check	Interval or Scalar	This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid exceptions in that case.

Estimation VEE Rules

Below is a list of the estimation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Interval Adjustment From Scalar	Interval	This rule performs adjustments to interval values based on the values from the associated scalar data on the same device.

Copyright © 2026, Oracle and/or its affiliates.

Interval Averaging Estimation	Interval	This rule finds historical interval data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.
Interval Create Estimation IMD for Gap	Interval	This estimation rule creates a new Estimation IMD to fill gaps between the interval data received from the Head End. ***Note:*** *this estimation rule acts differently from the other rules as it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.*
Interval Interpolation Estimation	Interval	This rule attempts to interpolate gaps within an IMD using prior and subsequent intervals as starting points for linear interpolation.
Interval Profile Estimation	Interval	This rule estimates any missing interval data for the IMD based on a referenced Profile Factor.
Interval Proxy Day Estimation	Interval	This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement.
Scalar Calculation From Interval	Scalar	This rule performs adjustments to scalar values based on the values from the associated interval data on the same device.
Scalar Estimation	Scalar	This rule finds historical scalar data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.
Scalar Profile Estimation	Scalar	This rule estimates any missing scalar data for the IMD based on a referenced Profile Factor.
Scalar Proration	Scalar	This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries. It will also take into account any related interval data within the same period to exclude from the calculation.

Copyright © 2026, Oracle and/or its affiliates.

Subtractive Interval Adjustment Rule	Subtractive Interval Adjustment Rule	This rule performs adjustments to qualifying interval consumption values for subtractive interval measuring components based on an adjustment target calculated using a start and stop reading for the period that encapsulates the intervals to adjust.

Decision-Making VEE Rules

There are VEE Rules delivered as part of the base product that help with decision-making when executing VEE (listed below). For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Purpose
Exception Handler	This rule allows for termination of the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.
Execute VEE Group	This rule performs a call to execute a separate VEE Group which includes execution of all VEE Rules within that group.
Successful Termination	This rule allows VEE to be successfully terminated based on a list of exceptions.
VEE Group Matrix (Factor)	This rule provides a way to choose different instances of a VEE Rule using a Factor. This factor leverages characteristics that are defined on Service Point, Device, or Measuring Component.

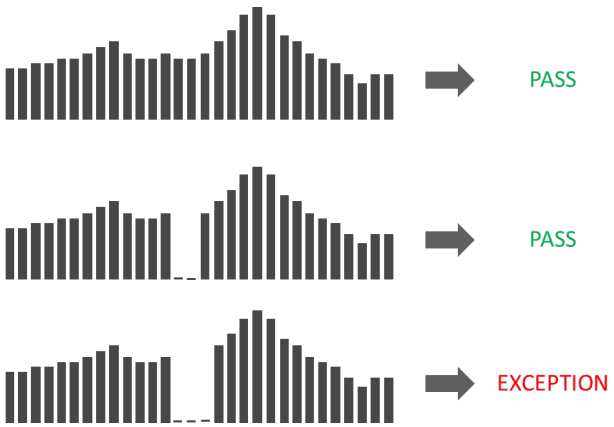
Consecutive Interval Check

Overview

This rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data. It can be used to find faulty meters that are reporting consecutive outage codes, zero measurements, or negative values. It can also be used by water utilities to identify leaks based on the interval never reaching zero.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CONSINTRV Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

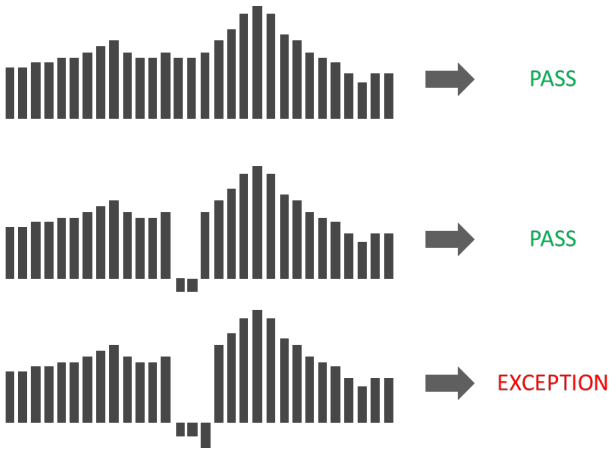


D2-ConsecutiveIntervalCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Rule configured to fail for zero values



Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 2: Rule configured to fail for negative values

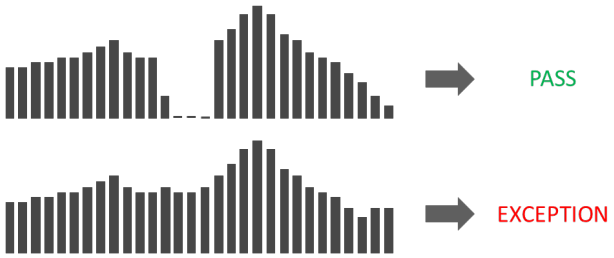
Copyright © 2026, Oracle and/or its affiliates.

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Less Than
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 3: Rule configured to fail for missing condition codes

Parameter Name	Configuration Value
Check performed	Consecutive Condition Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	
Value for Comparison	
Bottom Range Condition	Missing
Top Range Condition	Missing

Scenario 4: Rule configured to fail for outage condition codes only if its zero



Parameter Name	Configuration Value
Check performed	Both
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	Outage
Top Range Condition	Outage

Scenario 5: Rule configured to fail if a long period of consecutive water values are greater than 0.1

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	20:00:00
Look To Prior Measurements When First Interval Matches Criteria	No
Equation Type	Greater Than
Value for Comparison	0.1
Bottom Range Condition	
Top Range Condition	

Scenario 6: Look back at prior measurements when the first interval matches criteria

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	Yes
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Duplicate IMD Check

If the current Initial Measurement Data (IMD) being validated is determined to be a duplicate of an existing IMD for the same measuring component, this rule will produce a VEE exception of the type and severity configured on the VEE Rule. The algorithm logic looks for duplicate IMDs using the following criteria:

- associated to the same measuring component as the current IMD
- utilizes the same IMD business object as the current IMD (for example, Initial Load Scalar)
- references the same To Date/Time (ends on the same date) as the current IMD
- exists in a "Finalized" state
- the contents of pre-VEE are identical to the pre-VEE of the current IMD

If any IMDs are found that meet all of the above criteria, the current IMD is deemed to be a duplicate.

> **Note**
>

D1-DuplicateIMDCheck

Dynamic Comparison Validation

This validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Setting up these Measuring Component Statistics is a prerequisite to using the rule.

Users can define formulas (no programming required) for the comparison of current measurements to these statistics. This is powerful rule will allow utilities to look for unusual usage patterns. For example:

- Lowest/highest usage ever
- Current usage is more than three standard deviations from the mean
- Detect unexpected zero usage
- Detect negative usage while ruling out known cases
- Abnormal usage
- Voltage threshold monitoring
-

Final Measurement Replacement

This validation rule allows you to define a variety of configuration options to decide if new scalar or interval data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking. One common use for this rule is rejecting trivial measurement changes to prevent very small changes for a bill from being sent to a customer.

Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

High/Low Check

This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.

Numerous configuration options are provided including:

- A Historical Pre-Window and Post-Window that determines the number of days to check before and after the period being examined.
- Percentages to control how much of the historical data can be user edited, estimated, or non-normal data.
- What type of historical data to look at first
- What to do when an outage has occurred

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-HILO-CHK Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-VEERuleHighLowCheck

Inactive Measurement Check

This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a usage subscription.

Copyright © 2026, Oracle and/or its affiliates.

- When the 'Check Measurements on Disconnected Device' flag is set to "Yes", the logic will compare the IMD measurements total to the threshold configured. If the total measurements are above the threshold, then logic compares the IMD dates to two things: 1) On/Off Dates related to the Install Event and 2) the Installation and Removal Dates of the Install Event. If the On or Off falls within the dates for an interval IMD, then the logic will only sum intervals that fall during the disconnected periods.
- When the 'Check for Uninstalled Device' flag is set to "Yes", the logic will check for a valid Install Event based on the IMD dates.
- When the 'Check for Missing Usage Subscription' flag is set to "Yes", the logic will check for an active Usage Subscription based on the IMD dates.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INACTVCHK Algorithm Type.

Example 3: Data received when device has no Install Event records

Example 4: Data received when not connected to a Usage Subscription record

Interval Size Validation

Copyright © 2026, Oracle and/or its affiliates.

This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSIZVAL Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSizeValidation

Interval Spike Check

This rule looks for spikes by taking the highest interval and the third-highest interval, and determining the percent difference between the two. If the percent difference is larger than the tolerance configured on the rule, the algorithm logs an exception of the type and severity configured on the rule.

The rule can be executed in one of two modes (as configured on the rule):

- The spike check is performed for every 24-hour chunk of data in the initial measurement data set
- The spike check is performed for the entire initial measurement data set

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSPKCHK Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D2-RegisterMultiplierCheck

Negative Consumption Check

This rule checks if the total consumption of the initial measurement is less than zero. If the rule encounters negative consumption, an exception will be logged if the related Measuring Component Type is not configured to "allow negative consumption", or if the Override MC Type Allow Negative Consumption flag on the rule is set to “Yes”.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-NCON-CHK Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-NegativeConsumptionCheck

Prolonged Estimation Check

This validation rule can be used on either interval or scalar and will alert you when a device has been estimated for an extended period of time. The IMD must first fall within the condition code range configured on the rule for this to execute. Next the validation finds the 'Most Recent Non-Estimated Read Date Time' from the Measurement Component. If this date plus the 'Days of Estimation Allowable' from the VEE Rule is less than the IMD End Date then a Prolonged Estimation Exception is created.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-PROESTCHK Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D2-ProlongedEstimationCheck

Example Scenario

Below is an example scenario that can be achieved based on configuration of this rule.

Raise Missing Quantity Exception

This rule flags any missing interval data while providing a soft parameter on the algorithm to exclude a condition range if desired.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RAIMISQTY Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RaiseMissingQuantityExcp

Sum Check

This rule evaluates whether consumption for the current Initial Measurement Data is within a tolerance of the sum of the consumption during the same period for any measuring components related to the current one. If the values are not within the defined tolerance of each other, and exception is logged.

Copyright © 2026, Oracle and/or its affiliates.

The rule can be used to evaluate consumption totals for an interval measuring component that has a related scalar measuring component with the same UOM to ensure that the total consumption of the interval measuring component is within a tolerance of that of the scalar value. It can also be used to evaluate consumption totals for scalar TOU meters that have a "check" register (for example, three registers that measure ON-PEAK, OFF-PEAK, and SHOULDER, with a fourth check register that measures the total consumption).

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUM-CHK Algorithm Type.

Estimation VEE Rules

- Interval Adjustment From Scalar
- Interval Averaging Estimation
- Interval Create Estimation IMD for Gap
- Interval Interpolation Estimation
- Interval Profile Estimation
- Interval Proxy Day Estimation
- Scalar Calculation From Interval
- Scalar Estimation
- Scalar Profile Estimation
- Scalar Proration
- Subtractive Interval Adjustment Rule

Interval Adjustment From Scalar

This rule adjusts interval Initial Measurement Data based on scalar values using one of two options configured on the VEE Rule. Both options require that a scalar measuring component be related to the current interval measuring component using the Consumption Reference Measuring Component, and that one or more final measurements be present for the related measuring component between the start and end date/times of the current Initial Measurement Data set.

1. Adjust all intervals. In this case, the scalar consumption provides a value that is then used to proportionally adjust all of the intervals in the set. The formula used is (Scalar Consumption / Total Initial Measurement Consumption) * Interval Amount. If the total of all of the intervals had been equal to zero originally, the rule adjusts all of the intervals to the same value.
2. Adjust intervals based on condition. For this option, a range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range. The adjustment is done by applying an adjustment factor to each of the intervals within range.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTADJSCA Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAdjustmentFrmScalar

Copyright © 2026, Oracle and/or its affiliates.

Interval Averaging Estimation

The algorithm estimates when the current Measuring Component is eligible. Estimation is performed only if all these conditions are satisfied:

- The Measuring Component is interval.
- The Measuring Component is linked to a Service Point or the VEE Rule's Estimate If Not Attached to SP field is set to "Estimate".
- The Percentage of Missing Intervals is less than the VEE Rule's Maximum Percentage Missing Intervals Threshold.

The algorithm will compute the Total Accumulated Consumption and the Total Number of Intervals using a variety of methods including scanning holidays, similar days of the week, or neighboring days. Once a set of valid comparison days are found then these are used as the basis of creating estimated intervals for the current IMD.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTAVGEST Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAveragingEstimation

Interval Create Estimation IMD for Gap

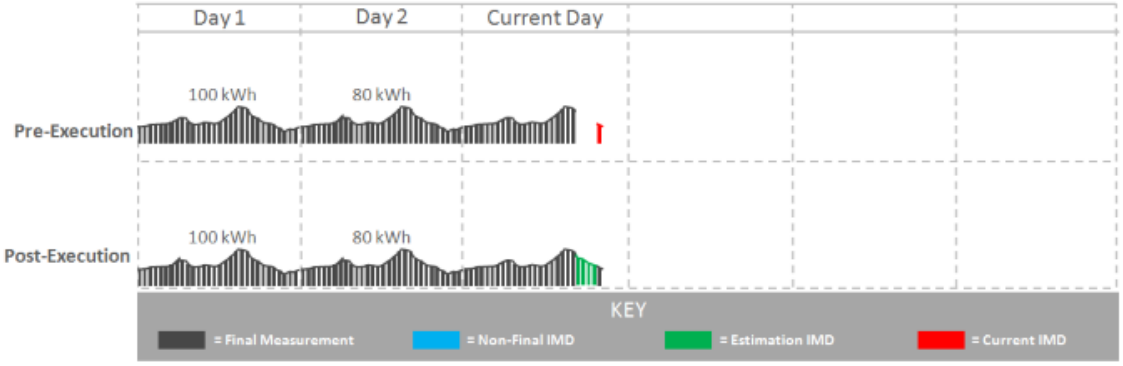
This rule is very different from other VEE rules in that it does not examine the current initial measurement but rather looks to see if there are any missing measurements prior to the initial measurement being processed (i.e. a gap exists). If so and the scenario meets the configured options it will generate an estimation initial measurement to fill in that gap.

This rule is intended to provide more real-time filling of missing measurements as opposed to running periodic estimation. However, it is still expected that periodic estimation will be used in conjunction with this rule such that any gaps that are not filled in by this rule would eventually be filled in by periodic estimation.

This rule can be configured to perform minimal validation of that gap that is identified and defer to the estimation initial measurement to validate against other initial measurements and final measurements that may overlap the gap. Conversely, it can also be configured to validate the gap and exclude any periods where a final measurement or in progress initial measurement overlaps the gap's duration.

Copyright © 2026, Oracle and/or its affiliates.

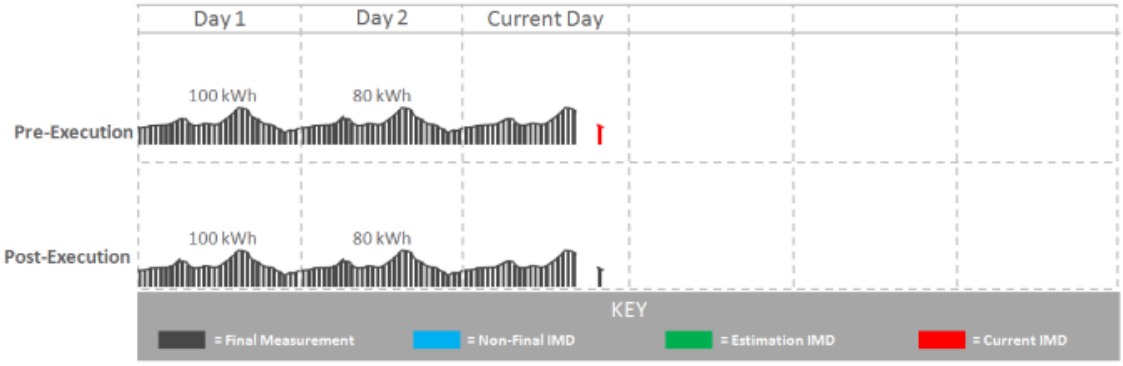
> **Note**
>
> This estimation rule acts differently from the other rules - it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CREESTIMD Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.



Business Object

D2-CreateEstimationIMDRule

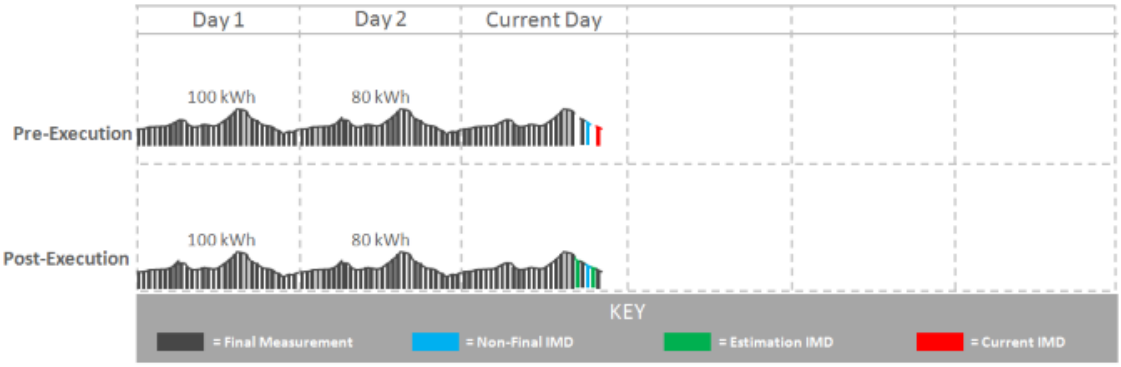
Example Scenarios



The following are sample scenarios that can be achieved based on configuration of this rule.

Example 1: A 4-hour gap exists and the rule is configured to always fill gaps. Maximum hours are set to 4 and the gap fill is set to "always".

Since the maximum hours has not been exceeded and the rule is configured to always fill the gap, a 4-hour estimation IMD is created to fill the gap.



Example 2: A 4-hour gap exists and the rule is configured to always fill gaps. However, the maximum number of hours to fill is 3.

Since the gap is 4 hours long and the maximum hours to gap fill is 3 hours, no estimation has been created. An exception would be created if the rule were configured this way.

Copyright © 2026, Oracle and/or its affiliates.

Example 3: A non-contiguous gap exists and the rule is configured to "Skip In-Progress IMDs and Final Measurements" with a maximum number of IMDs set to 2.

In this scenario:

- One interval in the 4-hour gap is covered by a final measurement.
- One interval in the 4-hour gap is covered by an in-progress IMD.
- Two estimation IMDs are generated one to fill each hour not covered by a final measurement or in-progress IMD.

Interval Interpolation Estimation

This rule attempts to interpolate gaps in Initial Measurement Data sets using prior and subsequent intervals as starting points for linear interpolation. A configuration parameter determines the maximum number of consecutive intervals within a gap before that gap can no longer be interpolated.

If a given gap lies at the beginning or end of the Initial Measurement Data set, this algorithm seeks out final measurements immediately before or after the set in an attempt to find two reference measurement values for interpolation. In this situation, assuming that the condition of the measurement retrieved lies in NEITHER of the algorithm parameter ranges you have configured (the measurement is neither "missing" nor an "outage"), this measurement value is then used as the basis for interpolation.

In the event that the gap is the entire length of the Initial Measurement Data set (and the VEE Rule is configured such that this is not too large of a gap), the routine attempts to find final measurements as described above.

If a valid measurement can be found for only one side of a given gap, the interpolation logic assigns each interval in the gap the same value - the value of the measurement retrieved. This is referred to as applying a "flat load".

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTINTEST Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

Copyright © 2026, Oracle and/or its affiliates.

D2-IntervalInterpolationEst

Interval Profile Estimation

This rule uses a profile measuring component's interval consumption as a source of values to assign to intervals in the current Initial Measurement Data set that are marked "missing" via the interval's condition. If the interval is marked with a condition indicating "outage", the algorithm skips it.

If a measurement is not available for the profile measuring component on the date/time, the interval is left unchanged.

>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProfileEstimation

Interval Proxy Day Estimation

This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement. Measuring component comparison periods are used as the main driver for determining similar temperature days.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTPROXY Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProxyDayEstimation

Scalar Calculation From Interval

This rule calculates a single consumption amount for a scalar measuring component's Initial Measurement using the total consumption for the same date/time range for a related interval measuring component.

The scalar value replaces any existing value within the Initial Measurement (in the post-VEE list) and updates the condition to the value configured on the VEE Rule. This VEE Rule

Copyright © 2026, Oracle and/or its affiliates.

updates the condition to the value defined in "Condition Value for High Quality Condition" when the measurement condition value for all underlying interval data and the previous scalar measurement (when Evaluate Condition Of Previous Scalar Measurement is configured as "Yes") is greater than or equal to the "Minimum Condition Quality to Override" (If "Minimum Condition Quality to Override" is defined) otherwise it updates the measurement condition of the Initial Measurement Data to the condition defined in "IMD Created Condition Value".

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCACALINT Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarCalcFromInterval

Scalar Estimation

This rule uses historical data for the same measuring component to derive an estimated value for a scalar Initial Measurement. Depending upon a VEE Rule configuration parameter, the routine uses historical data from a month ago followed by a year ago, or vice-versa. If the data for the first historical period turns out to be usable, the second historical period will not be evaluated. Whether historical data qualifies for use in estimation is configured via the rule parameters in conjunction with the below algorithm parameters.

The rule rejects consumption from a historical period as unusable for estimation if too great a portion of the period is covered by final measurements that are not high-quality. The first pair of parameter values are used when evaluating the acceptable System-Estimated Percentage for historical periods as configured on the VEE Rule. Once an estimated value is calculated, the routine backs into a reading (which involves backing out multipliers and, if the measuring component is subtractive, adding the result to the prior reading).

An interim High/Low can also be configured on this rule.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCALAREST Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarEstimation

Scalar Profile Estimation

Copyright © 2026, Oracle and/or its affiliates.

This VEE rule arrives at a scalar estimate by looking at final measurements for a profile measuring component covering the same date range as the current Initial Measurement. The profile measuring component to be used as a source of measurement data is defined via a profile factor on the rule. This rule is meant primarily for a configuration in which the profile measuring components are interval, although the profile could be scalar as well.

If a measurement already exists in the current Initial Measurement with a condition that lies within the ranges specified in the pairs of algorithm parameters for "system estimate" and "regular", the routine does not attempt to estimate.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCAPROEST Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarProfileEstimation

Scalar Proration

This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries.

If the scalar MC does have a related interval MC and 'Minimum Related Measurement Condition' is defined the algorithm will take into consideration any intervals during the proration period that meet a minimum condition quality defined by the 'Minimum Related Measurement Condition' when performing the proration. This is to keep the prorated scalar estimates in sync with any existing interval measurements. To do this the algorithm will augment the total duration and total quantity being prorated by the related interval MC's qualifying measurements. For example, take the following scenario:

- Scalar proration is executing for a scalar IMD for 01/01 12:00 AM - 01/02 12:00 AM (24 hours)
- The subsequent measurement is for 150 kWh and has a measurement date/time of 01/04 12:00 AM (72 hours)
- The related interval MC has measurements on 01/03 12:00 AM to 01/04 12:00 AM totally 100 kWh (24 hours)

Therefore the result of the calculation for the scalar IMD from 01/01 12:00 AM to 01/02 12:00 AM would be 25 kWh. Since the interval measurements covered 24 of the 72 total hours of the 150 kWh that would leave 50 kWh to be split among the remaining 48 hours. Which leaves 25 kWh for 01/01 12:00 AM to 01/02 12:00 AM and 25 kWh for 01/02 12:00 AM to 01/03 12:00 AM.

Business Object

D2-ScalarProration

Subtractive Interval Adjustment Rule

This rule adjusts qualifying consecutive intervals for a subtractive interval initial measurement (IMD) based on the known consumption between a set of actual readings. The readings can either be leveraged from other intervals within the IMD or from the final measurements when there are no suitable readings within the IMD. The adjustment is done by applying an adjustment factor to each of the qualifying intervals.

The rule supports adjusting multiple sets of qualifying consecutive intervals by calculating a consumption adjustment target and adjustment factor specific to each set of consecutive qualifying intervals.

Intervals are considered to be qualified for adjustment based on condition. A range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range.

D1-VEERuleExceptionHandler

Execute VEE Group

Many implementations need to execute a group of validations for any data being received. For example, you might want to perform device identifier validations, multiplier checks, and UOM checks on all measuring components. One inefficient way to meet this requirement would be to repeat these three rules in multiple VEE groups. However, this solution becomes hard to maintain if changes to the rules are required (or if new "global rules" are introduced) as each group would have to be updated. Instead of this, you can use the "Execute VEE Group" rule to execute a referenced VEE Group. Using the example above, you could create a group called "Rules for All MCs" that contains a device identifier validations rule, a multiplier check rule, and a UOM check rule, and then reference the "Rules for All MCs" group in a Execute VEE Group rule.

VEE Group Matrix (Factor)

Another situation likely to occur in many implementations is where specific rules may need to be applied to measurement data based on specific criteria, such as geography. For example, some geographic territories may have unique VEE Rules in addition to rules that are applied to all geographic territories. The "VEE Group Matrix (Factor)" rule allows for a Factor to determine which VEE Rule gets executed based on defined characteristics.

>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleGroupFactor

Prerequisite Setup

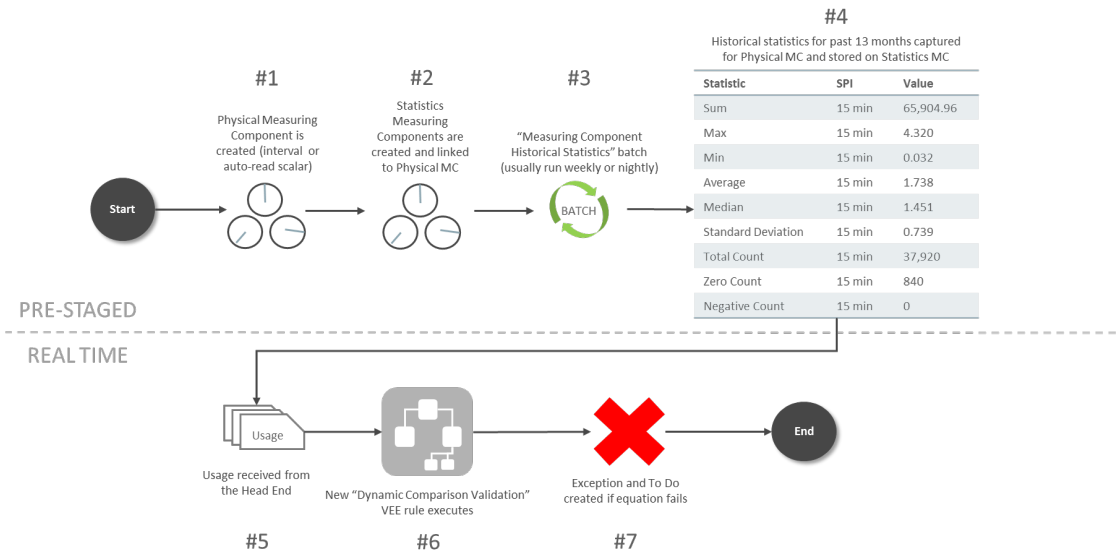
Since the prerequisite setup items for this rule are more involved, the following procedure describes these in detail:

1. Create the Characteristic Type and Values to be used by the factor that will be referenced by the rule.
2. Create the Characteristic Source Algorithm to be used by the factor that will be referenced by the rule.
3. Create the VEE Groups to be associated to the characteristic values.
4. Create the Factor that will be referenced by the rule.
5. Create the Factor Values for the factor, each referencing an effective-dated characteristic value/VEE group pairings.
6. Create the rule, referencing the factor

Measuring Component Statistics

Copyright © 2026, Oracle and/or its affiliates.

- Understanding Measuring Component Statistics
- Configuring Measuring Component Statistics



Understanding Measuring Component Statistics

Oracle Utilities Meter Data Management provides a way to stage statistics for Measuring Components in order to speed up VEE processing. These statistics are primarily meant for use in conjunction with the Dynamic Comparison Validation VEE Rule, but could also be generated for other analytics or reporting.

Some of the potential benefits of using Measuring Component Statistics are:

- Reduce the data volume for VEE queries by up to 1000 times (this is most beneficial when replacing VEE Rules that query historical data such as High/Low)
- Offload heavier processing of historical data to "system downtimes" - potentially nights or weekends

Below is an overview example of how Measuring Component Statistics can be implemented along with the Dynamic Comparison Validation:

The steps for pre-staging Measuring Component Statistics are detailed below:

1. A Physical Measuring Component is created. The algorithm to trigger the creation of Statistics Measuring Components is only set on Interval or Auto-Read Scalar BOs as part of base product.
2. New Statistics Measuring Component are created and linked to the Physical Measuring Component.
3. The Measuring Component Historical Statistics Batch (D1-MCHS) is run based on the schedule you've defined. The suggestion is to run this either nightly or on the weekends during quieter times for overall system processing.
4. A measurement is created for the Statistics Measuring Component that holds historical statistics related to the Physical Meter for a specific period of time (in this example it's set for 13 months).

The steps for how VEE can take advantage of Measuring Component Statistics are detailed below:

Copyright © 2026, Oracle and/or its affiliates.

1. IMDs are received from the Head End.
2. The Dynamic Comparison Validation VEE Rule is configured to execute for the meter. This validation uses the historical statistics from the Statistics Measuring Component in order to perform its validation logic.
3. An exception and potentially a To Do is generated based on the failure of the VEE rule.

Storage Impact from Statistics

Much consideration was given to the storage implications when designing Measuring Component Statistics. Below is an outline of the storage impact to customers who choose to calculate and store Channel Statistics. An example impact to a utility with 1 million Physical Meters (each with 4 channels of information) is shown in the far right column:

Area	Additional Data in MDM	Example Impact (assuming utility has 1 million Physical Meters)
Additional MCs *Assumption: Statistics are only configured on the primary billing channel MC Type for the majority of your Physical Meters.*	1-3 extra MCs per Physical Meter *Assumption: customers will only configure Statistics on their primary billing channel MC Type for the majority of their Physical Meters.*	1 - 3 million extra MCs *This increases the Measuring Component table by an extra 25% to 75% from its size without statistics.*
Additional Measurements *If 'Statistics Retention Mode' configured as "Only Retain Most Recent Record".*	1 extra Measurement per Physical Meter	1 - 3 million extra Measurements for the life of MDM *This data is a minuscule fraction compared to the overall AMI data footprint.*
Additional Measurements *If 'Statistics Retention Mode' configured as "Retain Historical Records".*	1 extra Measurement per Physical Meter per week	1 - 3 million extra Measurements per week (52-156 million per year) *This data is 0.2-0.5% of the size of the AMI data collected in that same week.*

Configuring Measuring Component Statistics

Measuring Component Types

In order to start generating Measuring Component Statistics, two different configurations must occur for Measuring Component Types:

- New Measuring Component Types must be configured that leverage the **Channel Statistics Type** business object. These should be setup as the periods for which Measuring Component Statistics should be calculated. For example, if you would like to be able to reference both last month, last year, as well as the past 13 months as statistics periods, then 3 different Channel Statistics Types must be setup for this. These could be setup as follows:
- – "Last Month" Channel Statistics Type:
  - – Calculation Lag Days = 0
  - – Calculation Horizon Days = 30

Copyright © 2026, Oracle and/or its affiliates.

- "Same Month Last Year" Channel Statistics Type:
- Calculation Lag Days = 365
- Calculation Horizon Days = 395
- "Prior 13 Months" Channel Statistics Type:
- Calculation Lag Days = 0
- Calculation Horizon Days = 395

NOTE: *it's recommended to set the Statistics Retention Mode to "Only Retain Most Recent Record" on the Channel Statistics Type to reduce the amount of data being stored in Oracle Utilities Meter Data Management.*

- For a Physical Measuring Component Type leveraging either "Interval Channel Type" or "Register - Auto-Read Type", the **Related Statistics Measuring Component Types** section must be filled in with the appropriate types that should be created for the Physical Measuring Component.

VEE Rule

If you have a desire to leverage Measuring Component Statistics for VEE, the Dynamic Comparison Validation VEE Rule section should be referenced. A number of detailed examples of how to implement this rule are provided in this section as well.

Related Batch Controls

There are a few batches directly involved with Measuring Component Statistics:

- **Measuring Component Historical Statistics** (D1-MCHS): this batch monitors any active Statistics Measuring Components to execute the logic for calculating a new set of historical statistics.
- **Statistics Measuring Component Creation** (D1-STMCC): this batch is used to create Statistics Measuring Components on any Physical Measuring Components that were created prior to configuring this module. This is especially useful for existing customers that want to implement Statistics Measuring Components for all of their devices.

> **Note**
>
> Refer to Understanding Measuring Component Statistics for more information.

Defining Usage Options

This section describes concepts and common tasks related to usage administration.

- The Big Picture of Usage Requests
- The Big Picture of Time of Use Mapping and Pricing
- Usage Subscription Types
- Integrating Usage Transactions
- Usage Transaction Exception Types
- Usage Calculation Groups

Copyright © 2026, Oracle and/or its affiliates.

- Usage Calculation Rules
- Usage Calculation Types
- Usage Subscription Quantity Types
- Dynamic Option Types
- Bill Cycle

The Big Picture of Usage Requests

Oracle Utilities Meter Data Management is used by some organizations who use a meter data management (mdm) system to record meter reading information. Since meter reads are not available in Oracle Utilities Customer Care and Billing to calculate consumption during the billing process, usage (or bill determinants) must be requested by Oracle Utilities Customer Care and Billing from the mdm system, Oracle Utilities Meter Data Management.

The following sections describe how the base-package usage request process works.

- Requesting Bill Determinants
- Usage Request Lifecycle
- Summary Billed Accounts and Usage Requests
- Corrected Read Notifications
- Configuring The System For Usage Request Integration
- Start and End Times for Billing

Requesting Bill Determinants

The term bill determinant request is another way to refer to a usage request. These usage requests are created during the batch billing process, and also when a user generates an online bill segment or performs cancel / rebill. The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request.

- Online Billing Usage Requests

Online Billing Usage Requests

- Usage requests created from an online billing request are not held in the initial state. These usage requests are transitioned through their lifecycle resulting in the request being sent to Oracle Utilities Meter Data Management (MDM) and, once a response is received, the bill segment is regenerated.
- The bill segment remains in the Freezable state until the user freezes the bill segment and completes the bill. If the freezable bill segment is regenerated, however, the system cancels the usage request and creates another usage request for the bill segment.
- In addition to the standard MDM usage request elements, the system captures the responsible user id.

Copyright © 2026, Oracle and/or its affiliates.

Usage Request Lifecycle

The usage request business object (BO) contains the rules that govern the processing of a usage request. The base product provides the BO C1-UsageRequest which serves as a parent BO and contains the following lifecycle:

- All usage requests are created in the initial Pending state. If the usage request was created from the batch billing process, the batch Usage Scheduled Monitor Process must be executed to transition the usage request.
- If there are pending sync requests for the usage request's service agreement, the usage request is held in the Awaiting Data Sync state until the sync is processed.
- Once all pending sync requests related to the usage request have been processed, the usage request transitions to the Send Request state. An enter algorithm on this transitory state is responsible for sending the usage request to Oracle Utilities Meter Data Management (MDM).
- The usage request sits in the Awaiting Bill Determinants state until a response is received from MDM, or a time out is encountered.
- When a response is received from MDM, the usage request is transitioned to either the Bill Determinants Received state, or the Error state. In the case of an error, the following occurs:
  - If the usage request was created from the batch billing process and the billing window is still open, a new usage request will be created the next time billing runs and the process is repeated. If however, the billing window is no longer open, a to do entry is created for manual follow up.
  - If the usage request was created from an online billing process, the user will be notified. The bill segment remains in the error state and the user can either delete the bill segment, or attempt to generate it again. If the bill segment is regenerated, a new usage request is created and the process is repeated.
  - The system transitions usage requests in the Bill Determinants Received state to the Bill Determinants Processed state. An enter algorithm on this final state is responsible for generating the bill segment. If the usage request was created from the batch billing process, the bill segment is frozen and the bill is completed. For online billing usage requests, the user is responsible for freezing the bill segment and completing the bill.

Summary Billed Accounts and Usage Requests

A "summary" account refers to an account with service agreements that cover more than one premise. If these premises are linked to service points that span different measurement cycle routes scheduled for reading on different dates, there's no guarantee that all the account's SAs will be billed at the same time. This is because batch billing for manually read meters is based on the meter's scheduled reading date.

For example, assume a summary account has two SAs each linked to a different premise. One is on route X, scheduled for reading every first of the month and the other is on route Y, scheduled for reading every 20th of the month. Assume that the account’s bill cycle is cycle X (which matches the schedule of premise/SP on route X). When billing runs on the first of the month, the service agreements tied to route Y won’t have any reads. And because route Y is not scheduled for reading, the system will not estimate the consumption. Instead, it will skip billing the route Y SAs until the next month. This means some SAs are always one billing cycle behind.

Copyright © 2026, Oracle and/or its affiliates.

If your implementation maintains meters and meter reads in CCB, then the base get consumption algorithm called ***Get Consumption From SP's Linked To SA*** handles the skipping of a summary billed account's service agreements based on bill cycle and measurement cycle schedules. The remainder of this section describes how this works in a CCB-MDM integrated environment.

- Requesting Bill Determinants for Summary Billed Accounts

Requesting Bill Determinants for Summary Billed Accounts

Usage requests for summary billed accounts are handled as follows:

- On the first night of the billing window usage requests are created for each SA and sent to Oracle Utilities Meter Data Management (MDM). MDM then checks what the next schedule read date is for each service point.
- Assuming Oracle Utilities Meter Data Management owns meter read schedules; when batch billing executes Oracle Utilities Customer Care and Billing (CCB) cannot determine whether a summary account's service agreement should be included on the bill or not.
- If MDM determines that an SA/usage subscription should be skipped from billing, it notifies CCB by including a skip indicator and reason on the usage response, as well as the SA's next scheduled read date. This date is captured as a ***MDM Next Scheduled Read Date*** characteristic on the SA, and the usage request is cancelled. The system still attempts to complete the bill since this might be the last outstanding usage request for the bill
- When billing next runs, the base ***Get bill segment consumption using a usage request*** algorithm first checks if the SA should be skipped as follows (Note that this check is also performed in first billing run):
- Get the ***MDM Next Scheduled Read Date*** characteristic on the SA. If this date is after the bill segment end date, we'll skip the SA from billing

If your implementation would like to wait until the bill cycle window end date before attempting to complete summary account's bills, ensure that the ***Complete Bill at End of Bill Cycle*** pre-bill completion algorithm is defined on customer class. This is useful if scheduled reads are expected in the bill cycle window, but not necessarily on the window start date.

Corrected Read Notifications

If a read that was used for bill determinant calculations is modified in the mdm system, notification is sent to Oracle Utilities Meter Data Management.. Resulting in the creation of an off cycle bill generator. The system uses the business object defined as the OCBG Corrected Read BO MO option on the Off Cycle Bill Generator maintenance object to create the OCBG.

What happens next depends on the lifecycle that your implementation has configured for the OCBG Corrected Read BO. Here are examples of what might occur:

- Create a To Do entry for manual follow up.
- Find any frozen bill segments that might be affected by the corrected read and perform cancel/rebill.

Configuring The System For Usage Request Integration

Copyright © 2026, Oracle and/or its affiliates.

Oracle Utilities Customer Care and Billing sends usage requests to Oracle Utilities Meter Data Management (MDM) in the form of an xml message. MDM sends responses back to Oracle Utilities Customer Care and Billing.

The following sections describe at a high level the data setup required to send usage requests to MDM.

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to Ways To Control The Start Date Of A Bill Segment and Ways To Control The End Date Of A Bill Segment for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing uses the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

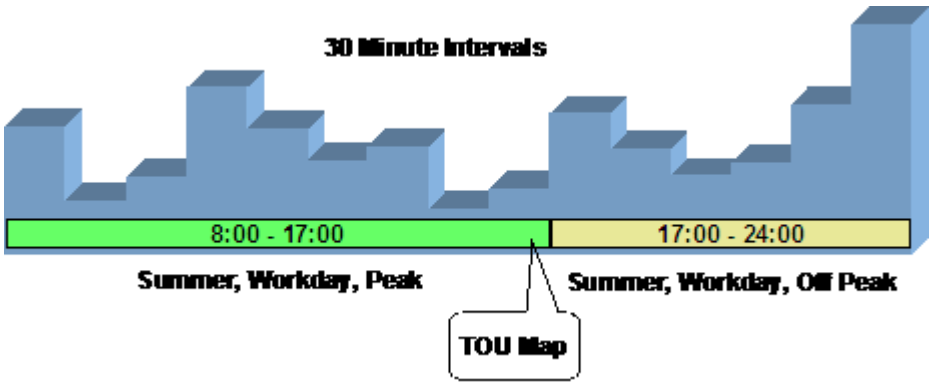
Oracle Utilities Customer Care and Billing lacks knowledge of the type of meter installed at a service point. Thus, both interval processing period as well as scalar processing information is captured on a usage request. Oracle Utilities Meter Data Management (MDM) then uses the appropriate period to calculate bill determinants based on the type of meter installed.

MDM returns the true usage period used to calculate bill determinants on the usage response. This usage period is captured on the bill segment.

The Big Picture of Time of Use Mapping and Pricing

This section provides an overview of the concepts related to setting up your control tables to support time of use mapping and pricing with the rates.

> **Note**
>
> Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.



- Mapping to Time of Use (TOU) Periods
- Grouping of TOU Codes for TOU Mapping
- Time of Use (TOU) Mapping and Pricing
- Designing Your Time of Use (TOU) Mapping and Pricing Options
- Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

Mapping to Time of Use (TOU) Periods

Copyright © 2026, Oracle and/or its affiliates.

Many customers choose not to price their interval data using interval prices. Customers may choose for their interval data to be mapped into time of use (TOU) periods. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

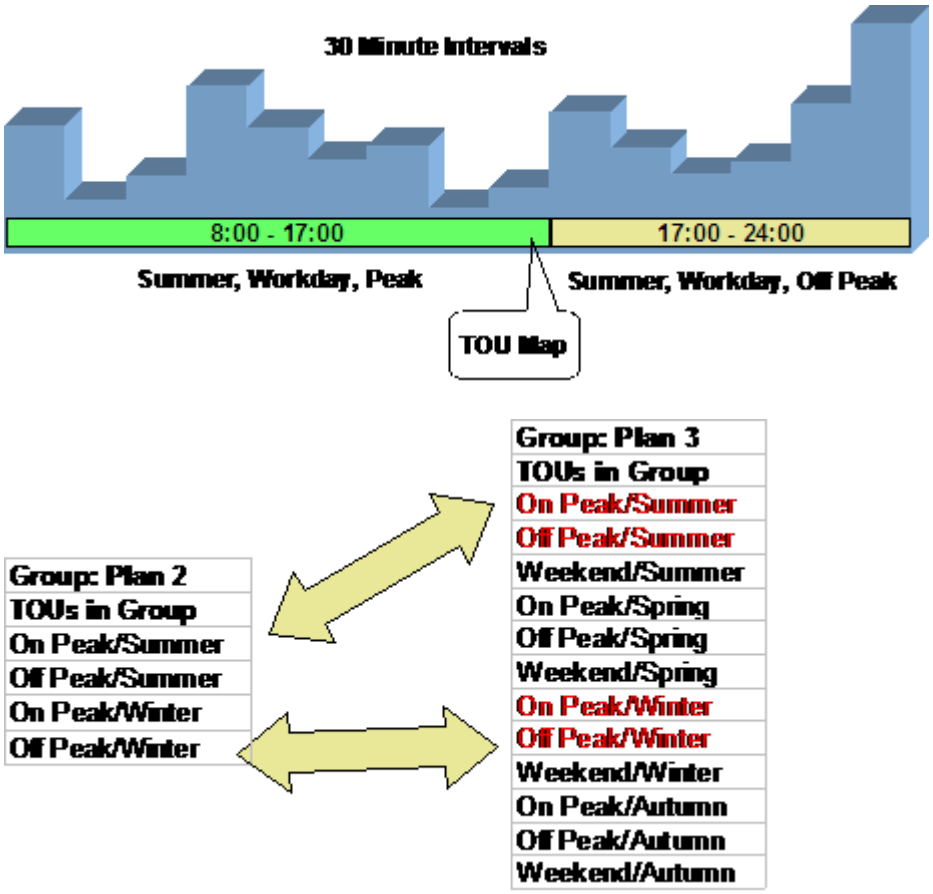
A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times). The TOU Map has a TOU Map Type, which defines the interval size between TOU map data rows.

Time of use periods can (and often do) change during the year.

Map #123 (TOU Group 2)	
Effective 1 Jan 2000	
Interval Date/Time	
30/Apr/00 16:30	On Peak/Winter
30/Apr/00 16:45	On Peak/Winter
30/Apr/00 17:00	Off Peak/Winter
30/Apr/00 17:15	Off Peak/Winter
...	
01/May/00 7:45	Off Peak/Summer
02/May/00 8:00	On Peak/Summer
02/May/00 8:15	On Peak/Summer
...	

All the possible TOU codes for a given map are grouped together in a TOU group. Refer to Grouping of TOU Codes for TOU Mapping for more information.

Grouping of TOU Codes for TOU Mapping



This section describes the relationship between TOU Codes and TOU Mapping.

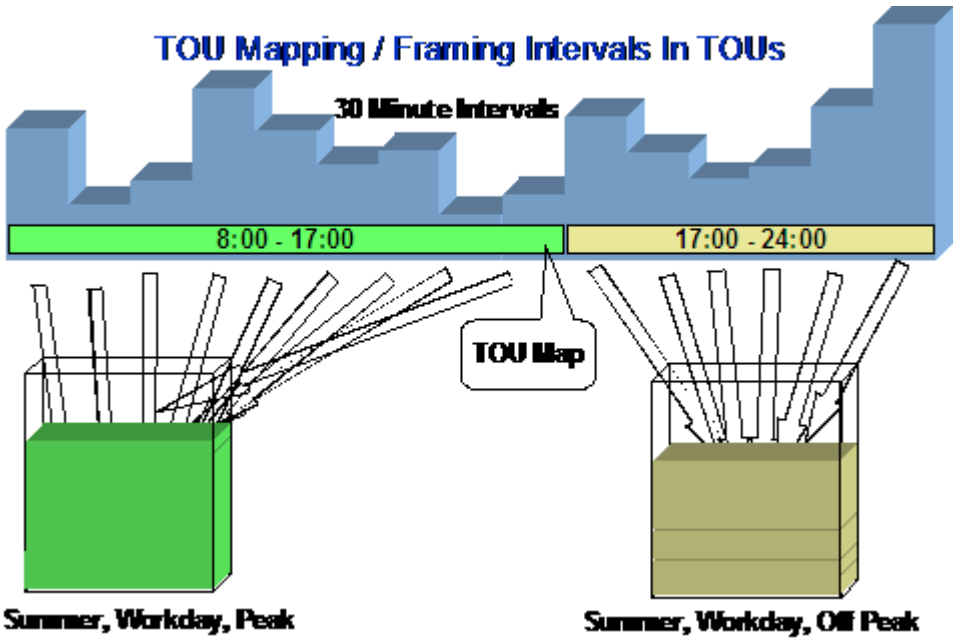
- Overview of TOU Codes and TOU Mapping
- TOU Sequence for TOU Mapping and Pricing

Overview of TOU Codes and TOU Mapping

Copyright © 2026, Oracle and/or its affiliates.

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times).

TOU Sequence for TOU Mapping and Pricing



If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Time of Use (TOU) Mapping and Pricing

The following section describes the logic used by the system to map an interval data curve to TOU periods using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take an interval data curve and will map the interval values to TOU periods based on a TOU Map. The interval data curve is retrieved from either a specific usage request or from the new rate engine buffer populated prior to calling the rate engine.

Copyright © 2026, Oracle and/or its affiliates.

This type of data manipulation is typically handled using a calculation rule based on the 'math' calculation rule type.

Once the interval data curve values have been mapped to TOU periods, prices can be applied to the time of use period quantities using calculation rules based on the 'service quantity' calculation rule type.

- Calculation Rules for TOU Mapping & Pricing
- TOU Map Used For Mapping

Calculation Rules for TOU Mapping & Pricing

Calculation Rules are used to perform time of use mapping and time of use pricing.

Time of Use Mapping

Time of use mapping will be typically handled using a calculation rule based on the 'math' calculation rule type. Calculation rules of this type can perform many functions. Two examples include:

- Applying a TOU map to an interval data curve to produce service quantities that will be added to the bill segment's SQ collection.
- Applying a TOU map to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the resultant curve.

For further details on the 'math' calculation rule type, refer to Base Package Math Calculation Rule for more information.

Time of Use Pricing

Time of use pricing will be typically handled using calculation rules based on the 'service quantity' calculation rule type. Calculation rules of this type can perform many functions. For example:

- Add or update a service quantity in the bill segments SQ collection

Copyright © 2026, Oracle and/or its affiliates.

- Create bill calculations lines that levy charges based on some type of consumption. For example, applying a price to a specific service quantity in the bill segment's SQ collection

For further details on the 'service quantity' calculation rule type, refer to Base Package Service Quantity Calculation Rule for further information.

> **Note**
>
> Calculation rules are implemented using algorithms that contain the logic to be performed. If your implementation requires a new type of calculation rule, you can configure a new calculation rule type and reference the appropriate algorithm on it.

TOU Map Used For Mapping

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule.

Attributes of TOU Maps

TOU map types define attributes shared by TOU maps of a given type. The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting.

Designing Your Time of Use (TOU) Mapping and Pricing Options

This section provides an overview for designing your control tables to support time of use (TOU) mapping and pricing with the new rating engine.

- Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules
- Designing Your TOU Codes for TOU Mapping
- Designing Your TOU Groups for TOU Mapping
- Designing Your TOU Map Types for TOU Mapping
- Designing Your TOU Map Templates for TOU Mapping

Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules

As you know from the rates chapter, the system can handle mapping of interval data curve values into different time of use periods and pricing these quantities using the 'math' and 'service quantity' calculation rule types respectively. Refer to Base Package Calculation Rule Descriptions for more information.

The following guidelines provides a high level outline on how you should go about designing a rate schedule that involves time of use mapping and pricing.

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up exactly how the information should appear on the customers' printed bills.
- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. Which time of use map is used to define the time periods?

Copyright © 2026, Oracle and/or its affiliates.

- In order to perform time of use mapping and pricing, calculation rules need to be designed
  - A calculation rule based on the 'math' calculation rule type may be used to map an interval data curve into time of use periods. This calculation rule must know the TOU map to apply to the interval data curve to map into the relevant time of use periods. The time of use period quantities are populated in the bill segments SQ collection.
  - Calculation rules based on the 'service quantity' calculation rule type may be used to apply prices to each mapped time of use period quantity. These calculation rules each require either a price or regular bill factor for pricing each time of use period quantity. The bill factor may contain the price directly, or may indicate that the price is customer specific and can be found as contract quantities for the service agreement.

Once you have your calculation rules designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Designing Your TOU Codes for TOU Mapping

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. It should be noted that it's possible that will not bill for every time of use period.

Designing Your TOU Groups for TOU Mapping

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are available to be used in a single map. You must also decide if you want to use a sequence number to define the relative order of a TOU code within a TOU group.

When TOU data is created for a TOU map, only TOU periods defined on a specified TOU group can be specified.

Designing Your TOU Map Types for TOU Mapping

Now that you have your TOU groups defined, you can begin defining TOU map types. Recall that the TOU map type defines the attributes that may be shared by TOU maps of the same type.

The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting. Refer to Designing Your Time Options for more information.

TOU Map Type Interval Size

The interval size of a TOU map must divide evenly into the interval size of the interval data curve that uses the map (because the system joins the date/time of the interval data curve values to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute interval data curve. However, it is not OK to have a 60 minute TOU map used with a 15 minute interval data curve because the join will miss 3 out of 4 interval data curve values.

Copyright © 2026, Oracle and/or its affiliates.

TOU Map Type Override Template

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support override templates. Refer to Designing Your TOU Map Templates for TOU Mapping for more information.

- A TOU map's TOU map type defines the default TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the default template.
- An individual TOU map can have override templates. If the TOU map doesn't have an override template, the default template defined on the TOU map type is used to generate the map's TOU data.

Refer to Creating TOU Map Types for further information.

Designing Your TOU Map Templates for TOU Mapping

In order to help your users to create and maintain data for TOU maps, you may define TOU map templates, which can be used to generate data for a TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates.

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period. The system periodically generates TOU map data for TOU maps by interpreting the rules defined in the template.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays by specifying the following:

- A Work Calendar that defines when holidays start and end
- Either:
  - A Holiday TOU period for consumption on holiday
  - A Holiday TOU Map Template that defines the TOU codes to use for different times in the year

TOU Map Template Interval Size

TOU map templates can also specify an interval size. This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

Copyright © 2026, Oracle and/or its affiliates.

A TOU map template can be used to generate TOU map data for TOU maps whose interval size is divisible by the template's interval size. For example, a 60 minute template can be used to generate TOU data for TOU maps with an interval size of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every interval size.

Refer to Creating TOU Map Templates for further information.

Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

This section provides an overview of setting up your control tables to support time of use mapping and pricing with rates.

- Creating TOU Map Templates
- Creating TOU Map Types

Creating TOU Map Templates

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates and used for TOU map data generation.

Prerequisites: You must define TOU groups and work calendars before you can create TOU map templates. Refer to the Oracle Utilities Application Framework online help for more information about creating work calendars.

To maintain existing TOU map templates, select **Admin**, and then **Usage**, and then **TOU Map Template**, and then **Search** then use standard actions to edit, duplicate, or delete a TOU map template.

To define a new TOU map template, follow these steps:

1. Select **Admin**, and then **Consumption**, and then **TOU Map Template**, and then **Add.** If your system supports more than one TOU map template business object, you will be prompted to select a business object for this TOU map template.
2. Enter a name and a meaningful description for the TOU map template.
3. Select the TOU group to be used by the TOU map template.
4. Select the default TOU for the TOU map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
5. Select the work calendar for the TOU map template. Work calendars define the days of the week on which work is performed, and specify holidays.
6. Select the holiday TOU for the TOU map template (from the TOU Group).
7. Select the TOU map template used for holidays (if applicable).
8. Specify the interval size for TOU map data created from the map template. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
9. To specify TOU schedule's date ranges and which TOUs should be used for this TOU map template, click the + or - sign in the TOU Schedule Section and enter or select the following:
    - Start and End Dates for a specific date range
    - Start and End Days of the Week: To add or remove Start and End Days of the Week pairs, click the + or - sign and select the appropriate weekdays

Copyright © 2026, Oracle and/or its affiliates.

- Start and End Times: To add or remove Start and End Times within a Start and End Days of the Week pair, click the + or - sign and enter the appropriate times
- TOU

10. Click **Save.**

Now you can use the TOU map template when creating TOU types.

Creating TOU Map Types

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule. TOU map types define attributes shared by TOU maps of a given type.

Prerequisites: You must define TOU map templates and time zones before you can create TOU map types. Refer to the Oracle Utilities Application Framework online help for more information about creating time zones.

To maintain existing TOU map types, select **Admin**, and then **Consumption**, and then **TOU Map Type**, and then **Search** then use standard actions to edit, duplicate, or delete a TOU map type.

To define a new TOU map type, follow these steps:

1. Select **Admin**, and then **Consumption**, and then **TOU Map Type**, and then **Add**

> **Note**
>
> If your system supports more than one TOU map type business object, you will be prompted to elect a business object for this TOU map type.

2. Enter a name and a meaningful description for the TOU map type.
3. Select the business object to use when creating TOU maps of this type
4. Select the time zone for the TOU map type.
5. Specify the interval size for TOU map data created from the map type. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
6. Select the default TOU map template for the TOU map type
7. To add or remove override TOU map templates for this TOU type, click the + or - sign in the Override TOU Map Templates section and select the TOU map template.
8. Click **Save**.

Now you can use the TOU map type when creating TOU maps.

Usage Subscription Types

- Understanding Usage Subscription Types
- Configuring Usage Subscription Types

Understanding Usage Subscription Types

Copyright © 2026, Oracle and/or its affiliates.

Usage Subscription Types define a collection of properties defining a class of Usage Subscriptions. Usage Subscription types also control valid values for various attributes of Usage Subscriptions.

For a deeper functional understanding, refer to the About Usage Subscriptions or About Usage Calculation sections .

Configuring Usage Subscription Types

This portal is used to display and maintain a Usage Subscription Type.

Refer to Understanding Usage Subscription Types for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Type List**: displays all of the Usage Subscription Types so you can choose the one you want to display in more detail
- **Usage Subscription Type**: shows the specific configuration for the selected Usage Subscription Type

The Usage Subscription Type defines a number of lists for "valid" objects that can be used in conjunction with the overall usage calculation process:

- Valid Usage Recipients
- Valid Service Point Types
- Valid Usage Calculation Groups
- Valid Dynamic Option Types

Integrating Usage Transactions

- Requesting Usage Transactions
- Processing Usage Transactions
- Generating Usage Transactions in Oracle Utilities Meter Data Management

Requesting Usage Transactions

Usage transactions can be created via a request from the billing process.

To invoke a usage transaction request, the billing process invokes a Usage Transaction Request Inbound service script which invokes the Usage Transaction Seeder (D2-UsgTranSeeder) business object. This business object does the following:

- Determines the usage subscription ID based on an external usage subscription ID
- Determines the appropriate usage transaction business object to create. This uses the "How To Create Usage Subscription Related Information" processing method defined for the "Usage Transaction Creation" processing role on the service provider that represents the external system.

For a deeper functional understanding of Usage Transactions, refer to the About Usage Transactions section.

Copyright © 2026, Oracle and/or its affiliates.

Processing Usage Transactions

In Oracle Utilities Customer To Meter, usage transaction information, including bill determinants and other data is requested and “sent” to the billing process.

Usage transactions are sent when they enter the "Sent" state via a number of Enter algorithms on the base package usage transaction business object (D2-UsageTransaction) .

- The "Send Usage" (D2-SEND-USG) algorithm determines the method used to send the information, based on the Usage Recipient (service provider) defined on the usage transaction's Usage Subscription (in most cases, Customer To Meter).
- The “Send Usage Response” (X1–SENDUSGRP) algorithm sends a response to the billing process, and transitions the related usage request to its next state.
- The “Transition Related Usage Request from UT” (X1-TRNUSGREQ) algorithm transitions the related usage requests in the “Awaiting BD” state to its next state (if the usage transaction had been previously stopped at a non-final status (such as Approval In Progress).

Usage transactions can be sent via either online real-time processing or periodically via batch processing.

Online Real-Time Processing

To set up the service provider to support online real-time notification of usage transactions, do the following:

- Create one or more Outbound Message Types that reference the outbound message business object to be used to send usage transaction information to the billing system. The base package include the following business object for Usage Transaction Outbound Message (X1-UsageTranOutboundMesg).
- Define a Message Sender that will be used to send the message to the external system.
- Add the outbound message type to the service provider's External System and reference the Message sender created above.
- Add a processing method to the service provider as follows:
  - **Processing Role**: Usage Transaction Notification - Online
  - **Processing Method**: How To Send US Related Information
  - **Status**: Active
  - **Default Processing Method**:
  - **Outbound Message Type**: the outbound message type created above
  - **Override Processing Method**: outbound message types for specific usage subscription types if applicable

For a deeper understanding of integrating usage transactions with Oracle Utilities Customer Care and Billing, refer to the Configuring the Bill Determinant Interface in the Interface section.

Batch Processing

Requests from the billing process that have been indicated as "batch requests" (such as those produced by Oracle Utilities Customer Care and Billing batch billing process) accumulate in a "calculation deferred" state to be processed specially by the **Usage Transaction Calculate Defer Monitor** batch control (D2-UTCD).

Copyright © 2026, Oracle and/or its affiliates.

Requests from Oracle Utilities Customer to Meter that have been indicated as "batch requests" accumulate in a "calculation deferred" state to be processed specially by the **Usage Transaction Calculate Defer Monitor** batch control (D2-UTCD).

To set up the service provider to support periodic batch processing of usage transactions, use a periodic monitor batch control. These batch programs should invoke the business objects that will contain the usage transaction information. The base package includes the following business object for this: Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).

Next, setup the following configuration:

- Add a processing method to the service provider as follows:
  - **Processing Role**: Usage Transaction Notification - Batch
  - **Processing Method**: How To Send US Related Information
  - **Status**: Active
  - **Default Processing Method**:
  - **Batch Control**: the batch control created above
  - **Override Processing Method**: batch controls for specific usage subscription types if applicable

Errors encountered when processing Usage Transactions can be reprocessed with the following batch controls:

- Reprocessing usage transaction "seeders" in error (D2-UTSED)
- Reprocessing usage transactions in error (D2-UTID)

If unexpected errors occur that leave usage transactions in an unmonitored state, the **Usage Transaction Monitor** batch control (D2-UT), or one based on this batch control with parameter values tailored to any specific requirements, can be used to process those usage transactions.

For a deeper functional understanding of Usage Transactions, refer to the About Usage Transactions section.

Generating Usage Transactions in Oracle Utilities Meter Data Management

There may be some cases where Usage Transactions should be generated in Oracle Utilities Meter Data Management rather than requested from an external system. Generation of these usage transactions are scheduled around the time when the meter installed on the service point is read.

Base product delivered a batch program that reads all pending measurement cycle schedule routes with selection date on or before the business date and creates as SP measurement cycle schedule route business object instance that stages the creation of these usage transactions.

For additional details refer to the D1-CSPSR batch control and D1-SPMsrmtCycScheduleRoute business object.

Usage Transaction Exception Types

- Understanding Usage Transaction Exception Types
- Configuring Usage Transaction Exception Types

Copyright © 2026, Oracle and/or its affiliates.

Understanding Usage Transaction Exception Types

Usage Transaction Exception Types define the groupings of exceptions for a Usage Transaction based on their functional similarity. This provides a way to define Usage Transaction Exceptions in a distinct enough way to understand the root issue that was generated from the usage calculation rule.

For a deeper functional understanding of Usage Calculation, refer to the About Usage Calculation section.

Configuring Usage Transaction Exception Types

You ue the **Usage Transaction Exception Type** portal to display and maintain usage transaction exception types .

Refer to Understanding Usage Transaction Exception Types for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Transaction Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Transaction Exception Type List**: displays all of the Usage Transaction Exception Types so you can choose the one you want to display in more detail
- **Usage Transaction Exception Type**: shows the specific configuration for the selected Usage Transaction Exception Type

Usage Calculation Groups

- Understanding Usage Calculation Groups
- Configuring Usage Calculation Groups

Understanding Usage Calculation Groups

Usage calculation groups are collections of usage calculation rules that are used to either calculate bill determinants or validate bill determinants. During the usage transaction process, the system executes the usage calculation rules defined in the usage calculation group referenced on the usage subscription. The rules within a usage calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

Usage calculation groups are associated with specific usage subscriptions and usage subscriptions types (or both). When assigned to usage subscriptions, usage calculation groups contain the usage calculation rules to be used to calculate usage / bill determinants. Usage calculation groups associated with usage subscription types are those groups considered valid for usage subscriptions of that type.

Usage calculation groups can also specify a list of device donfiguration types that are considered valid. Usage calculation groups should only be associated with usage subscriptions for service points related to device configurations of a valid device configuration type.

Usage calculation groups can also be referenced by the Execute Usage Calculation Group usage calculation rule.

Copyright © 2026, Oracle and/or its affiliates.

For a deeper functional understanding of usage calculation, refer to the About Usage Calculation section.

Configuring Usage Calculation Groups

This portal is used to display and maintain a usage calculation group.

Refer to Understanding Usage Calculation Groups for more information.

You can access the portal by selecting**Admin**, then **Usage**, then **Usage Calculation Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Group**: Defines basic information about usage calculation group
- **Usage Calculation Rules List**: lists the usage calculation rules belonging to the group
- **Referencing Usage Calculation Rules List**: lists the usage calculation rules that reference the group
- **Referencing Usage Subscription Type List**: lists the usage subscription types that reference the group
- **Referencing Usage Subscriptions List**: lists the usage subscriptions that reference the group

Usage Calculation Rules

- Understanding Usage Calculation Rules
- Configuring Usage Calculation Rules
- Detailed Configuration Examples

Understanding Usage Calculation Rules

Usage calculation rules are standard and custom rules that perform calculations on measurement data to generate bill determinants and other values used by external systems, such as billing systems, customer information systems, etc. Usage calculation rules are created for a specific usage calculation group. For example, if you were configuring two usage calculation groups and both included a specific usage calculation rule, you would need to create two instances of the usage calculation rule, one for each group.

The base package includes rules that calculate common bill determinants including:

- Scalar reads
- Time-of-use consumption (by applying a time-of-use map to an interval channel)
- Interval curves (either real or derived)
- Virtually anything else that can be calculated from the information in the system

For a deeper functional understanding of usage calculation, refer to the About Usage Calculation section.

Copyright © 2026, Oracle and/or its affiliates.

Usage Transaction Exceptions

On almost every usage calculation rule, the failure of the rule results in a usage transaction exception and the Usage Transaction Exception Type for the failure can be configured on the rule. These usage transaction exception types can also be set to a specific Exception Severity:

- **Information**: Used to highlight minor issues, but not sufficient to cause the usage transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues**: Used to report a problem that will prevent the usage transaction from being sent. Multiple "issue exceptions" can be created during usage transaction processing. If at least one issue exists after all rules have been applied, the usage transaction is transitioned to a failure state requiring review and approval.
- **Terminate**: Used to report a severe issue that will cause the usage calculation process to stop and the usage transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a Usage Transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full usage period should always be set to Terminate as an Exception Severity.

Rounding Usage Transaction Service Quantities

Several usage calculation rules provide a means for defining the manner in which service quantities are rounded during usage calculations. Service quantity rounding can be defined using the **SQ Rounding Details** which allow configuration of the method by which quantities are rounded (Up, Down, or Nearest) and the number of decimal positions retained after rounding.

Creating Measurement Data Snapshots

Daily Scalar Calculation Rule, Get Interval, Get Item Counts and Consumption, and Get Scalar Details usage calculation rules can be configured to create measurement data snapshots during usage transaction processing. Measurement data snapshots are used by data aggregation in Market Settlements Management.

Measurement data snapshot configuration is done in the **Extract To Measurement Data Snapshots** section, and includes the following options:

- **Measurement Data Snapshot Type**: The measurement data snapshot type for measurement data snapshots created by the usage rule.
- **Usage Transaction ID To Use**: A flag that designates the type of ID to use to identify the usage transaction on the measurement data extract. Options include:
  - **Usage Transaction ID**: The usage transaction's ID
  - **Usage Transaction External ID**: The external ID for the usage transaction. Used when the usage transaction is triggered by external system such as a CIS (or by the billing functionality in Customer To Meter)
- **Extract To Different Usage Subscription**: A flag that designates whether or not the measurement data snapshot should be extracted to a different usage subscription, such as one used by Market Settlements Management. Options include:
  - **No**: The extract will reference the usage subscription for which usage calculations are being processed. This option is used when Meter Data Management and Market Settlements Management are installed in different application environments. In this

Copyright © 2026, Oracle and/or its affiliates.

case, the extract can be exported from Meter Data Management for subsequence import into Market Settlements Management.

  - **Yes**: The extract will reference a different usage subscription such as one used by Market Settlements Management. This option is used when Meter Data Management and Market Settlements Management are installed in the same application environment. In this case, the measurement data snapshot is “exported” within the system to the Settlement Item, where it can be used in data aggregation processing. When this option is selected, the **Source Identifier Type** and **Target Identifier Type** fields must be configured to define how the system will determine the correct settlement usage subscription to use.

- **Irregular Data Flag Mapping**: Ranges of condition codes used to flag data as “irregular”. The value of the **Irregular Data Flag** (based on the IRREGULAR_DATA_FLG lookup) is used to flag data that falls with each range configured. A blank **Irregular Flag** value denotes that the condition range is considered to be "Regular".

See About Measurement Data Snapshots for more information about measurement data snapshot creation and processing.

Usage Calculation Rules and Anchor Time

Some usage calculation rules have been enhanced to support usage calculations based on an "Anchor Time". The Anchor Time is specified on certain measuring component types and defines the start and end time of the business day for purposes of processing measurement data and usage transactions. When processing usage calculations for measuring components whose type specifies an **Anchor Time**, the Start Time and End Time of the calculation period should match the **Anchor Time** on the measuring component type.

Configuring Usage Calculation Rules

This portal is used to display and maintain a usage calculation rule.

Refer to Understanding Usage Calculation Rules, Understanding Usage Calculation Groups, and Understanding Usage Transaction Exception Types for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Rule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Rule**: Defines the usage calculation rule, including parameters used when executing the rule
  - Click **Show All Rules** to open the **VEE Rules** List zone, which lists all of the usage calculation rules in the usage calculation group to which the current rule belongs.
- **Eligibility Criteria List**: Lists the eligibility criteria defined for the rule

Pre-Calculation Usage Calculation Rules

The following is a list of the pre-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose

Copyright © 2026, Oracle and/or its affiliates.

Alignment and Delay Usage Calculation Rule	Interval or Scalar	This rule can be used to handle two main needs: 1) aligns all measuring components for a Usage Subscription to the same date (whether on the same device or separate devices) 2) delays the usage transaction until the end of the retry window based on the quality of available data and other configured parameters.
Check Existence of Installed Device	Interval or Scalar	This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.

Calculation Usage Calculation Rules

The following is a list of the calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Apply Math (Interval Data)	Interval	This rule is used to perform calculations on interval data and stores the results in the usage transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions). This rule provides aggregated usage for all selected interval measuring components (filter by TOU, SQI & UOM) associated to a usage subscription. This rule can also multiply total usage by a factor using a custom formula.

Copyright © 2026, Oracle and/or its affiliates.

Coincident Peak and Individual SP Demand	Interval	This rule is used to calculate the coincident peak demand for all of the service points on the usage subscription and the demand values for each service point at the coincident peak. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).
Daily Scalar Usage Calculation Rule	Scalar	This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified usage period. It creates bill determinants by taking the difference between the beginning and ending reading for the bill period. This rule can also be used to provide register readings by measuring component. For consumption values, only the beginning and ending readings are exported This rule supports date breaks (the normal Get Scalar Data rule does not).
Get Interval Data	Interval	This rule is used to get interval quantities from interval measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Interval' usage period. This rule retrieves the interval data for measuring components associated to a usage subscription by TOU, SQI and UOM. This rule converts the interval data to another interval length or unit of measure.
Get Item Counts and Consumption	Interval or Scalar	This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption.

Copyright © 2026, Oracle and/or its affiliates.

Get Scalar Details	Scalar	This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period. This rule creates bill determinants by summing all scalar readings for the bill period. This rule can also be used to provide register readings by measuring component. All readings are exported by this rule. Note: This rule is used for traditional monthly read meters.
Get Subtractive Interval Details	Interval	This rule is used to get interval quantities from subtractive interval measuring components installed on the service points linked to the usage subscription for the specified 'interval' usage period. It also identifies the start and stop readings for each usage period using subtractive interval readings.
Get TOU Mapped Usage	Interval	This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.
Interval Tier Calculation	Interval	This rule calculates the difference between a source and reference vector. This rule loops through each tier that is configured and calculates the imbalance amount associated to that tier level. This rule breaks down that difference into one to many positive or negative tiers, and create a service quantity for each tier calculated.
Profile Accumulation	Interval	This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.

Copyright © 2026, Oracle and/or its affiliates.

Rolling Demand	Interval	This rule is used to calculate rolling demand for all of the service points on the usage subscription. Rolling demand can be based on a rolling consumption total, rolling consumption average, or coincident peak demand. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).
Round and Adjust Usage	Interval or Scalar	This rule copies identified source and target Service Quantities and inserts these as Service Quantities that are rounded and adjusted.
Vector and Service Quantity Math	Interval	This rule is designed to facilitate configuration of complex vector calculations. It is based on a series of underlying services with vectors configured as input to the calculations. Typical uses: Perform math using interval data, e.g., take the difference between two curves, find max values, find coincident peaks, multiply a curve by a value, apply TOU maps, etc. Define complex formulas using various interval curves, profile factor values or calculated service quantities (bill determinant values). Support math functions: sin, cos, square root, etc. Store derived curves in memory that can be used in subsequent calculations Please note, this rule is not as efficient as other rules.

Post-Calculation Usage Calculation Rules

Below is a list of the post-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose

Copyright © 2026, Oracle and/or its affiliates.

Usage High/Low Rule	Interval or Scalar	This rule compares the Service Quantities of the Usage Transaction to historical values. If the current value is too high or too low compared to historical data then an exception is thrown.
Validate Against Tolerance	Interval or Scalar	This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.
Business Flag Hold	Interval or Scalar	This rule can stop a usage transaction from proceeding when there have been business flags for the applicable service points. The hold can either be indefinite or set to expire a configurable amount of time prior to the calculation window ending.

Decision-Making Usage Calculation Rules

There are usage calculation rules delivered as part of the base product that help with decision-making when executing running the usage calculation process. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Purpose
Execute Usage Calculation Group	This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group.
Exception Handler	This rule is used to terminate execution of the usage processor if exception count criteria specified in the rule is met.

Advanced Aside: Using Factors For Variables

A situation common in some implementations involves converting one unit of measure (UOM) to another. However, the conversion factor used in conversions of this can differ based on many different types of criteria, such as the location of the service point or other characteristics. This sort of calculation can be implemented as a usage calculation rule that accumulates consumption for one UOM and converts the consumption to a different UOM by applying a factor to it.

Factors used for this purpose have a Factor Class of "Number," and use some unique rules:

- Number factors reference a characteristic type (with pre-defined values).
- Number factors reference an algorithm that retrieves or derives the value of the characteristic type at runtime.

Factor values for a Number factor are effective-dated pairings of a characteristic value and a corresponding value. Because these pairings are effective-dated, the value returned from the factor can change over time for each characteristic value. At run time, the rule retrieves /

Copyright © 2026, Oracle and/or its affiliates.

derives the characteristic value for the factor's characteristic type and then finds the value associated with the respective characteristic value. Factors can be related to any real or dynamic attribute, so rules of this type are very flexible. For example:

- **Real Attribute**: you could create a rule that retrieves a specific value based on the location of a service point.
- **Dynamic Attribute**: you could create a rule that retrieves a percentage value based on the amount the customer conserved as compared to the same period in the prior year, returning one value if the amount conserved is between 5% and 10%, another value if the amount conserved is between 10% and 20%, and yet a third value if the amount conserved is greater than 20%. The amount conserved is dynamically calculated at execution time and is compared to the characteristic values defined for the factor, and returns the appropriate value. In this example, if the amount conserved was anything less than 5%, no percentage value would be returned.

Pre-Calculation Usage Calculation Rules

- Alignment and Delay Usage Calculation Rule
- Check Existence of Installed Device

Alignment and Delay Usage Calculation Rule

This rule attempts to delay usage calculation until high quality data for calculating bill determinants have become available. It is especially useful for usage subscriptions having multiple sources of usages such as multiple service points or multiple measuring components on the installed meter. The rule ensures that the usage calculated is based on a common date or alignment date, identified for these sources.

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Get the total KWH for the period

- **Calculation Type** = Single Variable
- **Variable Name** = V1, where the following is configured:
  - Variable Type = Channel Accumulation
  - UOM = KWH
  - Set Function = Sum

Scenario 2: Get the higher value between the total KWH or total KVARH

- **Calculation Type** = Math Function
- **Math Function** = Max
- **Variable Name** = V1, where the following is configured:
  - Variable Type = Channel Accumulation
  - UOM = KWH
  - Set Function = Sum
- **Variable Name** = V2, where the following is configured:
  - Variable Type = Channel Accumulation
  - UOM = KVARH
  - Set Function = Sum

Scenario 3: Total KWH multiplied with a factor value

- **Calculation Type** = Mathematical Expression
- **Mathematical Expression** = V1 * V2
- **Variable Name** = V1, where the following is configured:
  - Variable Type = Channel Accumulation
  - UOM = KWH
  - Set Function = Sum
- **Variable Name** = V2, where the following is configured:
  - Variable Type = Factor
  - Factor = factor code that holds the multiplier

Daily Scalar Usage Calculation Rule

This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified 'Interval' usage period. Only automatically read scalar measuring components with value identifier that matches usage calculation rule's UOM/TOU/SQI will be processed.

Copyright © 2026, Oracle and/or its affiliates.

If configuring this rule with interval and scalar usage calculation rules under a usage calculation group, it should be executed after interval usage calculation rule and before the scalar usage calculation rule.

This rule calculates usage based on the beginning and ending reading values -- ignoring intermediate readings. This rule will not estimate data based on the usage transaction estimate flag. Frequently read scalar devices must use periodic estimation processes.

> **Note**
>

>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CalFrequentlyReadScalar

Get Interval Data

This rule is used to get interval quantities from interval measuring components installed in the service points linked to the usage subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule are processed. Measurements within the period are stored in the usage transaction's service quantities' interval data list. The SQ entry's quantity is calculated based on the **Calculate Function** defined in the usage calculation rule. This is done for every entry in the usage period list. Each service quantity recorded by this rule is linked to a service point and measuring component.

By supplying the Axis Conversion parameters on the usage calculation rule, this algorithm will convert the identified measuring component's consumption into the supplied UOM and interval size prior to storing the consumption into the service quantity's interval data list.

D2-GetIntervalData

Get Item Counts and Consumption

This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and

Copyright © 2026, Oracle and/or its affiliates.

Service Point, and calculates item-based consumption. Once the item detail entries are created, the rule processes goes through them to create usage period SQs.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETITEMCC Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetItemCountsConsumption

Get Scalar Details

This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period. By default all scalar measuring components are processed but if specific UOMs/TOUs/SQIs are defined in the usage calculation rule then only applicable measuring components are processed. Measurements within the period are retrieved. The usage transaction request may indicate whether or not 'Estimate' measurements are allowed. If the usage transaction request indicates that ‘Estimate’ measurements are allowed but an estimated end measurement cannot be found an Estimate initial measurement is created.

The measurement details are stored in the usage transaction's scalar details. The usage is also stored in the usage transaction's service quantities unless otherwise specified in the usage calculation rule (using Build Service Quantity indicator).

This rule can be configured to perform measurement quality assessment, which will result in the population of the measurement quality list with the quantities and corresponding conditions of those measurements (regular, estimated, etc.).

Please note: this rule should not be used with readings occurring daily or more frequently as it will retrieve all of the readings to store in the Usage Transaction. The Daily Scalar usage calculation rule may be a better option for this use case.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETSCALAR Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetScalar

Get Subtractive Interval Details

Copyright © 2026, Oracle and/or its affiliates.

This rule is used to calculate the usage for a subtractive interval measuring components. This differs from the Get Interval Data usage calculation rule in that it also retrieves a start and stop reading for each usage period it calculates. The start and stop readings are then used to provide entries into the usage scalar details table which are then made available in the usage transaction sent to the billing system for bill presentment.

> **Note**
>

Business Object

D2-GetSubtractiveInterval

Get TOU Mapped Usage

This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule instance are processed.

Measurements within the period are mapped to time of use quantities based on the TOU map defined on the usage calculation rule. If dynamic options are specified in the referenced TOU map and if there are dynamic option events in effect within the usage period then the TOU map associated with the dynamic option is used for the entire dynamic option event period. This calculation is performed for every usage period requested.

The calculated time of use quantities are stored in the usage transaction's service quantities per Service Point and measuring component.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETTOUUSG Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetTOUUsage

Interval Tier Calculation

This rule calculates the difference between a source and reference vector. It then breaks that difference into one to many positive or negative tiers. For each tier calculated it will create a service quantity with the optional ability to create additional service quantities for the total of all

Copyright © 2026, Oracle and/or its affiliates.

positive tiers and the total of all negative tiers. This rule will loop through each tier that is configured and calculate the imbalance amount associated to that tier level.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETINTIER Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalTierCalculation

Profile Accumulation

This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.

The typical application of this rule is for customer self-service rate compare, in which a self-service user has selected a set of usage adjustments to apply to their historical consumption to assess the effect on the amount consumed.

This rule algorithm retrieves the customer's usage (the source UOM) for the usage period using one of two options:

- A channel linked to a Usage Subscription
- A usage transaction service quantity

Then it takes each entry in the usage transaction's profile factor list, finds the profile measuring component for each, retrieves the measurement data for the profile, applies axis conversion to align it to the source UOM and target interval size, and adds it to the source vector. Each profile's data is added progressively to arrive at a final vector. The final vector may then be TOU-mapped, and the vector itself may be preserved or discarded.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-DYNPRFLAC Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileAccumulation

Profile Service Quantity

This rule intervalizes scalar service quantity values based on a profile measuring component.

Copyright © 2026, Oracle and/or its affiliates.

This rule first retrieves scalar service quantities, identified by the rule's UOM/TOU/SQI. If multiple service quantities exist for the service point they will be summarized at the service point level. In the case of a split or broken usage period for a service point, the usage period is merged and the quantities are summarized. Each service quantity is subject to intervalization. The profile measuring component is then derived using the profile factor supplied with either the usage subscription or service point as characteristic sources. If the profile is not available, an exception will be created using the exception details on the rule.

If a dynamic option type is provided, the events associated with it are retrieved for the usage transaction period. Any intervalized quantities that coincide with the dynamic option events start/end date time are then recorded in a new usage period service quantity of usage type “Correlated SQ”.

If no dynamic option type provided, the intervalized quantities are recorded in a new usage period service quantity of usage type “Profile SQ”.

> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileServiceQuantity

Rolling Demand

This rule is used to calculate rolling demand for all of the service points on the usage subscription. Demand is calculated from consumption. In electric service markets, these are typically represented by kilowatts (kW) and kilowatt hours (kWh) respectively, where demand values are calculated by multiplying consumption interval values by the number of intervals per hour. For example, the demand associated with a fifteen (15) minute interval value of 25kWh would be 100kW (25 x 4 intervals per hour).

Interval Data Retrieval Parameters

This rule can be configured to use specific data either directly from a specific device and measuring component on the service point or calculated from more than one devices and/or measuring components on the service point. Each type of data is referred to as a "channel" of data. For example, a service point with solar panels might have separate channels for "Consumed" and "Generated" usage, and the rule could be configured to use data from either or based on calculations involving both.

Parameters used to retrieve interval data for this rule include:

- **Check Missing Intervals**: A flag that indicates if the rule should check for missing intervals during the calculation period.
- **No Meter Condition**: The measurement condition assigned to intervals inserted to fill gaps during periods in which when no meter is installed. If not set, the measurement condition defaults to "No Read - System" (100000).

Copyright © 2026, Oracle and/or its affiliates.

- **SP Device Filter**: An algorithm used to filter the service point device configuration that will be processed by the rule.
- **Common UOM**: The unit of measure that is common among the multiple channels of data used by the rule, if applicable
- **Common Interval Size**: The interval size used to align service point data of different interval sizes. For instance, if a service point has channels measuring data in both 1-hour and 15-minute intervals, setting this to 01:00:00 (1 hour) would scale the 15-minute data to hourly intervals.
- **Channels**: A list of the data channels measured at the service point. Each should be assigned a variable name and the appropriate UOM, TOU, and SQI.
- **Aggregation Method**: The method by which data from multiple channels will be aggregated. Channels can be combined using a simple formula or using a conditional formula.

To define a single channel for the rule to use, configure the "Vector 1 (IV1)" variable in the **Channels** section and reference that variable in a simple formula.

To configure the rule to use multiple channels, define each as a variable in the **Channels** section and configure either a simple or conditional formula to perform any needed evaluations or calculations on the channels.

Defining Formula Operands

Operands used in both simple and conditional formulas are defined in the Operand Lookup (D1-CoincidentPeakOperandLookup) extendable lookup. Operands used to represent channels should use the values in parentheses in the **Variables** drop-down list in the **Channels** section. For instance, the operand for "Vector 1 (IV1)" should be "IV1", the operand for "Vector 2 (IV2)" should be "IV2", and so on.

Operands can also be simple formulas based on the variables defined in the **Variables** drop-down list in the **Channels** section. For instance, a simple formula in which the values from Vector 1 are subtracted from the values in Vector2 could be defined as "IV2 - IV1".

Calculation Modes

This rule has two main modes: calculating rolling demand for a usage subscription based on either a rolling consumption total (Rolled Total) or rolling consumption average (Rolled Average), or calculating the coincident peak among all of the service points on a usage subscription based on either a rolling consumption total (Rolled Total - Coincident Peak) or rolling consumption average (Rolled Average - Coincident Peak). The coincident peak calculation can be performed on either all readings, or those designated as "on-peak" or "off-peak" via time of use mapping using the Coincident On-Peak or Coincident Off-Peak function, See **Defining Time of Use Mapping Options** for more information about time of use mapping.

The number of intervals in the rolling total or rolling average is determined via rule configuration. The **Roll Interval Size** parameter (in the **Calculation Details** section) divided by the **Common Interval Size** parameter (in the **Interval Data Retrieval Parameters** section). For example, if **Roll Interval Size** was 01:00:00 (1 hour) and the **Common Interval Size** was 00:15:00 (15 minutes), the rolling total or average would be based on sets of 4 intervals (1 hour divided by 15 minutes).

Rolled Demand Total

The "Rolled Demand Total" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling consumption total.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

Copyright © 2026, Oracle and/or its affiliates.

- **Date/Time**: The date and time of each interval
- **Service Point n**: The kWh value for each interval at a specific service point
- **Total**: The combined total of consumption at the usage subscription's service points
- **Rolling Total**: The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand**: The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	100
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	**105**
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	105

Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak

The "Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak" **Roll Calculate Function** identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling total at the coincident peak.

The data used in the calculation is based on the specific **Roll Calculate Function** selected:

- **Total - Coincident Peak**: Evaluates all measurements matching the configured unit of measure
- **Total - Coincident On Peak**: Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Total - Coincident Off Peak**: Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time**: The date and time of each interval
- **Service Point n**: The kWh value for each interval at a specific service point
- **Total**: The combined total of consumption at the usage subscription's service points
- **Rolling Total**: The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand**: The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest total for all of the service points within the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	**100**
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	105

Copyright © 2026, Oracle and/or its affiliates.

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represent the demand at the coincident peak:

Date/Time	Coincident Peak Demand
10/27/2022 4:00 PM	100

> **Note**
>
> This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average

The "Rolled Demand Average" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling average (calculated from the rolling total).

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time**: The date and time of each interval
- **Service Point n**: The kWh value for each interval at a specific service point
- **Total**: The combined total of consumption at the usage subscription's service points
- **Rolling Total**: The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Rolling Average**: The rolling average of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand**: The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 12:00 PM	12	11	23			
10/27/2022 1:00 PM	10	12	22			
10/27/2022 2:00 PM	11	13	24			
10/27/2022 3:00 PM	13	13	26	95	23.75	23.75
10/27/2022 4:00 PM	14	14	28	100	25	25
10/27/2022 5:00 PM	13	13	26	104	26	26
10/27/2022 6:00 PM	12	13	25	105	26.25	**26.25**
10/27/2022 7:00 PM	11	12	23	102	25.5	25.5
10/27/2022 8:00 PM	12	13	25	99	24.75	24.75
10/27/2022 9:00 PM	13	14	27	100	25	25
10/27/2022 10:00 PM	12	14	26	101	25.25	25.25
10/27/2022 11:00 PM	12	12	24	102	25.5	25.5

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	26.25

> **Note**
>
> This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average- Coincident Peak /Rolled Demand Average-Coincident On Peak / Rolled Demand Average - Coincident Off Peak

The "Average -Coincident Peak / Average - Coincident On-Peak / Average - Coincident Off-Peak"**Calculate Function**identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling average at the coincident peak.

The data used in the calculation is based on the specific**Roll Calculate Function**selected:

Copyright © 2026, Oracle and/or its affiliates.

- **Rolled Demand Total - Coincident Peak**: Evaluates all measurements matching the configured unit of measure
- **Rolled Demand Total - Coincident On Peak**: Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the**Results**section based on a specified TOU Map Template.
- **Rolled Demand Total - Coincident Off Peak**: Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the**Results**section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period.This table includes the following:

- **Date/Time**: The date and time of each interval
- **Service Point n**: The kWh value for each interval at a specific service point
- **Total**: The combined total of consumption at the usage subscription's service points
- **Rolling Total**: The rolling total of 4 total values (based on a**Roll Interval Size**of 01:00:00 (1 hour) and**Common Interval Size**of 00:15:00 (15 minutes))
- **Rolling Average**: The rolling average of 4 total values (based on a**Roll Interval Size**of 01:00:00 (1 hour) and**Common Interval Size**of 00:15:00 (15 minutes))
- **Demand**: The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule wouldidentify the highest demand for the usage subscription during the calculation period (indicated in**bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand

Notes and Examples

Notes and Recommendations

- When using he "Coincident On Peak" or "Coincident Off Peak"**Roll Calculate Function**, you must specify either a TOU map (in the**TOU Map**field) or a TOU map template (in the**On Peak Off Peak Schedule**drop-down list) in the**Calculation Details**section,and specify the appropriate time of use period (On-Peak or Off-Peak, respectively) in the**TOU**field in the**Results**section.
- A recommended practice is to configure a Service Quantity Identifier (SQI) to uniquely identify coincident peak data and specify it in the**SQI**field in the**Results**section.
- Additional detail on the logic of this rule can be found in the **Detailed Description** of the D1-CALROLDEM Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-CalcRollingDemandRule

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Calculate demand for services points based on rolling total (based on a single channel)

- **Interval Data Retrieval Parameters**:
  - **Check Missing Intervals**: Yes
  - **No Meter Condition**: No Read - System
  - **Common UOM**: Kilowatt-Hour
  - **Common Interval Size**: 00:15:00
  - **Channels**:
    - **Variable 1**:

Copyright © 2026, Oracle and/or its affiliates.

        - **Variable Name**: Variable 1 (IV1)
        - **UOM**: Kilowatt-Hour
    - **Aggregation Method**:
        - **Formula Source**: Simple Vector Formula
        - **Simple Vector Formula**: IV1
- **Calculation Details**:
    - **Roll Calculate Function**: Rolled Demand Total
    - **Roll Interval Size**: 01:00:00
- **Results**:
    - **UOM**: Kilowatt
    - **TOU**:
    - **SQI**:

Scenario 2: Calculate demand for service points based on rolling total (based on two channels)

In this scenario, the service point has two channels, one for consumed energy, and one for generated energy (from a solar panel). If the consumed value is greater than the generated value, subtract the generated value from the consumed value. If the generated value is greater than the consumed value, use zero (0).

- **Interval Data Retrieval Parameters**:
    - **Check Missing Intervals**: Yes
    - **No Meter Condition**: No Read - System
    - **Common UOM**: Kilowatt-Hour
    - **Common Interval Size**: 01:00:00
    - **Channels**:
        - **Variable 1**:
            - **Variable Name**: Variable 1 (IV1)
            - **UOM**: Kilowatt-Hour
            - **TOU**:
            - **SQI**: Consumed
        - **Variable 2**:
            - **Variable Name**: Variable 2 (IV2)
            - **UOM**: Kilowatt-Hour
            - **TOU**:
            - **SQI**: Generated
    - **Aggregation Method**:
        - **Formula Source**: Conditional Vector Formula
        - **Conditional Vector Formula**:
            - **Sequence**: 10
            - **Left Operand**: IV1

Round and Adjust Usage

This rule copies identified source and target Service Quantities and inserts these as period Service Quantities that are rounded and adjusted. This rule captures the source and target Service Quantity identifiers, rounding method, and Service Quantity bucket to hold the adjustment. The usage calculation rule also has an option to validate the difference between the source and target service quantities.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RNDADJUSG Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RoundAndAdjustUsage

Vector and Service Quantity Math

This rule is designed to facilitate configuration of complex vector and scalar quantity calculations. It is based on a series of underlying services, including Axis Conversion, Apply Formula (most importantly), and Apply TOU Map. It can be configured to accept as input up to five vectors - where a single vector can represent the combination of all measuring components with linkages to the Usage Subscription with the configured UOM/SQI. It can also accept a list of scalar variables that can be taken in as factor values, usage transaction service quantities, set functions on a vector, or numeric values.

Vectors can be combined using a simple formula expression, or using condition formula expressions. Both interval values and interval conditions can be referenced. The result is interval-by-interval processing of the vector formula. The resulting final vector can be stored, TOU mapped, and/or subjected to a final set function (such as sum or max).

This rule stores service quantities of type "other" - meaning that the service quantities created by this rule do not have linkages to a specific Service Point or measuring component, given the potentially diverse sources of the data taken as input by this rule that lead to the final quantity.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-MATH Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-Math

Copyright © 2026, Oracle and/or its affiliates.

Vector and Service Quantity Math Usage Calculation Rules and Anchor Time

The Vector and Service Quantity Math usage calculation rule supports usage calculations based on an "Anchor Time". The Anchor Time is specified on certain measuring component types and defines the start and end time of the business day for purposes of processing measurement data and usage transactions. When processing usage calculations for measuring components whose type specifies an **Anchor Time**, the Start Time and End Time of the calculation period should match the **Anchor Time** on the measuring component type.

Post-Calculation Usage Calculation Rules

- Usage Calculation High/Low Rule
- Validate Against Tolerance
- Business Flag Hold

Usage Calculation High/Low Rule

This rule is used to validate the current usage against historical usage - previous year usage or previous usage. It ensures that any increase or decrease of the current usage relative to historical usage is within a tolerance.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-USGHIGLOW Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UsageHighLowRule

Validate Against Tolerance

This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-VALUSGTOL Algorithm Type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D2-ValAgainstTol

Business Flag Hold

This rule can be used to place a hold on a usage transaction until the business flags related to the usage transactions service points can be investigated. The hold can be placed in one of two ways:

- **Calculation Window Based**: holds will remain until either a user manually bypasses the usage exception error or the current date is within a configurable tolerance of the calculation window end (aka the retry until date time).
- **Indefinite**: holds require a user to manually bypass the usage exception that is generated.

Defining which business flags should result in a usage transaction is a matter of identifying which business flag types, priorities, and confidences should be included.

> **Note**
>
> Additional detail on the logic of this rule can be found in the Detailed Description of the D2-AUR-IBFH algorithm type.
>
> For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D2-BusinessFlagHold

Decision-Making Usage Calculation Rules

- Execute Usage Calculation Group
- Exception Handler

Execute Usage Calculation Group

This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group. It is especially useful in cases where repeating the same rule over and over would be hard to maintain.

For example, you may want to calculate a straightforward kWh sum for every usage calculation group. Creating a separate CALC_KWH_SUM usage calculation group for this one calculation allows you to isolate the configuration points. Then the CALC_KWH_SUM usage calculation group can be referenced in every other usage calculation group that needs this sort of service quantity.

D2-UsageRuleExceptionHandler

Detailed Configuration Examples

Demand Calculation Options Using Interval Data

There are a number of ways to calculate a demand value from interval data when retrieving bill determinants for CIS. A few examples of demand calculations are listed below:

Scenario1: Use interval data for demand at a common block size: the Vector and Service Quantity Math usage calculation rule can be used to calculate demand from the interval data. Below is one example of configuration to handle demand calculation based on 30 minute blocks:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.

Copyright © 2026, Oracle and/or its affiliates.

Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	Yes	
Result // SQ Entry Quantity Source	Set Function Against Derived Vector	
Result // Set Function Against Derived Vector	Max	This function pulls the max value based on the configuration in the "Vector Processing" section.

Scenario 2: Use interval data for demand by TOU period: This example is very similar to the last and again leverages the Vector and Service Quantity Math usage calculation rule. However, instead of calculating a single demand value for the entire period it will calculate a demand value for each TOU period:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.

Copyright © 2026, Oracle and/or its affiliates.

Result // Insert Primary SQ Entry	No	
Result // Apply TOU Map To Derived Vector	Yes	
Result // TOU Map	(your TOU Map)	Select the TOU Map you'd like to apply.
Result // Time Of Use Calculate Function	Max	This function pulls the max value based on the configuration in the "Vector Processing" section and then buckets it based on the selected TOU Map.

Usage Calculation Types

- Understanding Usage Calculation Types
- Configuring Usage Calculation Types

Understanding Usage Calculation Types

Usage calculation types define calculations executed at a customer level where there may be more than one calculation per usage subscription. For example, a customer may have a usage subscription for producing billing determinants but there may be additional calculations that will be executed on a much less frequent basis (annually, quarterly, etc). Usage calculation types provide a way to leverage a single usage subscription to drive multiple different calculations.

Usage calculation types use the following parameters:

- **Request Type**: Used to drive the creation and processing of the usage transactions for all usage subscriptions that are valid for the usage calculation type.

  > **Note**
  >
  > Request types for usage calculation types should be based on the Usage Calculation Request Type business object (D2–UsageCalculationReqType)

- **Service Point Quantity Creation**: Details of the quantities created by usage calculations of this type, including service point quantity type, and UOM, TOU, and SQI.
- **Applicable Usage Subscription Types**: A list of usage subscription types for which this usage calculation type is applicable. Each usage subscription type is defined by an effective date range, the usage transaction business object used for the usage calculation, the result UOM/TOU/SQI, and the usage calculation group used to perform the calculations.

Configuring Usage Calculation Types

You use the **Usage Calculation Type** portal to maintain and view usage calculation types.

Refer to Understanding Usage Calculation Types for more information.

Copyright © 2026, Oracle and/or its affiliates.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Type List**: This zone lists all usage calculation type records. Broadcast a record to display the details of the selected record.
- **Usage Calculation Type**: This zone displays details for the selected usage calculation type.

Usage Subscription Quantity Types

- Understanding Usage Subscription Quantity Types
- Configuring Usage Subscription Quantity Types

Understanding Usage Subscription Quantity Types

Usage subscription quantity types define types of quantities that can be stored for a usage subscription. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer’s usage compares to the profiled usage for their rate class.

In a settlement implementation, usage subscription quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Usage subscription quantity types use the following parameters:

- **Service Type**: The service type (electric, gas, water, etc.) for service point quantities of this type.
- **Usage Subscription Quantity Business Object**: The business object used for usage subscription quantities of this type.
- **Usage Subscription Quantity Identifiers**: Value identifiers related to the current usage subscription quantity type (used to provide shorthand descriptions of the various types of values measured by usage subscription quantities of this type).

Configuring Usage Subscription Quantity Types

You use the **Usage Subscription Quantity Type** portal to display and maintain usage subscription quantity types.

Refer to Understanding Usage Subscription Quantity Types for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Quantity Type List**: This zone lists all usage subscription quantity type records. Broadcast a record to display the details of the selected record.
- **Usage Subscription Quantity Type**: This zone displays details for the selected usage subscription quantity type.

Dynamic Option Types

- Understanding Dynamic Option Types
- Configuring Dynamic Option Types

Understanding Dynamic Option Types

Dynamic options specify terms that override how usage is normally calculated, such as a critical peak period that affects the TOU mapping of interval consumption. Dynamic option types store information common to dynamic options of a specific type.

There are two classes of dynamic options:

- **Interval Set**: Used to represent dynamic option types that provide a set of intervals that will be included in a calculation.
- **Usage Event**: Used to represent dynamic option types that provide a specific period of time during which a dynamic option is applicable.

Interval Set dynamic option types also define key information about the interval data they represent, including:

- **Unit of Measure**: Identifies the quantity that Interval Set dynamic options and Interval Set dynamic option events based on this type are measuring.
- **Interval Size**: Defines the size of the intervals for Interval Set dynamic option events of this type, represented as hours:minutes:seconds (HH:MI:SS).

Configuring Dynamic Option Types

This portal is used to display and maintain a Dynamic Option Type.

Refer to Understanding Dynamic Option Types for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Dynamic Option Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Dynamic Option Type List**: displays all of the Dynamic Option Types so you can choose the one you want to display in more detail
- **Dynamic Option Type**: shows the specific configuration for the selected Dynamic Option Type

Bill Cycle

- Understanding Bill Cycles
- Configuring Bill Cycles

Understanding Bill Cycles

Copyright © 2026, Oracle and/or its affiliates.

Bill cycles identify when a customer is going to be billed and when bill determinants are going to be calculated.

> **Note**
>
> Meter Data Management bill cycles are created from Customer Care and Billing bill cycles via Customer To Meter Master Data Synchronization.

Configuring Bill Cycles

This portal is used to display and maintain a Bill Cycle.

Refer to Understanding Bill Cycles for more information.

You can access the portal from other objects such as Measurement Cycles.

The following zones may appear as part of the portal's **Main** tab page:

- **Bill Cycle List**: displays all of the Bill Cycles so you can choose the one you want to display in more detail.
- **Bill Cycle**: shows the specific configuration for the selected Bill Cycle.
- **Bill Cycle List**: lists the bill cycle schedules of the current bill cycle.

> **Note**
>
> Meter Data Management bill cycles are created from Customer Care and Billing bill cycles via Customer To Meter Master Data Synchronization. Bill cycles should only be updated via the Customer Care and Billing Bill Cycle portal.

Defining Time of Use Options

- Time of Use Groups
- Time of Use Map Templates
- Time of Use Map Types

Time of Use Groups

- Understanding Time of Use Groups
- Configuring Time of Use Groups

Understanding Time of Use Groups

Time of Use (TOU) Groups are groups of TOUs that are associated to TOU templates that limit the TOUs available for use in a TOU schedule. These TOUs will be available as the default, holiday, and schedule TOUs within the template.

Copyright © 2026, Oracle and/or its affiliates.

Each TOU in the group is given a priority. The priority is important in a few ways:

- The TOU Overlay 360 Degree zone uses these priorities to decide which TOUs will be rendered as a unique shade and which will fall into a category of "other" when the maximum number of distinct TOUs to graph has been reached.
- These priorities are available for use in customized logic.

Configuring Time of Use Groups

This portal is used to display and maintain a TOU Group.

Refer to Understanding Time of Use Groups for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Group**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Group List:** This zone lists all TOU Group records. Broadcast a record to display the details of the selected record.
- **TOU Group:** This zone provides information about the selected TOU Group.

Time of Use Map Templates

- Understanding Time of Use Map Templates
- Configuring Time of Use Map Templates

Understanding Time of Use Map Templates

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period.

The system periodically generates TOU map data for TOU maps by interpreting the rules defined template.

Attributes used to define TOU map templates include the following:

- **TOU Group**: the TOU group used by the map template Default TOU: the default TOU for the map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
- **Work Calendar**: the work calendar used to identify holidays. On each holiday the Holiday TOU will be used. For additional information see Defining Work Calendar in the Oracle Utilities Application Framework *Administrative User Guide*.
- **Holiday TOU**: the TOU used for holidays (from the TOU Group)
- **Holiday Template**: the TOU map template used for holidays (if applicable)

Copyright © 2026, Oracle and/or its affiliates.

- **Interval Size**: the size of the intervals for TOU map data created from the map template, represented as hours:minutes:seconds (HH:MI:SS).
- **TOU Schedules**: date ranges (including month, day, and time ranges) and which TOU periods apply to each

Refer to Understanding Referencing Master Data by Identifiers for information on how admin configuration can reference a TOU map by a TOU template to ease migration of data between environments.

TOU Map Template Interval Size

TOU map templates can also specify an interval size (in seconds-per-interval, or SPI). This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose SPI is divisible by the template's SPI. For example, a 60 minute template can be used to generate TOU data for TOU maps with SPIs of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every SPI.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays in two ways. Both options require that the template references a Work Calendar that identifies each of the holidays throughout the year. In addition they require either:

- A Holiday TOU that will be used for each holiday for the duration of that holiday (e.g. Off Peak)
- A Holiday TOU Map Template that defines the TOUs that should be used for holidays that fall during different seasons within the year (e.g. Off Peak Summer, Off Peak Winter)

Important Time of Use Template System Events

The time of use template supports the following business object algorithm system events:

- **Derive TOU**: receives a date time and determines the TOU code for that date time based on the configuration of the time of use template schedule. See the Derive Time Of Use For Date Time (D2-DERTOU-DT) algorithm type as an example.

Configuring Time of Use Map Templates

This portal is used to display and maintain a TOU Map Templates.

Refer to Understanding Time of Use Map Templates for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Template**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Template List:** This zone lists all TOU Map Template records. Broadcast a record to display the details of the selected record.
- **TOU Map Template:** This zone provides information about the selected TOU Map Template.

Copyright © 2026, Oracle and/or its affiliates.

Time of Use Map Types

- Understanding Time of Use Map Types
- Configuring Time of Use Map Types

Understanding Time of Use Map Types

TOU Map Types define important properties of TOU maps of the type, including the interval size and the valid TOU map templates.

Attributes used to define TOU map types include the following:

- **Time Zone**: the time zone to be used when generating the TOU map data. Refer to Multiple Time Zone Support for more information about how time zones impact TOU map data in multiple time zone environments.
- **Interval Size**: the size of the intervals for TOU map data created from maps of this type, represented as hours:minutes:seconds (HH:MI:SS). The interval size cannot be larger than the interval size defined on the Default TOU Map Template or any of the Override TOU Map Templates.
- **Default TOU Map Template**: the default TOU map template used by maps of this type
- **Override TOU Map Templates**: one or more TOU map templates that can be used as an override on TOU maps of this type.

TOU Map Type Interval Size

The SPI of a TOU map must divide evenly into the SPI of any measuring component that uses the map (because the system joins the date/time of the measurement to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute measuring component. However, it is not OK to have a 60 minute TOU map used with a 15 minute measuring component because the join will miss 3 out of 4 measurements.

However, it is important to note that the TOU mapping process is at its most efficient when the measurement data that is being mapped is of the same interval size as the TOU schedule it is being mapped against. When there are differences in the interval size the process must first convert the measurement data into the appropriate interval size for the TOU Map prior to applying the TOU Map.

This means that for each TOU Map Template you should have sufficient TOU Map Types to cover the various interval sizes that will be supported by your measurement data. For example, if you have measuring components with interval sizes of 15 minutes, 30 minutes, and 60 minutes then for each TOU Map Template there should be TOU Map Types with interval sizes of 15 minutes, 30 minutes, and 60 minutes.

Default and Override TOU Map Templates

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support a fallback/override pattern used in other areas of the system.

- A TOU map's TOU map type defines the default (or "fallback") TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the "fallback" template.

Copyright © 2026, Oracle and/or its affiliates.

- An individual TOU map can have an override template. If the TOU map doesn't have an override template, the fallback template defined on the TOU map type is used to generate the map's TOU data.

Important Time of Use Map System Events

The TOU Map business object that is associated to a given TOU map type supports a special system event that is used in the generation of TOU map data:

- **Create TOU Map Data**: receives a date range and for that date range it will create the appropriate TOU map data for the TOU map. See the Create TOU Map Data (D2-CRETMD-CT) algorithm type as an example.

Configuring Time of Use Map Types

This portal is used to display and maintain a TOU Map Types.

Refer to Understanding Time of Use Map Types for more information.

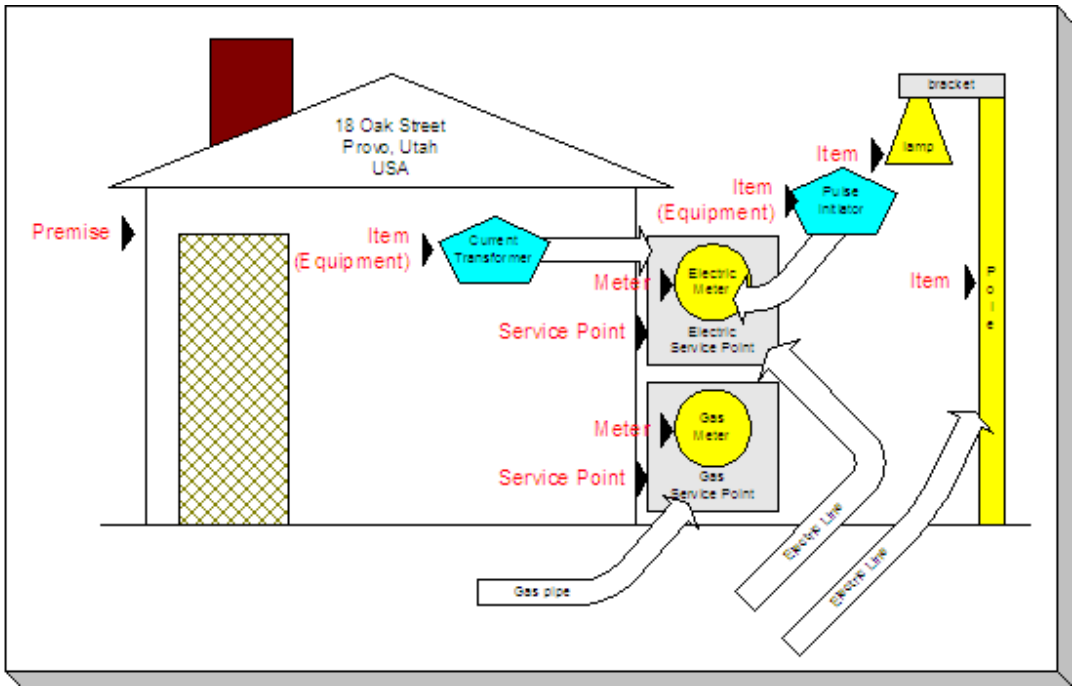
You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Type List:** This zone lists all TOU Type records. Broadcast a record to display the details of the selected record.
- **TOU Map Type:** This zone provides information about the selected TOU Map Type.

Defining Premise and Service Point Options

A premise is where a customer consumes the services supplied by your company. Located at a premise are the various devices that consume energy and measure consumption. Before you can define premises and devices, you must set up the control tables defined in this section.



> **Warning**
>
> The topics in this section do not describe every table that must exist in order to set up premises and service points. Many premise and service point control tables are described in Defining Device Options, and Defining Service Order Options. The tables described in this section are those that must be set up regardless of the type of service.

- An Illustration Of A Premise
- Setting Up Premise Options
- Setting Up Generic Service Point Options
- Setting Up Premise & Service Point Postal Defaults
- Designing SP Types

Copyright © 2026, Oracle and/or its affiliates.

An Illustration Of A Premise

The following picture illustrates a premise with 2 service points, 2 meters, and 2 badged items:

The following concepts are illustrated above:

Premise A premise describes a location at which your company supplies some type of service. In addition to the obvious address information, a premise also contains geographic coordinates, meter read instructions, and taxation jurisdiction information.

> **NOT_SUPPORTED**
>
> For more information about the control tables that must be set up before you can define a premise see Setting Up Premise Options.

Service Point A service point (SP) is a geographic location at which service(s) are delivered to a premise. The SP record maintains information about the type of service, the measurement cycle (if the service is metered), the field office responsible for maintaining the service, the distribution company that supplies the service, etc.

There are three major categories of service points:

- Those where the rate of consumption and the total amount of consumption is measured (e.g., electricity, gas, water) by a meter. You can think of this type of service point as a "socket" into which a meter can be plugged. Over time, many meters may be plugged into the socket. We refer to these types of service points as metered.
- Those that hold badged items. A badged item is a physical device with a unique identity (e.g., a specific street light, a specific hydrant). You can think of this type of service point as

Copyright © 2026, Oracle and/or its affiliates.

a "socket" into which a badged item can be plugged. Over time, many items may be plugged into the socket. We refer to these types of service points as item-based.

- Those used to hold one or more non-badged items. For example, if your organization doesn't badge street lamps, you can use a single service point to hold an infinite number of lamps. We refer to these types of service points as non-badged.

> **NOT_SUPPORTED**
>
> Refer to Service Points (SPs) for more information about non-badged items.

An unlimited number of SPs may exist at a premise. However in reality, the number of SP's is related to the number of services supplied by your company. For example, an electric and gas company will typically have two SPs per premise.

> **NOT_SUPPORTED**
>
> For more information about the control tables that must be set up before you can define service points refer to Setting Up Generic Service Point Options, Defining Device Options.

Field activities may be dispatched to all types of service points.

Meter A meter is a physical device used to measure the amount of gas, water, or electricity used by a customer. While most meters measure consumption in a single unit of measure (e.g., gallons, cubic feet, kilowatt-hours), some electric meters are extremely sophisticated and measure several different factors. For example, some electric meters measure how much was used, when it was used, the efficiency of consumption, the maximum amount used, and a few other unusual things.

> **NOT_SUPPORTED**
>
> For more information about the control tables that must be set up before you can define a meter, refer to Defining Device Options, and Setting Up Consumption Estimation Parameters.

Item An item that is not consider to be "equipment" is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. Items are related to service points and a service point can have one or more items linked to it.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about the control tables that must be set up before you can define an item, refer to Configuring Device Types.

For more information about premises and service points, refer to Understanding The "V".

Setting Up Premise Options

This section describes tables that must be set up before you can define premises.

- Defining Premise Types
- Implementing Address Validation

Defining Premise Types

Open **Admin**, and then **Geographic**, and then **Premise Type** to define the premise types used to categorize your premises.

Description of Page

Enter a unique **Premise Type** and a **Description** for every premise type.

Allow CIS Division controls whether premises of this type can use the CIS Division on the premise page. Valid values are Not Allowed, Optional, and Required.

If your implementation requires restricting data by CIS Division, it is recommended that Allow CIS Division be set to Required.

Implementing Address Validation

In order to set up address validation, you must ensure that the following Option Types are defined with their corresponding values on the General System Configuration – Feature Configuration page:

Option Type	Description
Address Validation Script	Indicates the name of the BPA script to invoke when a user clicks on the validate address button. This option is required if the Allow Address Validation option is set to Y. The base product includes sample script C1-ValAddr that uses Oracle Spatial procedures and functions to geocode an address and return its matching quality code.
Allow Address Validation	Indicates whether an integration with address validation software is implemented. If set to Y, the system will render a validate button along with the address fields displayed throughout the application to trigger address validation. Valid values are 'Y' and 'N'. If set to Y, the Address Validation Script to invoke must be specified.

Copyright © 2026, Oracle and/or its affiliates.

As described in the above table, the base product includes sample script C1-ValAddr uses Oracle Spatial procedures and functions to geocode an address and return a matching quality code. To use this script, ensure that the Oracle Spatial Geocoding (F1-ORAGEOCD) algorithm is plugged in on installation options for the geocoding service system event. A data source containing the geocoding data must also exist on the database.

If your implementation uses something other than Oracle Spatial for address validation, you'll need to create a new address validation BPA script to specify on the General System Configuration feature configuration. For additional information about creating this script, see the steps descriptions for the C1-ValAddr script in the application. The new script should contain the following move step to update the page:

- If the calling page is an old style page, the move from the BPA to the page can be achieved by specifying a move step from a source field to a User Interface Field.
- If the calling page is a display map, the move from the BPA to the page can be achieved by specifying a step to read the Business Object, modify the values as returned by the validation software, and then update the BO.

Setting Up Generic Service Point Options

This section describes tables that must be set up before you can define service points.

- Setting Up Service Point Types

Setting Up Service Point Types

Every service point must reference a service point (SP) type. The SP type controls almost all aspects of the service point's behavior (e.g., the type of field activity that may be dispatched to it, the type of service agreement that may be linked to it, the type of device that may be installed at it).

The topics in this section describe the windows used to set up your SP types.

> ⚠ **Warning**
>

Setting Up Premise & Service Point Postal Defaults

You set up postal defaults if your company is able to default field values onto new premises and service points based on the premise's postal code. The topics in this section describe how to maintain postal defaults.

Copyright © 2026, Oracle and/or its affiliates.

> **NOT_SUPPORTED**
>
> For more information about where these default values are used, refer to Maintaining Premises and Maintaining Service Points.

- Postal Defaults - Main
- Postal Defaults - Service Default

Postal Defaults - Main

To define premise postal defaults, open **Admin**, and then **Geographic**, and then **Postal Code Default**, and then **Add.**

Description of Page

Enter the **Country Code** and range of postal codes to which the default values apply using the **From Postal** and **To Postal**.

> **Note**
>
> You may not have postal defaults whose from / to postal codes overlap.

Trend Area is not applicable for Customer to Meter.

Enter the **County** to be defaulted onto new premises located in this postal code range.

Enter the **City** to be defaulted onto new premises located in this postal code range.

Enter the **CIS Division** to be defaulted onto new premises located in this postal code range.

Enter the **State** to be defaulted onto new premises located in this postal code range.

Enter the **Time Zone** to be defaulted onto new premises located in this postal code range.

Use the **Characteristic Types and Values** collection to define the **Characteristic Type**s and their respective **Characteristic Value**s to be defaulted on premises located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a premise.

> **NOT_SUPPORTED**
>
> For more information about characteristics, see Setting Up Characteristic Types & Their Values and An Illustration Of A Bill Factor And Its Characteristics .

Use the **Geographic Types and Values** collection to define the **Geographic Type**s and their respective **Value**s to be defaulted on premises located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

Copyright © 2026, Oracle and/or its affiliates.

This information is defaulted when a new Premise is added. Characteristics and geographic values are also defaulted when the postal code for a Premise is changed. Refer to Maintaining Premises for more information.

Postal Defaults - Service Default

To define values to be defaulted for a service point located in a postal range, open **Admin**, and then **Geographic**, and then **Postal Code Default**, and then **Search** and navigate to the **Service Defaults** page.

> **NOT_SUPPORTED**
>
> For more information about where these default values are used, refer to Maintaining Service Points.

Description of Page

Use the **Service Defaults** collection to define values to be defaulted on service points located in a given postal code range belonging to a given **Service Type** (note, a service point's Service Type comes from its SP Type).

Stock Location is not applicable for Customer to Meter.

- Use the **Characteristic Types and Values** collection to define the **Characteristic Type**s and their respective **Characteristic Value**s to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a service point.
- Use the **Geographic Types and Values** collection to define the **Geographic Type**s and their respective **Value**s to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Designing SP Types

Every service point must reference an SP type. When you set up an SP type, you define how the system manages many aspects of its service points' behavior.

> **Note**
>
> **Perfect foresight.** In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SP types. In reality, setting up your SP types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Copyright © 2026, Oracle and/or its affiliates.

Designing your SP types is an iterative process. To minimize the number of iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SP types.

SP Type	Service Type

- Service Segmentation
- Device Segmentation
- SA Type Segmentation

Service Segmentation

At a minimum, you will have one SP type for every different type of service that exists at your premises. If we assume that your organization sells gas, water, waste water and electricity services, you will need four SP types.

SP Type	Service Type
GAS	Gas service
WATER	Water service
WASTE WATER	Waste water service
ELECTRIC	Electric service

Device Segmentation

For each service, determine if there exist meters, badged items, or non-badged items at the service points. For example, if we assume:

- Electric service has service points with meters, badged lamps, and parking lots.
- Gas and water services just use meters.
- Waste water service doesn't actually have a meter installed at it (it uses the water consumption measured by the water service point's meter)

Then your SP types will be:

SP Type	Service Type	SP Sub Type
GAS - METERED	Gas service	Meter
WATER - METERED	Water service	Meter
WASTE WATER	Waste water service	Unbadged
ELECTRIC - METERED	Electric service	Meter
ELECTRIC - BADGED LAMP	Electric service	Item
ELECTRIC - PARKING LOT	Electric service	Unbadged

Copyright © 2026, Oracle and/or its affiliates.

SA Type Segmentation

Every SP Type whose service points can be linked to a service agreement has one or more SA types. These define which type of service agreements can pay for the service point's service. If different service points have different valid SA types, you will need to split the SP types accordingly.

The SA Type segmentation of SP Types is the most complicated design decision you'll have to make. Unfortunately, the decision making process is subjective and iterative. The iterations are caused by the fact that the number of SA types is dependent on the number of SP types (and vice versa). We recommend the following to help work your way through this conundrum:

- Design your SA types using the information in Defining Service Agreement Types.
- Return to your SP types and determine if, given the proposed SA types, you can define a list of valid SA types for each SP type. If you find the population of SA types (and their valid rates) could result in invalid rates paying for service at a service point, divide your SA types further.

Defining Bill and Measurement Cycles

This chapter is dedicated to issues related to defining cycles, routes and schedules in the system.

- Defining Bill and Measurement Cycles
- Defining Statement Cycles

Defining Bill and Measurement Cycles

Every account references a bill cycle. An account's bill cycle controls when it is billed.

Every manually read metered service point references a measurement cycle. A service point's measurement cycle controls when a service point's meter is measured.

The design of your measurement and bill cycles is inextricably linked because you probably want to bill your customers shortly after their meter devices are measured.

In this section, we describe how to design and set up these cycles. In addition, we discuss how to set up bill period schedules. These are used to define the bill segment end date for special types of non-metered service agreements.

> **Note**
>
> **Recommendation.** We recommend reviewing Bill Frequency - Bill Cycle vs Bill Segment Duration before setting up this information.

- A Description of the Cyclical Meter Read Process
- Designing Measurement Cycles, Routes, And Schedules

A Description of the Cyclical Meter Read Process

Manual meter readers using handheld devices record most meter reading measurements in the field. These meter reads are uploaded into the system for use by Oracle Utilities Meter Data Management.

A service point's installed meter device is measured due to the following data relationships:

- Every metered service point references a schedule route.
- A route references a measurement cycle.
- A measurement cycle has measurement cycle schedules that define when the service points in the cycle are measured.
- Every measurement cycle schedule contains two dates:
  - **Scheduled selection date.** This is the date Meter Data Management could use to select the service points in the cycle for download to your handheld software via custom algorithms to create handheld activities when pending measurement cycle schedules are proposed (refer to Measurement Cycle and Bill Determinants for more information).
  - **Expected work date.** This is the date the meter is expected to be read.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Overriding a route within a specific schedule.** Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to Designing Measurement Cycles, Routes, And Schedules for more information.

- On the scheduled selection date, Meter Data Management could create a download file, via custom algorithms, containing information to be sent to your handheld software. This download file should contain information about every register or measuring component on every meter in the routes being downloaded.
- Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant measurements are uploaded into the system for subsequent use by other processes such as usage transactions for billing.

> **Warning**
>
> It is very important to create a measurement cycle schedule for every expected read date regardless of whether the cycle's routes are downloaded. Why do you have to do this? Because Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement during usage calculations. If it can't find a reading on or near this date, Oracle Utilities Meter Data Management may estimate consumption. Without a measurement cycle schedule, MDM wouldn't know when to look for readings. So, for example, if you estimate a given cycle's consumption EVERY OTHER MONTH, you must create a measurement cycle schedule for EVERY month. On each month's schedule, you must define if the routes should be downloaded.

> **NOT_SUPPORTED**
>
> For more information about the how to control when a cycle is read, refer to Setting Up Measurement Cycle Schedules.

Designing Measurement Cycles, Routes, And Schedules

The topics in this section provide information describing how to design your measurement cycles, routes, and schedules.

- Designing Measurement Cycles For Meter Reading
- Designing Schedule Routes For Meter Reading
- Designing Metered Measurement Cycle Schedules

Designing Measurement Cycles for Meter Reading

Copyright © 2026, Oracle and/or its affiliates.

The criterion that affects the number of measurement cycles has nothing to do with when meter readers physically read your meter devices. Rather, the frequency that you bill the meter's consumption (real or estimated) is what controls the number of measurement cycles.

So, for example, if you bill every month, but read every OTHER month, you'll have 20 measurement cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 measurement cycles. If you bill quarterly, you'll have 60 measurement cycles. Etc.

> **Note**
>
> **Different billing frequencies are possible for different service points.** If you have different billing frequencies for your different types of metered service, you'll need a different set of cycles for each billing frequency. For example, if you bill water quarterly and electricity monthly, you'll have 20 bill cycles (one for each bill day during a month), but you'd need 60 quarterly measurement cycles for your water service points, and 20 monthly measurement cycles for your electric service points. This would result in a customer getting billed every month. However, four times a year, their bill would contain a charge for both electricity and water.

Top of the Page

Designing Service Routes For Meter Reading

The following points describe the relationship between a meter read, a route and a measurement cycle:

- A measurement cycle contains one or more routes.
- A route has one or more service points.
- A service point holds an installed meter device.
- And a device is what is measured.
- Therefore, the number of devices a person can read in a day limits the number of service points in a route.

> **Warning**
>
> If your company supplies electric service and uses MV90's, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because usage calculation is dependent on the route's cycle to determine the expected meter read date.

Top of the Page

Designing Metered Measurement Cycle Schedules

The process of designing your measurement cycle schedules is either easy or complicated. It will be easy if all routes within a cycle are downloaded when the measurement cycle is scheduled for download. It will be complicated if you download a subset of routes within a cycle on any given download date. We'll provide a few examples to help explain why.

Copyright © 2026, Oracle and/or its affiliates.

If you download all cycles in a route whenever the cycle is downloaded, your measurement cycle schedule will look as follows.

> **Note**
>
> **Bill cycles.** We've included each measurement cycle's related bill cycle to help you understand when the measurement cycle's consumption will be billed. Bill cycles are discussed in Bill Cycles.

Measurement Cycle	Download Date	Expected Work Date	Which Routes To Download	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	All	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	All	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	All	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	All	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc. to 20						

Now let's complicate life. If we assume you physically read your routes every other month (but bill monthly using estimated consumption), then you'll need the following measurement cycle schedule.

Measurement Cycle	Download Date	Expected Work Date	Which Routes	Bill Cycle	Bill Window	Estimation Date
1	30-May-99	31-May-99	1, 2, 3 - Download 4, 5, 6 - Estimate	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc. to 20						
1	29-Jun-99	30-Jun-99	1, 2, 3 - Estimate 4, 5, 6 - Download	1	30-Jun-99 to 2-Jul-99	2-July-99

Copyright © 2026, Oracle and/or its affiliates.

2	30-Jun-99	1-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	2	1-July-99 to 3-Jul-99	3-July-99
3	1-July-99	2-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	3	2-July-99 to 4-July-99	4-July-99
4	2-July-99	3-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	4	3-July-99 to 7-July-99	7-July-99
Etc. to 20						

Notice the following:

- You still have 20 measurement cycles even though you only read the meters every other month. Why? Because Oracle Utilities Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement. If it can't find a reading on this date, Meter Data Management estimates consumption. Without a measurement cycle schedule, Meter Data Management wouldn't know when to look for readings.
- Every other month you download half the routes in each cycle and estimate consumption for the other half.
- If you don't download all routes when a measurement cycle is scheduled, you have to indicate how to handle every route in the cycle.

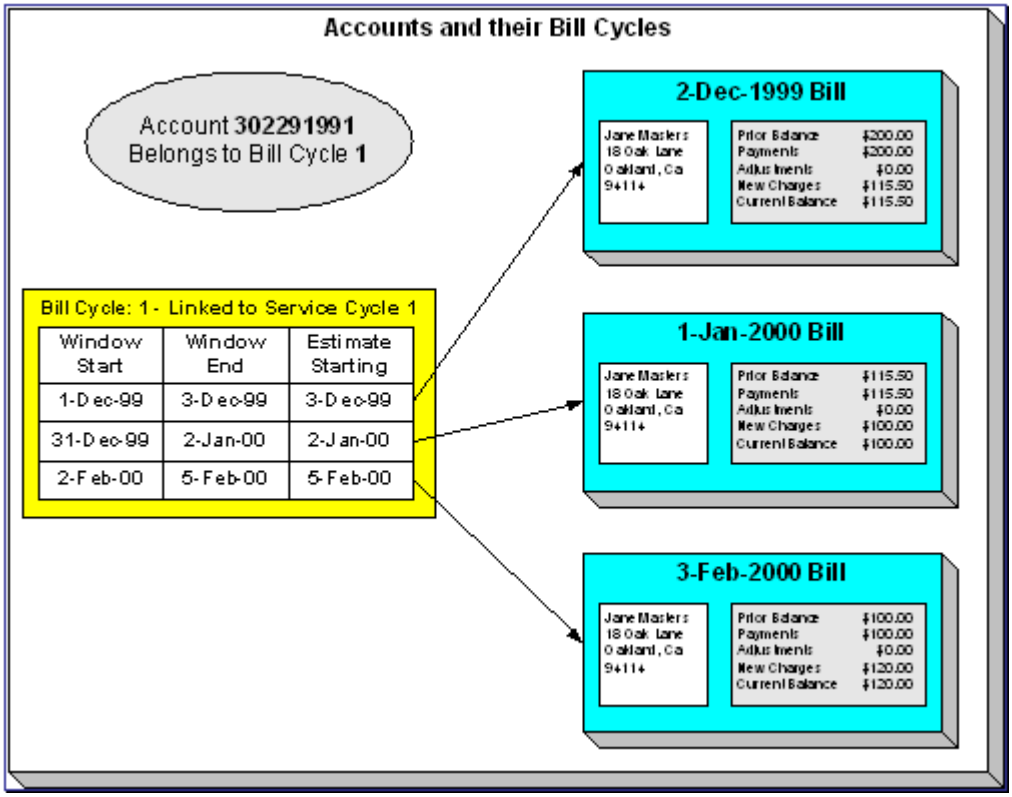
The above design is infinitely flexible. You can use it to handle any number of requirements:

- Estimate consumption every seventh month.
- Bill every month, but only read once a quarter.
- Etc.

Bill Cycles

The topics in this section provide background information about a variety of bill cycle features.

- The Cyclical Billing Process & Window Billing
- Designing Your Bill Cycle
- The Relationship Between Metered Measurement Cycles and Bill Cycles
- How Does An Account Get Its Bill Cycle?
- Protecting An Account's Bill Cycle
- What Happens If An Account Has Service Agreements Spanning Metered Measurement Cycles?



The Cyclical Billing Process & Window Billing

Copyright © 2026, Oracle and/or its affiliates.

The cyclical bill creation process creates most bills. This process works as follows:

- Every account references a bill cycle. The bill cycle's schedule controls WHEN the system attempts to create bills for the account.
- Every bill cycle has a bill cycle schedule that defines the dates when a cycle's accounts are to be billed. Rather than attempt to create bills on one evening, most bill cycles use a concept of "window billing" where the system attempts to produce bills for accounts over a few nights. The first night (i.e., the day the window opens) should be the earliest day on which meter reads for the account can enter the system. The last night (i.e., the day the window closes) should be the last possible day in which a meter read can enter the system. This concept of window billing allows you to start billing accounts on the earliest possible day and then bill the stragglers over successive evenings. This results in much better cash flow.
- When the bill cycle creation process runs, it looks for bill cycles with open bill windows. It then attempts to create bills for the accounts in each such cycle. If a bill is created, it will send it out that evening. If a bill cannot be created, the system will create a bill in the "error" state with a message that can be analyzed by your billing staff. The next day, your staff can either correct the problem or not. When the bill cycle creation process next runs, it deletes all "error" bills and attempts to recreate them. It continues this throughout the bill window. If bills are in error at the end of the window, they will remain in this state until a user fixes them. If the bills are still in error when the cycle's next window opens, a billing error will be generated.

The following diagram should help clarify the above.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about the how to control when bills are produced for a cycle, refer to Bill Cycle - Bill Cycle Schedule.

Designing Your Bill Cycle

The number of bill cycles is determined by the frequency that you bill your customers. So, for example, if you bill every month, you'll have 20 bill cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 bill cycles. If you bill quarterly, you'll have 60 bill cycles. Etc.

Keep in mind the following:

- You may need additional bill cycles if you allow customers to be billed off-cycle. For example, you could create a bill cycle called "Seniors" and link this to every senior citizen. You would set up this bill cycle's schedule to create bills shortly after social security checks are issued.
- You may need other bill cycles for customers with non-metered services (e.g., land leases, one time invoices).

Important

An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to Bill Frequency - Bill Cycle vs Bill Segment Duration for more information.

The Relationship Between Metered Measurement Cycles and Bill Cycles

As you can deduce, a service point's measurement cycle is related to an account's bill cycle.

The following table is an example of how you would set up the various dates on the various schedules that control meter reading and billing.

Measurement Cycle	Download Date	Expected Work Date	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc.					

Copyright © 2026, Oracle and/or its affiliates.

Notice the following about this example:

- The bill cycle code is the same as the measurement cycle. This is not necessary, it's just good practice.
- The bill window starts on the first date on which a meter read could be uploaded.
- The bill window ends on the day after the last possible day a read could be uploaded for the bill cycle.
- Oracle Utilities Meter Data Management only estimates consumption on the last day of the bill window.

NOT_SUPPORTED

For more information about the bill cycle schedule, refer to Setting Up Bill Cycles.

How Does An Account Get Its Bill Cycle?

Most accounts are created behind-the-scenes when a user uses the "add account" option on Person - Main Information. An account created like this doesn't have a bill cycle. Rather, it sits in limbo awaiting the activation of its first service agreement. When a service agreement is activated, the system populates the account's bill cycle using the following algorithm:

- If an account's bill cycle is protected, the activation of a service agreement will not affect an account's bill cycle. Refer to Protecting An Account's Bill Cycle for more information.
- If the service agreement being activated is for metered service, the account is given a bill cycle that will generate bills shortly after the service point is read. The route the system follows to get this bill cycle is a bit indirect:
  - A metered service agreement references one or more metered service points.
  - Every metered service point references a measurement cycle (the measurement cycle controls when the meter at the service point is read).
  - Every measurement cycle references a default bill cycle. It is this bill cycle that is populated on the account paying for service at the service point.
- If the service agreement being activated is for metered service and the associated service point is externally managed along with its measurement cycle and bill cycle, an external call is made to obtain the bill cycle from Meter Data Management. This bill cycle is assigned to the service agreement's account.
- If the service agreement being activated is not metered, the system cannot populate the account's bill cycle because there is no measurement cycle from which to default the bill cycle. This means the account's bill cycle will be blank until a user specifies a bill cycle for the account (using the Account page).

Note

A To Do entry highlights accounts without a bill cycle. A To Do entry highlights those accounts that require a user to specify a bill cycle. This entry is generated for accounts without a bill cycle that have active service agreements.

Copyright © 2026, Oracle and/or its affiliates.

When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. Refer to What Happens At Finalization Time? for more information.

When a service point's measurement cycle is updated, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the measurement cycle. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options Feature Configuration is set to Y.

When an externally managed service point's measurement cycle is updated that results to a change in the bill cycle, a change notification is sent by Meter Data Management to trigger an corresponding update of the associated account's bill cycle in Customer Care and Billing. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options Feature Configuration is set to Y.

Protecting An Account's Bill Cycle

Over time, as a customer moves from premise to premise, their bill cycle is changed behind-the-scenes to be in sync with the latest service point's measurement cycle (as described in the previous section). If you do not want the system to change an account's bill cycle when a metered service agreement is activated, you need to turn on the account's **protect bill cycle** flag. You would do this if a customer liked to be billed at the start of the month regardless of when their device was read.

When the last service agreement for an account is stopped, the protect bill cycle flag is reset. This is to ensure that if the customer returns to start new service again, the bill cycle can be set based on How Does An Account Get Its Bill Cycle.

What Happens If An Account Has Service Agreements Spanning Metered Measurement Cycles?

A single account can have service agreements that are in several measurement cycles. The bill cycle on such an account will default based on the last activated metered service agreement.

It's important to be aware that an account will only have bills created when its bill cycle schedule so indicates. This means that the consumption for some service points could remain unbilled for a few weeks.

Designing Bill Periods

Bill periods are used by non-metered service agreements whose bill end dates need to fall on strict dates. You need only set up this information if you have this type of service agreement.

NOT_SUPPORTED

Refer to Ways To Control The End Date Of A Bill Segment for more information.

Copyright © 2026, Oracle and/or its affiliates.

Every bill period has a calendar that defines when bill segments are created for service agreements that use the bill period. Examples of bill periods include:

- Quarterly Bill - Last Day Of Quarter
- Quarterly Future Bill - Last Day Of Quarter
- Monthly - 15th Day Of Month.
- Monthly Future Bill - Last Day Of Month.

The Quarterly Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
1-Oct-1998	30-Sep-1998
1-Jan-1999	31-Dec-1998
1-Apr-1999	31-Mar-1999
1-Jul-1999	30-Jun-1999
...	

The Quarterly Future Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
15-Dec-1998	31-Mar-1999
15-Mar-1999	30-Jun-1999
...	

The remainder of this section provides examples using the above calendars.

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Future Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempt to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
18-Dec-1998	18-Dec-1998 thru 31-Mar-1999
15-Mar-1999	1-Apr-1999 thru 30-Jun-1999
...	

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempts to create segments as soon as possible) for several bill periods:

Copyright © 2026, Oracle and/or its affiliates.

Earliest Date Segment Will Be Produced	Bill Period
1-Jan-1999	18-Dec-1998 thru 31-Dec-1998
1-Apr-1999	1-Jan-1999 thru 31-Mar-1999
...	

NOT_SUPPORTED

Refer to Setting Up Bill Periods for information about how to define this information.

Setting Up Bill Cycles

An account references a bill cycle. The bill cycle defines when the account is billed and when the account's debt is checked to determine if it's overdue. To define a bill cycle and its bill cycle schedule, open **Admin**, and then **Billing**, and then **Bill Cycle**, and then **Add.**

Description of Page

Enter a unique **Bill Cycle** and **Description** for every bill cycle.

If your implementation requires restricting bill cycles to accounts by CIS Division, specify a **CIS Division** on the bill cycle.

Use the **Bill Cycle Schedule** collection to define when bills are produced for the accounts in a given bill cycle. The following fields are required for each instance:

Window Start Date Specify the date on which the system should start trying to create bills for accounts in the cycle.

Window End Date Specify the last day on which the system will create bills for accounts in the cycle. This should be the last possible date on which a meter read could be loaded into Oracle Utilities Meter Data Management for the account.

Accounting Date Specify the financial date associated with the bills' financial transaction. The accounting date defines the financial period(s) to which the bills will be booked in your general ledger.

Estimate Date The date on which Oracle Utilities Meter Data Management may start estimating consumption if a real measurement cannot be found. When specified, this date is typically on or shortly before the window end date.

Freeze and Complete Turn on this switch if the system should freeze and complete any bill that is created without errors. If this switch is turned off, all bills created by the billing process will be left in the unfinished state. You would only turn this switch off if you want to verify an entire bill run prior to freezing it (e.g., if you are introducing a new version of a rate). If you turn this off, you will need to return to this page after verifying a bill run and turn it back on for the customers to receive bills. When the system next runs, it deletes all unfrozen bills and recreates them as per the instructions on the bill cycle schedule.

The batch bill creation process uses this schedule to define the bill cycles for which it should create bills.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Don't forget.** After you set up the bill cycles that correspond with measurement cycles, go to Setting Up Measurement Cycle Schedules and update the measurement cycles accordingly.

Setting Up Service Cycles And Measurement Cycle Schedules

Refer to Measurement Cycles, Measurement Cycle Processing, and Setting Up Measurement Cycle Schedules sections for more information

Setting Up Measurement Cycle Schedules

> **NOT_SUPPORTED**
>
> Refer to Designing Cycles for Metered Services for more information about measurement cycle. Refer to The Relationship Between Metered Service Cycles and Bill Cycles for more information about how measurement cycles are linked to bill cycles.

Description of Page

When you want to add a new measurement cycle schedule, you must specify the following information:

Service Cycle Enter the measurement cycle ID of the cycle whose routes will be downloaded.

Scheduled Selection Date Specify the date on which the system is meant to download information about the cycle's meters. This date should be a day or two before the scheduled work date.

Define the date the meters in the route are scheduled to be read using **Scheduled Work Date**. This date is extremely important as billing uses it when it looks for meter reads for service points in this cycle. If billing can't find a reading, consumption will be estimated as of this date (assuming the service agreement allows estimation).

Click **Pre-Generate Routes** if you need to finesse the cycle's routes on this Scheduled Selection Date (e.g., because some of the routes shouldn't be downloaded on a given date because the system is meant to estimate consumption). If you don't click this button, the system will create the routes on the scheduled selection date. It does this by creating a route extract for each downloadable route within the cycle (as defined by the route type). If you click this button, the system shows all routes within the cycle in the grid below. You must then define how the system is supposed to download each route on the scheduled selection date.

Click **Delete Routes** if you have pre-generated the routes and you was to remove them and allow the system to create the routes on the scheduled selection date.

Use the **Service Schedule Routes** to define how individual routes within the cycle should be handled during the download. The following fields are required for each schedule read date:

Copyright © 2026, Oracle and/or its affiliates.

Service Route The unique ID of the service route. The route's route type is displayed adjacent.

Schedule Type This defines if and how the system is supposed to download the route's meter reads. Valid values are: Cust Read, Download, Estimate. Only those routes defined as Download will have meter reads downloaded. The other values are used to document why the route won't be downloaded.

Schedule Status This defines the download status of the route. Valid values are Pending and Complete. This value is only displayed for routes with a schedule type of Download.

Where Used

This information is used by the meter read download process to determine which meter reads to download.

This information is used by the billing process to determine the date on which it expects to find a read. If it cannot find a read on or around this date, and it's OK to estimate consumption, consumption will be estimated as of the scheduled work date. The system uses the service agreement's rate schedule's frequency to determine the period of time around the scheduled work date in which it looks for a read. Refer to Defining Frequency Codes for more information.

Setting Up Bill Periods

Some SA types reference a bill period. The bill period defines when the service agreement's bill segments are produced and the respective end date of each bill segment.

> **NOT_SUPPORTED**
>
> Refer to Designing Bill Periods for more information.

To define a bill period and the bill period schedule, open **Admin**, and then **Billing**, and then **Bill Period**, and then **Add.**

Description of Page

Enter a unique **Bill Period** and a **Description** for every bill period.

Use the **Bill Period Schedules** collection when the system should create bill segments for service agreements that use a given bill period. It also defines the end date of each respective bill segment. The following fields are required:

Bill Date Specify the earliest date on which the system is allowed to create a bill segment for service agreements using this bill period.

Bill Seg End Date Specify the end date of the bill segment. For future bills, this will be after the bill date. For retro bills, this will be before the bill date.

This information is used by the bill segment creation process to determine the end date of service agreements that use a bill period.

Defining Statement Cycles

Copyright © 2026, Oracle and/or its affiliates.

If you have persons set up in the system to receive statements with financial information, you will need to assign them to a statement cycle and define a schedule for the statement cycle.

NOT_SUPPORTED

Refer to The Big Picture of Complex Statements for more information about statements.

- The Big Picture Of Statement Cycles
- Setting Up Statement Cycles

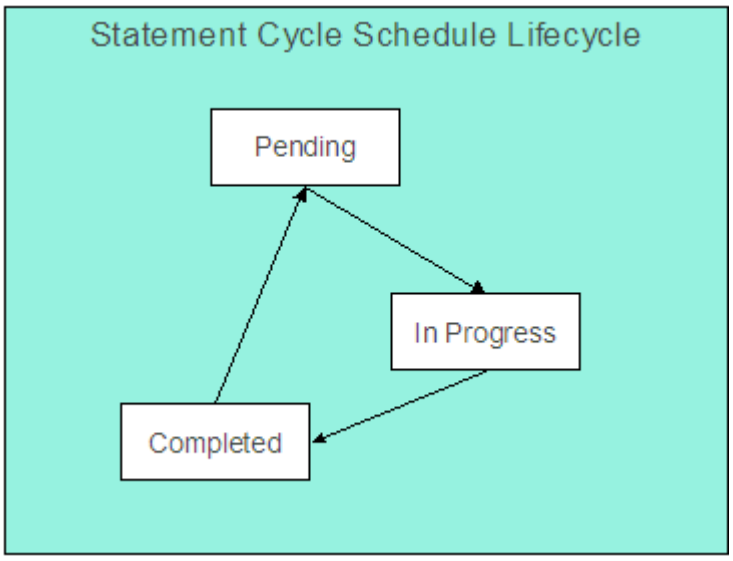
The Big Picture Of Statement Cycles

A statement cycle has a similar purpose to that of a bill cycle. It controls when statements will be produced.

- The Cyclical Statement Process
- Designing Your Statement Cycles
- Lifecycle of a Statement Cycle Schedule

The Cyclical Statement Process

Persons who wish to receive statements will work with you to determine how often these statements should be produced. Some persons may want a monthly statement, some a quarterly and some annually. For each unique schedule that is designed for your various statement persons, you will set up a Statement Cycle and its schedule.



Designing Your Statement Cycles

The number of statement cycles is determined by a combination of the frequency that you will send statements to the statement persons and how many statement cycles you wish to manage within the same frequency.

So, for example, for all the statement persons who wish to receive a monthly statement, will you create only one monthly Statement Cycle so that all monthly statements are produced the same day? Or will you have several monthly statement cycles scheduled throughout the month? The answer will depend on the volume of statements being produced and on how you want to manage the statement production.

Lifecycle of a Statement Cycle Schedule

Copyright © 2026, Oracle and/or its affiliates.

Pending The statement cycle schedule is added in this state. The Create Statements background process find records in this state to process on the appropriate date.

> **NOT_SUPPORTED**
>
> Refer to Create Statements Background Process for more information.

In Progress Records in this state are currently being processed by the Create Statements background process.

Completed Records in this state have already been processed by the Create Statements background process. If a problem occurs with the Create Statements background process and it needs to be rerun, simply change the status back to pending and rerun the process.

Setting Up Statement Cycles

A Statement Construct references a statement cycle. The statement cycle defines when the statement person will receive statements with financial information related to the accounts and service agreements linked to the statement construct. To define a statement cycle and its statement cycle schedule, open **Admin**, and then **Billing**, and then **Statement Cycle**, and then **Add.**

Description of Page

Enter a unique **Statement Cycle** and **Description** for every statement cycle.

Use the **Statement Cycle Schedule** collection to define when statements are produced for the persons with statement construct records in the given statement cycle. The following fields are required for each instance:

Processing Date Specify the date on which the system should create statements for persons with statement construct records in the cycle.

Copyright © 2026, Oracle and/or its affiliates.

Status Indicates the status of the cycle schedule. Refer to Lifecycle of a Statement Cycle Schedule for more information.

The batch statement creation process uses this schedule to determine which statement cycles for it should create statements for the statement construct records. Refer to Create Statements Background Process for more information.

Defining Service Agreement Type (SA Types)

Every service agreement must reference a SA type. The SA type defines what you sell, how much you sell it for, to whom you sell it, how overdue debt is collected, and how sales will be booked in your general ledger.

> **Note**
>
> **Perfect foresight.** In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SA types. In reality, setting up your SA types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

- Designing SA Types For SAs Without Service Points
- Designing SA Type For Other Segmentations
- Designing Prepayment Billing Options
- SA Types And The Financial Design
- Setting Up SA Types

Designing SA Types For Service Agreements With Service Points

Designing your SA types is an iterative process. To minimize some iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SA types.

Division/SA Type	Service Type

The topics in this section provide guidelines describing how to fill in this table for SA types associated with service agreements that charge for service point-oriented services.

- CIS Division Segmentation
- Service Segmentation
- Receivable Segmentation

Copyright © 2026, Oracle and/or its affiliates.

- Revenue Segmentation
- Rate Segmentation
- Service Point (SP) Type Segmentation
- Company Usage Segmentation
- Debt Class Segmentation
- Budget Billing Segmentation

CIS Division Segmentation

A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

If we assume that you are located in a single jurisdiction - say California - we will need a single CIS division for all of our SA types.

CIS Division/SA Type
CA

Service Segmentation

At a minimum, you will have one SA type for every different type of utility service offered by your organization. If we assume you sell electricity, gas, water, wastewater and cable; your SA Types will be as follows:

CIS Division/SA Type	Service Type
CA/G	Gas service
CA/W	Water service
CA/E	Electric service
CA/WW	Waste water service
CA/CABLE	Cable

Receivable Segmentation

Many organizations segregate their receivable balances in the general ledger. For example, the receivable amount associated with gas and water service may be maintained in separate GL accounts.

If your organization does this, you will probably have at least one SA type for each such receivable account because each SA type references a distribution code that typically contains the receivable account.

Copyright © 2026, Oracle and/or its affiliates.

- The word *probably* is underlined because this is a rule of thumb. There are situations where the number of receivable accounts isn't directly related to the number of SA types. This happens when an organization maintains very detailed receivable accounts in the general ledger and maintaining a one-to-one relationship between SA types and distribution codes would lead to a massive proliferation of SA types (and you don't want this!). If your organization maintains very detailed receivable accounts, please speak to your implementers, they should be able to introduce a small customization to generate the appropriate receivable account rather than extract it from the distribution code.
- The word *typically* is underlined because there are several SA types that don't book to a receivable account when bill segments are generated. For example, company usage and charitable contributions. Refer to Company Usage Segmentation and Charitable Contribution Segmentation for examples of SA types that don't book to receivable accounts.

We'll simplify our example and assume your organization has one receivable account for all types of utility service. Given this, we won't need additional SA types to support receivable segmentation:

CIS Division/ SA Type	Service Type	Distribution Code
CA/G	Gas service	A/R-UTIL
CA/W	Water service	A/R-UTIL
CA/E	Electric service	A/R-UTIL
CA/WW	Waste water service	A/R-UTIL
CA/CABLE	Cable service	A/R-UTIL

Revenue Segmentation

Look at your rates and determine which rates can be used by each SA type. The following table shows the sample rates that can be used for each service:

CIS Division/ SA Type	Service Type	Distribution Code	Rates
CA/G	Gas service	A/R-UTIL	GALL-1
CA/W	Water service	A/R-UTIL	WALL-1
CA/E	Electric service	A/R-UTIL	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	CABLE

Now, look at the rates' calculation rule GL Distribution window. You're looking for calculation rules whose GL distribution is affected by revenue class. If there are no revenue classes referenced on the calculation rules, this means that the revenue associated with the rate will be booked to a single GL account regardless of the type of customer. If you see revenue classes, this means that the revenue account associated with the calculation rule(s) differs depending on the SA type's revenue class. If revenue classes are used in the rates, you must create a different SA Type for every revenue class.

Copyright © 2026, Oracle and/or its affiliates.

Let's assume the following:

- The gas rate (GALL-1) references the RESIDENTIAL, COMMERCIAL and INDUSTRIAL revenue classes in order to differentiate revenue based on the type of customer.
- None of the other rates differentiate revenue based on customer class.

Our SA types will now look as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Notice that we created new SA types for gas in order to specify the respective revenue class. We didn't do this for the other services because it isn't necessary. However, you should feel free to do this if it feels right or if you need it for reporting purposes. For example, if you want to report on all *residential* service agreements, but you differentiate only gas by residential versus commercial, you'll be in trouble.

Rate Segmentation

Every SA Type whose service agreements have their charges calculated with a rate must have one or more rates linked to it. These define which rates can be linked to the SA type's service agreements. If different service agreements have different valid rate combinations, you will need to split the SA types accordingly.

For example, look at the electric rates. If we assume:

- the RES rates can only be used for residential customer,
- the IND rates can only be used for industrial customers,
- the COM rates can only be used for commercial customers,
- the LAMP rates can only be used for lamp customers

Then you might want to set up a new SA type to indicate such. The advantage of doing this is that you get more control over which rates can be used on a given SA type. The disadvantage is that you proliferate SA types. Unfortunately, it's really a question of taste.

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1

Copyright © 2026, Oracle and/or its affiliates.

CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1
CA/LAMP	Electric service	A/R-UTIL	N/A	ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Warning

Don't be too specific in your analysis in respect of rate segmentation because you could end up with a separate SA type for every rate (and you don't want this). We understand this is a very subjective warning, but we recommend that you start out with broad bands of rates that can be used on a SA type and narrow it down if you end up unhappy with the results. For example, you don't have to set up a separate SA type for low-income residential gas customers just because they have a special rate. Rather, you can leave your SA types as they are and treat low-income gas customers as a subset of your residential gas customers. **For more information**, refer to Setting Up Start Options.

Note

Rate override. If a service agreement of this type may be linked to a terms of service record, you must also consider whether or not the rate schedule could be overridden by a template SA linked to the terms of service record. Refer to SA Type - Rate for information about the possible values for this field.

Service Point (SP) Type Segmentation

Every SA Type whose service agreements exist to bill for service point-oriented service has one or more SP types. These define which type of service points can be linked to the SA type's service agreements. If different service agreements have different valid SP types, you will need to split the SA types accordingly.

For each service point-oriented SA type, determine if there are any restrictions in respect of the types of service points that can use the SA type's rates. For example, if we assume that only commercial SP types can be used by commercial customers, industrial SP types by industrial customers, residential SP types by residential customers, your SA types will be:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM

Copyright © 2026, Oracle and/or its affiliates.

CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE

Notice the wastewater SA types reference both water and waste water service points. This is intentional as wastewater service uses the consumption from the water service to calculate some part of the wastewater charge.

Company Usage Segmentation

Up to now, we've discussed SA types associated with service agreements linked to your customers. The system has also been designed to keep track of the expenses associated with your company's use of power. If you want the system to do this, you must create at least one SA type for each service consumed by your organization.

For example, if we assume your organization consumes electric, gas, and water service; your SA types will now be as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES	BD-RATED
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM	BD-RATED
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND	BD-RATED
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED

Copyright © 2026, Oracle and/or its affiliates.

CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED
CA/E-COY	Electric service	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG
CA/G-COY	Gas service	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG
CA/W-COY	Water service	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG

Notice the three company usage SA types do not reference an A/R account as their distribution code. This is because when bill segments are created for these types of service agreements, the system must debit an expense account (or contra-revenue account) rather than a receivable account.

Also notice we introduced a new column - Bill Segment Type. Notice that the customer-oriented SA types use the BD-RATED bill segment type and the company usage SA types use the COMPUSAG bill segment type. Different bill segment types are necessary because company usage SA types use a different algorithm to calculate their bill segment's financial transaction algorithm because they don't affect either payoff or current balance.

NOT_SUPPORTED

For more information, refer to Designing and Defining Bill Segment Types.

Debt Class Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you will have to split the SA Type.

NOT_SUPPORTED

For more information about debt class, refer to Designing Your Collection Procedures.

If we assume that your residential services are regulated and your commercial and industrial services are deregulated, we won't have to introduce additional SA types.

Copyright © 2026, Oracle and/or its affiliates.

CIS Division/ SA Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type	Debt Class
CA/G-RES	A/R-UTIL	R - residential	GALL-1	G-RES	BD-RATED	REGU
CA/G-COM	A/R-UTIL	C - commercial	GALL-1	G-COM	BD-RATED	UNRE
CA/G-IND	A/R-UTIL	I - industrial	GALL-1	G-IND	BD-RATED	UNRE
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED	REGU
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED	UNRE
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED	UNRE
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED	REGU
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED	UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED	UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED	REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED	UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED	UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED	UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the three company usage SA types do not have a debt class. This is because their bill segment type's FT algorithm doesn't cause debt to be created and therefore there is no reason to have a debt class. However, you'll need to create a "dummy" debt class - call it N/A - for these SA types because every SA type must reference a debt class.

Budget Billing Segmentation

Many utilities offer their customers levelized payment plans to smooth out the seasonal bill variations. We call this levelized amount the *budget amount*.

NOT_SUPPORTED

Refer to Budget Billing for more information about budgets in general. Refer to Billing - Current Balance versus Payoff Balance for an example of budget billing accounting.

If we assume that you only allow budget billing on the electric and gas residential services, then you'll need to update your CA/G-RES and CA/E-RES SA types:

Copyright © 2026, Oracle and/or its affiliates.

CIS Division/ SA Type	Dist Code	Rev Class	Rates	SP Type	Bill Seg Type	Debt Class	Recurring Charge Control Info
CA/G-RES	A/R-UTIL	R	GALL-1	G-RES	BD-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/G-COM	A/R-UTIL	C	GALL-1	G-COM	BD-RATED	UNRE	
CA/G-IND	A/R-UTIL	I	GALL-1	G-IND	BD-RATED	UNRE	
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES	BD-RATED	REGU	
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM	BD-RATED	UNRE	
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND	BD-RATED	UNRE	
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	BD-RATED	REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM	BD-RATED	UNRE	
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND	BD-RATED	UNRE	
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	BD-RATED	REGU	
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	BD-RATED	UNRE	
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	BD-RATED	UNRE	
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE	BD-RATED	UNRE	
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt	
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt	
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt	

Notice the following:

Copyright © 2026, Oracle and/or its affiliates.

- We updated the two SA types to allow recurring charge information.
- The Recurring Charge Amount is Optional. Why? Because those customers who aren't on a budget plan won't have a recurring charge amount. Those customers on a budget will have a recurring charge amount.

> **Note**
>
> **Turn on Eligible for Budget.** Besides indicating that these SA types use recurring charges, you also need to turn on the Eligible for Budget switch on the SA type to indicate that this type of SA participates in budget processing.
>
> **Override Budget Eligibility**. You may plug in an override budget eligibility algorithm on an SA type that is configured to be Eligible for Budget if certain service agreements of this type are not eligible.

> **NOT_SUPPORTED**
>
> Refer to the Description of Page under SA Type - Billing for the definition of the recurring charge attributes.

Designing SA Types For SAs Without Service Points

The topics in this section provide guidelines describing how to design the SA types associated with your service agreements that don't have service points.

- Overpayment Segmentation
- Write Off Segmentation
- Connection Charge Segmentation
- Charitable Contribution Segmentation
- Payment Arrangement Segmentation
- Merchandise Segmentation - Installment Billing
- Deposit Segmentation - Installment Billing
- Billable Charge Segmentation
- Over/Under Cash Drawer Segmentation
- Payment Upload Error Segmentation
- CIAC Segmentation
- Loan Segmentation
- Non-Billed Budget Segmentation

Overpayment Segmentation

Copyright © 2026, Oracle and/or its affiliates.

When a customer pays more than they owe, you must decide what to do with the excess money. The following points describe two possibilities:

- You could create a new service agreement to hold the excess (let's call it an overpayment SA). The credit would be transferred from this service agreement to the billable service agreements when the next bill is completed. This means that all billable service agreements have the same opportunity to receive the overpayment when they are billed in the future.
- You could amalgamate the excess payment on one of the existing, billable service agreements. For example, if a customer has both electric and gas service, the excess funds could be kept on either the gas or the electric SA. This would result in the following:
  - The service agreements that do NOT receive the overpayment will have debt when they are next billed.
  - The service agreement that receives the overpayment could have its future debt offset by the overpayment (meaning that it could have a credit balance until the service agreement's future bill segments offset the overpayment amount).
- The above situation is not desirable unless the customer intentionally overpaid one service agreement. The first method (keeping the overpayment on a separate service agreement) obviates this potential problem. Obviously, if your organization sells a single service (and therefore your customers have a single service agreement) you would choose the second method.

You control which method is used by plugging in the appropriate Overpayment Distribution algorithm on each Customer Class (i.e., you can choose a different method for different customer classes). If you choose to hold overpayments on a separate SA, then you must set up an SA Type as described in the following table:

CIS Division/ SA Type	Service Type	Distrib. Code	Eligible for Billing	Debt Class	Pay Seg Type	Do Not Overpay	One-time
CA/ OVERPAY	Other	A/P - OVER	Not billed	N/A	Normal	No	Yes

Notice the following about the new overpayment SA type:

- It has an interesting distribution code. This is because when a payment segment is created for this type of service agreements, the system must credit a liability (an overpayment is a liability).
- It's important to indicate that the overpayment SA is a one-time service agreement. Why? Because this means that the system will automatically close the SA when it's balance falls to zero (i.e., when all of the overpayment has been used to satisfy future bills).
- A bill segment type is not needed because the system never creates bill segments for such service agreements (they exist only to hold excess credits).
- You may also want to turn on the alert message
- You must plug-in a bill completion algorithm on this SA type. This bill completion algorithm will transfer the credit balance to the account's other service agreements when the bill is completed. Refer to The Credit Transfer Algorithm for more information about this algorithm.
- You must also reference this overpayment SA type as the parameter value on your overpayment algorithm (this algorithm is plugged in on the desired customer classes). Refer to Overpayment Algorithm for more information about this algorithm.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **If overpayment means charitable contribution.** Some organizations sponsor a program that works as follows - if a customer overpays a bill by a given amount (say $5), this amount is assumed to be a charitable contribution. If you have this requirement, you will create another SA type to hold a customer's charitable contributions. This SA type will look similar to the one described below (see Charitable Contribution Segmentation) except it is not billable. The funds will be credited to this service agreement by creating a new overpayment algorithm that is similar to the base package Overpayment Algorithm. This new algorithm will be very similar to the existing algorithm. The main difference will be that it will have to check if the overpayment amount is an exact value (say $5). If so, it will create a payment segment for the charitable contribution SA type; otherwise it will create a payment segment for the overpayment SA.

Write Off Segmentation

When you write off non-collectable debt, you transfer the receivable from a "normal" service agreement onto one or more write-off service agreements. When the debt is transferred to a write-off service agreement, the distribution code on the "normal" service agreement is credited (typically an A/R GL account), and the distribution code on the write-off service agreement is debited.

You will almost always need a write-off service agreement whose distribution code is the write-off expense. However, you probably don't book all of the write-off amount to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you want to book the written off revenue to a write-off expense account and you want to reduce the liabilities (you don't owe the liability if you don't get paid). This means you'll need another SA type for the liabilities. Refer to The Ramifications of Write Offs in the General Ledger for a complete explanation.

The following table contains the minimum number of SA Types that you'll need to hold your write-offs.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class	Pay Seg Type	Do Not Overpay
CA/WO-STD	Other	EXP-W/O	Not billed	WO	Normal	Yes
CA/WO-LIA	Other	LIA-General	Not billed	WO	Normal	Yes

Notice the following about the new write-off SA types:

- They have interesting distribution codes. This is because when debt is transferred to these types of service agreements, the system must debit either an expense account (i.e., write-off expense) or a liability account. It's important to note that in The Ramifications of Write Offs in the General Ledger we explain how this liability account may be overwritten with the liability account that was originally booked.
- Neither needs a bill segment type because the system never creates bill segments for such service agreements (they exist only to hold uncollectable debt)
- Even though the debt is not collectable, it still has a debt class. Why? Because the system shows a customer's debt on many inquiries by debt class and it's important to show write-off debt on these queries.

Copyright © 2026, Oracle and/or its affiliates.

- The combination of Payment Segment Type and Do Not Overpay are important. Refer to The Ramifications of Write Offs in the General Ledger for a complete explanation.

> **Note**
>
> The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on each write-offable SA type. The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write-off SA type.
>
> **An Alternative.** If you have a limited number of liability accounts, you may decide to have a separate write-off service agreement for each liability account. Doing this would proliferate the number of service agreements created at write-off time. However, it would simplify the remittance of payment to the taxing authority if the reversed liability is ever paid.

Connection Charge Segmentation

If you levy connection charges, you have two options:

- You can create a SA type that exists purely to handle connect charge debt. After doing this, you'd create a start option for this SA type that causes an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had multiple services (e.g., a combined electric, gas, water utility) that only levies a single connection charge regardless of the number of services started. If you use this approach, make sure to indicate the SA type is non billable.
- You can levy a start adjustment on one of your existing SA types (e.g., CA/E-RES). The easiest way to do this is with a start option. On the start option you'd indicate an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had a single service offering (e.g., an electric-only utility). Refer to Setting Up Start Options for more information.

In the table below, we show what would be necessary if you want to have a separate service agreement for the connection charge.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class
CA/CONNECT	Other	A/R-UTIL	Not billed	REGU

Notice the following about the new connection charge SA type:

- It has a normal receivable distribution code.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (its charged via an adjustment).
- The debt class is interesting - REGU (for regulated). We are intentionally linking the connection charge debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the connection charge debt the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

Copyright © 2026, Oracle and/or its affiliates.

Charitable Contribution Segmentation

If your organization accepts charitable contributions made by your customers, you must create a SA type to hold these contributions.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/CHARITY	Other	A/P-CHAR	CHAR	RECUR	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Contrib. Amount

Notice the following about the new charitable contribution SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., charitable contribution payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the charitable contribution is created.
- It uses an interesting bill segment type - RECUR. This bill segment type was set up to create recurring charges that don't automatically stop at some point in time.
- The debt class is interesting - CHAR (for charity). This is done so that past due charitable contribution debt is treated separately from other types of debt.
- The recurring charge control information is set up as defined.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Warning

It's important that you assign the charitable contribution SA type with a payment segment type that only affect current balance (as opposed to affecting current AND payoff balance). This is because there is no receivable recognized when the contribution is billed and therefore there is no payoff balance to relieve when it's paid.

Copyright © 2026, Oracle and/or its affiliates.

Payment Arrangement Segmentation

If your organization allows customers to payoff outstanding debt using payment arrangements (e.g., current bill plus $X), you will need a new SA type for every debt class that can have a payment arrangement. If we assume you can have payment arrangements for both regulated and unregulated debt, then you'll need at least two more SA types (you may have more SA types if you need to segregate the payment arrangement receivable amount by utility type (or some other type)).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/PA-REGU	Other	A/R-ARRG	REGU	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount
CA/PA-UNRE	Other	A/R-ARRG	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount

Notice the following about the new payment arrangement SA types:

- They have an interesting distribution code. This is because when funds are transferred to these types of service agreements, the system must debit a receivable (i.e., payment arrangement receivable).
- They use an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- Each new SA type references the debt class whose debt it will pay off. We are intentionally linking the payment arrangement debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the arrangement debt as the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).
- The recurring charge control information is set up as defined.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use Start Options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Merchandise Segmentation - Installment Billing

If your organization allows customers to purchase merchandise using an installment plan, you must create a SA type for this.

Note

No installments. If the customer must pay for the merchandise in one lump amount, you'd create an SA type similar to the Connection Charge Segmentation example.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/MERCH-I	Merch	A/R-MRCH	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new merchandise SA type:

- It has a normal receivable distribution code.
- It uses an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- The recurring charge control information is set up as defined.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started. Refer to Start Option Considerations For SA Types That Use Initial Adjustments **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Deposit Segmentation - Installment Billing

If your organization allows customers to pay deposits using an installment plan, you must create an SA type for this.

Note

No installments. If the customer must pay for the deposit in one lump amount, you'd create an SA type similar to the Connection Charge Segmentation example. Just make sure the adjustment that's levied to charge for the deposit amount doesn't affect payoff balance (when you bill a deposit, the customer doesn't really owe anything because it's not a true receivable from an accountant's perspective).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/DEP-I	Other	A/P-DEPO	DEP	RECURATB	Amount to bill is Required Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new deposit SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., deposit payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the deposit is created.
- It uses an interesting bill segment type - RECURATB. This bill segment type was set up to create recurring charges that stop when the system has billed the Total Amount to Bill.
- The debt class is interesting - DEP (for deposit). This is done so that past due deposit "debt" is treated separately from other types of debt.

Copyright © 2026, Oracle and/or its affiliates.

- The recurring charge control information is set up as defined. Note well, the Amount to bill is Required.

NOT_SUPPORTED

Refer to the Description of Page under SA Type - Billing **for the definition** of the recurring charge attributes. Refer to Start Option Considerations For SA Types That Use Recurring Charges **for how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Note

Bill messages on receipt of deposit in full. The base package includes a special FT Freeze algorithm that can be specified on deposit SA Types. It recognizes when a deposit has been paid in full, and creates a bill messages to inform the customer. Refer to algorithm DEP PIF MSG in Algorithm Types for more information.

Billable Charge Segmentation

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line. You can also use billable charges to "pass through" other bill ready charges generated outside the system, by another application, or by a 3rd party supplier.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each service agreement with unbilled charges. If multiple unbilled charges exist for a given service agreement, only one bill segment will be created and it will contain details about all of the billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, you must set up at least one SA type to hold your billable charge debt. You may have multiple charges based on billing frequencies, A/R booking, debt monitoring, etc. It's really up to you.

The easiest way to determine how many billable charge SA types you'll need is to define every conceivable billable charge (which you should have done when you designed your billable charge templates). Then ask yourself if they have the same billing and payment behavior, if so, you'll have one SA type. If not, you'll need one SA type for each combination.

Copyright © 2026, Oracle and/or its affiliates.

We will assume your billable charges are all used to levy unusual one-off charges that can be collected in the same way, therefore we'll need one SA type.

CIS Division/ SA Type	Service Type	Distrib Code	Debt Class	Bill Seg Type	Billable Charge Templates	Rate
CA/ ONETIME	Other	A/R-UTIL	UNRE	BILLCHRG	TREETRIM DAMAGE	None
CA/ PASSTHRU	Electricity	A/R-OTHER	UNRE	BILLCHRG	None	None
CA/ADDON	Electricity	A/R-OTHER	EXTERNAL	BILLCHRG	None	TAXES

Notice the following about the new one time SA type:

- It has a normal receivable distribution code.
- Its debt class is unregulated.
- It uses an interesting bill segment type - BILLCHRG. This bill segment type was set up to create bill segments using billable charges.
- It references the valid billable charge templates that can be used on this SA type.

> **Note**
>
> **One Time Charge.** The ONE TIME example shown above implies this SA type exists to hold one-time charges. Because of this, you should turn on the One Time Charge switch on the SA type so that service agreement's of this type are automatically closed when final payment is received. You don't have to do this because a customer could have a single billable charge service agreement that is perpetually active for pass through charges (i.e., it doesn't have a stop date). If you do this, the system will create a bill segment for this service agreement whenever it finds an unbilled billable charge linked to the service agreement.

Notice the following about the pass through SA Type:

- It doesn't use the normal distribution code or debt class. This is done so that the debt and receivable can be tracked separately. If these charges were being pass through from another system, you might want to track these financial values separately.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- Templates are not relevant - these charges on not created on-line using templates, but are loaded via the Billable Charge Upload Staging.

Notice the following about the add on charges SA Type:

- This is an example of bill-ready charges (similar to pass through) to which the system adds on other charges, for example, taxes.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- It also uses a Rate. In this case, the bill creation algorithm (specified on the bill segment type) will take any billable charge lines and attach them to a bill. In addition, these billable charges will include billable charge service quantities (SQs). These service quantities will

Copyright © 2026, Oracle and/or its affiliates.

also be swept onto the bill segment, and the Rate (TAXES in this example) will be applied. In order for taxes to be calculated, the billable charge SQs must include the total taxable amount - the system is not able to apply the rate on top of the other billable charges. But, it can apply the tax rate to the SQs that are supplied.

- You can also use this technique to bill other rate-ready service quantities, like kWh, CCF, *etc.* This is a way to process rate-ready data for which you have a contract, but you do not know the meter (and therefore, cannot collect real meter reads).
- If the rate has pre-processing calculation groups, these will be applied as well.

NOT_SUPPORTED

For more information about billable charge templates, refer to Setting Up Billable Charge Templates.

Over/Under Cash Drawer Segmentation

In order to balance a tender control that is out-of-balance, your organization must set up an account with a service agreement whose SA type references the over/under expense account. You will probably only have one service agreement that references this SA type, but you still must have it if you remit funds via a cash drawer.

NOT_SUPPORTED

For more information about over/under processing, refer to How To Get An Unbalanced Tender Control In Balance (Fixing Over/Under).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/OVR UNDR	Other	EXP-OV/UND	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This is because when a payment segment is applied to this type of service agreement, the system must debit an expense account for under amounts (and credit it for over amounts).
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has over/under payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

Payment Upload Error Segmentation

If the payment upload process detects an invalid account on a payment upload record, it will create a payment for the suspense service agreement defined on the upload process' tender

Copyright © 2026, Oracle and/or its affiliates.

source (see Setting Up Tender Sources). You should create a special SA type for this service agreement.

NOT_SUPPORTED

For more information about the payment upload process, refer to Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/SUSPENSE	Other	EXP-MISC	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This code should probably be a suspense account. All payment segments that are created for this service agreement will eventually be transferred to a "real" service agreement and therefore this GL account's balance should be zero when no payments are in suspense.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has invalid account payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

CIAC Segmentation

If your company bills and refunds Contribution In Aid of Construction (CIAC) contracts, you must create one or more SA types. CIAC contracts are typically used to levy charges associated with line extensions. These types of service agreements are different from other service agreements because the initial amount charged is refunded to the original payee when new properties (or extensions) are added to the extension (or when the new properties are subsequently billed for service).

Note

Billable charges are used for the original CIAC service agreement. CIAC SA types are always Billable Charge SA types because an operator must specify the exact amount to charge the contractor using a billable charge. Refer to Billable Charge Segmentation for more information.

The following points describe how CIAC processing is implemented in the system:

- When a new line extension is build, you will create a new service agreement that references your CIAC SA type. This service agreement should be linked to a service point associated with the extension. The easiest way to create this service agreement and link it to the service point is by using the Start Account transaction. It's important to remember to define your CIAC SA type as a valid SA type for the SP type used to represent the line extension.

Copyright © 2026, Oracle and/or its affiliates.

- When a new premise / service point is built that "hangs" off the original extension, the new service point should be linked to the original service point. This can be done by referencing the original service point as the "parent" service point of the new service point using a foreign key value characteristic.
- The system periodically monitors the original CIAC service agreement. The process that performs this monitoring is referenced on the original CIAC service agreement's SA type. The exact processing that takes place during this monitoring is up to your organization's specific business requirement. For example, if you refund 10% of every bill produced for the "downstream" service points to the original contractor, you would have logic in your CIAC monitoring process that looks for recent bill segments produced for the "downstream" service agreements and then creates an adjustment for the master service agreement.

> **Note**
>
> **CIAC refunds are idiosyncratic.** Because CIAC refund processing is idiosyncratic, we do not supply any CIAC monitoring processes in the base package. This is because the likelihood that they could be used is extremely low because of your organization's unique requirements.

Therefore, if your organization performs CIAC processing, you should create a special SA type.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	CIAC Process	Bill Seg Type
CA/CIAC	Other	A/R - CIAC	UNRE	Refund based on percent of future bills	Billable Charge

Loan Segmentation

If you loan money to customers that is recouped using an amortization schedule, you need to set up an SA type for the loan service agreement.

CIS Division/SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/LOAN	Other	A/R - LOAN	A/R - STLN	UNRE	LOAN	

> **NOT_SUPPORTED**
>
> Refer to Setting Up The System To Enable Loans for more information.

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budget Segmentation

If you allow your customers to pay set amounts at specified intervals (e.g. every two weeks), you need to set up SA types for Non-Billed Budget service agreements. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. You may implement two types of Non-Billed Budgets monitored and unmonitored, each type requiring a different SA type. You may also implement different renewal options for Non-Billed Budgets.

CIS Division/SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/NBB-MON	Other	A/P - OVPY	Monitored	NBB	Optional	Not billed
CA/NBB-UNMON	Other	A/P - OVPY	Unmonitored	N/A	Optional	Not billed

NOT_SUPPORTED

For more information about monitored and unmonitored Non-Billed Budgets, refer to Defining Non-Billed Budget Options.

Designing SA Type For Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of SA Types. However, many obscure factors could cause the introduction of more SA Types. In this section, we explain these more obscure factors.

Warning

We strongly recommend not being too pedantic when considering the factors described in this section. If you can only think of a few strange situations that would necessitate a SA type, think carefully before you introduce it. It's better to be a little less than perfect than end up with large number of obscure SA types.

- Cash Distribution Segmentation
- Adjustment Profile Segmentation
- Late Payment Charge Segmentation
- Debt Classification Segmentation
- Allow Estimates Segmentation
- Severance Criteria Segmentation
- Deposit Class Segmentation

Copyright © 2026, Oracle and/or its affiliates.

- Sub SA Types
- Financial Settlement SA Types
- Usage Request SA Types
- Initial Consumption Period Considerations
- Processing Sequence Considerations

Cash Distribution Segmentation

Every SA Type has a payment segment type. The payment segment type defines the cash account to which the SA type's payments should be booked. If different service agreements have different cash accounts, you will need to split the SA types accordingly.

Adjustment Profile Segmentation

Every SA Type has one or more adjustment profiles. These profiles define the valid adjustment types that can be booked to the SA type's service agreements. If different service agreements within an SA type have different mixtures of valid adjustment types, you must split the SA types accordingly.

Late Payment Charge Segmentation

An option exists on SA Type that causes the system to generate a late payment charge if payment is not received on time. If you don't levy late payment charges on all service agreements, you will need to determine when you do and design your SA types accordingly.

In addition, if you levy late payment charges, the percentage levied and the algorithm that defines the amount of the outstanding balance subject to the charge is defined on the SA type.

Debt Classification Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you must split the SA Type.

NOT_SUPPORTED

For more information about debt class, refer to Designing Your Collection Procedures.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Write Off Debt Class vs. Normal Debt Class.** An SA type references both write off debt class and normal debt class. An SA type's write-off debt class controls the write-off rules imposed on service agreements of a given type. An SA type's normal debt class controls the collection rules imposed on service agreements of a given type. Refer to Different Collection Criteria For Different Customers And Different Debt for more information about collection rules. Refer to Different Write-Off Criteria For Different Customers And Different Debt for more information about write-off rules.

Allow Estimates Segmentation

Every SA Type has a switch that controls whether the system should have Oracle Utilities Meter Data Management estimate consumption if meter reads are missing at billing time. If a given SA Type has different situations when the system should and should not estimate, you will have to split the SA Type.

> **Note**
>
> **Override.** You can override the value of the SA Type's estimation switch on an individual service agreement. This means that if only a few service agreements don't abide by the SA Type's estimation switch, you can change the switch value of these service agreements.

Severance Criteria Segmentation

Every SA Type has severance criteria. The severance criteria define the severance process used to sever service if the customer doesn't pay. You can have multiple severance processes if different conditions warrant a different process. For example, you may have a different severance process if the customer has life support.

If you have a SA Type that requires different severance conditions other than those currently supported, you can make a programmatic change to introduce the additional conditions OR you can split the SA Type.

> **NOT_SUPPORTED**
>
> For more information about severance, refer to Designing Your Severance Procedures.

Deposit Class Segmentation

Copyright © 2026, Oracle and/or its affiliates.

Every SA Type that exists to hold a cash deposit will reference a deposit class. The deposit class defines the business rules that control various functions including interest calculation and refund criteria. You will need multiple deposit SA Types if any of the deposit class' rules / conditions differ for different types of deposits. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one SA type for residential deposits and another for commercial deposits (where the residential deposit SA type will reference the residential deposit class and the commercial deposit SA type will reference the commercial deposit class).

You will need additional deposit SA types if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one SA type for regulated deposits and another for unregulated deposits.

NOT_SUPPORTED

For more information about deposit class, refer to Designing and Defining Deposit Classes.

Sub SA Types

If you operate in a deregulated environment AND if you provide billing services for other service providers, you will need to create SA types to handle the billing of the service providers' charges.

NOT_SUPPORTED

Refer to Designing Your SA Types And Start Options For Sub SAs for more information.

Financial Settlement SA Types

If you operate in a deregulated environment, you may have to create financial settlement service agreements for the service providers. As explained in Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us service providers require a service agreement to hold adjustments used to increase how much you owe the service provider (or how much they owe you).

NOT_SUPPORTED

Refer to Designing SA Types For Service Provider Financial Settlements for more information.

Copyright © 2026, Oracle and/or its affiliates.

Usage Request SA Types

Oracle Utilities Meter Data Management stores meter reading information and is responsible for calculating bill determinants during billing. The SA types for these customers will require special setup.

NOT_SUPPORTED

For more information about usage requests, refer to The Big Picture Of Usage Requests.

Initial Consumption Period Considerations

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different utilities count the first day of a new service agreement differently than others. Because of this, a flag exists on SA Type called **Initial Start Date Option**. This flag controls whether the service agreement's start date is included in the consumption period in a service agreement's first bill segment.

The following table describes the ramifications of the options you can set for this flag.

Flag Value	Consumption Period Calculation	Use This Option When
Add 1 Day Always	The consumption period's start date is calculated by adding 1 day to the service agreement's start date. (The SA start date is never included in the consumption period for the first bill segment.)	You want the initial bill and all subsequent bills to have a consistently calculated consumption period (i.e., the consumption period for the first and all other bills is always one day less than the bill segment's period).

Copyright © 2026, Oracle and/or its affiliates.

Add 1 Day for Back-to-back	A back-to-back occurs when any service point for this service agreement was previously linked to a different service agreement that was stopped on the same date that the new service was started (i.e., there is no gap in the service). If a back-to-back is detected, the consumption period start date is calculated by adding 1 day to the SA start date. If no back-to-back is detected, the start date of the consumption period is the SA start date.	You want to flexibly handle consumption period calculation. If you start customers on the same date as the stop date of the previous customer, billing does not include the SA start date in the consumption period. However, if you start a new customer one day (or more) after the stop date of the previous customer, billing includes the first day of the service agreement in the consumption period.
Include First Day	The start date of the consumption period is the service agreement start date. (The SA start date is always included in the consumption period.)	You want to always include the first day AND you will never encounter a back-to-back situation.

The example below shows how the consumption period would be calculated with the various options for a customer who starts service on January 1.

	First Bill **Meter Read: Jan 31** **Bill Segment Period: Jan 1 to Jan 31**	Second Bill **Meter Read: Feb 28** **Bill Segment Period: Jan 31 to Feb 28**	Third Bill **Meter Read: Mar 31** **Bill Segment Period: Feb 28 to Mar 31**
Consumption period using Add 1 Day Always	Jan 2 to Jan 31 (**30 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is detected	Jan 2 to Jan 31 (**30 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is NOT detected	Jan 1 to Jan 31 (**31 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Include First Day	Jan 1 to Jan 31 (**31 days**)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)

There may be SA types for which the value of this flag does not affect the consumption period calculation and still other SA types where this flag is never used. For example,

- For billable charge service agreements, the consumption period is equal to the start and end dates on the billable charge and therefore this flag is not applicable.
- A sub SA either inherits the consumption period from the master SA or it uses billable charges. As a result, billing does not use this flag.

Copyright © 2026, Oracle and/or its affiliates.

- For some service agreements, the charges on the rate are not affected by the consumption period. For example, if you have a customer with a simple meter and a simple usage-based charge, billing calculates the amount of consumption between the start reading and end reading and applies the rate (i.e., the number of days in the consumption period doesn't impact the charges in some rates).
- Some service agreements are not billed, for example, overpayment service agreements. For this type of service agreement and other types of service agreements that are not billed, this flag is not applicable. However, the system does not prevent a value from being entered in these cases to allow for an implementation process to use the flag if needed.

Setting this flag to an appropriate value is significant for certain types of service agreements.

- For services whose rate includes daily charges, the configuration of this flag may impact the first bill segment for the service agreement. For example, if the first bill period is October 1st through October 31st, do you consider consumption period to be 31 days or 30 days? How you want to bill the customer on the first bill determines how you set this flag.
- For service agreements that request usage (or bill determinants) based on interval data, the interval usage recordings typically begin on the first day of service. If you add 1 to the start date, you miss billing for intervals on the first day. In this case, you should set the value to Add 1 Day for Back-to-back.

Processing Sequence Considerations

You may have customers with a complex collection of contracts such that the calculation for one bill segment relies on information calculated by another bill segment for the same account. For example, perhaps you need to process your bill segments as follows:

- Step 1: Calculate bill segments for all the account's "single site" service agreements (i.e., each service agreement related to a single premise)
- Step 2: Calculate the bill segment for additional charges for the "head office" service agreement where the charges are based on the aggregated consumption of all premises from all bill segments (calculated in the first step).

To create the "head office" bill segment for the account, you must control the order in which the system creates the bill segments for each service agreement.

The SA type allows you to indicate a billing processing sequence that controls the order in which the service agreements are processed. The processing sequence is optional and service agreements are processed in ascending order of their SA type's billing processing sequence. As a result, SA Types with a processing sequence of zero are processed first, then 1, then 2, etc.

> **Note**
>
> If you have sub SAs linked to a master SA, the billing processing sequence is used first to order the creation of bill segments for the master SAs. If you populate a processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other. Refer to Designing Your SA Types And Start Options For Sub SAs for more information.

Copyright © 2026, Oracle and/or its affiliates.

The billing processing sequence also controls the order of service agreements in the following other processes:

- Execution of pre bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the pre bill completion algorithms on its SA type are processed in the order of the algorithm's sequence.
- Execution of bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the completion algorithms on its SA type are processed in the order of the algorithm's sequence.

Designing Prepayment Billing Options

This section provides guidelines describing how to design service agreements that handle smart meter prepaid billing.

When a customer is subject to prepayment, normal cycle-based billing is not used to calculate the bill segments for their service. Rather, a prepay billing (PPB) process creates bill segments frequently (for example, daily) and periodically requests funds to maintain an adequate payoff balance. Bills will only be used to periodically inform the customer of the various financial transactions that have occurred since the last bill was produced.

Implementing prepayment billing requires the configuration of the following objects:

- SA Type
- Adjustment Types
- Bill Segment Type
- Service Task Type

These configuration tasks are described below.

> **Note**
>
> For additional information, see the detailed descriptions in the application for the C1-PrepayBillerTaskType and C1-PrepayBillerTask business objects.

SA Type for Prepay Billing

To configure a prepay billing SA Type, create a new SA type with the following attributes:

- Set the Special Role flag to **Bill Determinants Required.** The Prepay Option should be set to **Prepaid Smart Meter.**
- Specify the SA Creation system event with the algorithm CI_CREATEPPB to create the service agreement's prepay biller.
- Specify the Payment Freeze system event with the algorithm STPZ-RMVC to set current amount to zero on a payment.
- If required, specify the Bill Completion system event with an algorithm of the type C1-CREPPBBM to add a bill message that informs an end customer of their prepaid charges for the period. You may need to create an algorithm of this type if it does not exist in your system.
- **Eligible for Budget** should be set to false.

Copyright © 2026, Oracle and/or its affiliates.

- Reference a new **Prepay Bill Segment Type**, which is described below.

The following adjustment types must also be defined on the prepay SA type:

- **Adjustment Type (Xfer)** specifies the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement
- **Adjustment Type (Current=0)** specifies the type of adjustment used to set the prepaid current balance to zero after debt has been transferred
- **NSF Adjustment Type** specifies the type of adjustment used to levy an NSF charge. The NSF Adjustment Type is described in greater detail below.

The new SA types must be added to the data value mapping between CCB and MDM. This is to enable the synchronization of SAs of this type to MDM. The new CCB SA types can be mapped to existing US types in MDM. For additional information about this configuration, please see the integration documentation.

Adjustment Types for Prepay Billing

- **Funds Request Adjustment Type:** This adjustment type captures the type of adjustment used to request more prepaid funds. This adjustment type is specified on the prepaid biller task type. Specify the following algorithms on this adjustment type:
  - **Adj. Financial Algorithm** should reference the Adjustment FT creation algorithm ADJT-CA (Payoff=0/Current=Adj Amount (No GL)).
  - **Adjustment Freeze Algorithm** should reference an algorithm of the type C1-PPBADJFRZ (Set Prepaid Funds Request FT Details). You may need to create an algorithm of this type if it does not exist in your system.
- **NSF Adjustment Type:** For prepaid customers on autopay, when a user cancels an autopay tender the cancel reason must indicate that an NSF charge should be levied. The system invokes the NSF Charge algorithm specified on the tender's account's customer class which creates the NSF adjustment on the appropriate SA. The charge is levied using the NSF Adjustment Type specified on the SA's SA type. This adjustment type must reference the new adjustment freeze algorithm that will disable automatic payments on the PPB. This algorithm must be based on the algorithm type C1-DISPPBAP (Disable PPB's Automatic Payment). You may need to create an algorithm of this type if it does not exist in your system.

Bill Segment Type Required for Prepay Billing

Configure a new bill segment type for prepaid service agreements. This bill segment type should have the following attributes:

- **Create Algorithm** should be set to C1-BSBS-UR to create bill segment using a usage request.
- **Financial Algorithm** should be set to a new algorithm with algorithm type C1-NEM-GL (Payoff Amt = Bill Amt / Current Amt = 0 (GL affected)).You may need to create an algorithm of this type if it does not exist in your system.
- **Get Consumption Algorithm** should be set to C1-BSGC-USG to get bill segment consumption using a usage request.

Service Task Type for Prepay Billing

Configure a new service task type for prepay billing. This task type should reference the Prepay Biller (PPB)Task Type Business Object (C1-PrepayBillerTaskType). The task type must be specified on the new prepay billing SA creation algorithm. The task type captures the adjustment type used when an adjustment is created to request additional funds from the

Copyright © 2026, Oracle and/or its affiliates.

customer. Ensure that this adjustment type references the adjustment freeze algorithm (C1-PPBADJFRZ) that populates the financial transaction's arrears date.

SA Types And The Financial Design

In this section, we provide an example of how our SA Types map to Bill Segment Types, Payment Segment Types, and Adjustment Profiles. This example is meant to help solidify the power of the financial model, it is not necessarily indicative of how your specific implementation will look.

> **Warning**
>
> If you are not comfortable with the topics described in Defining Financial Transaction Options, the following table will not make sense.

Division/SA Type	Distribution Code	Bill Segment Type	Payment Segment Type	Adjustment Profiles
CA/G-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES, BUDGET
CA/G-COM	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/G-IND	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/W-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/W-COM	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/W-IND	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/E-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES, BUDGET
CA/E-COM	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/E-IND	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/WW-RES	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/WW-COM	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/WW-IND	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/CABLE	A/R-UTIL	BD-RATED	NORMAL	BALXFER, MISCFEES
CA/E-COY	E-COMP	COMPUSAG		
CA/G-COY	E-COMP	COMPUSAG		

Copyright © 2026, Oracle and/or its affiliates.

CA/W-COY	E-COMP	COMPUSAG		
CA/WO-STD			NORMAL	BALXFER
CA/WO-LIA			NORMAL	BALXFER
CA/CONNECT			NORMAL	BALXFER, MISCFEES
CA/CHARITY	A/P-CHAR	RECUR	CHARITY	CHARITY
CA/PA-REGU	A/R-ARRG	RECUR-AS	NORMAL	BALXFER, MISCFEES, DPA
CA/PA-UNRE	A/R-ARRG	RECUR-AS	NORMAL	BALXFER, MISCFEES, DPA
CA/MERCH-I	A/R-MRCH	RECUR-AS	NORMAL	BALXFER, MISCFEES, MERCH
CA/DEP-I	A/P-DEPO	RECUR-AS	NORMAL	BALXFER, MISCFEES, DEPOSIT
CA/ONETIME	A/R-UTIL	BILLCHRG	NORMAL	BALXFER, MISCFEES
CA/OVR UNDR	EXP-OV/UND		NORMAL	
CA/OVERPAY	A/P-OVER		NORMAL	BALXFER
CA/SUSPENSE	A/R-SUSP		NORMAL	
CA/NBB	A/P-OVPY		NORMAL	BALXFER, MISCFEES, NBB

If you operate in a deregulated environment, you will also have additional SA types as described under Designing Your SA Types And Start Options For Sub SAs and Designing SA Types For Service Provider Financial Settlements you may have additional SA types.

Setting Up SA Types

In the previous section, Designing SA Types, we presented a case study that illustrated a mythical organization's SA types. In this section, we explain how to use the windows on the SA Type window group to maintain your SA Types.

- SA Type - Main Information
- SA Type - Detail
- SA Type - Billing
- SA Type - Rate
- SA Type - SP Type
- SA Type - Adjustment Profiles
- SA Type - C&C
- SA Type - Billable Charge Template
- SA Type - Characteristics
- SA Type - Algorithms

Copyright © 2026, Oracle and/or its affiliates.

- SA Type - Billable Charge Overrides
- SA Type - Contract Option Type
- SA Type - NBB Recommendation Rule
- Setting Up Start Options
- Start Option Merge

SA Type - Main Information

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Add** to define core information about your SA Types.

> **Warning**
>
> Every SA Type is owned by a CIS Division. This Division controls many values that can be referenced on the SA Type. If you don't understand Divisions and their place in the application, do NOT attempt to set up your SA Types. Rather, refer to Setting Up CIS Divisions before proceeding.

Description of Page

Enter a unique combination of **CIS Division** and **SA Type** for every service agreement type.

Enter a **Description** for the SA type.

Service Type defines the type of service associated with the SA type. If the SA type has rates, only rates belonging to this service type may be linked to the SA type.

Select the **Distribution Code** and **GL Division** that defines the receivable account for receivable-oriented service agreements. For non-receivable oriented service agreements, this distribution code is typically as follows:

- Charitable contributions. The distribution code is a charity payable account.
- Deposits. The distribution code is a deposit payable account.
- Non-Billed Budgets. The distribution code is an overpayment payable account.
- Company usage. The distribution code is a company usage expense account.
- Write off. The distribution code is a write-off expense account.
- Payment arrangements. The distribution code is a payment arrangement receivable account.

> **NOT_SUPPORTED**
>
> For more information about GL accounts, refer to The Source Of GL Accounts On Financial Transactions.

Select the **Revenue Class** associated with the SA Type (and its service agreements). The revenue class may affect the revenue account(s) generated by the service agreement's rate.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Designing Calculation Groups and Rules for more information about revenue class.

Turn on **Start Options Required** if you want to force a customer service rep to choose a start option when they start service for this SA Type (on the Start Account window). If this switch is off and a rate is required for the SA Type, the system defaults the SA type's default rate on new service agreements. The default rate is defined on the SA Type - Rate page.

NOT_SUPPORTED

Refer to Setting Up Start Options for more information about the pros and cons of requiring start options.

Select the **Pay Segment Type** that defines how payment segments linked to service agreements of this type affect:

- The service agreement's payoff and current balances

NOT_SUPPORTED

For more information about payment segment types, refer to Setting Up Payment Segment Types.

When a tender is canceled, a cancellation reason must be supplied. If the cancellation reason indicates a NSF (non sufficient funds) charge should be levied, the system invokes the Levy an NSF Charge algorithm specified on the tender's account's customer class. Because adjustments must be linked to a service agreement, the algorithm must determine the appropriate service agreement to use to levy the adjustment based on business rules. The charge is levied using the **NSF Adjustment Type** of the appropriate service agreement's SA type.

Warning

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

NOT_SUPPORTED

For more information about adjustment types, refer to Setting Up Adjustment Types. For more information about cancellation reasons, refer to Setting Up Payment Cancellation Reasons.

Copyright © 2026, Oracle and/or its affiliates.

Select the **Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to Distribution Based on Payment Priority and Delinquent Payment Distribution Algorithm for information about payment distribution algorithms that use this field.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is PAY_PRIORITY_FLG.

> **NOT_SUPPORTED**
>
> For more information about distribution priority, refer to Distributing A Payment Amongst An Account's Service Agreements.

Select the **Delinquent Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to Delinquent Payment Distribution Algorithm for information about a payment distribution algorithm that uses this field.

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is DEL_PRIORITY_FLG.

Turn on **Do Not Overpay** if the system is not allowed to distribute an overpayment to this type of service agreement (i.e., the service agreement is not allowed to have a system-created credit balance). This field is available for use by algorithms that distribute overpayments. Refer to Overpayments Held On Highest Priority Service Agreement for information about an overpayment algorithm that uses this field.

Turn on **Late Payment Charge** if the system should generate a late payment charge for this type of service agreement if payment is not received on time. If this is turned on, you must define the **LPC Calc. Algorithm** used to calculate the late payment charge amount. Refer to Defining Late Payment Charge Options for more information about late payment charges. Examples of algorithm types used for calculating late payment charges are BILPC-SPRC and BILPC-TOTAL.

Define the **Adj**ustment **Type (Synch Curr)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type. This type of processing happens as follows:

- Most write-off algorithms that perform financial efforts (e.g., writing off debt), will issue an adjustment of this type if the service agreement's current and payoff balances are not equal.
- If a user stops a customer on a budget plan, the system issues adjustments of this type to synchronize the customer's current and payoff balances.

Copyright © 2026, Oracle and/or its affiliates.

- If a user stops a service agreement covered by a **Non-Billed Budget** , the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a cancellation of a bill segment occurs after a customer has stopped participating in a budget plan, an adjustment of this type is issued to synchronize the imbalance created when the bill segment's financial transaction is canceled.

Turn on **CIAC SA Type** and specify an appropriate **CIAC Refund Process** if service agreements of this type are used to bill for Contribution In Aid of Construction (CIAC) charges. Refer to CIAC Segmentation for more information.

SA Type - Detail

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Detail** page to define additional details about a given SA type.

Description of Page

Turn on **Display As Alert** if Control Central should display an alert if an account has a service agreement of this type that isn't Closed or Canceled. If this switch is on, also enter the **Alert Information** to appear on Control Central. We recommend only using this feature on unusual SA types (e.g., payment arrangements, write-offs) so that a CSR is not presented with an alert for every SA type.

If this SA Type is used for any of the **Special Roles**, defined in the dropdown, indicate which one. Valid values are: Billable Charge, Cash Deposit, Loan, Non-Billed Budget, Payment Arrangement, Write Off, Bill Determinants Required. This information is used on windows with functionality that can only be used by service agreements used for specific roles. For example, the Billable Charge window group can only reference Billable Charge service agreements.

If Special Role is Cash Deposit, you must define the **Deposit Class** of the deposit. You should also define a **Deposit Class** on every SA type to which a given deposit can be distributed.

> **NOT_SUPPORTED**
>
> Refer to What Do Deposit Classes Do? for more information.

If the Special Role is Loan, you must also define the following fields:

- Use the **Interest Bill Factor** to define the bill factor code for the loan interest rate.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the **Loan A/R Distribution Code** to define the distribution code to be used when posting the short-term receivable amount to the general ledger (the normal distribution code is used for the long-term receivable). If the normal distribution code is the same as the **Loan A/R Distribution Code**, the SA type does not differentiate between long- and short-term receivables. If the two distribution codes are different, the SA type differentiates between long- and short-term receivables.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Defining Loan Options for more information about **Interest Bill Factor**, **Override Interest** and **Loan A/R Distribution Code**.

If the Special Role is Non-Billed Budget , you must also define the following:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to the transfer accumulated credit from the Non-Billed Budget SA to the SAs covered by the Non-Billed Budget when the account is billed or the Non-Billed Budget SA is stopped.
- Use the **Non-Billed Budget Monitoring** to specify whether the Non-Billed Budget is monitored by the account debt monitor.

If the SA type is defined as Eligible for Non-billed Budget, you must also define the following:

- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the service agreement's current balance to zero when a service agreement of this type is linked to an active, monitored Non-Billed Budget.

If the Special Role is Payment Arrangement and you have not enabled Use Alternate PA Creation Logic, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the payment arrangement service agreement.
- Set **Use Alternate PA Creation Logic** if your payment arrangement SA Types share a debt class with other SA Types. When this is set, the current balance on the transfer adjustment on the payment arrangement SA is set to zero instead of using the below adjustment type to set the current balance to zero. When payment arrangements are in their own debt class, the additional credit adjustment offsets the transfer adjustment. This results in an offsetting credit and debit in the payment arrangement debt class and a single credit on the non-payment arrangement debt class. However, when a single debt class is used, the two credits inaccurately impact the way debt age (arrears) is calculated and presented. Using the alternate PA creation logic ensures that debt age is calculated and displayed accurately when a single debt class is used.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the payment arrangement's current balance to zero after funds have been transferred.

If the Special Role is Write Off, you must also define the following adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the uncollectable service agreements to the write off service agreement.

Note

It may be important to your organization to track the original source of debt that is being written off. The system is delivered with three characteristic types: C1-WODST, C1-WOCHT, and C1-WOCHV that can record the distribution code, characteristic type and characteristic value from the FT GL(s) being written off onto the write off adjustment. To enable this logic, specify these characteristic types as allowable characteristic types on your write off transfer adjustment type.

If the Prepay Option is **Prepaid Smart Meter**, you must also define two adjustment types:

Copyright © 2026, Oracle and/or its affiliates.

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the prepaid current balance to zero after debt has been transferred.

> **Warning**
>
> You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

The **Stop Option** can be used to automatically stop a service agreement when all other service agreements of an account are stopped. Valid values are: Automatically Stop SA. When all service point related service agreements of an account are stopped then all additional service agreements where the **Stop Option** is set to Automatically Stop SA will also be stopped. This is useful, for example, with charitable contribution service agreements. The charity service agreement should be stopped when all utility related services are stopped.

> **NOT_SUPPORTED**
>
> Refer to The Lifecycle of a Service Agreement for more information on the **Stop Option.**

Turn on **One Time Charge** if this SA type is used for one-time invoices. When a one-time invoice service agreement is created, the system sets the stop date of the SA to be equal to the start date.

Turn on **Sub SA** if this SA type is used to define the business rules for sub service agreements.

> **NOT_SUPPORTED**
>
> Refer to Sub Service Agreements for more information about sub service agreements.

Renewal of SAs of this type may be Optional, Not Allowed or Required depending on your business processes. If renewal is not allowed, the SA expires on the expiration date. Renewal treatment is an important consideration for SAs that require an expiration date, such as non-billed budget SAs.

If renewal is required or optional, specify the **Days Before Expiration for Renewal**. Note that currently this is only used by Non-Billed Budgets to calculate the renewal date based on the expiration date.

If the Special Role is Non-billed Budget, **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Credit and Collections and Non-Billed Budgets for more information about monitoring Non-Billed Budgets.

Set **Eligible for Payment Arrangement** to Eligible if this SA type can be included in a payment arrangement.

Note

This is automatically set to Ineligible on SA types with a Special Role of Payment Arrangement.

Where Used

The alert information is used by Control Central to alert a CSR when unusual service agreements exist for an account. Refer to Control Central - Search for more information.

Only SA types designated as being Billable Charge may have billable charges linked to them. Refer to Maintaining Billable Charges for more information.

Only SA types designated as being Cash Deposit are processed by the various deposit-related background processes (e.g., interest calculation, automatic refund, etc.). Refer to The Big Picture Of Deposits for more information.

Only SA types designated as Loan are used to define the loan terms for a loan SA. Refer to **Loans** for more information.

Only SA types designated as Non-billed Budget may be used to set up Non-Billed Budgets. Refer to **Non-Billed Budgets** for more information.

Only SA types designated as being Payment Arrangement may be used on the payment arrangement window group. Refer to Setting Up Payment Arrangements for more information.

Only SA types designated as being Write Off may be specified as the write off SA type on distribution codes. Refer to Setting Up Distribution Codes for more information.

Only service agreements whose SA type is designated as being Write Off appear on the Write Off SAs query. Refer to Write Off - Write Off SAs for more information.

SA Type - Billing

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Billing** page to define how the system manages bill segments for service agreements of a given SA type.

Description of Page

Turn on **Eligible for Billing** if the system should create bill segments for service agreements of this type. This will typically be turned on for all service agreements except for those used to hold write-off amounts or to levy one-off adjustments.

Copyright © 2026, Oracle and/or its affiliates.

Define the minimum number of days a bill segment (other than the final segment) must span using **Minimum Days for Billing**. This is useful to prevent initial bill segments that span only a few days.

> **NOT_SUPPORTED**
>
> For more information about minimum days, refer to Preventing Short Bill Segments.

Select the **Bill Segment Type** that controls both how bill segments for this SA Type will be created and how the related financial transaction affects the general ledger and the customer's debt.

> **NOT_SUPPORTED**
>
> For more information about bill segment types, refer to Setting Up Bill Segment Types.

Use **Default Description on Bill** to define the verbiage that should print on the customer's bill.

> **Note**
>
> **Rates overwrite this description.** The Default Description on Bill is not applicable for service agreements whose charges are calculated using a rate. Why? Because the description that appears on the bill segment is defined on the rate schedule's rate version calculation group.
>
> **Billable charges overwrite this description.** The Default Description on Bill is not applicable for service agreements whose charges are calculated using a billable charge. Why? Because the description that appears on the bill segment is defined on the billable charge.

Use the **Billing Processing Sequence** if you need to control the order in which service agreements linked to this SA type are processed by billing.

> **NOT_SUPPORTED**
>
> Refer to Processing Sequence Considerations for more information.

Use **Bill Print Priority** to define the order in which the SA type's bill segments should appear on bills (relative to the other SA types that appear on a bill).

> **Note**
>
> The values for this field are customizable using the Lookup table. This field name is BILL_PRT_PRIO_FLG.

Copyright © 2026, Oracle and/or its affiliates.

Use **Max Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, an operator truly intends to send the bill out, they should regenerate the bill. Refer to How To Correct A Bill Segment That's In Error for more information.

> **Warning**
>
> The value entered in this field will DEFAULT onto service agreements of this type when they are first created. An operator may change the default value on a service agreement in case a specific customer has unusually high bills that continually error out. It's important to be aware that if you change the value of High Bill Amount on an SA type and there already exist service agreements of this type, the existing service agreements will contain the original value (the new value on the SA type will not be propagated on the existing service agreements).

Use **Graph Unit Of Measure** to define the unit of measure of the graphed consumption on the bill (if any).

Turn on **Allow Estimates** if the system should indicate to Oracle Utilities Meter Data Management whether to generate estimated consumption if meter reading(s) cannot be found at billing time. This value is defaulted onto service agreements and can be overridden on an individual service agreement.

Turn on **Characteristic Premise Required** if a characteristic premise must be linked to the service agreement when the service agreement is activated. The characteristic premise is used to define the taxing authorities associated with the service agreement's bill segments. It is also used to identify where the service agreement's service is located on various windows.

> **NOT_SUPPORTED**
>
> For more information about how characteristic premise is used, refer to **An Illustration Of A Bill Factor And Its Characteristics**.

Use the **Initial Start Date Option** to control how billing should calculate the consumption period for the very first bill for service agreements of this type. This field is not applicable for sub SA types or SA types with a special role of Billable Charge. Valid values are Include First Day, Add 1 Day Always and Add 1 Day for Back-to-back. Refer to Initial Consumption Period Considerations for more information.

Non-metered service agreements may have the end date of their bill segments defined on a user-maintained bill period schedule. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter). If this SA type should be billed like this, select Use Bill Period in the **Use Calendar Billing** field. When this option is used, you must define the **Bill Period** whose schedule defines the bill segment end dates.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about bill period schedules, refer to Designing Bill Periods. For more information about other bill end date methods, refer to Ways To Control The End Date Of A Bill Segment.

Instead of the Use Bill Period method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16th of some month, the ongoing bill segments will start on roughly the 16th of each month. This option is frequently used to bill for garbage or cable service. If this SA type should be billed like this, select Anniversary Future Billing or Anniversary Past Billing in the **Use Calendar Billing** field. When either option is used, you must define the **Anniversary Bill Frequency**. This frequency defines the amount of time between bill segments.

NOT_SUPPORTED

For more information about anniversary billing, refer to Using The Anniversary Method. For more information about other bill end date methods, refer to Ways To Control The End Date Of A Bill Segment.

Total Bill Amount indicates whether service agreements of this type can use the total amount to bill field on the service agreement page. Valid values are Not Allowed and Required. Only SA types used to bill for deposits or loans should have this field set to Required.

If Required is selected, you must enter the **Total Amount To Bill Label**. The **Total Amount To Bill Label** defines the label that prefixes the total bill amount on the service agreement page for service agreements of this SA type.

NOT_SUPPORTED

For more information about total amount to bill and deposit service agreements, refer to Total Amount To Bill. For more information about total amount to bill and loan service agreements, refer to **Setting Up The System To Enable Loans** .

Recurring Charge indicates whether service agreements of this type can use the recurring charge field on the service agreement window. Valid values are Not Allowed, Optional and Required. If either Optional or Required are used, you must enter:

- **Recurring Chg Amt Label**. This defines the label that prefixes the recurring charge amount on the service agreement window for service agreements of this SA type.
- **Recurring Charge Frequency**. This defines the following:
  - Specifies the frequency at which the Recurring Charge Amount specified on service agreements of the SA Type is to be billed.
  - Serves as the basis for proration of the Recurring Charge Amount.
  - Specifies the frequency at which service agreements of the SA Type without a rate and/or meters will be billed.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information about how to use the recurring charge information, refer to Charitable Contribution Segmentation, Merchandise Segmentation - Installment Billing, Deposit Segmentation - Installment Billing, Payment Arrangement Segmentation, Budget Billing Segmentation, The Terms Of A Loan Are Stored On A Service Agreement.

Turn on **Eligible for Budget** if service agreements of this type can participate in budget billing. If this switch is turned on, then you must define the **Adj**ustment **Type (Synch Current)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type when a budget is cancelled. (The Adjustment Type (Synch Current) field is on the main page.)

NOT_SUPPORTED

Refer to Budget Billing for more information about budgets in general. Refer to Budget Billing Segmentation and Designing and Defining Budget Plans for more information.

Set the **Eligible for Non-Billed Budget** flag to Eligible for Non-Billed Budget if you want SAs of this type to be eligible to be covered by a Non-Billed Budget. If this flag is set to Eligible for Non-Billed Budget, you must also define the **Adjustment Type (Current = 0)** field (on SA Type - Detail).

NOT_SUPPORTED

Refer to Current Amount For SAs Covered By A Non-Billed Budget and SA Types for SAs Covered by Non-Billed Budgets for more information.

- Require Total Amount Switch versus Bill Segment Algorithm
- Allow Recurring Charge Switch versus Bill Segment Algorithm

Require Total Amount Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's required total amount switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Require Total Amount Switch: Not allowed	SA Type Require Total Amount Switch: Required

Copyright © 2026, Oracle and/or its affiliates.

Apply Rate To Usage Request	Metered services. Lamp services. Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	N/A
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	N/A	Deposit installment plans.
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices. Pass through charges	N/A
Loan	N/A	Loans.

Allow Recurring Charge Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's allow recurring charge switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	**SA Type Recurring Charge Switch:** Not allowed	**SA Type Recurring Charge Switch:** Optional	**SA Type Recurring Charge Switch:** Required
Apply Rate To Usage Request	Metered services - no budget Lamp services Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	Metered services - budget optional	Metered services - budget required
Recurring Charge With Auto Stop	N/A	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!
Recurring Charge For Amount To Bill	N/A	Deposit installment plans. SEE NOTE!	Deposit installment plans. SEE NOTE!
Recurring Charge	Charitable contributions	N/A	N/A

Copyright © 2026, Oracle and/or its affiliates.

Billable Charge	One time invoices. Pass through charges	N/A	N/A
Loan	N/A	N/A	Loans.

> **Note**
>
> Most recurring charge SA types require a recurring charge amount on their service agreements. However, the above matrix indicates you can have recurring charge SA types where this value is optional. Why? A special algorithm exists in billing that says if the recurring charge amount is 0 (zero) the system will bill the remaining payoff balance or total amount to bill. This algorithm exists so that you can easily bill the amount in one lump sum (i.e., don't bill it in installments).

Where Used

The billing information is used when the system creates a bill segment for service agreements of this type.

SA Type - Rate

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Rate** page to define the rates that may be referenced on service agreements of a given type.

Description of Page

Turn on **Rate Required** if the bill segment creation algorithm for the SA type expects a rate schedule to be referenced on service agreements of this type.

> **NOT_SUPPORTED**
>
> For more information, refer to **Rates** .

When a rate changes within a bill segment's consumption period, the period is divided into separate usage periods – one for each active rate schedule during that period. The usage periods and their related consumption (or billable quantities) are then prepared for billing, and the rate schedule calculations are applied to their associated periods.

This feature is possible if the usage subscription type is configured with the base Dynamic Usage Group Determination algorithm, which determines the applicable usage group for each effective rate schedule. This algorithm requires that the CCB rate schedule has usage group extendable look-ups configured for the rate schedule and device configuration type combinations.

A typical use case is when there is a smart meter rollout in the middle of billing period and there are rate schedule changes that coincide with the meter exchange date. The usage group that is tied to the old meter will have rules that calculate scalar consumption, and the usage group that is tied to the new meter will have rules that calculate interval consumption. The end

Copyright © 2026, Oracle and/or its affiliates.

result is that the customer is billed with scalar consumption for the period where old meter was installed, and billed with interval consumption for the period where new meter is installed.

If the Contract Management module is not turned off, which includes umbrella agreement management, indicate the **Rate Source**. Check SA Only indicates that the rate schedule currently in effect for the service agreement should always be used. Check TOS First, then SA indicates that if the service agreement is linked to a terms of service record, the service agreement's rate could be overridden by one linked to the terms of service record.

The information in the **Rate Schedules** collection defines the rates that may be referenced on service agreements of this type. The following fields are required for each SA Type:

Rate Schedule Specify the rate schedule; its description is displayed adjacent.

Use As Default Turn on this switch for the rate to be defaulted on new service agreements.

- Rate Required versus Bill Segment Algorithm

Rate Required versus Bill Segment Algorithm

The following table shows appropriate combinations of the SA type's rate required switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not applicable. Otherwise, we list typical types of service agreements that will use a combination. Be aware that no cross validation exists between the rate required switch and the bill segment creation algorithm when setting up the SA type.

Bill Segment Create Algorithm	SA Type Rate Required Switch: Not allowed	SA Type Rate Required Switch: Rate required on SA
Apply Rate To Usage Request	N/A	Metered services. Lamp services. Misc item services. Company usage.
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	Deposit installment plans.	N/A
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices.	Billable charges that require a rate to add-on extra charges (like taxes) or billable charges where the consumption is interfaced and the system is responsible for calculating the charges.
Loan	Loans.	N/A

Where Used

This information is used to default and validate the rate specified on a service agreement. Refer to Service Agreement - Rate Info for more information.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - SP Type

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **SP Type** page to define the service point types that may be referenced on service agreements of a given type.

Description of Page

Turn on **Service Points Required** if at least one service point should be linked to service agreements of this type in order to properly bill the service agreements.

The information in the **SP Types** collection defines the service point (SP) types that may be referenced on this SA type's service agreements. The following fields are required for each SA Type:

SP Type Specify the SP type; its description is displayed adjacent.

> **NOT_SUPPORTED**
>
> For more information about SP types, refer to Designing SP Types.

Where Used

This information is used to validate the types of service points linked to a service agreement. Refer to Service Ag reement - SA / SP for more information.

SA Type - Adjustment Profiles

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Adj Profile** page to define the adjustment profiles that define adjustment types that may be referenced on service agreements of a given type.

Description of Page

Define the **Adjustment Type Profiles** that, in turn, define adjustment types that may be referenced on service agreements of a given type.

> **NOT_SUPPORTED**
>
> For more information about adjustment type profiles, refer to Setting Up Adjustment Type Profiles.

Where Used

This information is used to validate the adjustments linked to the service agreement. Refer to Adjustment - Main Information for more information.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - C&C

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **C&C** page to maintain attributes that affect how the system severs the service agreement when collection attempts fail.

> **NOT_SUPPORTED**
>
> Refer to Designing Your Severance Procedures for more information.

Description of Page

Select the **Debt Class** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class.

Select the **Write Off Debt Class Code** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class during write-off processing.

> **Note**
>
> **Write Off Debt Class vs. Regular Debt Class.** It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt. Refer to The Big Picture Of Write Off Processing for more information.

The information in the **Severance Criteria** collection defines the SA Type's severance criteria. Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer or premise. For example, you may have a different severance process if the customer has life support equipment.

> **NOT_SUPPORTED**
>
> The following information is not intuitively obvious. Refer to Designing Your Severance Procedures for more information.

The following fields are required for each instance:

Priority The priority controls the order in which the system determines if the severance process should be applied (the first severance process whose algorithm applies is used). Higher priorities are checked before lower priorities.

Copyright © 2026, Oracle and/or its affiliates.

Severance Criteria Algorithm Select the algorithm to be used to check if the severance process should be initiated for service agreements of this type. If a condition is met, a severance process is created using the associated severance process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to Setting Up Algorithms).
- On this algorithm, reference an Algorithm Type that determines if the severance of a service agreement should be processed using the associated **Severance Process Template**.

> **Important**
>
> You must have at least one entry in this collection otherwise the system will not start a severance process when a service agreement of this type needs to be stopped due to non payment. This entry should have the lowest priority code and should reference a **Severance Criteria Algorithm** that references the SV CRIT DFLT algorithm type.

Severance Process Template Specify the severance process template to use to sever the service agreement; its description is displayed adjacent.

Where Used

The debt class has multiple uses:

- The system summarizes an account's debt by debt class on Account - Main Information and Account - Financial Balances.
- Debt class is one component that controls how the system analyzes an account's overdue debt (the others are the account's collection class and currency). Refer to Different Collection Criteria For Different Customers And Different Debt for more information.
- Write off debt class is one component that control how the system writes off an account's stopped service agreements. Refer to Different Write-Off Criteria For Different Customers And Different Debt for more information.

The severance criteria are used when a collection event is activated that indicates that service should be severed.

SA Type - Billable Charge Template

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **BC Template** page to define the billable charge templates that can be used on service agreements of a given type.

> **Note**
>
> **Only billable charges have billable charge templates.** Only service agreements that are defined as Billable Charges (in the Special Role on the Details window) may use the grid on this window.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

The information in the **Billable Charge Template** collection defines the SA Type's permissible billable charge templates. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge. The following fields are required for each template:

Billable Charge Template Specify the billable charge template. Its description is displayed adjacent.

Use As Default Turn on this switch for the template to be defaulted on new billable charges linked to service agreements of this type (if any).

> **NOT_SUPPORTED**
>
> For more information about billable charge templates, refer to Setting Up Billable Charge Templates.

Where Used

This information is used to limit the billable charge templates that can be used for a given SA type.

SA Type - Characteristics

To define characteristics common to all service agreements of a given type, open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define a **Characteristic Type**, **Sequence**, and **Characteristic Value** common to all service agreements of this type.

> **Note**
>
> You can only choose characteristic types defined as permissible on a SA Type record. Refer to Setting Up Characteristic Types & Their Values for more information.

SA Type - Algorithms

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for service agreements of a given type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).

Copyright © 2026, Oracle and/or its affiliates.

- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

> **Warning**
>
> These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description

Copyright © 2026, Oracle and/or its affiliates.

Bill Completion	Optional	These algorithms are executed whenever a bill is completed for an account that contains a non-canceled service agreement of this type. The following situations necessitate the definition of a completion algorithm on an SA type: - As explained under Technical Implementation of A/R Transfer and Technical Implementation of Routing Billable Charges To Service Providers, when a bill is completed, the system needs to set up the data necessary to interface any "master" SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate algorithm on the master SA types. - As explained under Billing For SAs Covered By The Non-Billed Budget, when a bill is completed for accounts that have a Non-Billed Budget SA, the system needs to distribute the Non-Billed Budget's credit balance to the covered SAs. The system will only do this if you specify an appropriate algorithm on the NBB SA types. - As explained under Overpayment Segmentation, when a bill is completed, the system may apply an excess credit from a prior overpayment to an account's service agreements. **Note**. Algorithms of this type are called for all non- Canceled service agreements, regardless of whether or not they are billed. If your algorithms should only be processed under certain conditions (for example, only process this algorithm for Active service agreements), then it is the responsibility of the algorithm to check the conditions before continuing.

Copyright © 2026, Oracle and/or its affiliates.

Bill Eligibility	Optional	These algorithms are executed during billing and allow logic to be introduced to check additional criteria to determine if an SA is eligible for billing.
Break NBB SA	Optional	These algorithms are executed when a Non-Billed Budget is manually stopped via the **Non-Billed Budget maintenance page** . Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.
Break Pay Arrangement	Optional	These algorithms are by executed by severance events when the event is created for payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place when a customer breaks a payment arrangement. Refer to Monitoring Payment Arrangements for more information about breaking payment arrangements.
Budget Eligibility	Optional	These algorithms are executed when determining if a service agreement is eligible for budget. Algorithms of this type are only applicable on SA types that are marked as eligible for budget and may be used to override that setting and indicate that the service agreement is not eligible. For example, maybe service agreements in a certain rate are not eligible. Or perhaps service agreements with a given characteristic value are not eligible.
Cut Process Rule	Optional	These algorithms are executed to create a cut process for service agreements of this type. Refer to The Big Picture Of Cut Processes for more information.

Copyright © 2026, Oracle and/or its affiliates.

FT Freeze	Optional	These algorithms are executed whenever a financial transaction is frozen that is linked to a service agreement of this type. The following situations necessitate the definition of an FT freeze algorithm: - As explained under Technical Implementation of Routing Consumption To Service Providers, when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. - As explained under Technical Implementation of Paying The Service Provider, when a financial transaction (FT) is frozen that is associated with a sub SA, the system must check if this FT should trigger the "payment" of a service provider. If so, it has to create an adjustment to increase how much we owe the service provider. The system will only do this if you specify an appropriate FT Freeze Algorithm on the sub SA types.

Copyright © 2026, Oracle and/or its affiliates.

High Bill Amount	Optional	This algorithm type checks for high bill amounts during batch billing. A bill threshold amount can be defined on a service agreement. By default the system compares this threshold amount to the bill segment amount during batch billing. If the bill segment amount exceeds the given threshold value, a bill error is generated. No proration takes place on the threshold amount if the bill segment's consumption period falls outside of the rate frequency's normal period. This algorithm may be used to override the default system behavior. It will prorate the SA's bill threshold amount before comparing it to the batch bill segment amount if the consumption period falls outside of the rate frequency's normal period.
Landlord Reversion	Optional	These algorithms are used to create, update or cancel a service agreement for a landlord when service is started, stopped or updated for a premise that references a landlord agreement. Algorithms of this type are called: - When starting a new SA (start initiation) - When stopping an SA (stop initiation) - When canceling a pending start SA - When changing the stop / start dates of back-to-back service agreements
Loan Interest Charge	Optional	These algorithms are executed whenever the interest charge needs to be calculated for a loan, such as when the loan amortization schedule is created and when a bill segment is created for a loan SA. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.

Copyright © 2026, Oracle and/or its affiliates.

Loan Periods and Amount	Optional	These algorithms are executed whenever a user clicks the Calculate button on **Loan - Main** or on the Start SA Confirmation dialog for a loan SA. It calculates either the number of periodic payments or the payment amount (depending on whether the user specifies the number of payments or the payment amount as input). This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Loan Schedule	Optional	These algorithms are executed whenever the system needs to create a **loan amortization schedule** for a loan, such as when you renegotiate the terms of a loan on **Loan - Main** . This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.
Override Proration Days	Optional	This algorithm is invoked from rate application, right after base has determined if proration applies. It is used to override base days, normal days and “is within proration window” indicator, which were determined by base logic. Only one algorithm may be plugged-in to this system event. This is available only in the calculation rule based rating engine.

Copyright © 2026, Oracle and/or its affiliates.

Payment Arrangement	Optional	These algorithms are by executed to handle the creation, breaking and canceling of payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place during the lifecycle of a payment arrangement. Refer to Monitoring Payment Arrangements for more information about payment arrangements. Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.
Payment Freeze	Optional	These algorithms are executed whenever a payment is frozen. The following situations necessitate the definition of such an algorithm: - For a loan SA, such an algorithm is required to create a frozen adjustment that transfers any credit balance resulting from an overpayment to the loan's principal balance. Refer to Defining Loan Options for more information.
Pre-Bill Completion	Optional	These algorithms are executed immediately prior to bill completion when a bill contains a bill segment for a service agreement whose SA type has such an algorithm. The following situations necessitate the definition of such an algorithm: - If you want to delete a bill segment that's in error on the last night of a bill cycle when there are other bill segments that aren't in error, use such an algorithm.

Copyright © 2026, Oracle and/or its affiliates.

Process NBB Scheduled Payment	Optional	These algorithms are executed by the NBB Scheduled Payment Processing background process whenever a scheduled payment is due. If the Non-Billed Budget SA is unmonitored, this algorithm is not called. This algorithm should be specified on Non-Billed Budget SA types to create the necessary adjustments for the Non-Billed Budget SA.
Proposal SA Acceptance	Optional	These algorithms are executed when a proposal service agreement is accepted. Refer to Enabling The Creation Of A Real Service Agreement for more information.
Proposal SA Bill Segment Generation	Optional	These algorithms are executed to generate simulated bills segments for a **proposal service agreement** . Refer to **Enabling The Generation Of Simulated Bill Segments** for more information.
Proposal SA Creation	Optional	These algorithms are executed when a **proposal service agreement** is created. Refer to **Enabling The Automatic Generation Of Billing Scenarios** for more information.
SA Activation	Optional	These algorithms are executed when a service agreement status changes from Pending Start to Active. It performs any additional activities that are necessary to activate an SA. The following situations necessitate the definition of such an algorithm: If you want to create a customer contact to indicate that a non-billed budget has been activated, use such an algorithm.

Copyright © 2026, Oracle and/or its affiliates.

SA Cancel	Optional	These algorithms are executed when a service agreement status changes to Canceled. It performs any additional activities that are necessary to cancel an SA. An example of when you may use this algorithm is that perhaps your business rules dictate that the creation of a payment arrangement should create a credit rating history transaction. When a payment arrangement SA is canceled, the credit rating should be updated with an end date.
SA Creation	Optional	These algorithms are executed when a service agreement is created. The following situations necessitate the definition of such an algorithm on an SA type: - If you want to create a To Do entry whenever a new service agreement of a given type is added, specify such an algorithm. - If you want to automatically activate SAs of a given type (instead of waiting for the background SA activation process to run), specify such an algorithm. - If you want to create a Workflow Process when a service agreement of a given type is added, specify such an algorithm.
SA Information	Optional	We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm. Plug an algorithm into this spot to override the "SA information" algorithm on installation options or the system default "SA information" if no such algorithm is defined on installation options.

Copyright © 2026, Oracle and/or its affiliates.

SA Renewal	Optional	These algorithms are executed by the Service Agreement Renewal background process whenever an SA is due for renewal or when the user clicks the **Renew** button (for **Non-Billed Budgets**). It performs any activities that are necessary to renew an SA and returns the new renewal and expiration dates for the SA.
SA Stop	Optional	These algorithms are executed whenever a service agreement's status changes from pending stop to stopped. The following situations necessitate the definition of a SA stop algorithm: - For Non-Billed Budgets to distribute any remaining credit balance from the Non-Billed Budget SA to the covered SAs, you must specify such an algorithm. - For service credit memberships that have a refundable membership fee, an SA Stop algorithm attempts to refund the fee if this is the last SA linked to the membership that is being stopped.

Copyright © 2026, Oracle and/or its affiliates.

SA Stop Initiation	Optional	These algorithms are executed whenever a service agreement's status becomes pending stop. The following situations necessitate the definition of a stop initiation algorithm on an SA type: - As explained under Finalizing Pending Stops, service agreements are normally transitioned from pending stop to stopped by a background process (or manually). For Non-Billed Budget SAs to transition to stopped automatically (without waiting for the background process), you must specify such an algorithm. **When does a SA become pending stop?** Service agreements typically become pending stop when a user initiates a request to stop service on Start Stop - Main. A severance process with an Expire SA severance event causes a service agreement to become pending stop (when the event is executed). Additionally, the Stop Expired Service Agreements background process starts the process to initiate the stop of an SA when the expiration date is on or before the process date.
Start Stop Field Work	Optional	These algorithms are executed to create the field activities necessary to start and stop service. Refer to Starting Service and Field Activities and to Stopping Service and Field Activities for a description of when algorithms of this type are called. The following situations necessitate the definition of a start stop fieldwork creation algorithm: - If a service agreement has field activities created to start and stop service at its service points, its SA type must have an appropriate start stop field work creation algorithm.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Billable Charge Overrides

The BCU2 - Create Billable Charge background process is responsible for creating billable charges for each billable charge upload staging record interfaced into the system. This process will override the values of the various switches referenced on a billable charge upload staging line if the respective service agreement's SA type has an override value for the billable charge upload staging line's billable charge line type.

> **Note**
>
> **This information is optional.** If you don't need to override the values of a **Billable Charge Line Type** you don't need to set up this information.

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **BC Upload Override** page to define override values for a given SA Type / Billable Charge Upload Staging Line Type.

Description of Page

Use the **Billable Charge Overrides** collection to define values to be overridden on billable charge lines uploaded from an external system (refer to the description above for the details). The following switches may be overridden for a given **SA Type** and **Billable Charge Line Type.**

- Use the **Show on Bill** switch to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.
- Use the **Appear in Summary** switch to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.
- Use **Memo Only, No GL** switch to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.
- Use **Distribution Code** to define the value to be defaulted into the Distribution Code on billable charge upload lines that reference this line type.

SA Type - Contract Option Type

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **Contract Option Type** page to define the contract option types, which are valid for service agreements of a given type.

> **Note**
>
> **This tab may not appear.** This tab is suppressed if the interval billing Contract Options module is turned off.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

If the SA Type's special role flag is set to Bill Determinants Required, you may define the **Contract Option Types** that are valid for contract options linked to a service agreement of this type.

Where Used

This information is used to validate the contract options linked to the service agreement. Refer to Service Agreement - Contract Options for more information.

SA Type - NBB Recommendation Rule

Open **Admin**, and then **Customer**, and then **SA Type**, and then **Search** and navigate to the **NBB Rec'n Rule** page to define the recommendation rules that are valid for Non-Billed Budget SAs of this type.

Description of Page

If the SA Type's special role is Non-Billed Budget, you may define the **Recommendation Rules** that are valid on non-billed budget SAs of this type. Check the **Use As Default** box to indicate the default recommendation rule for service agreements of this type.

> **NOT_SUPPORTED**
>
> For more information about Non-Billed Budgets, refer to **Defining Non-Billed Budget Options** .

Where Used

The Non-Billed Budget recommendation rules are used to recommend the payment amount and payment schedule for Non-Billed Budget service agreements. Refer to **Maintaining Non-Billed Budgets** for more information.

Setting Up Start Options

Start options save users time and prevent data entry errors because they default many values on a service agreement (e.g., the rate schedule, recurring charge amount, contract riders, contract terms, characteristics, terms and conditions, etc. can all be defaulted onto a service agreement from a start option).

A SA type may have zero or more start options.

- A SA type without start options is usually one that has a very limited number of options. For example, if a SA type has a single valid rate and no customer-specific contract values, you don't need to setup a start option (the SA's default rate can default based on the information defined when you setup the SA type).
- A SA type with multiple start options is one where many different permutations are possible. For example, a SA type that can have multiple rates and each rate can have multiple riders is a good candidate for start options (where each start option will default, for example, a specific rate and set of contract riders).

Copyright © 2026, Oracle and/or its affiliates.

When the Start/Stop transaction is used to start service AND the service being started uses a SA type with start options, the user is asked to select one of the start options. The service agreement that's created is populated with fields from the start option.

When the Order transaction is used to start service, the user selects start options, but only indirectly. It works like this:

- A user selects a "package" of services to start service for a customer.
- A "package" contains one or more start options.
- When a user selects a package, the system creates a service agreement for each start option on the package (and defaults the information on each service agreement from the respective start option).

A start option's default values may change over time (i.e., the information on a start option is effective-dated). The start service logic uses the version of the start option that is effective on the day service starts.

Start options can cause a great deal of information to be populated on a service agreement. There are several ways to change this default information:

- A user may override this information using the Service Agreement transaction.
- If the service agreement is in the pending start state, you can use the Start/Stop - Pending SAs page to change the service agreement's SA type and/or start option.
- If the service agreement is in active or pending stop states, a button appears on Service Agreement - Main called **Apply New Start Option**. When pressed, the user is allowed to define a start option and the date its terms become effective on the service agreement. Refer to Changing A Start Option for the details of this functionality.

The topics in this section describe how to setup start options.

> **Note**
>
> **The merge transaction can save setup time.** The Start Options Merge transaction can be used to construct a start option by copying pieces from other start options.

- Start Option Considerations - Rate-Oriented SA Types
- Start Option Considerations - SA Types That Use Recurring Charges
- Start Option Considerations - Initial Adjustment SA Types
- Start Option - Main
- Start Option - Rate Info
- Start Option - Characteristics & Qty
- Start Option - Contract Option

Start Option Considerations - Rate-Oriented SA Types

To understand the following discussion, you should be familiar with the following concepts:

- SA types that use rates have one or more valid rate schedules. Only these rate schedules may be defined on service agreements of a given type.

Copyright © 2026, Oracle and/or its affiliates.

- One of a SA type's rate schedules may be designated as the "default" rate. The system assigns the "default" rate to new service agreements when a CSR doesn't choose a start option.
- Start options may be used by customer service reps when a service is started for a customer. A start option causes the customer's new service agreement to be populated with a specific rate and contract terms (e.g., contract riders, contract values). The use of start options is not allowed if the service's SA type does not require a start option. The use of start options is required if the service's SA type requires a start option.

Whether or not a SA Type has start options is dependent on the following factors:

- If a SA Type has only one valid rate and the rate doesn't use customer-specific contract terms (e.g., contract riders, contract values), the SA Type does not need any start options. Why? Because the system default's the SA type's default rate on new service agreement when no start option is used at start time.
- If a SA Type has only one valid rate, but under unusual circumstances, it uses customer-specific contract terms, you'll want an option for every situation (both the standard one and the unusual ones).
- If a SA Type has a single rate with a variety of contract terms (which, by definition, are different for each customer), then you'd want a start option for each permissible combination of contract terms. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).
- If a SA type has multiple valid rates and a variety of contract terms (a combination of the previous two points), you'd need a start option for each permissible combination. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).

Start Option Considerations - SA Types That Use Recurring Charges

To understand the following discussion, you should be familiar with the following concepts:

- Many SA types use the recurring charge algorithms to generate the bill segments. For example, if you let a customer pay for a $900 heat pump in 3 installments of $300, you'd have an SA type called CA/MERCH-I and indicate it uses the recurring charge algorithm.
- When a CSR creates an SA type that uses recurring charge algorithms, they can enter the recurring charge amounts on Start/Stop Service - Start Confirmation window OR they can specify a start option on this window and let the system populate the recurring charge amount. For example, if you let a customer pay for a $900 heat pump in 3 installments of $300, you can set up a start option called HP 3PAY with an installment amount of $300.
- Depending on the type of service being started, you might also need to generate an adjustment when service is started in order to initialize the total debt. For example, when a customer buys a heat pump we'll need an adjustment issued to realize the entire $900 of revenue.

The following table provides examples of recurring charge SA types with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments

Copyright © 2026, Oracle and/or its affiliates.

CA/CHARITY	DONATE $5		5	This causes a charitable contribution to be created with an installment amount of $5.
CA/CHARITY	DONATE $10		10	This causes a charitable contribution to be created with an installment amount of $10.
CA/PA-REGU	PAY $10 PM		10	This causes a payment arrangement to be created with an installment amount of $10.
CA/PA-REGU	PAY $20 PM		20	This causes a payment arrangement to be created with an installment amount of $20.
CA/PA-UNRE	PAY $10 PM		10	This causes a payment arrangement to be created with an installment amount of $10.
CA/PA-UNRE	PAY $20 PM		20	This causes a payment arrangement to be created with an installment amount of $20.
CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of $300. It also causes an adjustment to be issued to realize the $900 of revenue.

Copyright © 2026, Oracle and/or its affiliates.

CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of $250. It also causes an adjustment to be issued to realize the $750 of revenue.
CA/DEP-I	PAY $40 PM		40	This causes a deposit service agreement to be created with an installment amount of $40. The CSR would be required to define the total deposit amount to be billed over the life of the service agreement on the secondary SA window on the Start Account window.

Start Option Considerations - Initial Adjustment SA Types

To understand the following discussion, you should be familiar with the following concepts:

- Some SA types depend on an adjustment to book their initial debt. For example, the CA/MERCH-I SA type requires an initial adjustment to book the payoff amount for the entire cost of the merchandise. Another example would be a loan service agreement (refer to Booking The Principal Amount Using An Adjustment for the details).
- When a CSR starts an SA type that requires an initial adjustment, they can create the adjustment immediately after starting service OR then can specify a start option when they start service and let the system generate the adjustment. You could let the system create the adjustment to book the $900 associated with the heat pump as shown in the previous section.

The following table provides examples of SA types that use adjustments with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments

Copyright © 2026, Oracle and/or its affiliates.

CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of $300. It also causes an adjustment to be issued to realize the $900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of $250. It also causes an adjustment to be issued to realize the $750 of revenue.
CA/CONNECT	CONNECT	CONNECT		This causes an adjustment to be issued to realize the connection charge.

Start Option - Main

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Add** to define a SA type's start options.

Description of Page

Every start option is uniquely identified by the following fields:

CIS Division & SA Type Enter the Division and SA type to which the start option is linked.

Start Option Enter the unique identifier of the option. Pick something easy to recognize as this will be used by CSRs to pick an option when they start service.

Effective Date Enter the earliest effective date. It should be the same as the earliest effective date of the start option's rate (although it doesn't hurt for it to be earlier). The date defaults to the current date. (The status, below, should be Active.)

The remaining fields further describe a start option.

Enter a **Description** for the start option.

Indicate its **Status**. For new start options, the status should be Active. When it's no longer applicable, change it to Inactive.

Enter the primary **Rate Schedule** that should be defaulted onto service agreements created using this option. Refer to Start Option Considerations For SA Types That Use Rates for more information.

Copyright © 2026, Oracle and/or its affiliates.

> **NOT_SUPPORTED**
>
> For more information about a service agreement's rates, refer to Service Agreement - Rate Info.

Enter the **Adjustment Type** that should be generated, if any, when service is started using this option. Refer to Start Option Considerations For SA Types That Use Initial Adjustments for more information.

Enter the **Recurring Charge Amount** that should be defaulted onto service agreements created using this option. This field is only visible when the SA type allows recurring charges. In addition, the prompt for this field is defined on the SA type table on the billing window (e.g., it could appear as Payment Amount, Budget Amount, or Installment Amount). Refer to Start Option Considerations For SA Types That Use Recurring Charges for more information.

Enter the **Currency Code** in which monetary amounts are denominated.

> **Note**
>
> The currency code defaults from the installation record.

Enter the **Total Amount to Bill** that should be defaulted onto service agreements created using this option. This is useful to initiate either a loan or a deposit. The prompt for this field is defined on the SA type table on the billing window (e.g., it could be Deposit Amount or Loan Amount).

Use **Number of Periods** to default the number of payment periods of service agreements created using this option. This field is only allowed for SA types with special role of Loan. Refer to The Terms Of A Loan Are Stored On A Service Agreement for more information.

If your SA Type has a special role of Billing Determinants Required, you may enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements that are created using this option. For start day option, you may choose **Current Day** or **Previous Day**.

If your SA Type has a special role of Billable Charge, then you can setup the start option to automatically create a billable charge when a service agreement is created using this start option. For example, you might have a start option that automatically creates a "one-time invoice" service agreement along with a "tree trimming" billable charge. To use this feature you should turn on the **Create Billable Charge** switch and specify the **Billable Charge Template** that will be used to create the billable charge. These fields are only allowed for SA types with special role of Billable Charge.

> **NOT_SUPPORTED**
>
> Refer to Setting Up Billable Charge Templates for more information about templates. Refer to An Easier Way To Create One Time Charges for an example of how you can setup a campaign with packages that use this type of start option.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The duplicate action in the page actions toolbar enables you to copy another start option. Refer to Duplicate Button in the system wide standards document for more information.

Start Option - Rate Info

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Rate Info** page to define the start option's default values for contract riders and contract values.

Description of Page

The information in the **Contract Riders** collection defines the contract riders to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Bill Factor The bill factor defines the type of rider. You may only reference bill factors designated as being applicable for contract riders.

Number of Days The number of days the rider should be in effect. This value is used by the system to set the stop date on the service agreement's contract rider. If the rider has no expiration, set this field to 0. Default note: this field will be set to 0 if left blank.

> **NOT_SUPPORTED**
>
> For more information about a service agreement's contract riders, refer to Service Agreement - Contract Riders.

The information in the **Contract Values** collection defines the contract values to be defaulted onto service agreements created using this start option. The following fields are required for each event:

Bill Factor The bill factor defines the type of value. You may only reference bill factors designated as allowing values in contract terms.

Number of Days The number of days the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Value The amount of the contract value.

> **NOT_SUPPORTED**
>
> For more information about a service agreement's contract values, refer to Service Agreement - Contract Values.

Copyright © 2026, Oracle and/or its affiliates.

Start Option - Characteristics & Qty

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Characteristics & Qty** page to define the start option's default values for characteristics and contract quantities.

Description of Page

The information in the **Characteristics** collection defines the characteristics to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Characteristic Type This defines the type of characteristic. Note: you may only define characteristics valid on service agreements.

Characteristic Value This defines the characteristic value that will be defaulted.

> **NOT_SUPPORTED**
>
> For more information about a service agreement's characteristics, refer to Service Agreement - Characteristics.

The information in the **Contract Quantity** collection defines the contract quantities to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Contract Quantity Type This defines the type of contract quantity.

Contract Quantity The amount of the contract quantity.

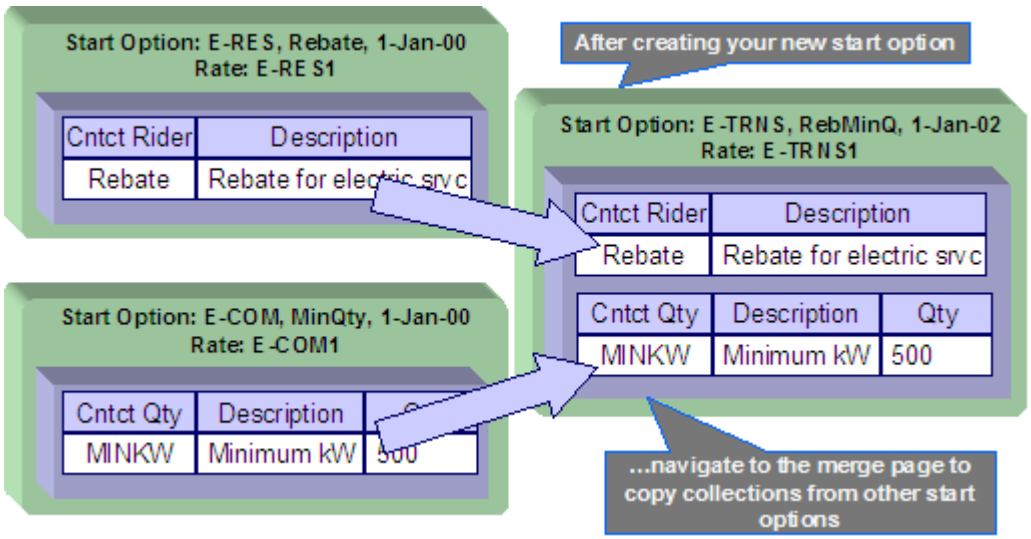
> **NOT_SUPPORTED**
>
> For more information about a service agreement's contract quantities, refer to Service Agreement - Contract Quantity.

Start Option - Contract Option

> **Note**
>
> **This tab may not appear.** This tab is suppressed if the interval billing Contract Options module is turned off.

Open **Admin**, and then **Customer**, and then **SA Type Start Option**, and then **Search** and navigate to the **Contract Option** page to define the start option's contract option default values.

Copyright © 2026, Oracle and/or its affiliates.



Description of Page

The collection of contract option types will be used to link contract options to a service agreement that will be created with this start option. If the contract option to create for the service agreement will be SA Specific, simply indicate the **Contract Option Type**. This will cause a new contract option to be created with this contract option type and the new contract option will be linked to the new SA at start time. If the contract option to create for the service agreement will be Shared, indicate the contract option type and the **Contract Option ID**. This will cause the specified contract option to be linked to the new SA at start time.

Start Option Merge

Use this page to modify an existing start option by copying information from other start options. This page may be used to copy records from the contract rider, contract value, contract quantity, characteristic, contract option and TOU contract value collections from one or more existing start options to another.

> **Note**
>
> The target start option must exist prior to using this page. If you are creating a new start option, you must first go to the Start Option page to add the new start option and then navigate to the merge page to copy collection information.

> **Note**
>
> **Duplicate versus Merge**. The **Start Option** page has Duplication capability. You would duplicate a start option if you want to a) create a new start option AND b) populate it with all the information from an existing start option. You would use the start option merge page if you want to build a start option using pieces of one or more start options.

- Start Option Merge - Main

Copyright © 2026, Oracle and/or its affiliates.

- Removing A Row From A Grid
- Adding A New Row To A Start Option
- Removing An Uncommitted Row From A Start Option
- Start Option Merge - Characteristics and Quantities
- Start Option Merge - Contract Option
- Start Option Merge - Terms and Conditions

Start Option Merge - Main

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge.**

Description of Page

Select the **Original Start Option**, which is the target for merging the start option collection information.

Select the **Merge From Start Option**, which is your template start option to copy the collections from.

> **Note**
>
> You may only copy information from one Merge From start option at a time. If you wish to copy information from more than one start option, select the first Merge From start option, copy the desired records, Save, then select the next Merge From start option.

The left portion of the page will display any existing records in the collections for the original start option. The right portion of the page will display the existing records in the collections for the Merge From start option.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From start option to the Original start option. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **Contract Riders** collection initially displays existing contract riders linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **Number of Days** for each contract rider is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Values** collection initially displays existing contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor**, **Number of Days** and **Value** for each contract value is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The topics, which follow, describe how to perform common maintenance tasks:

Removing A Row From A Grid

Copyright © 2026, Oracle and/or its affiliates.

If you wish to remove a record linked to the Original start option, click the "-" button to the left of the record.

Adding A New Row To A Start Option

You may move any of the records from the Merge From start option to the original start option by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing An Uncommitted Row From A Start Option

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Start Option Merge - Characteristics and Quantities

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Characteristics and Quantities** page to copy rows in the characteristic and contract quantity collections.

Description of Page

The left portion of the **Characteristics** collection initially displays existing characteristics linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Characteristic Type** and **Characteristic Value** for each characteristic are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Quantity** collection initially displays existing contract quantities linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Quantity Type** and **Contract Quantity** for each contract quantity are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

NOT_SUPPORTED

Refer to Start Option Merge - Main for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Contract Option

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Contract Option** page to copy rows in the contract options collection.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **This tab may not appear.** This tab is suppressed if the interval billing Contract Options module is turned off.

Description of Page

The left portion of the **Contract Option** collection initially displays existing contract option information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Option Type**, **Contract Option ID** and **Description** of the contract option for each contract option row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

> **NOT_SUPPORTED**
>
> Refer to Start Option Merge - Main for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Terms and Conditions

Open **Admin**, and then **Customer**, and then **SA Type Start Option Merge** and navigate to the **Terms and Conditions** page to copy terms and conditions (T&Cs).

Description of Page

The left side of the **Terms and Conditions** grid initially displays the T&Cs linked to the original start option. On the right side, the T&Cs linked to the merge from start option are displayed initially.

> **NOT_SUPPORTED**
>
> Refer to Start Option Merge - Main for a description of how to perform common maintenance tasks for the grids displayed on this page.

Defining SA Relationship Options

We use the term "SA Relationship" to describe functionality that supports the following situations:

- When companies other than your own provide a service to your customers AND you have some type of interaction with these companies. For example, in a deregulated market, customers deal with both distribution and energy supply companies. These companies typically exchange a great deal of information about their joint customers.

Copyright © 2026, Oracle and/or its affiliates.

- When multiple rates are associated with a service (where each rate corresponds with a sub-category of service). For example, most water companies charge for both water and wastewater service using separate rates for each. While it is possible to set up water and wastewater as separate service agreements, the SA relationship functionality allows you to set up a single "master" service agreement (for the water service) and associate with it a "sub" service agreement (for the wastewater service).
- When a party representing a group of customers negotiates a contract that is applied over and above those of the individual service agreements. For example, the head office of a national chain may negotiate for additional discounts that should be calculated together or individually. The SA relationship functionality may be used to track the covered service agreements and to calculate and transfer discounts to the head office's service agreement. Refer to the special discounts section.

> **Warning**
>
> Setting up the SA relationship control tables is as challenging as your organization's business rules. If you don't have requirements similar to those described above, you don't have to set up anything. If you have these types of requirements, your setup process will be taxing as you must design and set up control tables that manage the financial and consumption interactions that take place between you, your customers, and the various service providers.

The topics in this section describe tables that control your SA relationship functionality.

- The Big Picture of SA Relationships and Service Providers
- Designing Your SA Relationship Types and Service Providers
- Setting Up SA Relationship Information
- Negotiated Terms

The Big Picture of SA Relationships and Service Providers

You must set up service providers if companies other than your own provide a service to your customers AND you have some type of interaction with these companies. You will have one service provider for each such company. For example, if you are a distribution company in a deregulated market, you will have a service provider for each company that provides any of the following services:

- Energy (commonly referred to as Energy Supply Companies, Energy Service Providers, Retailers, and Suppliers)
- Meter service (commonly referred to as Meter Service Providers and Meter Agents)
- Meter reading (commonly referred to as Meter Data Management Agencies and Meter Reading Service Providers)
- Billing (commonly referred to as Billing Agents)

The topics in this section provide background information about service providers.

- Persons and Service Providers
- Service Providers Are Linked To Service Agreements

Copyright © 2026, Oracle and/or its affiliates.

- Service Providers May Change Over Time
- How To Set Up SA Relationships On A Customer's Service Agreement
- When Your Company Is A Service Provider
- Service Providers Have To Communicate About Customers
- Relationships Between Service Providers
- A Service Agreement Can Have Many Types Of Relationships
- Billing Relationships
- Consumption Relationships
- Deposits Issues
- Credit and Collection Issues
- An Object-Oriented Perspective Of Service Providers
- How Do You Communicate With Service Providers?
- Off Cycle Switch

Persons and Service Providers

A great deal of information about your service providers is defined using a person. For example, a service provider's name, address, phone numbers, electronic ID's, etc. are all defined on the person object.

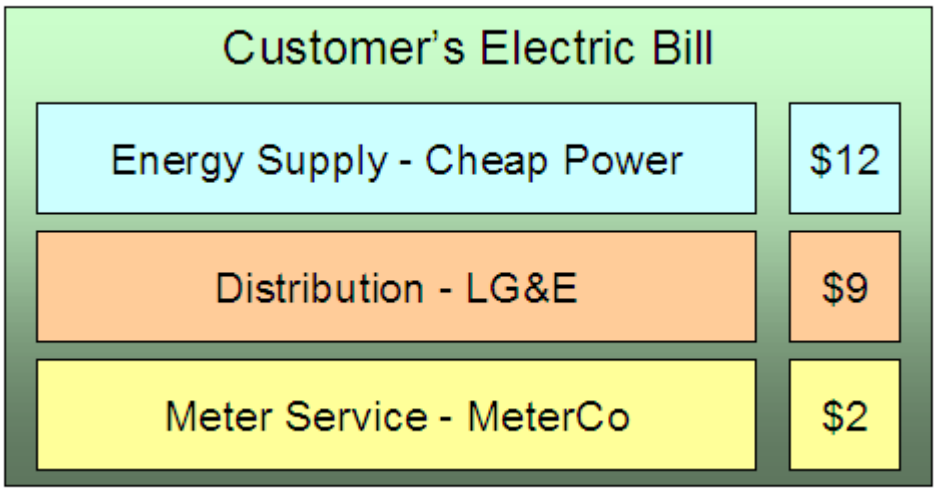
In addition, every service provider must have a service provider object created for it. The service provider object contains information about a provider's relationships with the customer and your organization, for example:

- Do you calculate bills for the service provider? If so, do you have their rates or do they interface their charges to you? Refer to Billing Relationships for more information.
- Do you send the customers' consumption to the service provider? Do they send it to you? Refer to Consumption Relationships for more information.
- How are financial settlements between your organization and the service provider implemented (do you pay them when you get paid?, do you purchase the receivable for them?, etc.). Refer to Service Providers Have Service Agreements Too for more information.
- Etc.

NOT_SUPPORTED

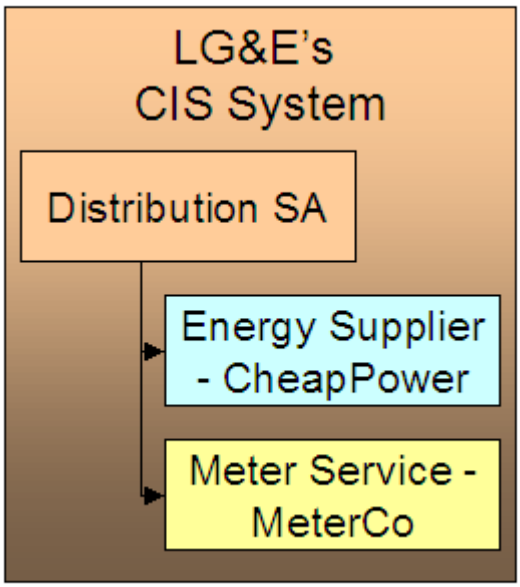
Refer to Designing Your SA Relationship Types and Service Providers for more information.

Note



In some situations, you will need to set up a service provider for your own company. Refer to When Your Company Is A Service Provider for the details.

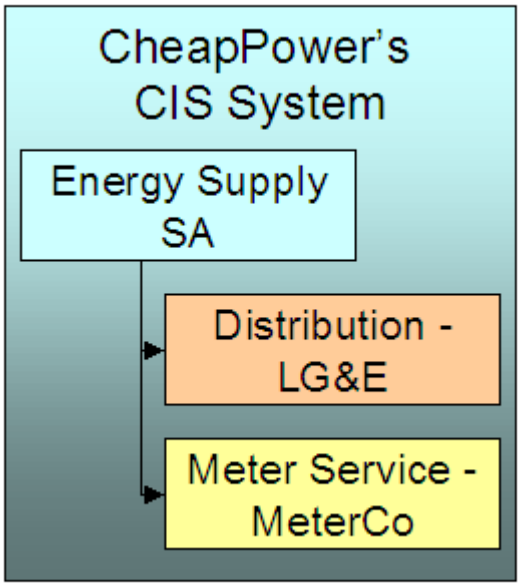
Copyright © 2026, Oracle and/or its affiliates.



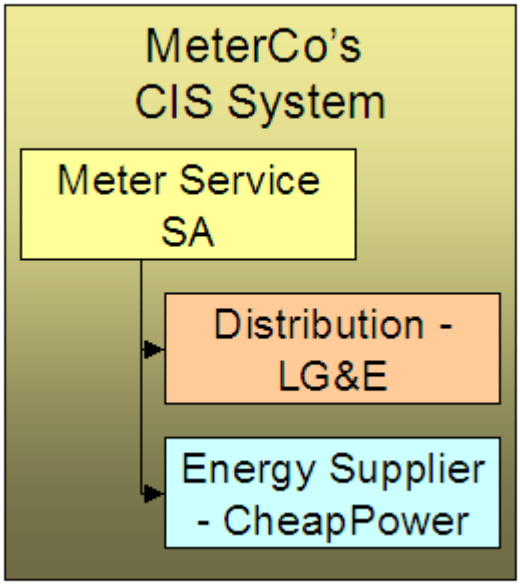
Service Providers Are Linked To Service Agreements

The following diagram illustrates a customer's bill for electric service in a deregulated market. Notice that there are separate sections for energy, distribution and meter service.

> **Note**
>
> **Consolidated billing.** The following is an example of a bill that consolidates charges from many service providers. Rather than receive a consolidated bill, it is possible for the customer to receive 3 separate bills, one from each service provider (we refer to this as Dual billing).



If we were to look at this customer's service agreement in the distribution company's CIS system, we'd find a service agreement for distribution charges, and linked to it would be information about the meter service and energy service providers:



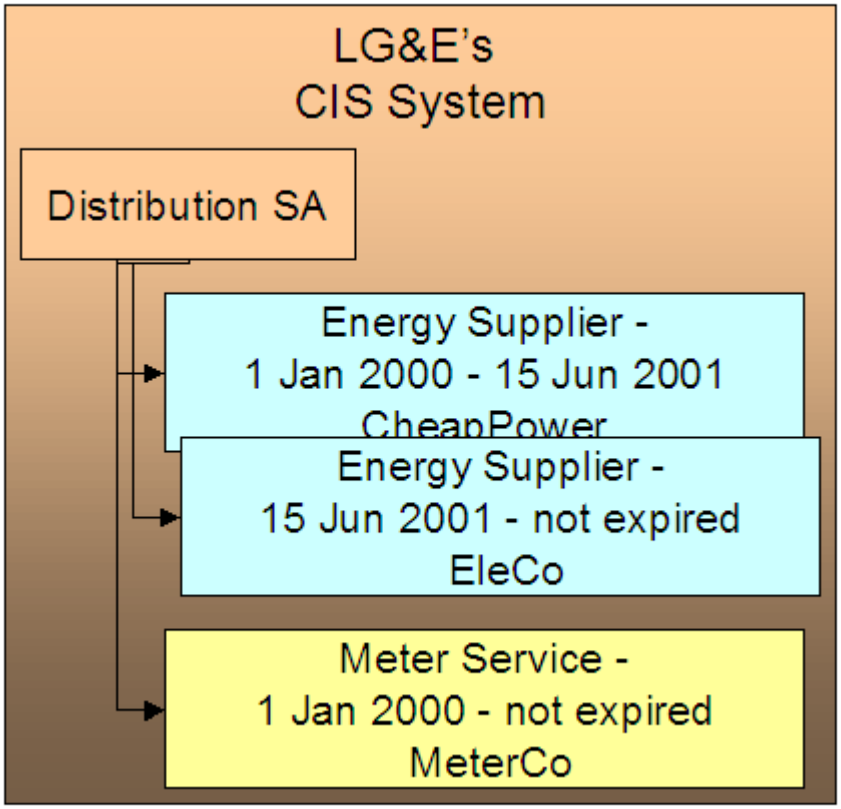
Copyright © 2026, Oracle and/or its affiliates.

If we look at this customer's service agreement in the energy supply company's CIS system, we'd find a service agreement for energy charges, and linked to it would be information about the distribution and meter service providers:

And finally, if we look at this customer's service agreement in the meter service company's CIS system, we'd find a service agreement for meter service charges, and linked to it would be information about the distribution and energy providers:

> **Note**
>
> **Bottom line.** A customer's service providers keep track of the customer and each other in their respective CIS systems. A customer will have a service agreement (or the equivalent) in each service provider's CIS system. A customer's service agreement defines the service providers who supply each type of service.

Copyright © 2026, Oracle and/or its affiliates.



NOT_SUPPORTED

Because information about customers and their services needs to be kept up-to-date in many different CIS systems, there is a need for automated communications between service providers. Refer to Service Providers Have To Communicate About Customers for more information.

Service Providers May Change Over Time

A customer typically has a choice of service providers. Over time, their choice may change. The system keeps track of a customer's service providers throughout time so that it can accurately cancel / rebill historical bills. This means that the service provider relationship is *effective-dated*.

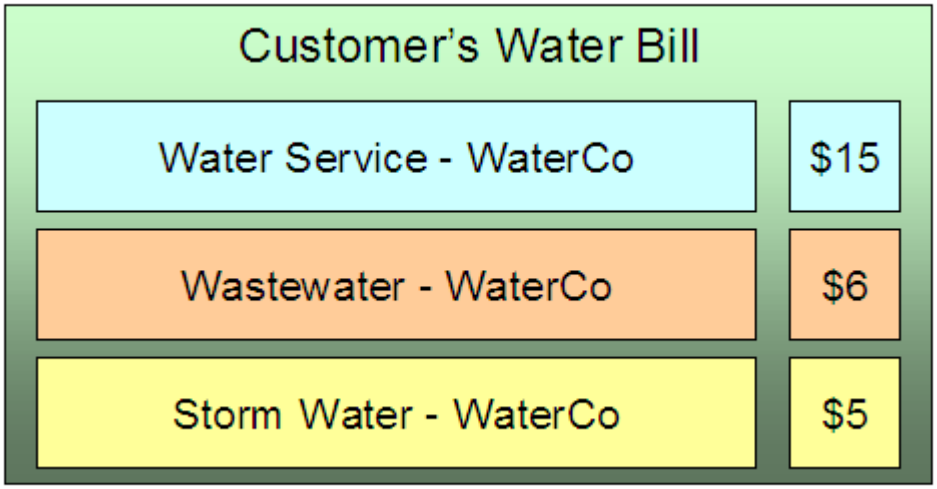
The following diagram illustrates how a distribution company's system keeps track of a customer's service providers (notice the customer changed energy suppliers):

How To Set Up SA Relationships On A Customer's Service Agreement

There are three ways to set up a customer's service providers:

- **Manually.** An operator can manually change a service agreement's SA relationships. The manual method is NOT recommended as changing service providers typically involves

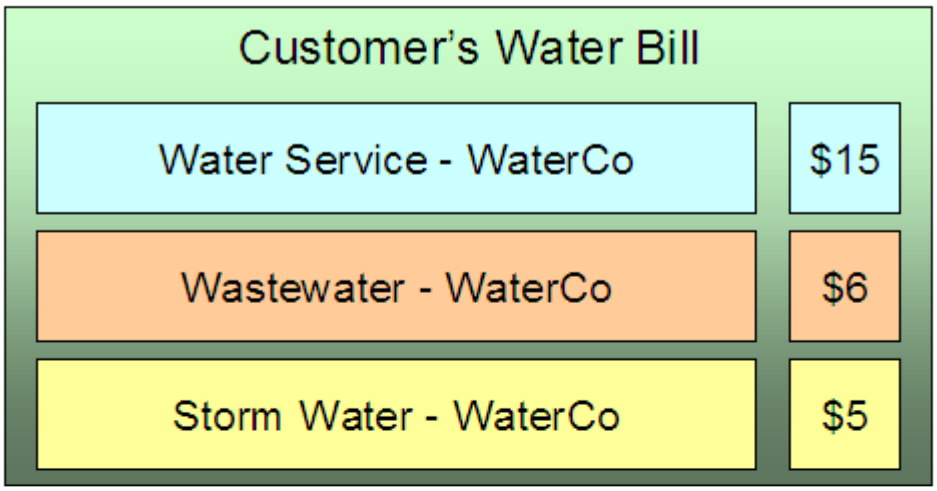
Copyright © 2026, Oracle and/or its affiliates.



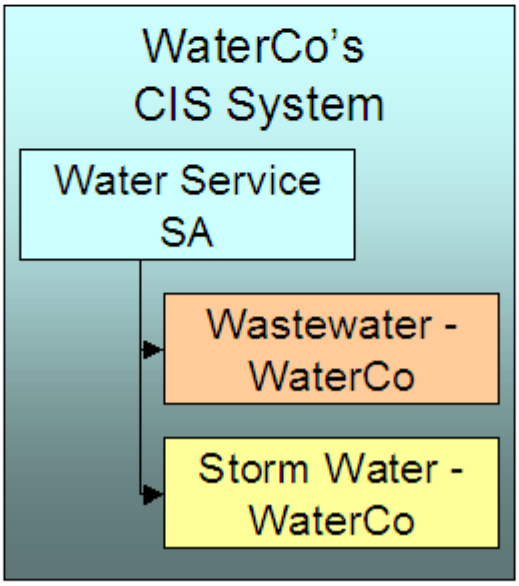
many events (e.g., you have to notify the current service provider that they will be dropped).

- **Use Default Service Providers.** The system will default a service provider on a required SA relationship when a service agreement is activated. Refer to Defaulting Relationship Types And Defaulting Service Providers for more information.

When Your Company Is A Service Provider



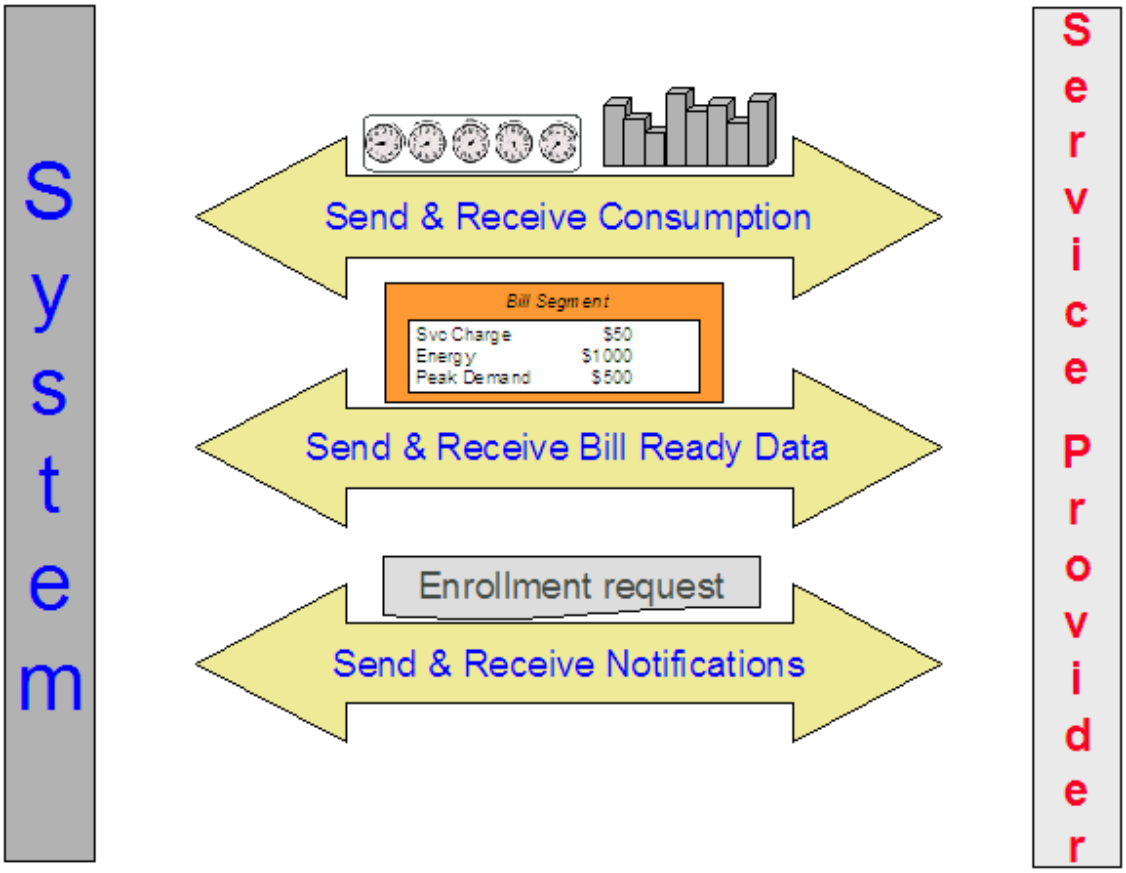
Besides setting up service providers for other companies that provide services to your customer, you may have to set up a service provider for your own company. You have to do this when:



- **Your organization can supply one of the services.** Refer to the illustration in Service Providers Are Linked To Service Agreements. If you are LG&E and you supply energy in addition to distribution, you would need to set up a service provider for your own organization. Why? Because whenever you have a subcategory of service (e.g., energy supply), you must indicate the service provider who provides this service; even when it's you.
- **You decide to break up a service into subcategories** (and have a separate service agreement for each category). For example, a water company may choose to break up service charges into water, wastewater and storm water (they may do this because there are different rates for each category of service). The following is an example of the segregated charges associated with this water company's service charges.

This water company system may benefit by creating a single service (for water) and indicating there are subcategories of service (for wastewater and storm water). Whenever you have a subcategory of service, you must indicate the service provider who provides this service. And, in this example, the water company would be the sole service provider for each subcategory of service.

Copyright © 2026, Oracle and/or its affiliates.



Note

Refer to We Bill For Them - Rate Ready Bill Segments Are Special for restrictions in respect of using subcategories of service.

Service Providers Have To Communicate About Customers

The providers of service typically have to communicate with each other in respect of the customer's service. The following diagram illustrates the major interfaces of information between your system and your service providers.

Copyright © 2026, Oracle and/or its affiliates.

Depending on where your organization fits in the service provider hierarchy, you may:

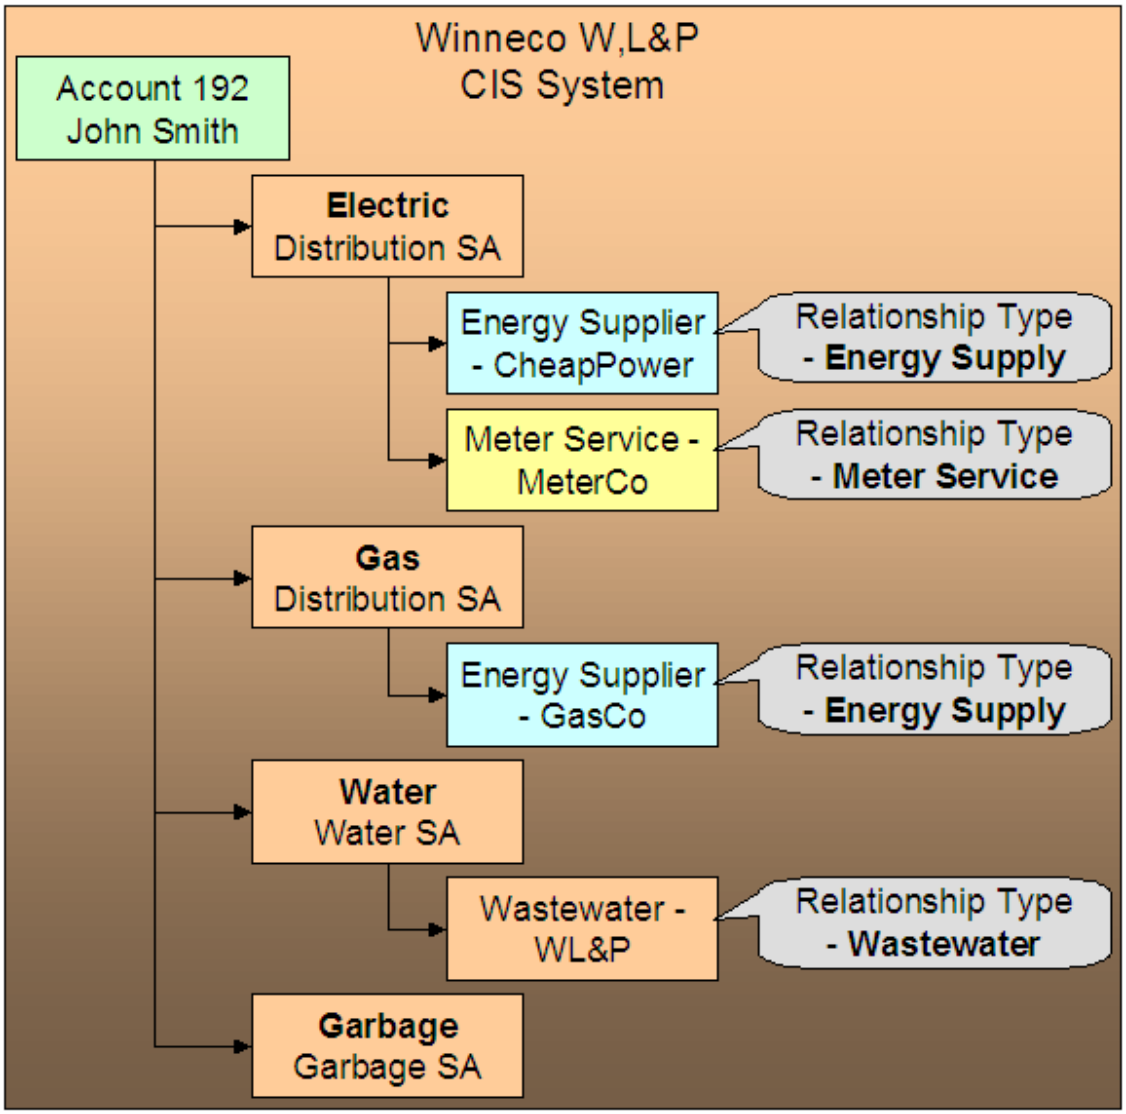
- Bill for other service providers (or they may bill for you). Refer to Billing Relationships for more information about billing communications.
- Send the customer's consumption to service providers (or they may send it to you). Refer to Consumption Relationships for more information about consumption communications.
- Apprise service providers of the changes to the customers' service (or they may apprise you). Refer to How Do You Communicate With Service Providers? for more information about communications between service providers.

Relationships Between Service Providers

Service providers may arrange contractual relationships with other service providers to provide additional services, e.g., an energy service provider may work with a specific meter data management agency to gather and report interval meter read data.

The system does nothing special to enforce or record these inter-relationships. Why? Because most service provider switches are received by notification records. Notification records indicate all the associated service providers. There is no need for the system to maintain the inter-service provider associations.

A Service Agreement Can Have Many Types Of Relationships



Copyright © 2026, Oracle and/or its affiliates.

As described in the previous sections, a given service can be subdivided into subcategories. Each type of service can have zero, one or more subcategories. We call each subcategory a **SA Relationship Type**. The topics in this section provide information about SA relationship types.

- An Example
- Valid Relationship Types and Service Providers Are Defined On SA Types
- Defaulting Relationship Types And Defaulting Service Providers
- Required Relationship Types and Billing
- Relationship Types Do Not Impact Start/Stop

An Example

We'll use the following example of a customer in a municipal utility's CIS system to explain SA Relationship types:

Note the following:

Copyright © 2026, Oracle and/or its affiliates.

- Electric service has 2 SA relationship types: energy supply and meter service.
- Gas service has 1 SA relationship type: energy supply.
- Water service has 1 SA relationship type: waste water.
- Garbage service has no SA relationship types.

> **Note**
>
> **Bottom line.** Service providers are related to the customer via "your" service agreement. Each service provider linked to a service agreement is defined in respect of a SA Relationship Type. This relationship is effective-dated because we care about how it changes over time.
>
> **Your relationship type is implied.** The SA relationship type of "your" service agreement is implied, e.g., if you are a distribution company, "your" service agreement's implied SA relationship type is "distribution".

Valid Relationship Types and Service Providers Are Defined On SA Types

You control which services have SA relationships (and which don't) when you set up your SA types. Each SA type can have zero, one or more SA relationship types. Each relationship type, in turn, can have one or more valid service providers.

> **NOT_SUPPORTED**
>
> Refer to Setting Up SA Relationships For SA Types for the page used to define the service providers and SA relationship types for each SA type.

Defaulting Relationship Types And Defaulting Service Providers

Please be aware of the following:

- A SA relationship type for a given SA type can be marked as being **Required**.
- A service provider for a given SA relationship type / SA type can be marked as being the **Default**.

If, at activation time, the customer's master SA is missing a **Required** SA relationship that has a **Default** service provider, the activation process automatically creates the SA relationship type and links to it the **Default** service provider. If a master service agreement doesn't have all **Required** SA relationships, the service agreement cannot be activated. This is handy when your organization is the default service provider for a relationship type.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Automatic Creation of Sub SAs for information about how the system will automatically create sub service agreements for the defaulted SA relationship / service provider if your organization provides billing services for the service provider. Refer to Setting Up SA Relationships For SA Types for the page used to define the service providers and SA relationship types for each SA type.

Required Relationship Types and Billing

When the system attempts to create a bill segment for a service agreement whose SA type has **Required** relationship types, it checks if all such relationships are defined for the service agreement. If not, a bill segment error will be generated.

The reason this restriction exists is to handle the situation when your required relationship types change over time. For example, assume on your first day of production you only need energy suppliers defined on electric service agreements. After several months, gas deregulates. When this happens, you will need to change your control tables to indicate that your gas SA types require an energy supplier. If you don't write a default program to update your existing gas service agreements, billing will complain.

Relationship Types Do Not Impact Start/Stop

Customer service representatives (CSR's) are typically not involved with the customer's choice of service providers. Most organizations hear about a customer's service providers from the service providers or from a central body. This means that the start/stop dialog is not impacted by SA relationships. This also means that CSR's are not impacted by SA relationships (unless something goes wrong). If something goes wrong, the CSR's may need to manually correct SA relationships. Refer to How To Set Up Service Providers On A Customer's Service Agreement for more information.

Billing Relationships

When you set up a service provider, you must define your organization's billing relationship with the service provider. The following points provide examples of the billing relationships supported in the system,

- If you are an energy supply company, you may provide billing services for the distribution company. This means that your bill contains both your charges and the distribution company's charges. We refer to this as the **We Bill For Them** billing relationship.
- Alternatively, the distribution company may provide billing services for you. This means that the distribution company's bill contains your charges and their charges. We refer to this as the **They Bill For Us** billing relationship.
- Alternatively, you may both send bills to the customer. We refer to this as the **Dual Billing** relationship.
- Alternatively, if you subcategorize your services OR if your company provides one of the services that is provided by your service providers, then the system will create a separate

Copyright © 2026, Oracle and/or its affiliates.

bill segment for the subcategory of service. We refer to this as the **It's Us** billing relationship.

If you provide billing services for another service provider (i.e., you bill for them), there are two ways to determine the service provider's charges:

- You can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.
- You can let the service provider calculate their own charges and interface them to you. We call this the **Bill Ready** calculation method.

If a service provider provides billing services for you (i.e., they bill for you):

- If the service provider has a suitable CIS system, they can load your rates in their system and calculate your charges for you. We call this the **Rate Ready** calculation method.
- You can calculate your charges and interface them to them. We call this the **Bill Ready** calculation method.

If you don't have a billing relationship with a service provider, you still need a service provider record to define such. Why? Because the system needs to know that it doesn't have to worry about a particular service provider in respect of billing. In addition, you may have other interactions with a service provider that have nothing to do with billing, e.g., you may send or receive consumption.

The topics in this section provide a wealth of information about the various billing relationships and the ramifications of each.

- Sub Service Agreements
- We Bill For Them
- Service Providers Have Service Agreements Too
- They Bill For Us
- Combinations Of Service Provider Billing Methods
- Different Service Providers Can Bill Different Services
- If You Deal With TBFU Service Providers, You Cannot Reopen Bills

Sub Service Agreements

If you provide billing services for another service provider OR if you subcategorize your own charges, there will be a separate service agreement (SA) linked to the customer's account that holds these unique charges. We refer to this new service agreement as a **Sub SA**. We use the term "sub" because this service agreement is subservient to the "master" service agreement. By subservient we mean:

- A sub SA's start and stop dates are the same as the master SA. This statement may seem odd, but it's true – all sub SAs linked to a master service agreement have the same start and stop dates as the master.
- A sub SA's status (i.e., *pending start*, *active*, *pending stop*, *stopped*, etc.) is controlled by its master service agreement. As a rule, the master SA transitions its status first and the sub SA(s) follow.

Copyright © 2026, Oracle and/or its affiliates.

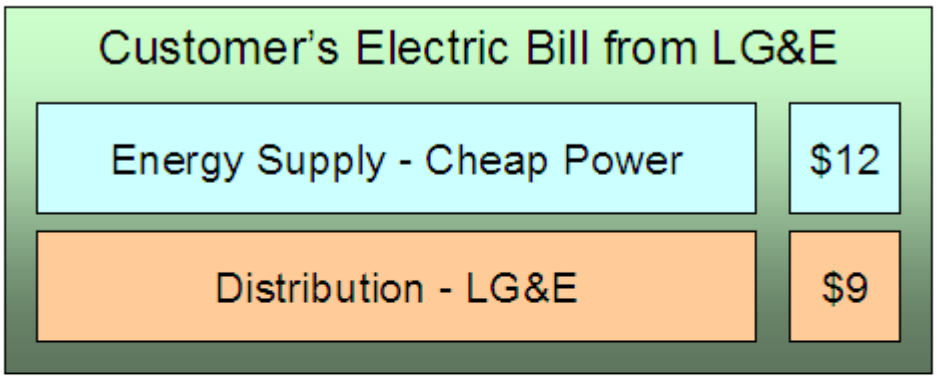
> **Note**
>
> There are situations where the master service agreement transitions its status and the sub service agreement(s) does not. One example of this is when both the master and sub SAs are closed and a payment cancellation occurs that only affects the master SA. In this scenario, the master SA becomes reactivated and the sub SA remains closed. Another example is when a straggling billable charge posts to a sub SA; the master SA is not affected.

- Refer to The Rate Ready Calculation Method for additional examples of subservience.

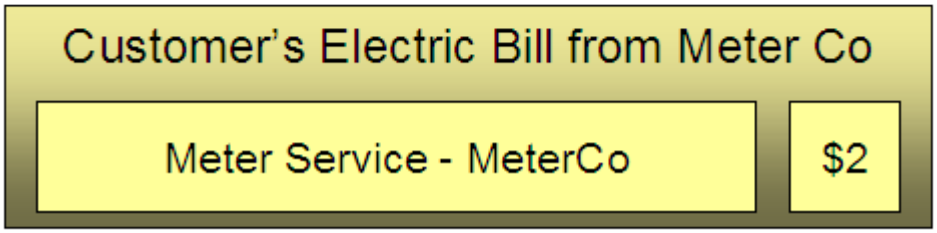
> **Note**
>
> You may find it helpful to keep in mind that sub SAs are only used for service providers with a billing relationship of It's Us and We Bill For Them. This is because these are the only relationships that have implicit billing responsibilities.

The topics in this section provide additional information about sub SAs.

- Only Some Service Providers Have Sub SAs
- Automatic Creation of Sub SAs
- Sub SA State Transition

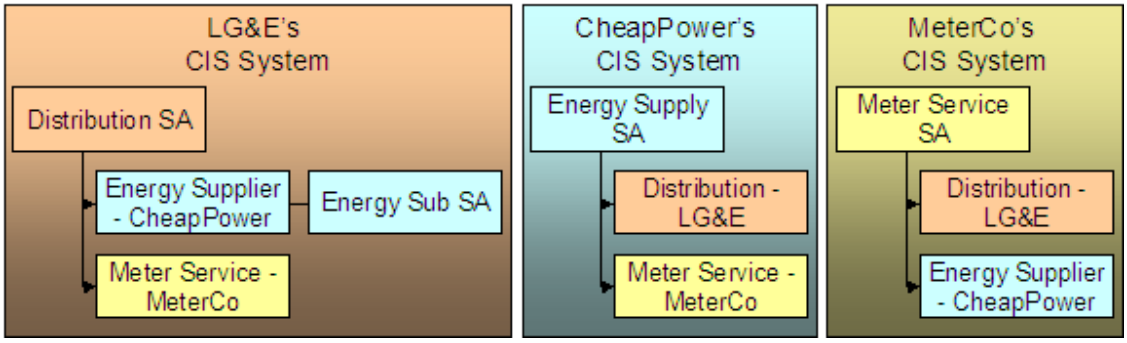


Only Some Service Providers Have Sub SAs



If you do not provide billing services for a service provider, there will be no sub SAs associated with the service provider's SA relationships. Let's use an example to make the point; assume:

- Service is divided into distribution, energy and meter service charges.
- You are the distribution company and you provide billing services for the energy supply company.
- The meter service company bills the customer independently.



In this situation, the customer will receive two bills: one from you (LG&E), the other from MeterCo. Notice that your bill (LG&E) contains your distribution charges AND CheapPower's energy charges:

Copyright © 2026, Oracle and/or its affiliates.

If we were to look at the customer information in the three service providers' respective CIS systems, we'd find the following service agreements and SA relationships for the customer:

Notice the following:

- The customer has a service agreement in each supplier's CIS system.
- Because LG&E (the distribution company) bills for CheapPower, all customers who have their energy supplied by CheapPower will have a sub SA in LG&E's system. This sub SA maintains the charges (and receivable balance) associated with CheapPower's energy charges.
- Notice that neither CheapPower's nor MeterCo's CIS systems use sub SAs. This is because neither company bills for other service providers.

> **Note**
>
> **Sub SAs are needed if you subcategorize your charges.** The above example shows sub SAs being used when a company provides billing service for another company. Sub SAs are also used when you subcategorize your charges - each sub SA contains the rate associated with each subcategory.

Copyright © 2026, Oracle and/or its affiliates.

Automatic Creation of Sub SAs

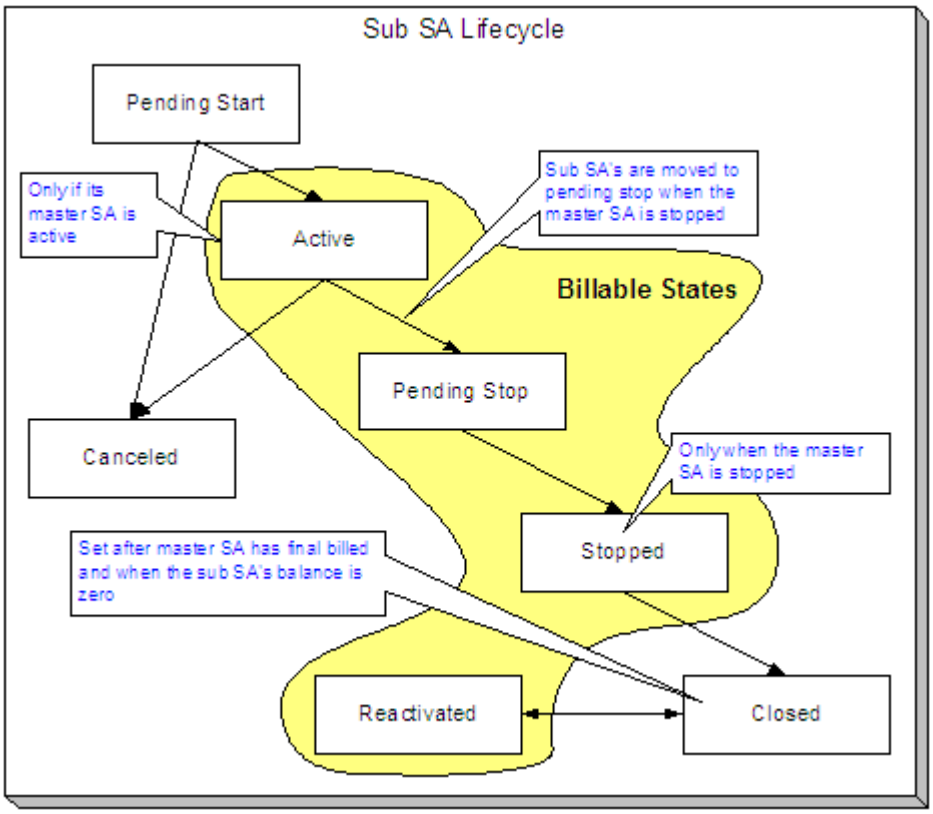
The system creates sub SAs for customers choosing service providers where the billing option is It's Us or We Bill For Them. The system creates sub SAs via the following mechanisms:

- The analyze SA relationships background process (ANLYZSAR) monitors newly activated SA relationships. If the respective service provider is It's Us or We Bill For Them, this process creates the sub SA(s) using the information defined on SA Type SA Relationship Type. Refer to Setting Up SA Relationships For SA Types for more details.

> **Note**
>
> The analyze SA relationships background process also activates and stops sub SAs. Refer to Sub SA State Transition for the details.

- A button exists on the SA Relationships page. This button, when pressed, creates sub SAs real-time. This button would only be used if the operator couldn't wait for the background process to run.

The SA type associated with the new sub SAs is defined when you set up each SA Type / SA Relationship Type. Refer to Setting Up SA Relationships For SA Types for more information.



If the SA type uses start options, the start option contains additional values (e.g., rates, contract riders) that are used to populate the newly created sub SAs. Note: start options are typically not used for We Bill For Them - Bill Ready service provider because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs. Refer to Setting Up SA Relationships For SA Types for more information.

> **Note**
>
> **Manually created sub SAs.** In very unusual situations, an operator may create a sub SA manually. An operator would do this using the SA Relationship transaction.

Sub SA State Transition

Sub SAs follow normal SA state transition rules, but have a few additional rules about when the transitions can take place.

Copyright © 2026, Oracle and/or its affiliates.

The following points highlight the additional state transition rules:

- A sub SA can only become Active if its master SA is Active. Most sub SAs are activated by the analyze SA relationships background process. However, a user can manually activate a sub SA using the activate button on the SA maintenance page.
- Sub SAs become Pending Stop when their master becomes Stopped . This typically occurs when the SA activation background process stops the master SA. However, this can happen real time if a user manually stops a master SA using the stop button on the SA maintenance page.
- A sub SA can only become Stopped if its master SA is Stopped . Most sub SAs are stopped by the analyze SA relationships background process. However, a user can manually activate a sub SA using the stop button on the SA maintenance page.
- A sub SA becomes Closed if its master has been final billed and it has a balance of zero. Most sub SAs are closed when their balance becomes zero after the master SA is final billed. However, a user can manually close a sub SA using the close button on the SA maintenance page. Note, if additional billable charges are interfaced after the master has been closed, the sub SA will be Reactivated.

We Bill For Them

If you provide billing services for another service provider, then you have a We Bill For Them billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

- Sub SAs Are Used When We Bill For Them
- The Rate Ready Calculation Method

Copyright © 2026, Oracle and/or its affiliates.

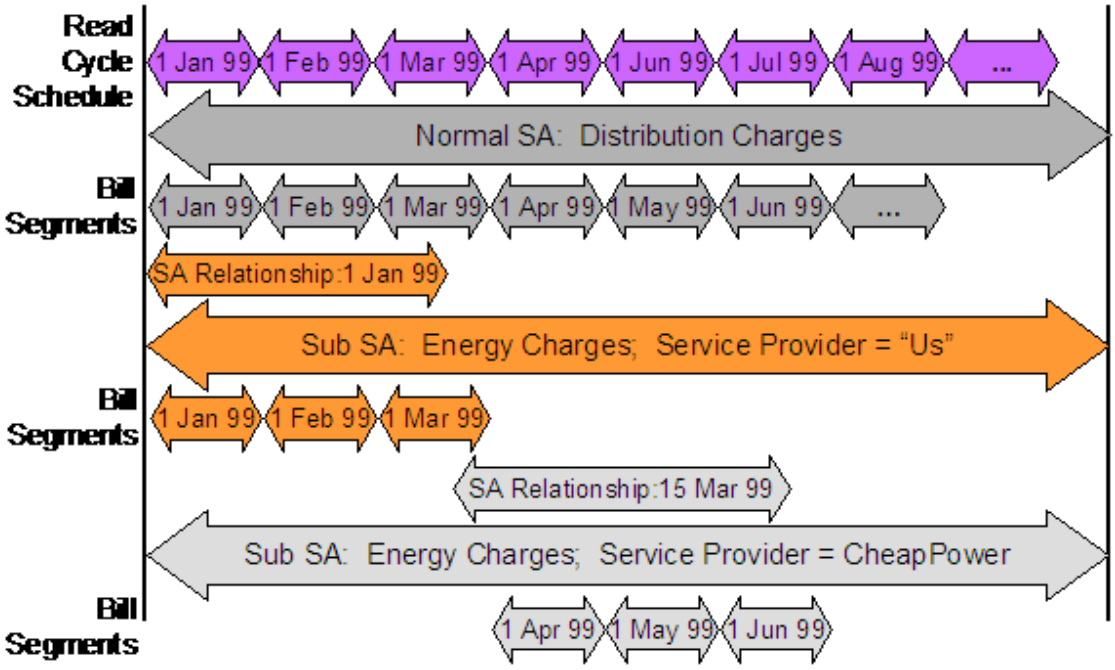
- The Bill Ready Calculation Method
- Pay at Bill Time Versus Pay at Pay Time
- Paying The Service Provider - Technical Implementation

Sub SAs Are Used When We Bill For Them

As described under Sub Service Agreements, sub SAs are used for We Bill For Them service providers. The sub SAs hold the service providers charges. It's important to note that the system allows more than one sub SA to be created for a given service provider.

The Rate Ready Calculation Method

If you provide billing services for a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.



> **Note**
>
> It's Us **can be Rate Ready.** The prior paragraph indicated that the Rate Ready billing option was used for We Bill For Them service providers. If you subcategorize your services and use rates to calculate each subcategory's charges, the service provider(s) set up for your own organization will also be subject to the Rate Ready rules described below.

If a customer uses a We Bill For Them - Rate Ready service provider, the system will create a separate bill segment for the service provider's charges. Keep in mind the following in respect of these types of bill segments:

- The consumption is copied from the "master" service agreement (note: we copy item details and read details after pre-processing calculation groups, if any exist, have been applied). This means that the bill period on the sub SA's bill segment is identical to that on the normal SA. This also means that if the "master" SA is in error, bill segments for the sub SA will not be created.
- The rate defined on the sub SA is applied against this consumption. All pre-processing calculation groups defined on the service provider's rate will be used to manipulate this consumption. If you have pre-processing calculation group on your master SA's rate to apply a line loss or convert a cubic foot to a therm, you don't have to have these pre-processing calculation group on the sub SA's rate (because we copy the consumption from the master to the sub after pre-processing calculation group, if any exist, have been applied).

The following illustration should help:

Copyright © 2026, Oracle and/or its affiliates.

Be aware of the following:

- This example is from a distribution company's perspective.
- From 1 Jan 99 through 15 Mar 99, the distribution company distributes power AND supplies energy (i.e., the distribution company is the service provider of energy).
- On 15 Mar 99, CheapPower becomes the energy supplier. However, the next bill period ends on 30 Mar 99. This means that CheapPower will only start supplying energy on 1 Apr 99. See the following note for why the effective date of the supplier switch is not the true effective date from billing's perspective.

> **Note**
>
> **Service Provider Changes Take Effect On The Next Bill.** If the service provider is changed within a customer's billing period, the system assumes that the service provider in effect at the START of the period is effective the entire billing period. This means that a change of service providers will only take effect on the bill whose start date follows the change date.

Please be aware of the following characteristics of Rate Ready bill segments:

- You cannot cancel a Rate Ready bill segment independently from the master bill segment. If you need to cancel / rebill the sub SA's bill segment, you must cancel / rebill the master SA's bill segment.
- You cannot delete a Rate Ready bill segment independently from the master bill segment. If you need to delete the sub SA's bill segment, you must delete the master SA's bill segment.
- Similarly, if you cancel / rebill the normal SA's bill segment, all Rate Ready bill segments will be cancelled / rebilled.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** Creating, freezing, deleting, and canceling a "master" bill segment does the same with all Rate Ready bill segments. You cannot create, freeze, delete or cancel a Rate Ready bill segment independent of its master bill segment.

The Bill Ready Calculation Method

If a customer uses a We Bill For Them - Bill Ready service provider, the service provider calculates their own charges and interfaces them to the system. We then present their charges on our bill; we don't actually calculate anything (sometimes this is referred to as "pass through" billing).

The sub SA linked to a We Bill For Them - Bill Ready must be a billable charge SA. Why? Because billable charge SAs exist to hold bill lines until such time as a bill is created for the customer's account. Refer to Setting Up Billable Charge Templates for more information.

Please be aware of the following characteristics of Bill Ready bill segments:

- Unlike Rate Ready bill segments, Bill Ready bill segments can span different time periods than the master SA. This is because you cannot predict when a service provider will interface their billable charges to you. In fact, a given bill could contain billable charges that span different periods and these charges could have been interfaced from historic and existing service providers.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be created and deleted independently from the master bill segment.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be cancelled independently from the master bill segment.

Sending Consumption And Waiting For The Charges

Uploading Consumption (Rather Than Uploading Calculated Charges)

Calculating Taxes On Uploaded Charges

Sending Consumption And Waiting For The Charges

If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service provider to calculate their charges, you need to be aware of the following:

- We do NOT recommend sending raw meter reads to service providers. Rather, we recommend sending these service providers the same consumption that you use on your bill segments. Remember, the system maintains a snapshot of billed consumption on bill segments associated with service agreements that are linked to service points.
- But to implement our recommendation (of only interfacing billed consumption to service providers), we need to create a bill segment for the master SA and then wait until the service provider returns the billable charge before sending out the bill. The following points describe how this works:
  - Early in the bill cycle, the system creates a bill segment for the master SA (remember, the system maintains a snapshot of billed consumption on bill segments linked to service points). When the master bill segment is frozen, the system interfaces the snapshot consumption to all service providers associated with the master service

Copyright © 2026, Oracle and/or its affiliates.

agreement who need consumption (this is defined on the service provider). Refer to We Can Send Billed Consumption To Any Service Provider for more information about interfacing consumption to service providers.

- The bill associated with the bill segment will not be completed. Why? Because the bill segments associated with the We Bill For Them - Bill Ready service providers will be in Error. This only happens if you use the Billable Charge bill segment creation algorithm (this algorithm is plugged in on the sub SA's SA type). On the algorithm, make sure to specify a value of Y for the parameter **Wait For The Last Day Of The Bill Cycle**. By doing this, a bill segment in the Error state will exist for the sub SA until the last night of the bill cycle's window.
- On the last night of the bill cycle window, when the system attempts to create a bill segment for the billable charge SA associated with the We Bill For Them - Bill Ready, it will either find recently interfaced billable charges or it won't. If it finds unbilled, billable charges, a bill segment will be created for the sub SA and the billable charges will be swept onto it. If it doesn't find unbilled billable charges, the bill will be completed (i.e., sent out) without the service provider's charges.

> **Note**
>
> **Bottom line.** If a customer's account uses We Bill For Them - Bill Ready service providers, the bill will not be completed (i.e., sent out) until the last night of the bill cycle (if you use the appropriate algorithm). Why? Because we wait until the last night of the bill cycle before trying to sweep on recently interfaced billable charges. If no billable charges have been interfaced from the service provider by the last night of the bill cycle, the bill will be sent out without the service provider's charges.
>
> **Batch versus Online Bill Creation.** If you create a bill online, the system will NOT create an Error bill segment for the We Bill For Them - Bill Ready service provider. Why? Because if you want to create an online bill, either the service provider has interfaced their charges or they haven't. If they have, they should be swept on the bill (via the creation of a bill segment). If they haven't, it shouldn't prevent you from completing the bill.

Top of the Page

Uploading Consumption (Rather Than Uploading Calculated Charges)

We understand this is confusing, but it is quite possible to set up the system so that the We Bill For Them - Bill Ready service provider passes in CONSUMPTION rather than the calculated bill lines. They would only do this if they are not able to calculate the charges in their system and have therefore provided you with their rates. To do this, you would set up everything as described above. In addition, when you upload the billable charges, you must specify the consumption to be rated in the billable charge's service quantity (SQ) collection.

Top of the Page

Calculating Taxes On Uploaded Charges

It is possible to set up the system to calculate taxes for billable charges. You would do this if the service providers are passing through the charges and want you to calculate the taxes.

If you want taxes calculated on top of billable charges:

- Create a service quantity (SQ) on the billable charge that contains the total monetary amount that taxes will be calculated on. Note, you would not have to do this if you have a

Copyright © 2026, Oracle and/or its affiliates.

pre-processing calculation group in your rate that calculates the total monetary amount to which taxes should be applied.

- Specify a rate on the billable charge service agreement. This rate will contain calculation rules that calculate taxes. Note, the calculation rules will be simple SQ calculation rules that apply a percentage to the value of the SQ that represents the monetary amount on which taxes should be calculated.

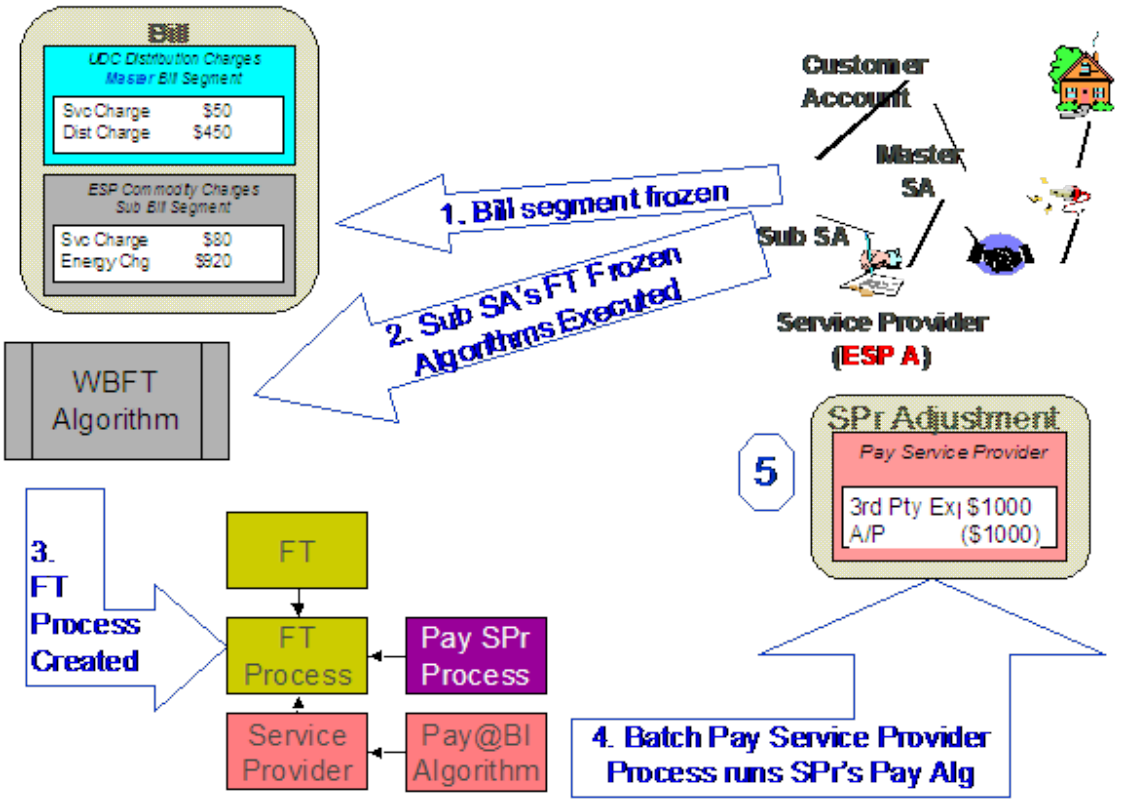
When the system creates the bill segment for the billable charge, it will call the rate and the rate will calculate the taxes and add additional lines (actually, bill calculation headers) to the bill segment.

Pay at Bill Time Versus Pay at Pay Time

If you provide billing services for another service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will owe them money because you will be receiving money from their customers for their service. You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you freeze the customer's bill segment. Some people refer to this method as "purchasing the receivable from the service provider". We call this the **Pay At Bill Time** method.
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer. We call this the **Pay At Pay Time** method.

The method used for a service provider is defined on the service provider's record.



> **NOT_SUPPORTED**
>
> Refer to When We Bill For Them, We Owe Them Money for more information.

Paying The Service Provider - Technical Implementation

> **Warning**
>
> This section describes, technically, how we increase the amount we owe a We Bill For Them service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with increasing how much we owe a We Bill For Them service provider.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the sub SA's SA type), one of these algorithms will determine if there is a WBFT service provider associated with the sub SA. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that looks at new FT's and determines if a related "payable" adjustment should be created for the We Bill For Them service provider. This batch process uses the service provider's Payment Relationship and Pay Service Provider algorithm to determine when and how to create these "payable" adjustments.

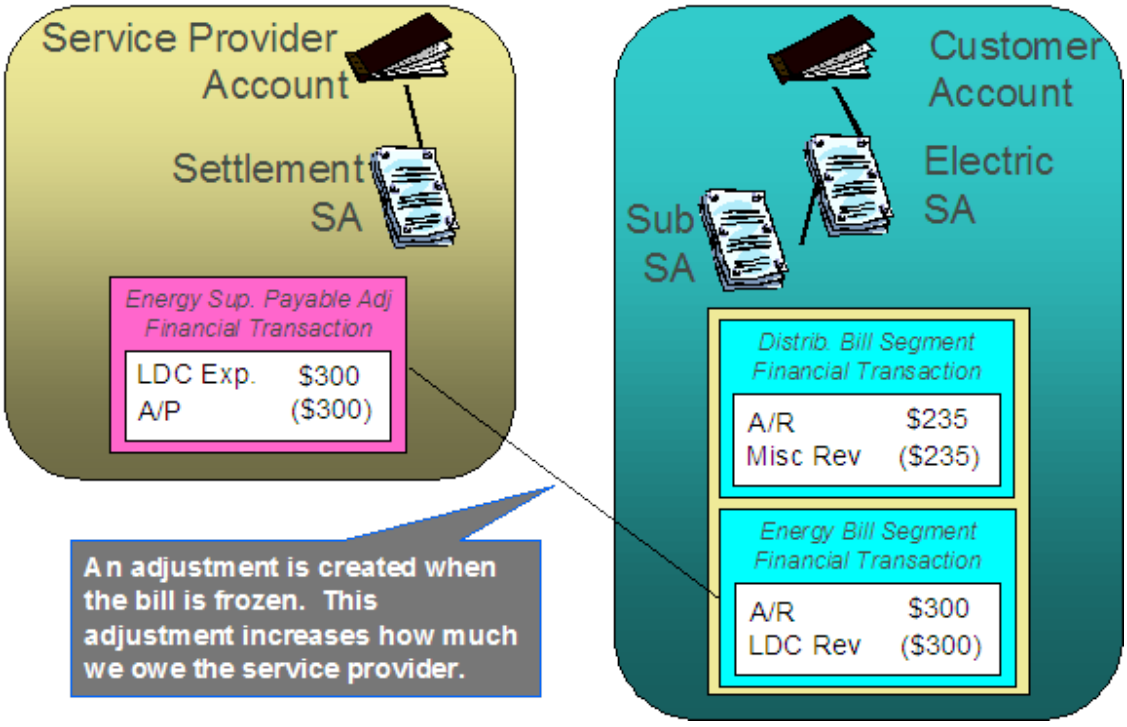
Service Providers Have Service Agreements Too

Most service providers need service agreements as explained in the following topics.

- When We Bill For Them, We Owe Them Money
- Adjustments and We Bill For Them Service Providers
- When They Bill For Us, They Owe Us Money

When We Bill For Them, We Owe Them Money

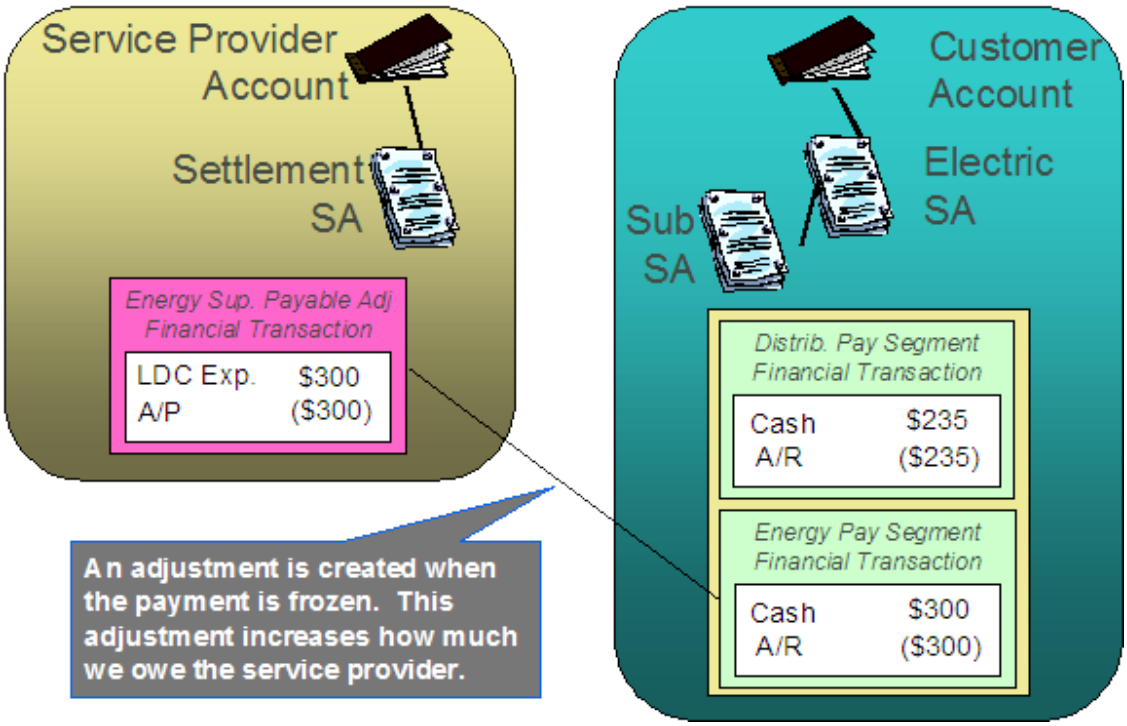
When you bill on behalf of a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will eventually owe them money (because the customer pays you



Copyright © 2026, Oracle and/or its affiliates.

for the service provider's service). You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you create the customer's bill. Some people refer to this method as "purchasing the receivable from the service provider".
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer.



The system keeps track of how much you owe a service provider on a service agreement linked to the service provider's account. The system creates adjustments against this service agreement to increase how much you owe them.

If you "purchase the receivable" (i.e., you owe them when you bill the customer), an adjustment is created when the customer is billed. If you owe them only when you are paid by the customer, an adjustment is created when the customer pays. The following example illustrates an adjustment being created when the bill is frozen (illustrating the "purchase the receivable" scenario):

If you only pay the service provider when you are paid, the example would look as follows:

Copyright © 2026, Oracle and/or its affiliates.

Adjustments and We Bill For Them Service Providers

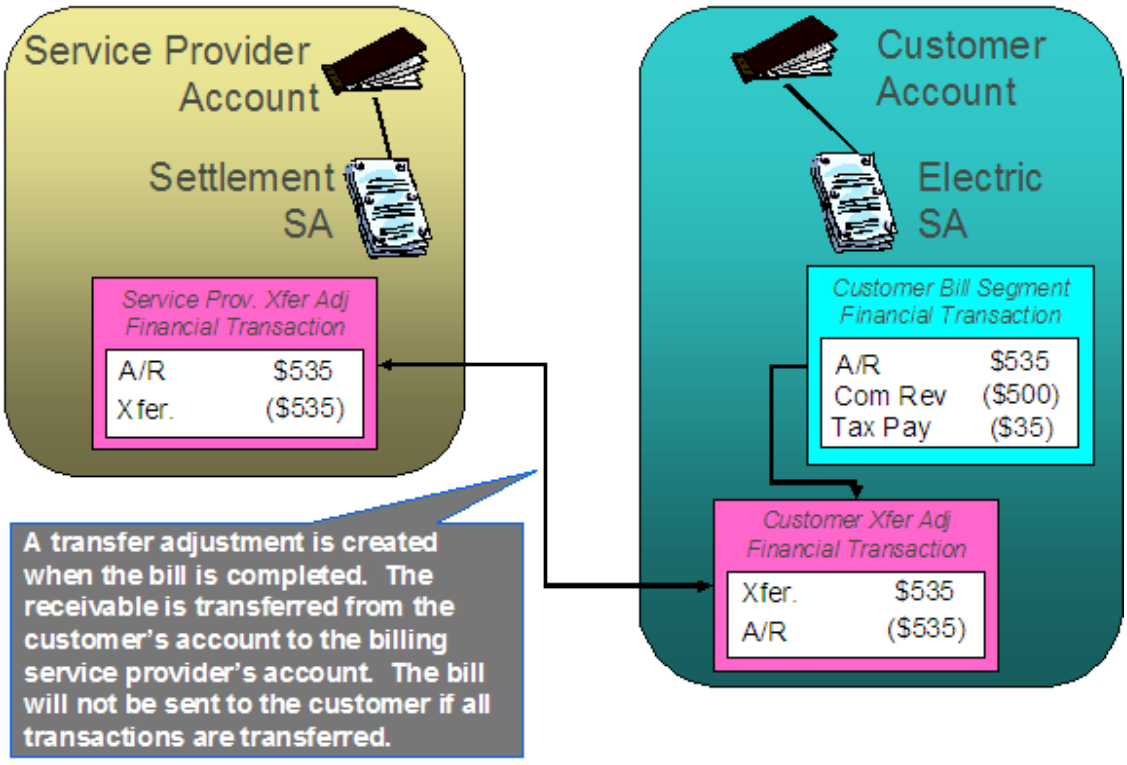
NOT_SUPPORTED

It's important that you are comfortable with the information described under When We Bill For Them, We Owe Them Money before reading this section.

Adjustments associated with We Bill For Them sub service agreements are tricky. The following points describe how the system "pays" the related service provider when adjustments are issued against the customer's sub service agreement:

- For Pay At Bill Time service providers, most adjustments are treated just like bill segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. The reason "most" is underlined in the previous sentence is because A/P adjustments (i.e., adjustments used to interface check requests to your A/P system) are excluded. Why? Because A/P adjustments are used to refund overpayments to the customer. Overpayments are purely between the customer and your company (you never transferred the overpayment to the service provider because it's associated with a Pay At Bill Time service provider).
- For Pay At Pay Time service providers, A/P adjustments are treated just like payment segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. All other types of adjustments are ignored. Why? Because A/P adjustments are used to refund overpayments to the customer. Think of it like this - when the customer originally overpaid, you transferred this overpayment to the Pay At Pay Time service provider; therefore, when you refund the overpayment, you get to take the money back from the service provider.

Copyright © 2026, Oracle and/or its affiliates.



When They Bill For Us, They Owe Us Money

When a service provider bills on behalf of your organization, they will eventually owe you money (because the customer pays them for your service).

The system keeps track of how much a service provider owes you on a service agreement linked to the service provider's account. The question is, How does the system determine how much you are owed when you don't produce a bill? Well, you do produce a bill, it just doesn't get sent to the customer. We understand this is a little confusing, but think about it like this:

- The service provider is presenting your charges on their bill.
- You still have to calculate how much the customer owes your organization otherwise you'll never know how much you are owed by the service provider.

As illustrated below, when a bill is completed, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these, it transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.

> **Note**
>
> **Bottom line.** We always generate a bill for "us", even though we don't send it to the customer.

Copyright © 2026, Oracle and/or its affiliates.

They Bill For Us

If a service provider provides billing services for you, then you have a They Bill For Us billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

- The Customer Still Needs A Service Agreement
- They Bill For Us - Bill Ready
- They Bill For Us - Rate Ready
- A/R Transfer - Technical Implementation
- Routing Billable Charges To Service Providers - Technical Implementation
- Bill Routings Are Changed

The Customer Still Needs A Service Agreement

If a service provider bills for you, you still need a service agreement for the customer. Why? Because:

- As explained under Service Providers Are Linked To Service Agreements, service providers are defined in respect of a customer's service agreement (therefore the customer must have a service agreement).
- As explained under When They Bill For Us, They Owe Us Money, you still have to calculate bills for the customer.

> **Note**
>
> **A customer's bill history still exists.** Be aware that even when a service provider bills for us, you will still be able to see the customer's billing history. It's just that the customer won't owe you anything because the receivable balance will be transferred to the service provider's account.

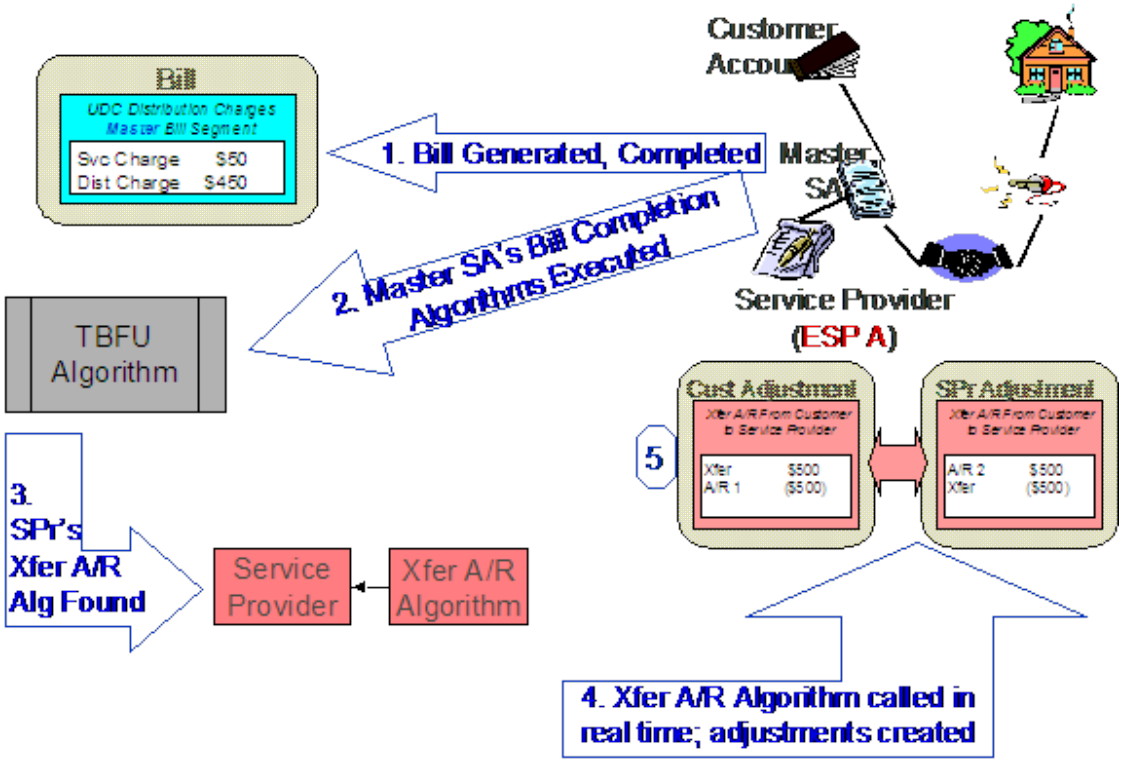
They Bill For Us - Bill Ready

At bill completion time, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these,

- It transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.
- Note that payments and A/P adjustments are not transferred. Why? Because payments and A/P adjustments are purely between the customer and your company.
- Each bill segment and adjustment is marked to be interfaced to the service provider (via a separate background process).

Copyright © 2026, Oracle and/or its affiliates.

They Bill For Us - Rate Ready



The They Bill For Us - Rate Ready option is not a recommended option. Why? Because you really have to compute how much the customer owes as explained above. If you go to the trouble of figuring out how much the customer owes, then it makes sense to interface this to the billing service provider.

The only difference between this option and They Bill For Us - Bill Ready is that the system will not interface the bill segments and adjustments to the billing service provider.

A/R Transfer - Technical Implementation

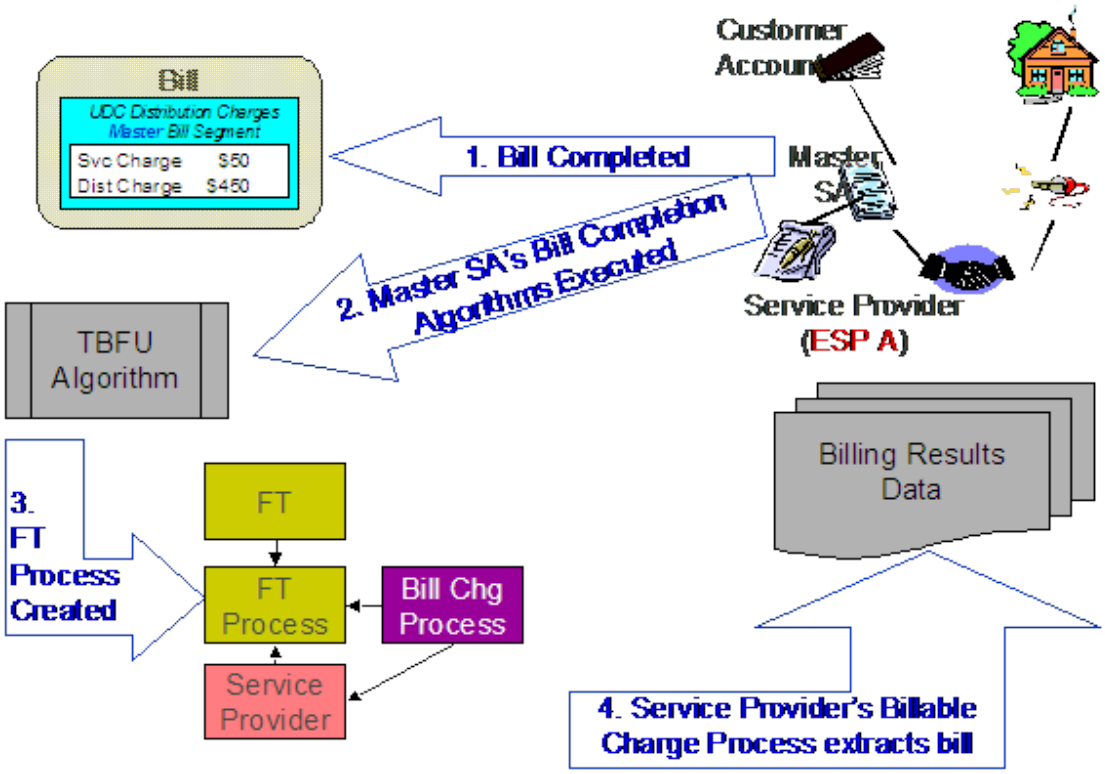
> **Warning**
>
> This section describes, technically, how a customer's A/R balance is transferred to a They Bill For Us service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with the transference of a customer's A/R balance to a They Bill For Us service provider.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.

Copyright © 2026, Oracle and/or its affiliates.



- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will execute the Transfer A/R algorithm defined on the service provider's record. This algorithm causes a transfer adjustment to be created (transferring the financial transaction's affect on the customer's balance from the customer to the service provider).

> **Note**
>
> If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be transferred to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Routing Billable Charges To Service Providers - Technical Implementation

> **Warning**
>
> This section describes, technically, how we send billable charges to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending billable charges to service providers.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

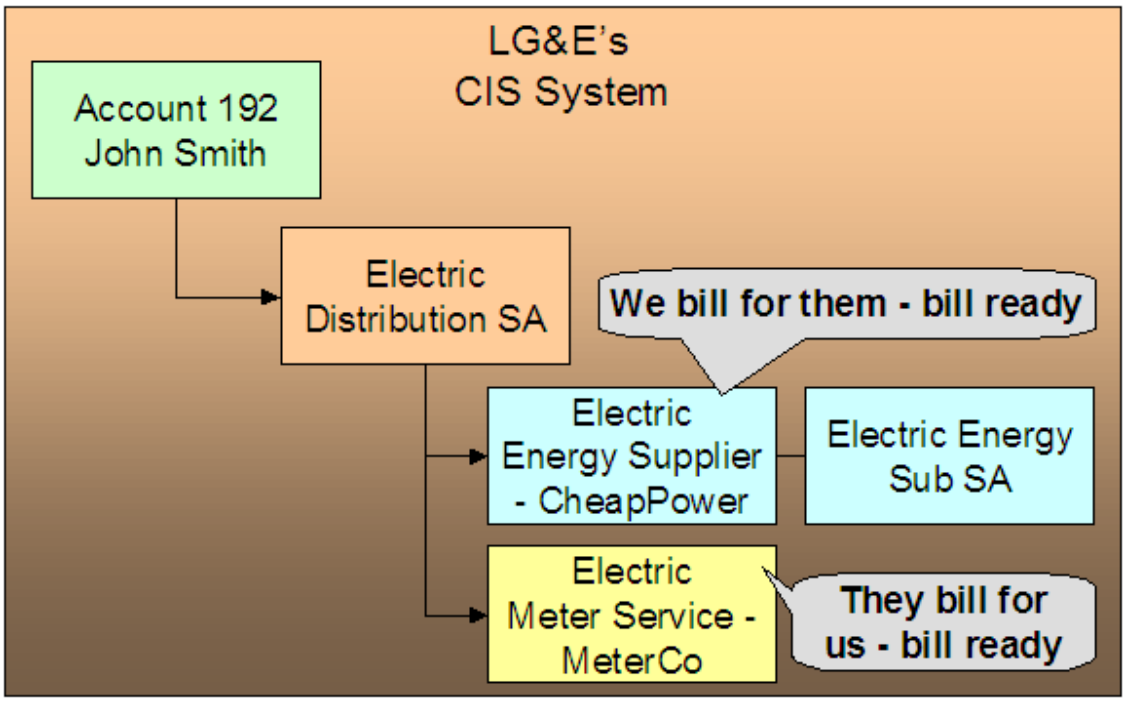
- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable charges to the service provider. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Billable Charge Download Process.

> **Note**
>
> If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be routed to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Bill Routings Are Changed

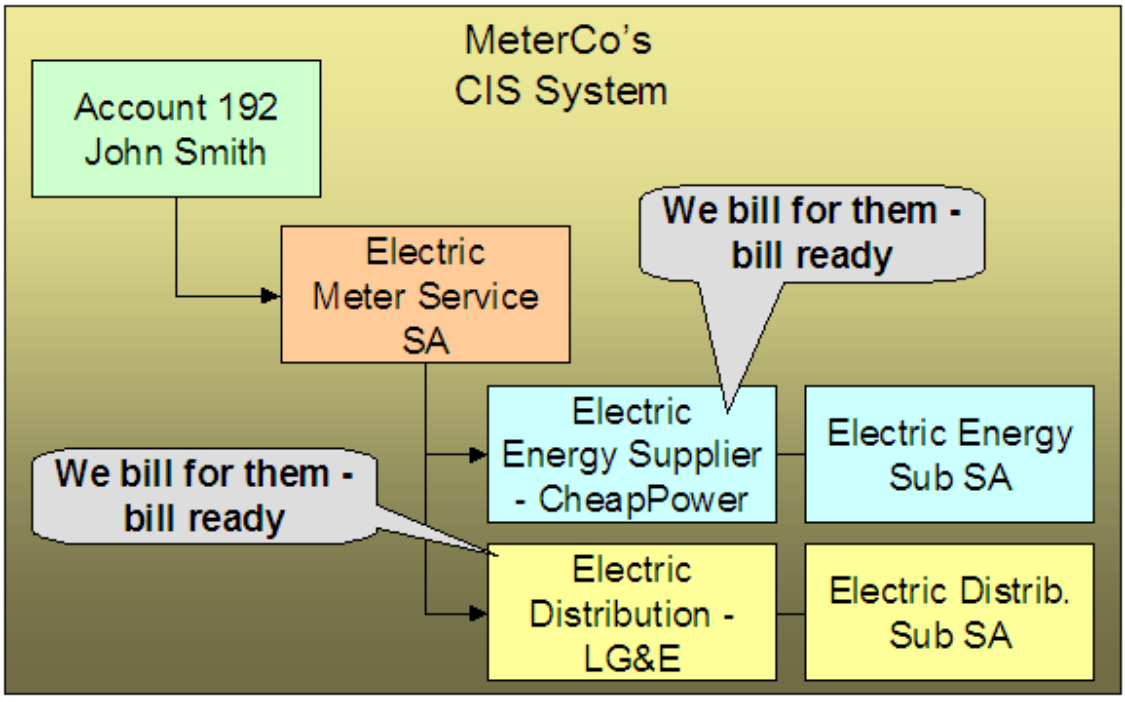
If all of an account's "master" SAs have a SA relationship with a service provider who bills for us (i.e., the service provider's billing relationship is They Bill For Us), then we have nothing to send to the customer. The system still creates bill routings, but with a couple of differences:

- The Batch Process Id and Run Number are reset.
- The Customer's Name is prefixed with the text from a bill message code 6, 10103. This message code's text is *** Bill not sent.



This way, the operators can easily see that that the bill was not routed and why.

> **NOT_SUPPORTED**
>
> Refer to Different Service Providers Can Bill Different Services for information about how the various services under an account could be billed by different service providers.

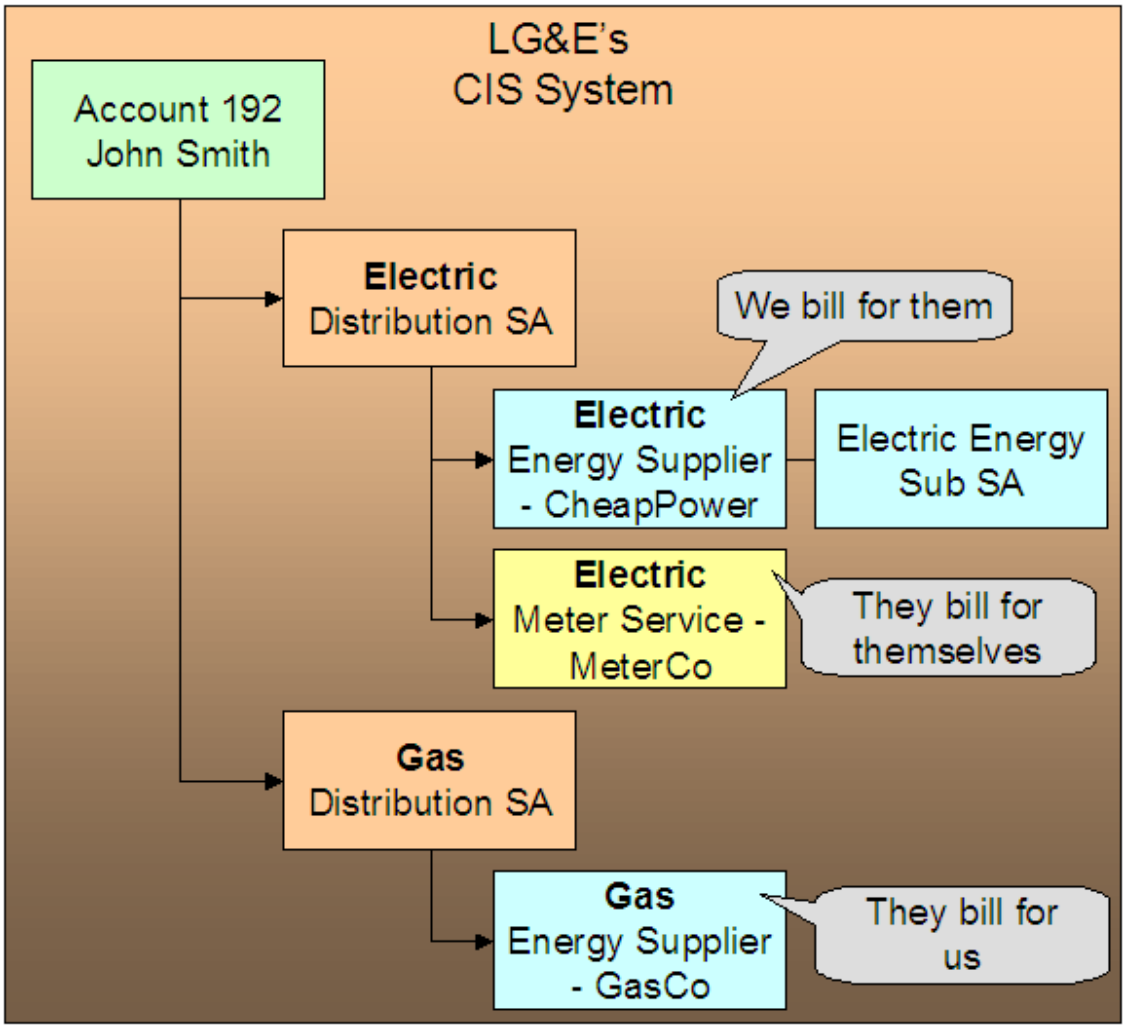


Combinations Of Service Provider Billing Methods

Consider the following situation:

Copyright © 2026, Oracle and/or its affiliates.

In the above example, we are billing for the energy service provider and the meter service provider is billing for us. This means that we will calculate the charges for ourselves, interface charges from CheapPower, and then interface our charges and CheapPower's charges to MeterCo. MeterCo will then produce a bill for the customer that contains our distribution charges, CheapPower's energy charges, and MeterCo's service charges. To help solidify this point, let's look at how this customer would look in MeterCo's CIS system.



There are some restrictions in respect of permissible combinations of service providers that may supply service to a customer as described in the following points:

Copyright © 2026, Oracle and/or its affiliates.

- If the system encounters a customer with a We Bill For Them (WBFT) - Bill Ready service provider and another service provider that is They Bill For Us (TBFU) - Rate Ready, a billing error will be produced. Why? Because TBFU - Rate Ready means they have everything they need to calculate our bills and therefore we do not interface bill lines to them. If we don't interface our bill lines to them, then we can't interface the charges that were interfaced from the WBFT - Bill Ready service provider. You may wonder why we don't prohibit WBFT - Rate Ready and TBFU - Rate Ready, because it's conceivable for the TBFU service provider to have our rate and the WBFT service provider's rate.
- If the system encounters a WBFT - Pay At Pay Time service provider and another service provider that is TBFU, a billing error will be produced. Why? Because when the system detects a TBFU service provider, it transfers the receivable from the customer to the service provider (and therefore the customer's account will never be paid).

Different Service Providers Can Bill Different Services

Be aware that the system determines billing relationships at the service agreement level, NOT at the account level. To make the point, check out the following customer in a distribution company's system:

Be aware of the following in respect of the above illustration:

Copyright © 2026, Oracle and/or its affiliates.

- The distribution company (LG&E) distributes both electricity and gas.
- The customer has a choice of energy service providers for both gas and electricity.
- This customer - John Smith - purchases electricity from CheapPower, and purchases gas from GasCo.
- LG&E provides billing services for CheapPower.
- GasCo provides billing service for LG&E.

In this situation, LG&E will send bills to the customer that contain both electric distribution and energy charges (but no gas distribution charges). GasCo will also send bills to the customer; these will contain both LG&E's gas distribution charges as well as their own energy charges.

If You Deal With TBFU Service Providers, You Cannot Reopen Bills

NOT_SUPPORTED

Refer to Bill Lifecycle for information about reopening previously completed bills.

If your organization deals with They Bill For Us (TBFU) service providers, a great deal happens when a bill is completed (e.g., the receivable is transferred from the customer to the service provider, we may mark the bill segments and adjustments for routing to the service provider, etc.). These things cannot be undone and therefore the system will not let you reopen bills when these things have occurred.

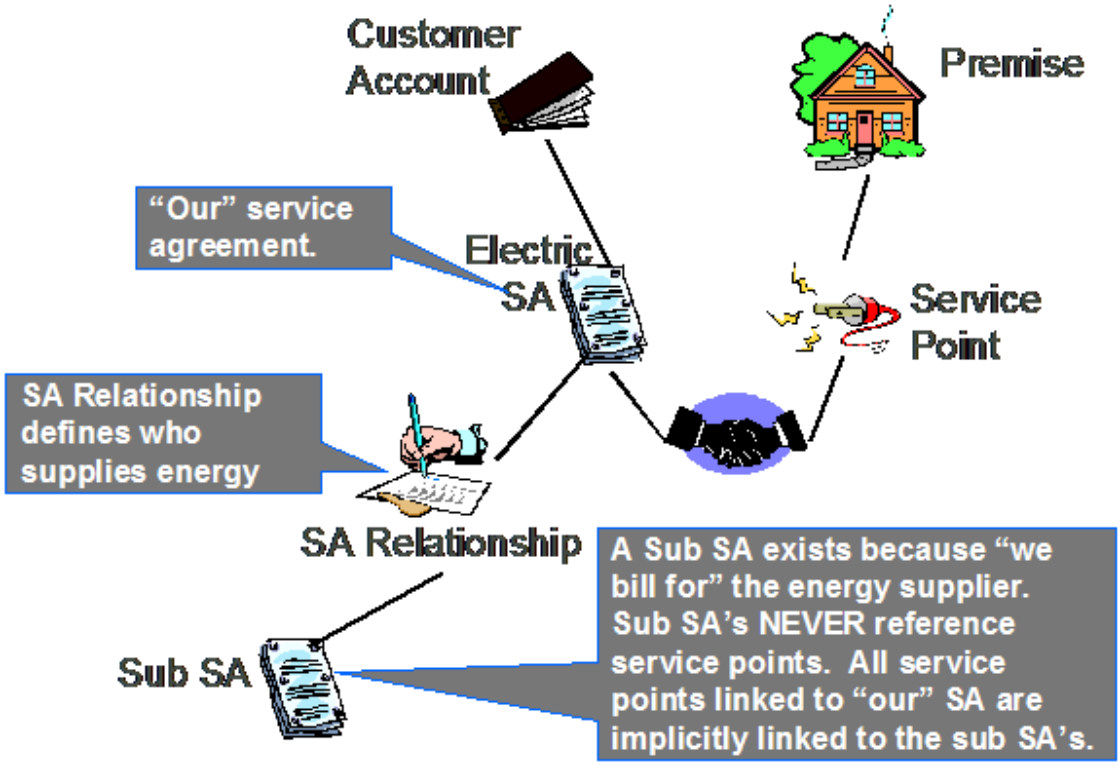
Note

Technical rule. The specific rule that prevents the reopening of bills is as follows: if a bill contains a service agreement whose SA type has one or more bill completion algorithms, the system will not allow the bill to be reopened. Refer to SA Type - Algorithms for more information about bill completion algorithms.

Consumption Relationships

When you set up a service provider, you must define your organization's consumption relationship with the service provider - a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

The topics in this section provide a wealth of information about the various consumption relationships and the ramifications of each.



- Only The Master SA Is Linked To Service Points
- We Can Send Billed Consumption To Any Service Provider
- Routing Consumption To Service Providers - Technical Implementation
- We Can Receive Consumption From Service Providers

Copyright © 2026, Oracle and/or its affiliates.

- MDMAs And Service Cycles

Only The Master SA Is Linked To Service Points

The following diagram makes the point that service points cannot be linked to sub SAs (i.e., service agreements that exist to hold charges associated with We Bill For Them service providers). This is because all service points associated with our "master" SA are implicitly linked to all sub SAs.

It's important to understand why the system does not allow sub SAs to reference service points:

- The consumption associated with all service providers should be the same, otherwise the customer will receive inconsistent bills from different service providers.
- The easiest way to ensure consumption is the same for all service providers is to make sure that they all have the same service points (which they must if sub SAs "inherit" their service points from their master).

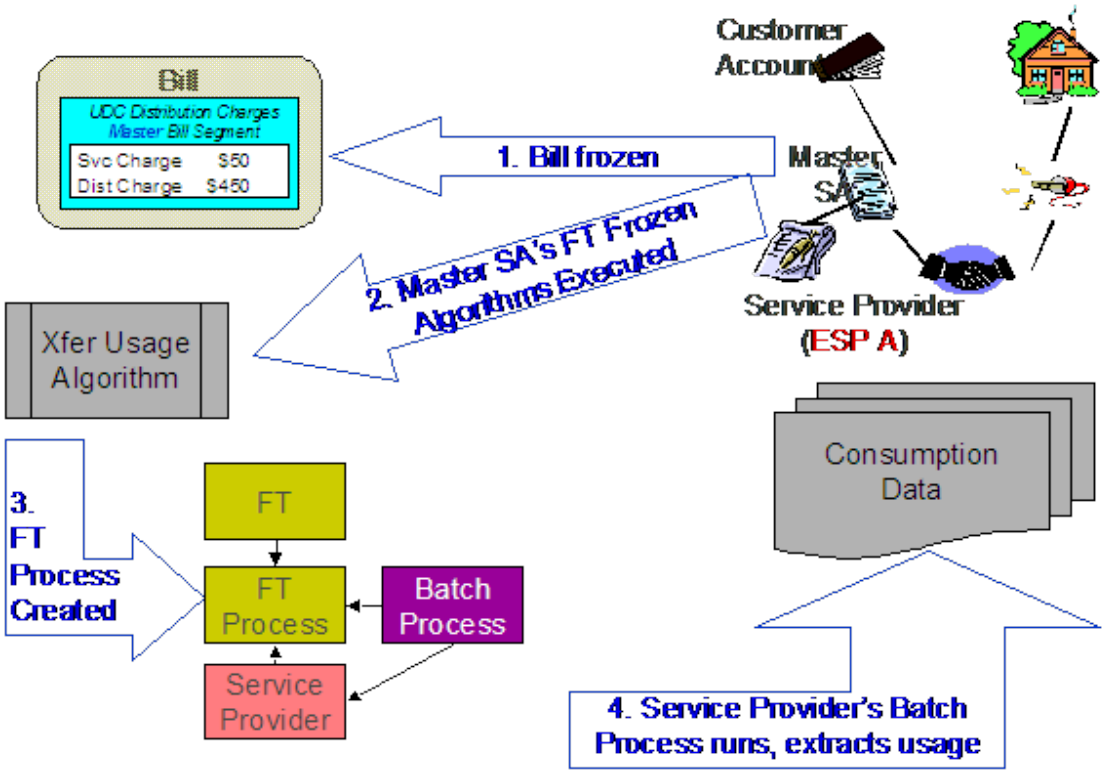
We Can Send Billed Consumption To Any Service Provider

You can send consumption to any service provider. It doesn't matter what their billing relationship is. Information on the service provider object tells the system if AND how to send consumption to a service provider.

Rather than send raw reads to service providers, we download consumption that has been calculated and snapshot onto the "master" bill segment. We send this billed consumption because:

Copyright © 2026, Oracle and/or its affiliates.

- It is clean and validated
- Register indexes have been subtracted
- Multiple registers have been summed



> **Note**
>
> We only send consumption after a bill segment is Frozen. If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service providers to calculate their charges, please refer to The Bill Ready Calculation Method for an explanation of how the system waits a given amount of time for the recipient of the consumption to interface their charges back to the system before sending the bill to the customer. In other words, the bill sent to the customer should contain the bill segment that triggered the consumption download as well as bill segments containing uploaded billable charges.

Routing Consumption To Service Providers - Technical Implementation

> **Warning**
>
> This section describes, technically, how we send consumption to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending consumption to service providers.

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the master SA's SA type), one of these algorithms will determine if there are service providers associated with the master SA who need consumption. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable consumption to the service provider. If multiple service providers need consumption, multiple rows will be inserted. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Consumption Download Process.

We Can Receive Consumption From Service Providers

We can receive consumption from any source. The system can receive consumption from service providers. Each customer must have:

- A premise
- A service point
- A device with measuring components sufficient to hold the interfaced consumption

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **You don't have to perfectly model the service points and meters.** If you are not the distribution company, you may be worried about how to keep devices and service point information up-to-date. Be aware that you don't have to model the SPs and devices perfectly. Why? Because you just need to set up enough information so that consumption can be received accurately.

MDMAs And Service Cycles

> **Warning**
>
> This section uses terminology and concepts described in The Cyclical Meter Read Process.

A Meter Data Management Agency (MDMA) is a service provider who reads meters. In some locales, a meter can be read by a variety of MDMAs, in other locales there is no MDMA as the meter is read by the distribution company. If your organization has MDMAs, then you need to be aware of the following:

- MDMAs must be linked to service agreements as a service provider. Like all service providers, they can change over time.
- When an MDMA is reading a service agreement's meters, the MDMA may override the customer's service cycle (and schedule) with their own cycle. If they do this, the customer's service cycle in the MDMA's system is defined on the service agreement's SA relationship information for the MDMA. Note: whether or not a service provider can override a service cycle is controlled by a switch on the service provider's record. Refer to Setting Up Service Providers for more details.
- A service provider's service cycle schedules are maintained using the system's normal service cycle schedule. The ID of the service provider associated with each schedule is defined on the service cycle; in other words, if a service provider reads meters and they can override the customer's service cycle, the service provider's service cycles must be defined in the system. Refer to Designing Service Cycles, Routes, And Schedules for more information.
- At billing time, the system determines if a service agreement is covered by an MDMA. If so, it uses the service cycle defined on the service agreement's MDMA SA relationship record.
- If your organization ever reads the customers' meters, your regular read cycle should be maintained on your service points. You can think of the service cycle that is defined on a service agreement's MDMA SA relationship record as an override of your service points normal service cycle.
- If the meter read download process detects that a service point is linked to a service agreement with an active MDMA, it still creates a meter read download staging record; however, it marks it as Do Not Need To Read. This means that when a service point is no longer read by an MDMA, the meter read will be downloaded normally.

Copyright © 2026, Oracle and/or its affiliates.

- Refer to We Can Receive Consumption From Service Providers for a description of how a service provider interfaces consumption into the system.

Deposits Issues

> **Warning**
>
> This section uses terminology and concepts described in The Big Picture Of Deposits.

Deposits should be held using normal deposit service agreements (SAs). You should NOT use the Sub Service Agreements (sub SA) functionality to hold or bill for deposits because deposit service agreements do not have the same state transition as do master SAs (e.g., you can activate or stop a deposit independent from its master).

However sub SAs can be covered by a deposit. If so, their SA type must reference a deposit class. To make the point, let's examine a few scenarios:

- Assume you have a sub SA for your own charges (this can happen when we use sub SAs to unbundle charges from the Master SA). In this case, it is likely that the sub SA and master SA will be in the same deposit class. This means that a single deposit SA would cover both the master and the sub SA.
- Assume They Bill For Us (Bill or Rate Ready). In this situation, we still have a master SA for our charges and we transfer the charges to the service provider who does the billing. In this case, it is likely that we would be holding the deposit for the service provider, not on the end-use customer. If we are in a situation where 1) we cannot hold a deposit against the service provider, and/or 2) we are not assured of the service provider paying us when the customer doesn't pay them, then we might want to put the master SA in a deposit class and hold a deposit against the customer's account using a normal deposit SA. We would not expect the service provider to bill the customer for the deposit, so we don't need a sub SA. We bill the customer directly for the deposit using our normal deposit SA.
- Assume We Bill For Them (Bill or Rate Ready). In this situation, we could hold a normal deposit SA for the customer's master SA. For sub SAs, we have two scenarios:
  - **We pay at billing time.** Since we purchase the receivable, we would want to increase our normal deposit to cover the Sub SA. To do this, the sub SA's SA type's deposit class should be the same as our master SA's deposit class.
  - **We pay at payment time.** It seems unlikely that we would want to hold a deposit on behalf of a service provider when we don't purchase the receivable. However, it is possible to do so by putting the sub SA into its own deposit class. If you did this, the system will require a separate deposit SA for the service provider's deposit. The system would calculate and refund such deposits using the algorithms defined on the new deposit SA's SA type's deposit class. It's important to be aware that the deposit is not held with respect to the specific service provider. Rather, it is just held in the system as separate deposit that could be used for any service agreement that belongs to its deposit class.

Credit and Collection Issues

Copyright © 2026, Oracle and/or its affiliates.

> **Warning**
>
> This section uses terminology and concepts described in The Big Picture Of Credit & Collections (C&C).

C&C is only tricky if you deal with We Bill For Them service providers. We'll run through the service provider billing relationships to explain why:

- If we have a Dual relationship with a service provider, we don't have their debt, so we only have a responsibility to tell them when we cut a customer (via a Notification). We don't have to worry about collecting their debt.
- If we have a They Bill For Us relationship with a service provider, there is no debt on the customer's SA because it gets transferred to the service provider (and the service provider's SA will fall into arrears if they don't pay us).
- If we have a We Bill For Them or It's Us relationship with a service provider, the customer's debt associated with the service provider's service is maintained on a sub SA (i.e., it is segregated from our debt). This segregation of debt is both a powerful feature and a cause of administrative difficulties. The topics in this section provide more information about this issues.
- Debt Class Recommendations
- Severing Service

Debt Class Recommendations

A service agreement's debt class is an important element in determining how a customer's debt is collected. In general, we recommend the following:

- If the service provider has a billing relationship of It's Us, we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Billing Time), we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you don't buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Pay Time), you may want to use a different debt class on the sub SA. Why? Because you may collect the service provider's debt differently.

> **Note**
>
> **Bottom line.** If both the "master" and the sub SAs fall into arrears, you will have 1 or 2 collection processes, it all depends on the debt class assigned to each SA type.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Automating Your C&C Activities for information describing how debt class plays a part in this processing.

Severing Service

Sub SAs and severance is tricky. Why?

- Because it's possible for the master SA to be in arrears when the sub SA isn't (for all the standard reasons - directed payments, cancel / rebills, etc.).
- Because it's possible for the sub SA to be on one collection process and the master to be on another (due to different debt classes or different time lines).

Both of these situations could result in severance starting for only one of the service agreements in the master / sub relationship. However, YOU CAN'T CUT SERVICE FOR ONE WITHOUT CUTTING THE OTHER because there is only one service point.

Before we describe how to deal with this conundrum, we'd like to remind you that the system starts a unique severance process for each SA (sub or normal) to be severed. It only creates a severance process for those service agreements linked to a collection process when the collection process' Start Severance event is activated. The type of severance process that is created is controlled by each service agreement's SA Type's severance criteria. Please keep in mind the following when designing these severance processes:

- Only The "Master" Service Agreement Is Linked To Service Points. This means only master SAs should have a "cut for non payment" severance event. Note: typically, such a severance process will expire the "master SA" several days after the cut event if funds are NOT received.
- As described under Sub SA State Transition, a sub SA becomes Pending Stop (and eventually Stopped) when its "master" is stopped. This means the sub SAs will be finaled when the master is finaled.
- If you start severance on a sub SA when the master isn't being severed, you have a problem because you can't cut the sub SA independent from the master SA.

We'll use an example to illustrate how you should design your severance processes to deal with the above challenge. Assume you have a master and a sub SA where both are being managed under the same collection process. Also assume that the Start Severance event kicks off on 18-Dec-1999. In this situation, we'd recommend the following severance processes to be kicked off.

Master SA Severance Process

Trigger Dt.	Event Type	Status
18-Dec-99	Set door hanger	Pending
Pending	Cut for non pay	Pending
Pending	Expire SA	Pending

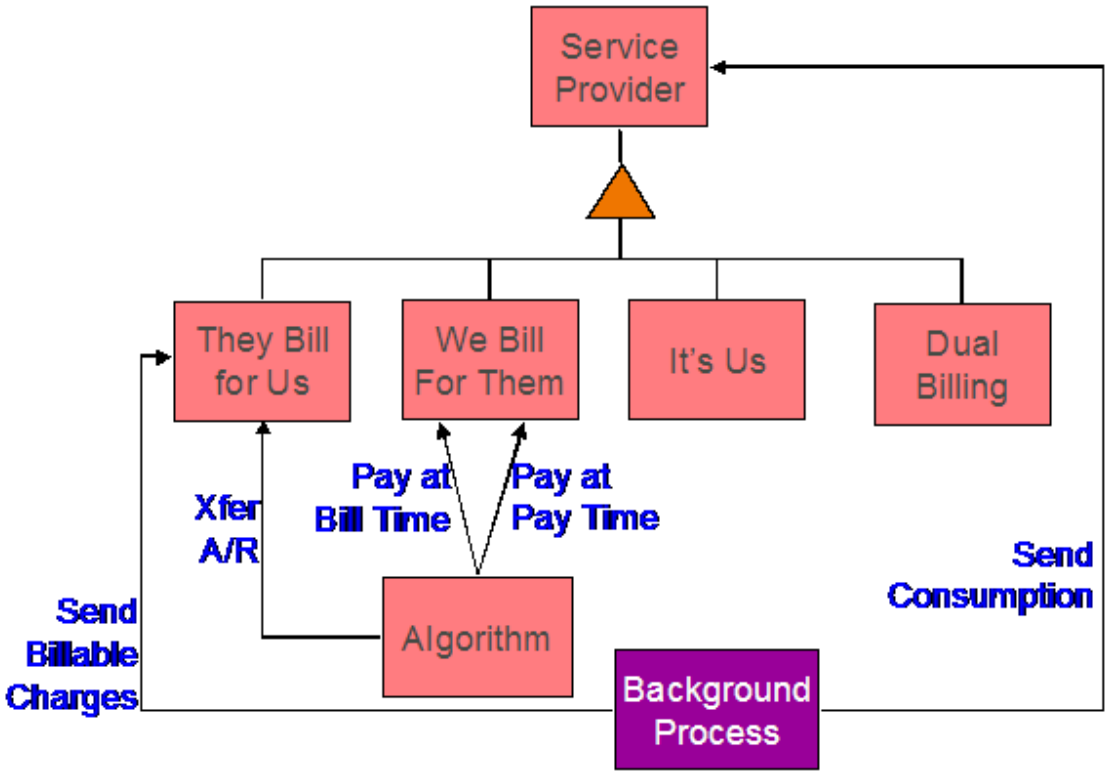
Sub SA Severance Process

Trigger Dt.	Event Type	Status
3-Jan-00	Create To Do Entry	Pending

Copyright © 2026, Oracle and/or its affiliates.

Notice that the sub SA's severance process contains a single event that generates a To Do Entry on a date in the future of the Expire SA event on the Master SA. This entry should be something like "sub being severed independent of its master". This event will only be triggered if the master SA is paid off and the sub SA isn't. Why? Because if the master SA's Expire SA event is executed, the Sub SA will be Stopped and stopping a SA cancels outstanding severance processes. If the sub gets paid, the system will cancel the sub's severance process.

Let's change the example and assume that the master starts severance and the sub doesn't. In this situation, the master SA will eventually hit the Expire SA event and the sub SA will also stop. There's no alternative.



And let's change the example again and assume the sub starts severance and the master doesn't. In this situation, the To Do Entry will only be created X days after the start of severance. If you can't stand this date being X days in the future of the creation of the severance process, create an "Severance Criteria Algorithm" that checks if the master is not being severed or collected and generates a different severance process (with a different start date). Refer to Designing Your Severance Procedures for more information about Severance Criteria Algorithms.

An Object-Oriented Perspective Of Service Providers

> **Warning**
>
> Skip this section if you are not technically inclined.

The following object diagram illustrates in a concise format the various types of service providers and the plug in algorithms and processes available for each.

Copyright © 2026, Oracle and/or its affiliates.

How Do You Communicate With Service Providers?

You communicate with service providers (and they communicate with you) using the following mechanisms:

- You can use traditional interface techniques. For example, if you send consumption to service providers every month (so they can compute their charges), you could use the Consumption Download interface.
- You can use "notifications" to communicate with service providers. Notifications are electronic transactions that service providers exchange to communicate information about a customer. For example, you could use a notification to send a message to an energy supplier when a customer stops service. Note: the term "Direct Access Service Request" (DASR) is synonymous with Notification.

The difference between notifications and traditional interfaces is subtle. Think of notifications as a generic interface that can be used to communicate many different things (e.g., you can use notifications to advise stops, meter exchanges, supplier switches). Traditional interfaces communicate only one thing (and you need one traditional interface for each "thing"). For example, one interface is devoted to downloading consumption, another is responsible for uploading pass through charges, etc.

Off Cycle Switch

If the customer care and billing application integrates with meter data management (mdm) system, it may be set up to generate sub-bill segments for each and every service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, that is effective in the billing period. This requires that the meter data management system can calculate the consumption for each effective SA relationship period.

Copyright © 2026, Oracle and/or its affiliates.

If the switch is from or to a service provider having **They Bill for Us** billing relationship, separate bills have to be generated manually for each relationship effective in the billing period. This restriction is due to requirement for CCB application to generate a bill for a **They Bill for Us** relationship, so that the customer's charges are calculated and eventually transferred to the service provider. The generated bill for **They Bill for Us** billing relationship is not sent to the customer.

- Billing Master Configuration
- Rate Schedule
- Sub-SA Type
- Usage Request
- Sending Consumption to Service Providers

Billing Master Configuration

To enable Off Cycle Switch, navigate to **Admin**, and then **General**, and then **Master Configuration** and add a new entry for Billing Master Configuration.

Specify the values for **Off Cycle Switch Option**, **Implementation Date** and **Off Cycle Switch Option for Old Bill**. Refer to the embedded help on billing master configuration portal for details.

Rate Schedule

Rate schedules assigned to the sub-SA of service provider, having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, must be configured with an SQ rule (for component-based engine) or a pre-processing calculation rule (for rule-base engine) that will obtain the sub-usage's consumption and load it into the bill segment SQ collection during rate application.

For more information, refer to the base package algorithm types provided for this purpose: US (component based engine) and C1-ACRSUBUSG (rule based engine).

Sub-SA Type

When implementing this feature, sub-SA types of service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship must be configured as non-bill determinant.

Usage Request

Usage request is sent to the Oracle Utilities Meter Data Management (MDM) system, to obtain the calculated consumption for the billing period - this is used to calculate master bill segment's charges.

In addition, sub-usage request is sent to the mdm system, for each relationship that is effective during the billing period. Calculated consumption on these sub-usage requests is used to calculate sub-bill segment charges.

Sending Consumption to Service Providers

Calculated consumption on these sub-usage requests also serves as the source for consumption download process if consumption is required to be sent to the service provider. A

Copyright © 2026, Oracle and/or its affiliates.

base package algorithm type - C1-STGCNSMP, stages the download by creating an entry in the general process table, capturing the sub-usage id, batch control for consumption download and the batch number.

> **Note**
>
> It is implementation responsibility to build the consumption download batch process that will extract the consumption for sub-usage request as required.

Designing Your SA Relationship Types and Service Providers

As explain in A Service Agreement Can Have Many Types Of Relationships, SA relationship types and service providers are only required when you subcategorize your service agreements.

The topics in this section describe how to design your SA relationship types.

- Designing SA Relationship Types
- Designing Service Providers
- Designing Your SA Types And Start Options For Sub SAs
- Reference Send Consumption Algorithm On Master SA Types
- Reference TBFU Algorithm On Master SA Types
- Designing SA Types For Service Provider Financial Settlements

Designing SA Relationship Types

The easiest way to design SA relationship types is to start with the matrix of SA types designed in SA Types And The Financial Design. For each SA type in the matrix, determine if either of the following questions is true:

- Can companies other than your own provide some subcategory of the service (and do you have some type of interaction with these companies)? For example, this would be true if you are an energy supply company because a different company is responsible for distributing the power to the customer (and you probably exchange consumption and financial transactions with this company).
- Does your organization use different rates for subcategories of the service? For example, this would be true if you use separate rates for water and wastewater service (even though both are based on the customer's water consumption).

If either of the above is true, you will need a SA relationship type for each subcategory of service.

We'll use an example to help make the point. Using the SA types we designed earlier (see SA Types And The Financial Design), we'll assume the following:

- We are designing the system for an electric, gas, water, waste water, and cable utility.
- Residential electric customers have a choice of energy supplier.

Copyright © 2026, Oracle and/or its affiliates.

- Commercial and industrial electric customers can choose an energy supplier and a meter service provider.
- Commercial and industrial gas customers have a choice of energy supplier.

> **Note**
>
> We are not showing most of the SA types that we designed earlier because they do not have subcategories of service.

CIS BU/ SA Type	SA Relationship Type
G/COM	Energy supply
G/IND	Energy supply
E/RES	Energy supply
E/COM	Energy supply
	Meter service
E/IND	Energy supply
	Meter service

> **Note**
>
> Notice that we did not design a SA relationship type for our own distribution service. This is because our relationship type is implied (e.g., if you are a distribution company, you do not have to set up a SA relationship type for distribution service because the customer's "master" service agreement is implicitly associated with distribution service).

Designing Service Providers

After you design your SA relationship types, you need to list every potential service provider for each SA relationship type.

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas
		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power

Copyright © 2026, Oracle and/or its affiliates.

		Us
E/COM	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us
E/IND	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us

Next, list each unique service provider identified above:

Service Provider
AmeriGas
TransGas
Green Power
Cheap Power
Us
ElectriCorp
TeniCorp
MeterCorp

You will have at least one service provider for each entry in the above list. However, you may have to set up more than one service provider in the system for a given company. The topics below explain how this happens.

- Billing Relationship Segmentation
- We Bill For Them - Payment Relationship Segmentation
- Consumption Relationship Segmentation
- Other Segmentations
- Geographic Area Segmentation

Billing Relationship Segmentation

As described under Billing Relationships, a service provider may bill for you, you may bill for them, or you may each send a separate bill to the customer. In the table below, we have shown the assumed billing relationships for each service provider.

Service Provider	Billing Relationship
AmeriGas	We Bill For Them - Bill Ready
TransGas	We Bill For Them - Bill Ready

Copyright © 2026, Oracle and/or its affiliates.

Green Power	We Bill For Them - Rate Ready
Cheap Power - Res	We Bill For Them - Rate Ready
Cheap Power - Com/Ind	Dual Billing
Us - Billable	It's Us
Us - Non billable	None
ElectriCorp	They Bill For Us - Bill Ready
TeniCorp	We Bill For Them - Bill Ready
MeterCorp	Dual Billing

Notice that we had to introduce additional service providers:

- Cheap Power has two service providers - one for residential customers, the other for commercial/industrial customers. This is necessary because we provide billing service for them for residential customers (We Bill For Them - Rate Ready), but for commercial and industrial customers they bill for themselves (Dual Billing).
- Our own service provider (the service provider known as "Us") has two service providers - one for energy supply because we bill for the energy we supply (It's Us), and another for meter service because we don't create bills for meter service (None).

We Bill For Them - Payment Relationship Segmentation

As described under Pay At Bill Time vs. Pay At Pay Time when you provide billing service for a service provider you have to define if you pay the service provider when you bill the customer OR only later, when the customer pays you.

In the table below, we have shown the payment relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Com/Ind	Dual Billing	N/A
Us - Billable	It's Us	N/A
Us - Non billable	None	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time
MeterCorp	Dual Billing	N/A

Notice that we had to introduce an additional service provider for TeniCorp because for commercial customer we purchase the receivable (Pay At Bill Time), but for industrial customers we only pay them when we're paid by the customer (Pay At Pay Time).

Copyright © 2026, Oracle and/or its affiliates.

Consumption Relationship Segmentation

As described under Consumption Relationships a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

In the table below, we have shown the consumption relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Notice that we didn't have to proliferate service providers due to consumption relationships.

Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of service providers. However, many obscure factors could cause the introduction of more service providers. In this section we explain these more obscure factors.

- Payment Method
- Transfer Receivable Method
- Billable Charge Download Process
- Consumption Download Process
- Notification Upload Processing
- Notification Download Processing
- Financial Settlement Service Agreement

Copyright © 2026, Oracle and/or its affiliates.

Payment Method

As described under Pay At Bill Time vs. Pay At Pay Time, when you provide billing service for a service provider you have to pay the service provider at some point in time. The algorithm that defines the amount to pay (and how the related adjustment is generated) is defined on the service provider record. If a service provider has different payment algorithms for different customer segments, you must split the service provider accordingly.

Transfer Receivable Method

As described under When They Bill For Us, They Owe Us Money, a service provider will owe you money if they provide billing service for you. The algorithm that defines how to transfer the customer's receivable to the service provider is defined on the service provider record. If a service provider has different transfer A/R algorithms for different customer segments, you must split the service provider accordingly.

Billable Charge Download Process

As described under They Bill For Us - Bill Ready, billable charges are interfaced to service providers who provide billing service for you. The background process that performs the interface of billable charges is defined on the service provider record. If a service provider has different billable charge interfaces for different customer segments, you must split the service provider accordingly.

Consumption Download Process

As described under We Can Send Billed Consumption To Any Service Provider, consumption can be sent to any service provider. The background process that performs the interface of consumption is defined on the service provider record. If a service provider has different consumption interfaces, you must split the service provider accordingly.

Notification Upload Processing

A service provider can send you notifications. Whenever a notification is uploaded, the system creates a workflow process to process each such notification. The type of workflow process that's created is controlled by the service provider's workflow process profile. If a service provider requires a different workflow process for a given type of notification (for whatever reason), you must split the service provider accordingly.

Notification Download Processing

The system will send notifications to service providers when something noteworthy happens and when information is needed from a service provider. The type of notification that is sent to a service provider and the background process that interfaces the notification to the service provider is defined on the service provider's notification download profile. If a service provider

Copyright © 2026, Oracle and/or its affiliates.

requires a different type of notification to be sent or they have different interface protocols for a given type of notification, you must split the service provider accordingly.

Financial Settlement Service Agreement

As described under Service Providers Have Service Agreements Too, service providers have service agreements. These service agreements contain how much you owe the service provider (if you bill for them) and how much they owe you (if they bill for you). If you want to have separate service agreements for financial settlements associated with distinct customer segments, you must split the service provider accordingly.

Geographic Area Segmentation

The following table reflects the new service providers that were added since we started Designing Service Providers.

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas
		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power - Res
		Us - Billable
E/COM	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
		TeniCorp - Com
	Meter service	MeterCorp
		Us - Non billable
E/IND	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
		TeniCorp - Ind
	Meter service	MeterCorp
		Us - Non billable

Next, determine the postal code ranges in which a service provider is allowed to provide service.

CIS BU/ SA Type	SA Relationship Type	Service Provider	Postal Range
G/COM	Energy supply	AmeriGas	94000 - 95999

Copyright © 2026, Oracle and/or its affiliates.

		TransGas	94000 - 95999
		Green Power	94000 - 95999
G/IND	Energy supply	AmeriGas	94000 - 95999
		TransGas	94000 - 95999
		Green Power	94000 - 95999
E/RES	Energy supply	Green Power	94000 - 95999
			93000 - 93999
		Cheap Power - Res	94000 - 95999
		Us - Billable	94000 - 95999
E/COM	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Com	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999
E/IND	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Ind	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999

Next, we need to strip off the SA types because the postal ranges are defined for combinations of service provider and SA relationship type. Notice the problem - we have a service provider - Green Power has different postal ranges for the same SA relationship type. You have two ways to fix this problem, you can split your service provider (have one for the gas and another for the electric), or you can split the SA relationship type (have one for the gas and another for the electric). We've chosen the former in our example.

SA Relationship Type	Service Provider	Postal Range
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	Green Power - Electric	94000 - 95999
		93000 - 93999
	Cheap Power - Res	94000 - 95999
	Us - Billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999
	Cheap Power - Com/Ind	94000 - 95999
	TeniCorp - Com	94000 - 95999
Meter service	MeterCorp	94000 - 95999

Copyright © 2026, Oracle and/or its affiliates.

	Us - Non billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999
	Cheap Power - Com/Ind	94000 - 95999
	TeniCorp - Ind	94000 - 95999
Meter service	MeterCorp	94000 - 95999
	Us - Non billable	94000 - 95999

In the table below, we have shown the final list of service providers.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power - Electric	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Green Power - Gas	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Designing Your SA Types And Start Options For Sub SAs

When you were Designing Service Providers, you defined the service providers that were valid for every combination of SA type and SA relationship type. If you provide billing services for another service provider or if you subcategorize your own services, you another task - you have to design the SA types for your sub SAs.

As described earlier, there will be a separate Sub Service Agreement for every SA relationship for which we calculate a bill segment. Every sub SA must reference an SA type. The following table shows sample SA types (notice that they are only used for We Bill For Them and It's Us service providers).

CIS BU/ SA Type	SA Relationship Type	Service Provider	SA Type(s) for Sub SAs

Copyright © 2026, Oracle and/or its affiliates.

G/COM	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GC1
G/IND	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GI1
E/RES	Energy supply	Green Power - Electric	GP-ER1
		Cheap Power - Res	CP-ER1
		Us - Billable	US-ER1
E/COM	Energy supply	ElectriCorp	Not applicable - they bill for us
		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Com	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing
E/IND	Energy supply	ElectriCorp	Not applicable - they bill for us
		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Ind	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing

The design steps required to set up these SA types are similar to those described under Designing SA Types For Service Agreements With Service Points. The following points provide a few suggestions that will help you design your SA types for sub SAs:

- The business unit should be the same as defined for the master service agreement.
- Service type should be set up as per Service Segmentation.
- Distribution code should be set up as per Receivable Segmentation.
- Obviously, the sub SA switch should be turned on.
- Start options:
  - If the SA type is used for a We Bill For Them - Rate Ready service provider or for yourself, the start options should be Required because rates, contract riders and/or contract values will be populated on the sub SA from a start option. Refer to Automatic Creation of Sub SAs for more information.
  - If the SA type is used for a We Bill For Them - Bill Ready service provider, the start options should be not allowed because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs.
- The payment distribution and late payment information should be set up as for any SA type. Refer to Cash Distribution Segmentation and Late Payment Charge Segmentation for more information.

Copyright © 2026, Oracle and/or its affiliates.

- If the SA type is used for We Bill For Them - Bill Ready service provider, the special role should be Billable Charge, otherwise it should not be used. Remember, you should not use sub SAs for Cash Deposits.
- Deposit class should be used if the sub SA is covered by a deposit. Refer to Deposits Issues for more information.
- The one time charge switch should be off.
- Bill segment type:
  - If the SA type is used for a We Bill For Them - Bill Ready service provider, the bill segment type should reference a bill segment creation algorithm that creates bill segments from billable charges (and generates bill segment errors until the last night of the bill cycle). Refer to The Bill Ready Calculation Method for more information.
  - If the SA type is used for a We Bill For Them - Rate Ready service provider, the bill segment type should reference a get consumption algorithm that gets consumption from the master SA, and a bill segment creation algorithm that applies a rate.
- Specify a characteristic premise is required if the sub SA is associated with premise-oriented service.
- The calendar billing options should not be used.
- The recurring charge information should not be used.
- Sub SAs used for We Bill For Them - Rate Ready service providers should NOT be eligible for budgets and therefore the eligible for budget switch should be off. This admonition is given because budget billing causes current amount due to be out-of-sync with payoff amount due and we don't want this to happen for sub SAs. Why? Because we use the bill segments associated with these sub SAs to determine how much we owe the service provider.
- If the SA type is used for a We Bill For Them - Rate Ready service provider or for your own company, rates need to be set up; otherwise they should not be used.
- Sub SAs never reference service points. Refer to Only The "Master" Service Agreement Is Linked To Service Points for more information.
- Adjustment types profiles should be set up accordingly.
- Refer to Credit and Collection Issues for recommendations in respect of the debt class, write off debt class, and severance criteria associated with these SA types.
- Billable charge templates should not be used.
- Completion algorithms cannot be used for sub SAs.
- If the SA type is used for a We Bill For Them service provider, you should link to the SA type the FT freeze algorithm that controls how we pay the service provider. Refer to Pay At Bill Time vs. Pay At Pay Time for how this algorithm is used.
- The creation of bill segments for the sub SAs occurs after the bill segment for the related master SA is created. If you populate a billing processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other.

Refer to Setting Up SA Types for how to set up these new SA types in the system.

Reference Send Consumption Algorithm On Master SA Types

Copyright © 2026, Oracle and/or its affiliates.

As explained under We Can Send Billed Consumption To Any Service Provider, when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. Refer to SA Type - Algorithm (FT Freeze Algorithm) for more information.

Reference TBFU Algorithm On Master SA Types

As explained under They Bill For Us, when a bill is completed, the system needs to check if there are any service providers who bill for us associated with the bills "master" SAs. If so, it sets up the data necessary to interface the master SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate FT Completion Algorithm on the master SA types. Refer to SA Type - Algorithm (Bill Completion Algorithm) for more information.

> **Note**
>
> If there are multiple master SAs on a bill, the financial transactions associated with each respective master SA could be routed to different service providers (e.g., one service provider could bill for gas and another could bill for electricity). Refer to Different Service Providers Can Bill Different Services for more information.

Designing SA Types For Service Provider Financial Settlements

As explained in Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us service providers require a service agreement. You must create SA types for these types of service agreements. The following points provide a few suggestions that will help you design these financial settlement SA types:

- Service type should probably be a non-service oriented service type.
- Distribution code for We Bill For Them settlement SAs should be a payable account (or treat it as a "contra" receivable. Refer to Receivable Segmentation for more information.
- The sub SA switch should be turned off.
- Start options are not allowed.
- The payment distribution and late payment information should be set up as for any SA type. Refer to Cash Distribution Segmentation and Late Payment Charge Segmentation for more information.
- Special role should not be used.
- Deposit class should be used if the settlement service agreement is covered by a deposit. This would probably only be used for They Bill For Us service providers (because they will owe us money).
- The one time charge switch should be off.
- These service agreements are not billable and therefore none of the billing information should be specified.

Copyright © 2026, Oracle and/or its affiliates.

- The characteristic premise switch should be off.
- Rates should not be used.
- Service points should not be used.
- Adjustment types profiles should be set up accordingly.
- Debt class, write off debt class, and severance criteria should be set up accordingly.
- Billable charge templates should not be used.
- Completion algorithms should not be used.
- Freeze algorithms should not be used.

Refer to Setting Up SA Types for how to set up these new SA types in the system.

Setting Up SA Relationship Information

In the previous section, Designing Your SA Relationship Types and Service Providers, we presented a case study that illustrated a mythical organization's SA relationship information. In this section we explain how to set up this information.

- Setting Up SA Relationship Types
- Setting Up Service Providers
- Setting Up SA Types and Start Options For Sub SAs
- Setting Up SA Types For Financial Settlements
- Update Master SA Types With FT Freeze and Bill Completion Algorithms
- Setting Up SA Relationships For SA Types
- Setting Up Market SA Relationship Options

Setting Up SA Relationship Types

Open **Admin**, and then **Open Market**, and then **SA Relationship Type** to define your SA relationship types. Refer to Designing SA Relationship Types for more information.

Description of Page

Enter an **SA Relationship Type** code, **Description** and **Service Provider Model** for every relationship type.

Specify the **Market Service ProviderService Provider Model** if the SA relationships of the type reference a Service Provider Market Option — i.e. Market, Provider Configuration Option and Market Relationship Service Provider are specified in addition to SA Relationship Type and Service Provider.

Otherwise, specify the **Service ProviderService Provider Model** .

Setting Up Service Providers

This portal is used to maintain Service Providers.

Copyright © 2026, Oracle and/or its affiliates.

Refer to The Big Picture of SA Relationships and Service Providers for more information.

You can access the portal from **Admin**, and then **Open Market**, and then **Service Provider**. You are brought to a query portal with options for searching for a specific service provider. Once a service provider is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Service Provider** zone shows the details of the service provider. Refer to the zone's embedded help for more information.

Setting Up SA Types and Start Options For Sub SAs

The SA types and start options described under Designing Your SA Types And Start Options For Sub SAs must be set up. Refer to Setting Up SA Types for how to do this.

Setting Up SA Types For Financial Settlements

The SA types described under Designing SA Types For Service Provider Financial Settlements must be set up. Refer to Setting Up SA Types for how to do this.

Update Master SA Types With FT Freeze and Bill Completion Algorithms

Refer to SA Type - Algorithm for more information.

Setting Up SA Relationships For SA Types

This portal is used to maintain SA Type SA Relationship Types.

Refer to Designing Your SA Relationship Types and Service Providers for more information.

You can access the portal from **Admin**, and then **Open Market**, and then **SA Type SA Relationship Type**. You are brought to a query portal with options for searching for a specific SA Type SA Relationship Type. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **SA Type SA Relationship Type** zone shows the details of the SA Type SA Relationship Type. Refer to the zone's embedded help for more information.

Setting Up Market SA Relationship Options

The following sections describe how to set up Provider Configuration Options, Market Provider Configuration Options and Service Provider Market Options.

- Setting Up Provider Configuration Options
- Setting Up Market Provider Configuration Options

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Provider Configuration Options

This portal is used to maintain Provider Configuration Options.

You can access the portal from **Admin**, and then **Open Market**, and then **Provider Configuration Option**.

The following zones may appear as part of the portal's **Main** page:

- **Provider Configuration Option List** zone lists all Provider Configuration Option records. Broadcast a record to display the details of the selected record.
- **Provider Configuration Option** zone provides information about the selected Provider Configuration Option.
- **Market Provider Configuration Options** zone lists the existing Market Provider Configurations for the selected Provider Configuration Option. Maintenance actions are available on this zone.

Setting Up Market Provider Configuration Options

This portal is used to maintain Market Provider Configuration Options.

You can access the portal from **Admin**, and then **Open Market**, and then **Market Provider Configuration Option**. You are brought to a query portal with options for searching for a specific Market Provider Configuration Option. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** page:

- **Market Provider Configuration Option** zone shows the details of the Market Provider Configuration Option.
- **Service Provider Market Options** zone shows the service providers with their start dates, end dates (if applicable) and statuses. Maintenance actions are provided. A broadcast icon appears if the Service Provider Market Option has sub-SA(s) and/or entries in the Status History log. Clicking on the broadcast icon displays the following zones:
  - **Service Agreements** zone shows the Service Provider Market Option’s sub-SAs.
  - **Status History** zone shows the history of changes to the Service Provider Market Option, which can include changes to Start Date, End Date and/or Status.

Negotiated Terms

The topics in this section describe the use of SA relationship functionality for applying certain types of negotiated terms. It assumes that you are familiar with SA relationship functionality in general.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Negotiated terms are optional.** The functionality described in this section is only relevant if your organization offers this functionality.
>
> **Umbrella agreements**. If the Contract Management module is not turned off, you may also choose to use umbrella agreements to manage the functionality described here.

Imagine that the head office for a multi-site organization negotiates special terms that cover a number of its sites, each of whom have their own account and service agreement. The negotiated terms typically involve discounts. These discounts may be realized

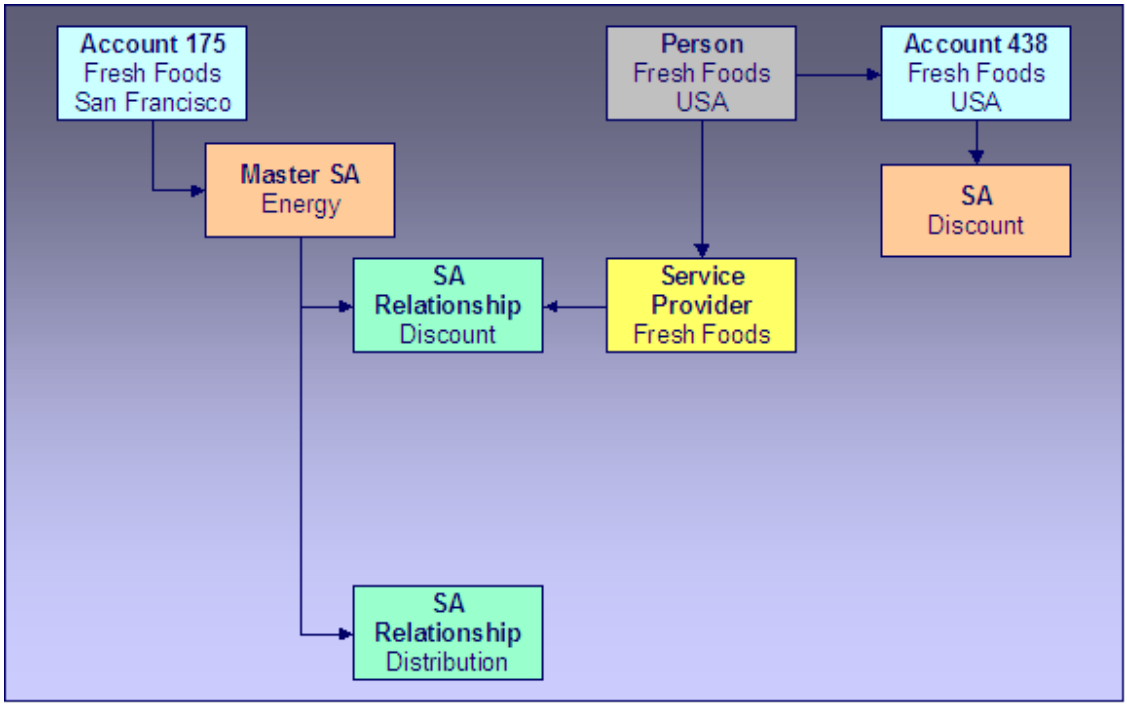
- Under a single service agreement, separate and distinct from the service agreements that are covered, or
- Individually, for each covered service agreement. In this case, two sub-scenarios exist:
  - The discounts may be reflected on the bill segment of each service agreement, or
  - The discounts may be transferred to another service agreement (the group's service agreement). The discount does NOT appear on the individual bill segment for the service agreements that are covered by the negotiated terms.

SA relationships track and manage complex business relationships between a customer and a service provider. You can define the above relationships using service agreement relationship functionality. This is a special type of SA relationship in which the head office is the service provider.

- Examples Of Special Discounts
- Setting Up The System To Enable Negotiated Terms

Examples Of Special Discounts

The following topics illustrate examples of how your organization may configure the system to handle this business functionality.



- Example Using Aggregated Consumption
- Example Using Site-by-site Discount

Example Using Aggregated Consumption

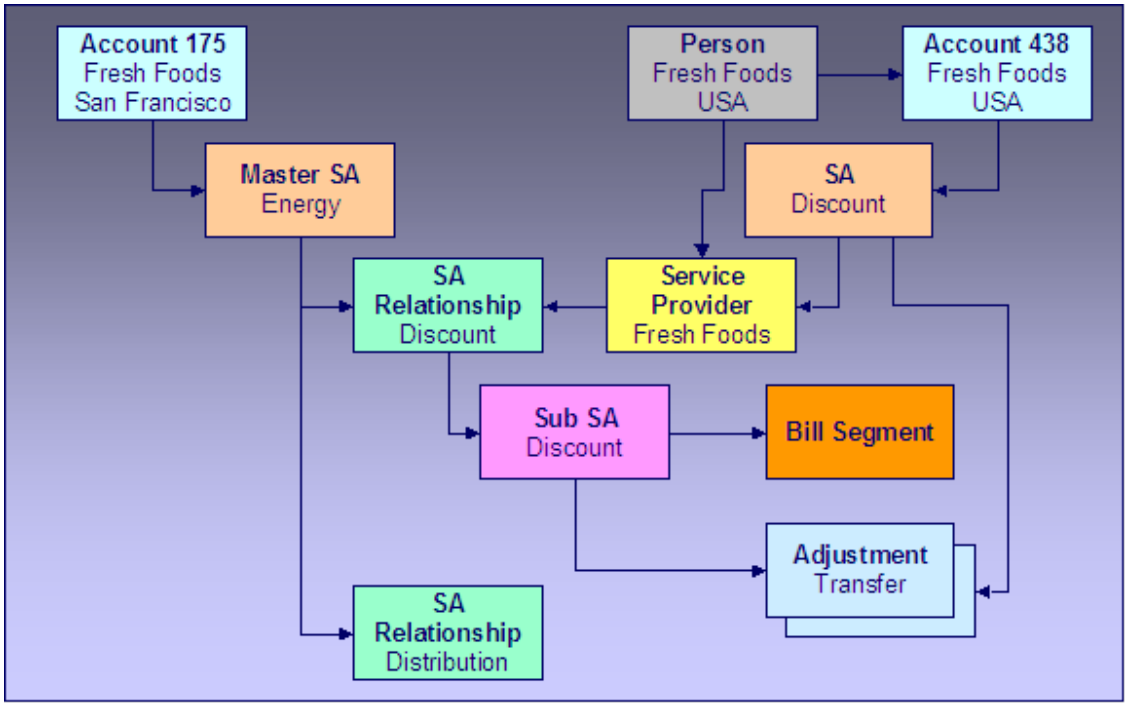
A customer, Fresh Foods has 10 stores each with its own account and electric service agreement, i.e., each store is billed separately. Fresh Food's head office decides to negotiate a group discount that applies to one or more of the individual stores.

In the following diagram, one store's account is shown.

Copyright © 2026, Oracle and/or its affiliates.

Example Using Aggregated Consumption

Note the following:



- An SA relationship is created for the energy SA covered by the negotiated terms.
- The service provider in the relationship is the head office.
- This relationship does not have a sub-SA because no additional billing services are provided for each individual covered service agreement.
- Discounts are calculated using the head office discount service agreement and affect only this service agreement and therefore only the head office's account.
- The master SA may have other deregulated relationships, such as the distribution relationship shown.

> **Note**
>
> **Aggregated consumption algorithm.** In this scenario, the service provider's service agreement amalgamates the group's consumption and applies a rate to calculate the discount. This algorithm is not provided - you get to write this algorithm to meet your needs.

Example Using Site-by-site Discount

In this scenario, the discount is calculated on a site-by-site basis.

Copyright © 2026, Oracle and/or its affiliates.

Example Using Site By Site Discount

Note the following differences between this example and the one where consumption is aggregated:

- Each service agreement participating in the discount has an SA relationship with a sub SA.
- Discounts are calculated on a site-by-site basis by the sub SA for each service agreement covered by the discount agreement.
- The discounts may be transferred to the head office service agreement using transfer adjustments. In this case, you may choose to not show the discount on the individual site's bills.

Setting Up The System To Enable Negotiated Terms

The above topics provided background information about how special negotiated terms could be supported in the system. The following discussion summarizes the various setup tasks alluded to above. These notes highlight the setup required in addition to that detailed in Setting Up SA Relationships Information.

- Algorithm
- SA Relationship Type
- Service Provider
- SA Type SA Relationship Type
- SA Type

Algorithm

Copyright © 2026, Oracle and/or its affiliates.

If you use sub SAs to calculate charges / discounts for each covered service agreement individually and you want to transfer the charges / discounts to the service provider's service agreement at bill completion, you will need to set up a bill completion algorithm to do this.

Refer to the algorithm type BCMP-TR for more information.

SA Relationship Type

You will need an SA relationship type that will be used for each type of negotiated term or discount.

Service Provider

Set up a service provider using the principal party of the negotiated discount. For example, if a head office negotiates a special agreement for its sites, you should set up a new service provider representing the head office.

- **Billing Relationship** will depend on the type of negotiated terms you choose to set up. For terms where debits / credits are calculated for each covered service agreement individually, select We Bill For Them, Rate Ready. We are effectively billing on behalf of the principal party. For terms where the discount is calculated on an amalgamated SA there is no billing relationship because no additional billing services are provided for each covered service agreement.
- Select a **Payment Relationship** of Pay SPR Not Applicable if debits / credits to the sub-SA should not be transferred to the service provider. If you want to transfer charges at bill completion time using a bill completion algorithm, you should also select Pay SPR Not Applicable because you will not be creating adjustments to pay the principal party service at payment time or at billing time.
- Enter a **Transfer A/R Algorithm** to transfer the debit / credit from the sub-SA to the principal party's service agreement. If you do not want to transfer the debit / credit to the principally party's service agreement, you do not need to specify a transfer algorithm.

SA Type SA Relationship Type

Associate the SA relationship type setup for negotiated terms with the SA type(s) of the service agreements that are covered by the terms. The following are suggested values for the SA type SA relationship type:

- **Required**. Relationships of this type should not be required for the SA type because the negotiated terms will only cover selected service agreements with that SA type.
- **Gaps in SA Relationship** are Allowed if service agreements of this type do not have to have an SA relationship of this type with a service provider throughout the effective period of the SA.
- Add the service provider set up above to the list of valid service providers for this SA type and SA relationship type combination.

Copyright © 2026, Oracle and/or its affiliates.

SA Type

Set up an SA type for the sub SAs that will be used to calculate discounts. This SA type should use the BCMP-TR bill completion algorithm if you want to transfer the discounts to the head office.

> **Note**
>
> **TBFU Deregulated Relationship with WBFT Negotiated Terms Relationship**. If you have the unusual situation where a master service agreement has a relationship with a TBFU service provider as well as a negotiated term "relationship" with a WBFT service provider, and you transfer charges / discounts from the discount agreement sub SA to the WBFT service provider, you will not be able to use the algorithms provided to transfer receivables to the service providers. This is because bill completion algorithms associated with the SA type of a master service agreement are executed before any bill completion algorithms associated with the SA types of sub service agreements. Consequently the TBFU XFER algorithm associated with the master service agreement will transfer all receivables from related sub SAs to the TBFU service provider before the BCMP-TR algorithm can transfer the discount agreement receivables. You will need to modify the TBFU XFER bill completion algorithm that transfers receivables from the customer to the TBFU service provider to exclude the discount agreement receivables.

Defining Service Credit Options

Some companies allow their customers to participate in a special rewards program. The term "service credits" is used to describe a program that rewards customers for their business. The topics in this section provide details to help you set up the control tables required to support any service credit program that your company supports.

> **Note**
>
> **Penalty Points**. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

- The Big Picture Of Service Credits
- Designing Your Service Credit Options
- Setting Up Service Credit Options
- Service Credit Examples

Copyright © 2026, Oracle and/or its affiliates.

The Big Picture Of Service Credits

The topics in this section provide background information about service credit functionality.

- Service Credit Membership

Service Credit Membership

Let's look at some examples of special programs that may use service credits functionality:

- Capital credits - When customers receive their utility service from a cooperative, they are considered "members" of the cooperative and may over time receive capital credit allocations from the cooperative based on their service history and the cooperative's profits allocated during that time period.
- Frequent flier miles - Perhaps your company has made an agreement with one or more airlines to allow customers to accumulate frequent flier miles for every x amount spent on service.
- Free pay-per-view movies - Maybe your cable service offers free pay-per-view movies under certain conditions. Using service credits, you can set up your system to accumulate the free pay-per-view movies and use the free movies to offset actual movies viewed by the customer.
- Any other type of loyalty program where the customer earns credits that may later be redeemed in some way.

To participate in a program such as those described above, the customer is linked to a service credit membership. The membership record provides the following functionality:

- It defines the accounts that are linked to the membership.

> **NOT_SUPPORTED**
>
> Refer to Who are the Members? for information about linking persons and accounts to a membership.

- It defines a membership type, which controls certain behavior about the membership.
- It may define an external ID if the membership is associated with an external program, such as a frequent flier mile program.
- It may define a service agreement to use for miscellaneous financial transactions that may get created.
- It may define characteristics used to capture miscellaneous information about the membership.
- Over time, service credit events are created for a membership. The events indicate an amount that either adds or subtracts credit units (i.e., points, miles, movies, dollars, etc) for the membership.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture of Service Credit Membership for more information about functionality related to a membership.

- How Are Service Credits Earned?
- How Are Service Credits Redeemed?
- Service Agreements For a Membership

How Are Service Credits Earned?

Service credits may be monetary rewards for service or they may be non-monetary rewards such as free movies or frequent flier miles. In any case, how the membership earns the points or rewards depends on the business rules for the program you are offering.

A typical scenario is that the service credits are earned for a membership as a result of other services linked to the membership's accounts. For example:

- Perhaps free pay-per-view movies are earned when signing up for cable service. In this case, the pay-per-view movie membership is related to the membership account's cable service agreement. Refer to Service Credits Earned When Starting Service for more information.
- Perhaps one frequent flier mile is earned for every $10 spent on electricity. In this case, the frequent flier membership is related to the membership account's electricity service agreements (for example, electricity distribution, electricity retail and lamp service). Refer to service credits earned through billing for more information.
- For a capital credits membership, capital credit allocations are calculated based on the amount spent by the customer for standard service, for example electricity and/or gas service. In this case, the capital credit membership is related to the membership account's electricity and/or gas service agreements. For capital credits, a background process is used to calculate the allocated amounts. Refer to Allocating Capital Credit for more information.

It is also possible to earn service credits irrespective of other service for the membership's accounts. (Again, it depends on the business rules for the program you are offering.) For example, perhaps you offer 500 frequent flier miles for signing up for service with your company, regardless of the type of service chosen. In addition, assume that no additional miles are earned for ongoing service. In this example, there is no need to link the membership to any service agreements.

NOT_SUPPORTED

Refer to Service Agreements Contribute to a Membership for more information.

Each earned service credit amount is linked to the membership via a service credit event.

Copyright © 2026, Oracle and/or its affiliates.

How Are Service Credits Redeemed?

Once service credits have been earned for a membership, how may a customer redeem these credits? The method by which the credits are redeemed depends on the business rules for the program you are offering. Here are some examples of how a service credit may be redeemed:

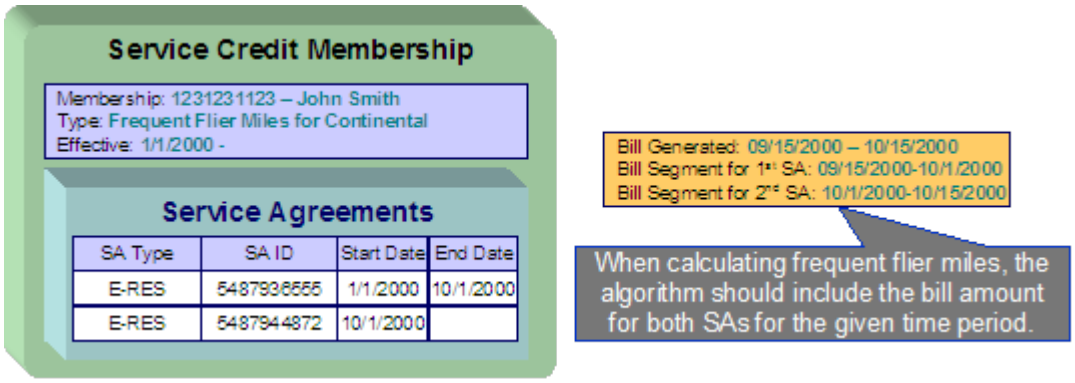
- For free pay-per-view movies, perhaps your customer's monthly cable bill is credited for any pay-per-view movies until all free movies are used. Refer to Service Credits Redeemed Through Billing for more information.
- For frequent flier miles, the information about the earned miles is exported to the appropriate airline. The miles are actually redeemed by the customer through the airline, not through your company. Refer to Interface Membership Information to a Third Party for more information.
- For a capital credit membership, the company periodically (maybe once a year) decides if credits should be redeemed (referred to as "retired") and if so, how much. The company runs a background process to calculate the "retirement" amount. When an amount is retired, the membership balance is reduced by the retirement amount and the amount is transferred to service agreements related to the membership. Refer to Capital Credit Retirement for more information.

> **Note**
>
> **Tracking Membership Balances**. If service credits are redeemed via the system, your membership should probably be configured to keep track of a balance. Refer to Event Amounts May Contribute to a Balance for more information.

Each service credit amount redeemed through the system is linked to the membership via a service credit event.

Service Agreements For a Membership

There are three types of service agreements that may be associated with a service credit membership. The following sections describe these types.



- SAs Contribute to the Membership
- SA Used for Miscellaneous Transactions
- Membership Fee SAs

SAs Contribute to the Membership

As described in how are service credits earned , many memberships are related to specific service agreements for the membership's accounts. We refer to these service agreements as the SAs that contribute to the membership because often the service credit amounts earned for the membership are based on amounts spent by the customer for these services.

Copyright © 2026, Oracle and/or its affiliates.

During the lifetime of a membership, service agreements that contribute to a membership may be stopped and other service agreements started. For example, perhaps you have a frequent flier membership that is related to electric service. Imagine that the customer starts out with a certain rate for electric service, but later decides to opt for a different type of rate that requires expiring the old service agreement and creating a new one. How does this affect your frequent flier mile calculation? It depends on how you design the algorithm that creates the frequent flier events. Essentially, the algorithm must cater for this situation. The following diagram illustrates the scenario.

The service agreements that contribute to a membership are not linked directly to the membership record. This would cause a maintenance burden, requiring links to be updated when service is stopped or started for applicable service agreements. Rather, this link is indirect. The list of service agreement types is defined for the membership type. The system can determine which service agreements are "linked" to the membership by looking at the SA types for the membership type.

NOT_SUPPORTED

Refer to Determine The Types of Service Agreements That Contribute to the Membership for more information on designing your membership type to include appropriate SA types.

SA Used for Miscellaneous Transactions

For some memberships, you may need to define a special service agreement to use for miscellaneous transactions. For example:

If events created for a membership cause an adjustment to be created to affect the general ledger, rather than allowing the system to arbitrarily pick a service agreement to use for this adjustment, the SA to use should be indicated on the membership. Refer to An Event May Cause Other Actions to Occur for more information.

Membership Fee SAs

For some memberships, a membership fee may be applicable. A special service agreement is used to hold the fee. This service agreement is not linked directly to the membership, but is simply a service agreement linked to one of the membership's accounts.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Some fees may be refundable.** The refunding of a fee must be handled by an algorithm. Refer to SAST-RF for information about the algorithm type provided with the base product.

Designing Your Service Credit Options

This section helps you to determine how to design your service credit membership types and service credit event types.

- Designing Your Membership Types
- Designing Your Service Credit Event Types
- How Are Service Credit Events Created?

Designing Your Membership Types

This section discusses the options to consider when designing your service credit membership types.

First consider the type of unit that your membership's service credit events represent.

- Is it related to a currency? If so, ensure that your currency is correctly defined on the currency page.
- Is it a non-currency unit, such as movies, points or miles? If so, you need to define the unit on the credit unit page.

Next, consider other behavior that your membership may exhibit.

- Should your membership calculate an overall balance ?
- Will miscellaneous financial transactions be created for you membership over its lifetime? If so you may need to link a service agreement to your membership.
- Should events linked to your membership reference a fiscal year ?

The table below illustrates three types of memberships: one for capital credits, one for frequent flier miles and one for free pay-per-view movies.

Membership Type	Description	Unit Type / Currency or Credit Unit	Has Balance?	Require SA?	Fiscal Year?
STDCAPCR	Standard capital credit membership	Currency / $	Yes	Yes	Yes
FFDELTA	Delta frequent flier miles	Credit Unit / Miles	No	No	No
FREEPPV	Free pay-per-view movies	Credit Unit / Movies	Yes	No	No

Copyright © 2026, Oracle and/or its affiliates.

The following points explain the settings for each membership above:

- The capital credit membership uses a currency of US dollars for its units. Over time, capital credits are allocated and retired. The overall balance of the credits and debits should be calculated and displayed for information purposes. It is common for the allocation and retirement of capital credits to affect the GL, and as a result, a membership SA is required for posting these financial effects. Finally, in a capital credit situation, the allocation is typically related to a specific fiscal year. When calculating and displaying balances, the balance for each fiscal year must also be available. As a result, the fiscal year must be set to required.
- For the frequent flier membership type, a separate membership type must be created for each different airline. This is because a separate membership must exist for each separate airline in order to keep track of the accumulated miles correctly. The membership type does not have a balance because the accumulated miles are interfaced to the airline and the airline keeps track of the balance. In this example, no SA is required because an assumption is being made that the creation of frequent flier miles does not affect the GL. (Accumulating miles is no liability or expense for the company. The miles are simply accumulated on behalf of a third party.) Finally, the frequent flier miles do not need to indicate a fiscal year.
- For the free pay-per-view movies membership, we assume that the credits are redeemed from within the system. For example, perhaps a calculation rule calculation algorithm or pre-processing calculation rule redeems the free pay-per-view movies over time as customers are billed for the movies. As a result, the membership should have a balance. In this example, no SA is required because an assumption is being made that any affect on the GL is posted at the time the free movies are redeemed (i.e., when calculating a bill). (This is just an example. It's possible that you may want to post to the GL when free movies are accumulated to mark a payable for the company.) Finally, free pay-per-view movies do not need to indicate a fiscal year.

More options must be considered for each membership type.

- Consider Whether the Membership Should Indicate Subcategories
- Determine the Types of Service Agreements Linked to the Membership
- Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership
- Determine Whether The Membership Requires Additional Information

Consider Whether the Membership Should Indicate Subcategories

For some types of memberships, the amount of each service credit event is further grouped by a subcategory. Refer to Events May Indicate a Subcategory for more information.

Use subcategories if multiple subtypes of credits may be accumulated and redeemed and if balances need to be tracked for each subcategory.

For our sample membership types, only the capital credits type should indicate subcategories.

Membership Type	Description	Subcategories
STDCAPCR	Standard capital credit membership	Distribution Transportation
FFDELTA	Delta frequent flier miles	
FREEPPV	Free pay-per-view movies	

Copyright © 2026, Oracle and/or its affiliates.

Determine the Types of Service Agreements Linked to the Membership

Memberships typically exist to reward customers for participating in standard service with the company. Refer to How Are Service Credits Earned? for more information. If memberships of this type are related to standard service for your company, determine the SA types for these service agreements.

> **Note**
>
> **Standard Service SA Types**. These service agreement types are probably different from the type of service agreement you may link as the membership SA. The membership SA is used for miscellaneous charges like general ledger posting. These SA types are related to electricity service, gas service, etc.

For our three examples, assume that the company provides electric service and cable. The capital credits are related only to electric service, frequent flier miles are accumulated for a combination of services, and free pay-per-view movies are related only to cable service.

Membership Type	Description	SA Types
STDCAPCR	Standard capital credit membership	E-RES (Electric Residential) AL-RES (Area Lighting)
FFDELTA	Delta frequent flier miles	E-RES (Electric Residential) AL-RES (Area Lighting) CABLE - RES (Cable Residential)
FREEPPV	Free pay-per-view movies	CABLE-RES (Cable Residential)

Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership

Should a letter or bill message be generated when a membership is created or activated? Should anything happen when a membership is inactivated? If so, you may need to define one or more algorithms to be plugged in on the membership type.

For our examples, let's say that a bill message is generated when a frequent flier or free pay-per-view membership is created. Let's say that a letter is generated when a capital credits membership is activated. We also assume that when a capital credits membership becomes inactive, any outstanding balance is redeemed. For the frequent flier miles and pay-per-view memberships, we assume nothing special occurs when the membership becomes inactive.

> **NOT_SUPPORTED**
>
> Refer to Lifecycle of a Membership for more information about the various status values for a membership.

Copyright © 2026, Oracle and/or its affiliates.

Membership Type	Description	Algorithm System Event	Algorithm
STDCAPCR	Standard capital credit membership	Membership Activation	Send Letter
		Membership Inactivation	Redeem Balances
FFDELTA	Delta frequent flier miles	Membership Creation	Generate Bill Message
FREEPPV	Free pay-per-view movies	Membership Creation	Generate Bill Message

> **Note**
>
> **Sample Algorithms**. The base package does not provide sample algorithms for all the above examples. Refer to Service Credit Membership Type - Algorithm for more information about the algorithms provided with the system.

Determine Whether The Membership Requires Additional Information

Is there any information about your membership that you need to capture that is not already provided by the base system logic? If the answer is yes, you may need to define characteristics for your membership. Use the characteristic collection on the membership type to define the types of characteristics allowed for memberships of this type. You may also define default values for you membership's characteristics.

Designing Your Service Credit Event Types

Now that you have designed your membership types, you need to design the types of service credit events that may be created for your membership.

In many cases, a credit event should cause additional functionality to occur. Algorithms are executed when an event is completed and when an event is canceled and are used to perform additional functionality. The following points illustrate possible algorithms that may be needed when a credit event is completed.

- Validate the event as compared to other events. For example, perhaps a new event should never cause the overall membership balance to fall below zero. You could use an algorithm on the service credit event type to check this condition.
- Create an adjustment that posts to the general ledger. Your credit event may not affect the customer's balance when created, but perhaps it should have an effect on the general ledger. For these types of credit events, you may need to create an adjustment to post to the GL.
- Create adjustments to affect the customer's balance. When "redeeming" a credit, you may need to transfer a monetary amount to one or more of the customer's service agreements.

Copyright © 2026, Oracle and/or its affiliates.

- Create a bill message. Perhaps when a credit is accumulated, you want to inform the customer via a message on the bill indicating the credit amount. A temporary bill message is added to one of the membership's accounts.

> **Note**
>
> **One Account Message of the Same Message Type**. The temporary bill message collection on the account allows only one bill message of the same bill message type. If it's possible for multiple types of events to be generated for the same account, consider creating a different bill message type for each event type.

- Stamp a batch code and batch run number onto the event. This would be used when your event information needs to be interfaced to an external system.

The following points illustrate possible algorithms that may be needed when a credit event is canceled.

- Validate the event as compared to other events. For example, perhaps canceling an event should never cause the overall membership balance to fall below zero.
- Cancel adjustments that may have been created when the event was completed.

To illustrate examples of when to use some of the algorithms above, we'll design event types for the membership types designed above.

- Designing Capital Credit Event Types
- Designing Frequent Flier Event Types
- Designing Pay-per-view Event Types

Designing Capital Credit Event Types

The following event types illustrate typical events for a capital credits membership.

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ALLOCATECCR	Capital credit allocation	STDCAPCR	Event Creation	Create Simple Adjustment
			Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments
RETIRECCR	Retire capital credit (apply to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Adjustments to Affect Customer's Balance
			Event Cancellation	Cancel Related Adjustments

Copyright © 2026, Oracle and/or its affiliates.

FORFEITCCR	Forfeit capital credit (retirement not applied to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Simple Adjustment (affect GL only)
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments

These event types assume the following:

- When credit events are allocated, the customer is notified via a bill message, the general ledger is affected so a simple GL only adjustment is created. If an event of this type is canceled, any adjustments that were created should be canceled. The event amount should always be positive, so checking that the membership balance does not fall below zero is only checked for event cancellation.
- When capital credits are retired, it's possible that the full membership balance is not applied to the customer's balance. For the portion of the retirement that does affect the customer's balance, you need an algorithm that applies the credits to the customer's service agreements via adjustments. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.
- For the portion of the retirement that is not applied to the customer's balance, the event amount should simply affect the GL so a GL only adjustment is created. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.

> **Note**
>
> **Service credit event types are independent of subcategories.** A capital credits membership typically uses subcategories. When events are created for different subcategories, the same service credit event type may be used. As a result, all subcategories use the same event completion and event cancellation algorithms.

Designing Frequent Flier Event Types

The following event types illustrate typical events for a frequent flier membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDMILES	Add miles to the membership	FFDELTA	Event Creation	Generate Bill Message
			Event Creation	Populate Batch Information

Copyright © 2026, Oracle and/or its affiliates.

			Event Cancellation	Event may not be canceled.

This event type assume the following:

- A new event should generate a bill message.
- Information about the event amount should be interfaced to an external system so batch information should be populated when the event is completed.
- Events of this type may not be canceled because the information is interfaced to an external system. Rather, to reverse an event, simply create a new event whose amount is a credit. This credit amount is also interfaced to an external system.

> **Note**
>
> **Sample Algorithm.** The system does not provide a sample cancellation algorithm that prevents the event from being canceled.

- There is no validation to ensure that the balance does not fall below zero. Recall that this membership was defined as not requiring a balance.

Notice that only one type of event has been defined for this membership. That is because the credits for this membership are not redeemed via this system. Rather they are accumulated on behalf of an external system.

Designing Pay-per-view Event Types

The following event types illustrate typical events for a free pay-per-view movies membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDPPV	Free pay-per-view movies	FREEPPV	Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
REDEEMPPV	Redeem pay-per-view movies	FREEPPV	Event Creation	Validate Balance Not < Zero
			Event Creation	Generate Bill Message

These event types assume the following:

- Any type of new event should generate a bill message.
- For adding free movies, it is assumed that the quantity is positive so when the event is cancelled, the algorithm verifies that the balance does not become negative.
- For redeeming free movies, it is assumed that the quantity is negative so when the event is completed, the algorithm verifies that the balance does not become negative.
- These events do not affect the general ledger and they do not directly affect the customer's balance so no adjustment algorithm is needed.

Copyright © 2026, Oracle and/or its affiliates.

How Are Service Credit Events Created?

Now that you have designed the behavior of your service credit events, an important issue is to determine how these events are created. Consider your business practice for each type of membership.

Let's use our sample memberships to work through different ways that you may create service credits.

- Service Credits for Capital Credit Memberships
- Service Credits for Frequent Flier Memberships
- Service Credits for Free Movies Memberships

Service Credits for Capital Credit Memberships

For a capital credit membership, capital credit allocations are calculated once a year based on billing history and the cost of service. To accomplish this, a background process calculates the amount and creates the service credits. Refer to allocating capital credits for a sample process provided with the base package.

Credits are redeemed via the retirement process. The company determines when to retire capital credits based on analysis of their financial situation. This retirement process is also handled by a background process. Refer to capital credit retirement for a process provided with the base package.

For capital credits memberships, special functionality is required when a member dies. The capital credits are considered part of the person's estate and may need to be retired and applied to a beneficiary's account. This process depends on the company's business practice. However, typically, the membership status would change to inactive so that new capital credit allocations are not created for the membership. The system provides a sample inactivation algorithm called SCMI-RB that transfers part or all of the outstanding credit balance to the member's service agreements. From there, a user can cut a check to the beneficiary.

> **Note**
>
> **Some Credits Are Never Retired**. For many cooperatives, some types of allocated credits are never retired. Refer to Partial Retirement for more information.

Service Credits for Frequent Flier Memberships

In our example, frequent flier miles were related to both the electricity and phone service. Let's assume that frequent flier miles are accumulated every $x spent on electricity and phone service. In this example, a bill completion algorithm creates service credits based on the bill segment amounts for these service agreements. Refer to Service Credits Earned Through Billing for more information.

Copyright © 2026, Oracle and/or its affiliates.

As mentioned before, the frequent flier miles are not redeemed using this system, but are interfaced to a third party for redemption.

Service Credits for Free Movies Memberships

> **Note**
>
> **Sample Algorithms**. No base package algorithm types are provided to support the logic described in this example.

In this scenario, let's suppose that a customer receives three free pay-per-view movies when signing up for new service. To handle this, perhaps an SA creation algorithm creates the membership and the service credits when the service is started. Or perhaps you want to wait until the first bill is generated and a bill completion algorithm is used to generate the first credit. It depends on your business practice.

For redeeming the free pay-per-view movies, it is assumed that the movies are credited during billing after it is determined that the customer has been billed for a movie. The number of movies used for the membership is reduced until all the free movies are used.

> **NOT_SUPPORTED**
>
> Refer to Service Credits Redeemed Through Billing for more information.

Setting Up Service Credit Options

- Setting Up Credit Units
- Setting Up SC Membership Inactive Reasons
- Setting Up Service Credit Membership Types
- Setting Up Service Credit Event Types

Setting Up Credit Units

Credit unit is used for service credit membership types whose events record non-monetary units. Open **Admin**, and then **Service Credit**, and then **Credit Unit** to set up credit units.

Description of Page

The following fields display for each credit unit:

Credit Unit The unique identifier of the credit unit.

Copyright © 2026, Oracle and/or its affiliates.

Description The description of the unit. This also acts as a label for the unit when displaying information about a service credit event.

Symbol / Label Position Indicates whether or not the label for this credit unit appears as a Prefix or as a Suffix to the service credit event amount.

Decimal Positions Indicates the number of decimal positions used for this credit unit. This information should be used by any algorithm or background process that creates a service credit event to determine how to store the event amount. It is also use to correctly display the service credit amounts.

Setting Up SC Membership Inactive Reasons

The service credit membership inactive reason must be specified when the status of a service credit membership changes to inactive. Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Inactive Reason** to set up service credit inactive reasons.

Description of Page

The following fields display for each inactive reason:

Inactive Reason The unique identifier of the service credit membership inactive reason.

Description The description of the inactive reason.

Setting Up Service Credit Membership Types

- SC Membership Type - Main
- SC Membership Type - Algorithm
- SC Membership Type - Characteristics

SC Membership Type - Main

Service credit memberships have a membership type. Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Add** to define the membership type.

Description of Page

Enter a unique **Service Credit Membership Type** and **Description** for each membership type.

Use the **SA Requirement** flag to indicate whether a miscellaneous SA must be linked to memberships of this type. The possible values are SA Required and SA Not Allowed .

> **Note**
>
> The value defaults to SA Required.

Copyright © 2026, Oracle and/or its affiliates.

Use the **Fiscal Year Requirement** flag to indicate whether events linked to memberships of this type should indicate a fiscal year. The possible values are Fiscal Year Required and Fiscal Year Not Allowed.

> **Note**
>
> **Default Note**. The value defaults to Fiscal Year Not Allowed.

Use the **SCM Event Balance** flag to indicate whether or not a balance of service credit events linked to memberships of this type should be calculated and displayed. The possible values are Has a Balance and No Balance.

> **Note**
>
> **Default Note**. The value defaults to Has a Balance.

Use the **SC Membership Type Unit** flag to indicate whether or not the unit for the event amounts for events linked to memberships of this type is Currency or Credit Unit. When the unit is currency, indicate the **Currency Code**. When the unit is credit unit, indicate the **Credit Unit**.

If events linked to memberships of this type must indicate a subcategory, enter a valid **Subcategory Name** and **Description** for each subcategory applicable to this membership.

> **NOT_SUPPORTED**
>
> Refer to Events May Indicate a Subcategory for more information.

Use the **SA Types** grid to indicate the types of service agreements that contribute to memberships of this type. Indicate the **CIS Division** and **SA Type** for each type of service agreement that is related to a membership of this type.

SC Membership Type - Algorithm

Open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Search** and navigate to the **Algorithm** page to define any algorithms that are associated with a membership type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

Copyright © 2026, Oracle and/or its affiliates.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Membership Creation	Optional	Use this system event for algorithms that are executed when a membership is created.

Copyright © 2026, Oracle and/or its affiliates.

Membership Activation	Optional	Use this system event for algorithms that are executed when a membership becomes active.

> **Note**
>
> **Creating Memberships In Active Status**. A membership may be created in either pending status or in active status, based on your business practice. For memberships created in active status, the system executes the

Copyright © 2026, Oracle and/or its affiliates.

		membership creation algorithms and the membership activation algorithms.
Membership Inactivation	Optional	Use a system event of Membership Inactivation for algorithms that are executed when a membership becomes inactive .

SC Membership Type - Characteristics

To define characteristics that can be defined for service credit memberships of a given type, open **Admin**, and then **Service Credit**, and then **Service Credit Membership Type**, and then **Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define characteristics that can be defined for service credit memberships of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on service credit memberships of a given type. Turn on the **Default** switch to default the **Characteristic Type** when service credit memberships of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Service Credit Event Types

Service credit events created for a service credit membership have an event type. Open **Admin**, and then **Service Credit Event Type**, and then **Add** to set up service credit event types.

Description of Page

Enter a unique **Service Credit Event Type** and **Description** for each event type.

Indicate the **Service Credit Membership Type** to which this event type belongs.

Copyright © 2026, Oracle and/or its affiliates.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Event Completion	Optional	Use a system event of Event Completion for algorithms that are executed when an event is completed. Refer to An Event May Cause Other Actions to Occur for more information.
Event Cancellation	Optional	Use this system event for algorithms that are executed when an event is canceled.

Service Credit Examples

In this section, we provide examples of how to define your control tables to support functionality related to different types of service credit memberships. While your company may not define your environment exactly the same way, this section should help solidify your understanding of how to set up your company's service credit options.

- Defining Control Tables for a Refundable Fee
- Defining Control Tables for a Nonrefundable Fee
- Defining an SA Type for Miscellaneous Transactions
- Using Campaigns/Packages to Set Up Membership
- Defining Another Person for Your Account
- Service Credits Earned When Starting Service
- Service Credits Earned Through Billing
- Service Credits Redeemed Through Billing
- Designing Your Rate Options for Capital Credits
- Partial Retirement
- Interface Membership Information to a Third Party

Defining Control Tables for a Refundable Fee

If your membership requires payment of a fee that is refundable, you must define an SA type to use for the refundable fee.

- Adjustment Type for Refundable Fee

Copyright © 2026, Oracle and/or its affiliates.

- SA Type for Refundable Fee
- Start Option for Refundable Fee
- Algorithm for Refunding the Fee

Adjustment Type for Refundable Fee

This example assumes that the fee is set up similarly to a deposit. The adjustment used to charge the fee would affect the current balance, but not the payoff balance or the general ledger because the fee is not considered a "receivable", rather it is an amount collected and held for the customer.

Create an adjustment type for levying the fee. Indicate the fee amount and indicate the ADJT-CA adjustment FT creation algorithm, which affects the current balance, but not the payoff balance or the general ledger.

> **Note**
>
> **Adjustment Type Profiles**. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Refundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which should cause the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Refundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

> **NOT_SUPPORTED**
>
> Refer to Including The Membership Fee on campaigns and packages for more information about levying the fee via the order transaction.

Algorithm for Refunding the Fee

Copyright © 2026, Oracle and/or its affiliates.

The base product provides an algorithm type SAST-RF that refunds a fee when service agreements that contribute to the membership are stopped. You must create an algorithm for this algorithm type and enter the SA type created above as an input parameter.

This SA stop algorithm must be plugged in on all SA types that you defined for the membership type.

Defining Control Tables for a Nonrefundable Fee

If your membership requires payment of a fee that is not refundable, you can set this up in two ways:

- You can create a special SA type to handle charging the fee. For this SA type, define a start option that causes an adjustment to be levied as part of the start service process. This adjustment contains your fee. You may use this option if the membership is related to multiple types of services and not all services need to be present in order to create the membership.
- You can levy an adjustment on one of the other service agreements that is being started. To do this, you would use a start option to define an adjustment to be levied as part of the start service process. You may use this option if the membership is related to a single service (for example, free pay-per-view movies).

For our example, we will set up the SA for the nonrefundable fee with a separate 'fee' SA type.

- Adjustment Type for Nonrefundable Fee
- SA Type for Nonrefundable Fee
- Start Option for Nonrefundable Fee

Adjustment Type for Nonrefundable Fee

Create an adjustment type for levying the fee. Indicate the fee amount and indicate the ADJT-NM adjustment FT creation algorithm, which affects the current balance and payoff balance by the adjustment amount, and affects the general ledger.

> **Note**
>
> **Adjustment Type Profiles**. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Nonrefundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the

Copyright © 2026, Oracle and/or its affiliates.

payment amount, which causes the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Nonrefundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

> **NOT_SUPPORTED**
>
> Refer to Including The Membership Fee on campaigns and packages for more information about levying the fee via the order transaction.

Defining an SA Type for Miscellaneous Transactions

Does your membership require a service agreement to support miscellaneous transactions? If so, you need to consider the SA type to use for this service agreement. This SA type should be marked as not billable.

If you choose to use the order transaction to set up the membership, this SA type must be defined on the algorithm that creates the membership.

It is possible that you may require a start option for this SA type, for example if you want to define a characteristic for service agreements of this type.

Using Campaigns/Packages to Set Up Membership

If enrollment in a membership is a common occurrence for your customers when starting service, you should consider using the order page to start service for the customer and to create the membership as well.

> **Note**
>
> This section only makes sense if you are familiar with the Sales and Marketing chapter.

The recommendation is to use a question/miscellaneous field to ask the customer service representative to indicate the appropriate membership type. Algorithms validate this membership type and use it to create a membership of that type.

This section walks you through how to set up the campaign / package required to support this.

- Column Reference for Membership Type
- Algorithms to Create Membership via Order
- Define a Campaign for Creating a Membership When Starting Service

Copyright © 2026, Oracle and/or its affiliates.

- Including the Membership Fee

Column Reference for Membership Type

In order to ask the customer service representative to define an appropriate service credit membership type, you must define a column reference for the membership type.

Add a new column reference with the following information:

- Column Reference: SCM-TYPE
- Description: SC Membership Type
- FK Reference: SCM TYPE
- Long Description: Service Credit membership type to use when creating a service credit membership at start time.

> **Note**
>
> **Column Reference Algorithms**. This column reference indicates a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information.

Algorithms to Create Membership via Order

The base product provides two algorithm types to support the creation of a membership record via the order page: a validation algorithm type and a posting algorithm type.

Validate Membership Information

This algorithm is a column reference validation algorithm that checks that an input membership type is valid. Refer to CRVL-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: VAL MEM TYPE
- Description: Validate SC Membership Type
- Algorithm Type: CRVL-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE

Post Membership Information

This algorithm is a column reference posting algorithm that creates a membership using the membership type indicated by the user. Refer to CRPS-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: CREATE MEMBRSHP
- Description: Validate SC Membership Type
- Algorithm Type: CRPS-ME

Copyright © 2026, Oracle and/or its affiliates.

- Parameter1: (Column Reference for Membership Type): SCM-TYPE
- Parameter2: (Service Credit Membership Status): 10 -Pending or 20 -Active. Refer to Lifecycle of a Membership for more information.
- Parameters3-5: (Division, SA Type, Start Option): Indicate the information needed to create an SA for miscellaneous transactions.

> **Note**
>
> This algorithm first looks for an existing service agreement of this division / SA type linked to the membership's accounts. If one exists, it uses that SA to link to the membership. If an SA does not exist, it creates one with the input division, SA and (optional) start option.
>
> **Update the Column Reference.** Now that you have defined the validation and posting algorithms, return to your column reference for membership type and define the algorithms there.

Although your company may support multiple types of memberships, this column reference and its algorithms have been designed such that only one column reference for membership type would be needed to set up any type of membership. Although the posting algorithm for the membership type column reference indicates an SA type to use for miscellaneous transactions, a service agreement is only created and linked if your membership type indicates that an SA is required. As a result, you may use the same column reference for both memberships that require an SA and those that don't require an SA. However, if you have different membership types that require an SA and each uses a different SA type or a different start option for the membership SA, you need to define more than one posting algorithm and, as a result, more than one column reference.

Define a Campaign for Creating a Membership When Starting Service

Many factors must be considered when designing your campaigns and packages. The possible creation of a membership when using the order page is simply another factor to consider.

If you plan to define a question/miscellaneous field to capture a service credit membership type, the available packages linked to the campaign should be ones that are related to memberships. For example, if your membership is related to electric service, it doesn't make sense to create a membership for a campaign designed to generate a one-time charge.

When defining a question/miscellaneous field, you must indicate its applicability. Consider whether a membership type is required, optional or only applicable for certain packages. This helps ensure that your users capture this information when appropriate.

Including the Membership Fee

You must determine the best way to setup your campaign/package to handle the levying of your membership fee, if applicable. Consider some of the following questions.

- If the membership has a fee, is it a refundable fee or a non-refundable fee?

Copyright © 2026, Oracle and/or its affiliates.

- Is the fee always applicable for the membership? Or is it waived under certain conditions? For example, maybe the fee is applicable if a customer signs up for a single service, but the fee is waived if the customer signs up for two or more services.

The SCM type column reference and question/miscellaneous field are set up to ask the user what type of membership to create. Because the applicability of the fee may differ for each membership type, you should carefully consider the campaign / package setup to levy the fee correctly.

- If a fee is always applicable for a membership, you may consider creating a membership creation algorithm that creates a fee SA with a start option to levy the fee when the membership is created.

> **Note**
>
> **Sample Algorithm**. The base product does not provide a membership creation algorithm to do this.

- If the fee is not always applicable for a membership, you must determine when the fee is applicable. The recommendation is to include the fee SA type in the SAs-to-create collection for the appropriate package. For example,
  - If the fee is applicable when the customer signs up for a single service, you should define a package for each single service that includes one SA to create for the single service and the fee SA as another SA to create.
  - If the fee is waived when the customer signs up for two or more services, you should define a package for each combination of the multiple services. These packages do not include the fee SA in the SAs to create.
- If the customer signing up for service is a former customer who has returned, perhaps the fee was paid earlier when the customer originally had service. In this case, maybe your business practice is to waive the fee at this time. To do this, you should set up a question/ miscellaneous field for the user to mark that this is a returning customer. Based on the answer to this question, perhaps only packages that do not levy any fee are eligible for selection.

Defining Another Person for Your Account

It is common for a capital credit membership to define more than one person for the account being turned on and linked to a membership. A typical example is a married couple. Both spouses are indicated on the account and financially responsible persons and as a result, both are considered members.

Column reference algorithms have been provided by the base product to enable linking a second person to your account via the order page.

This section walks you through how to set up the column reference and campaign to support this.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Linking A Second Person to the Account.** This logic is not restricted to service credit functionality. Any campaign may be designed to include the ability to link a second person to the account being started.

- Column References for Additional Person
- Algorithms to Link Additional Person via Order
- Design a Campaign to Include Linking an Additional Person

Column References for Additional Person

In order to ask the customer service representative to link an additional person for the account, you must define several column references to use as questions/miscellaneous fields.

- We should assume that the person may already exist in the database. As a result, a question to record the person ID is needed.
- If the person does not already exist, the user should capture the person's name, an ID type and an ID number. Questions for these three fields are needed. The system uses this information to create a new person.
- Whether we are using an existing person or creating a new one, the person's link to the account must include an account relationship type. A question to record the account relationship type is needed.

Add a new column reference for person ID:

- Column Reference: PERSON-ID
- Description: Person ID
- FK Reference: PER
- Long Description: Person ID of the additional person to link to the order's account.

Add a new column reference for person name:

- Column Reference: PERSON-NAME
- Description: Person Name
- FK Reference: not applicable
- Long Description: Name of a new person to create.

Add a new column reference for identifier type:

- Column Reference: PER-ID-TYPE
- Description: Person Identifier Type
- FK Reference: ID TYPE
- Long Description: Person Identifier type for the primary ID of the additional person to link to the order's account.

Add a new column reference for identifier number:

- Column Reference: PER-ID-NUM

Copyright © 2026, Oracle and/or its affiliates.

- Description: Person ID Number
- FK Reference: not applicable
- Long Description: Identifier number for the primary ID of the additional person to link to the order's account.

Add a new column reference for account relationship type:

- Column Reference: ACCT-REL-TYPE
- Description: Account Relationship Type
- FK Reference: ACCT REL
- Long Description: Relationship type to use for the link between the additional person and the order's account.

> **Note**
>
> **Column Reference Algorithms**. One of the column references above must indicate a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information. We recommend using the account relationship type record because that is used for all additional persons.

Algorithms to Link Additional Person via Order

The base product has provided two algorithm types to support the linking of an additional person to the account via the order page: a validation algorithm type and a posting algorithm type.

Validate Addition Person Information

This algorithm is a column reference validation algorithm which checks that either a person id or person name, a valid ID type and ID number are provided and that a valid account relationship type is provided. Refer to CRVL-PE for more information. You must define an appropriate algorithm for this algorithm type and on that algorithm you must define the column reference used for the five fields required for this validation. For example:

- Algorithm: VAL ADD PER
- Description: Validate Additional Person Info
- Algorithm Type: CRVL-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

Post Addition Person

This algorithm is a column reference posting algorithm that may link an existing person to the order's account or create a new person and link that person to the order's account. Refer to CRPS-PE for more information. You must define an appropriate algorithm for this algorithm

Copyright © 2026, Oracle and/or its affiliates.

type, and on that algorithm you must define the column reference used for the five fields required for this logic. For example:

- Algorithm: LINK ADDNTL PER
- Description: Link additional person to order's account
- Algorithm Type: CRPS-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

> **Note**
>
> **Update the Column Reference.** Now that you have defined the validation and posting algorithms, return to your column reference for account relationship type and define the algorithms there.

Design a Campaign to Include Linking an Additional Person

Any campaign related to a specific account may include the questions and miscellaneous fields defined here to create/link an additional person to the account.

Simply create entries in the questions and miscellaneous fields collection to prompt the user to ask for the required information. A question should exist for each column reference created above. The following table illustrates a possible setup.

Seq	Description	Prompt on Order	Column Reference	Dependency
10	Account relationship type for additional person.	If you would like to link another person to this account, please enter an account relationship type.	ACCT-REL-TYPE	Must have account
20	Person ID for additional person	If the additional person already exists in the database, enter the person id.	PERSON-ID	Must have account
30	Person name for additional person	If you would like to create a new person, please enter the person name.	PERSON-NAME	Must have account
40	ID type for additional person	Please enter the ID type of the new person.	PER-ID-TYPE	Must have account

Copyright © 2026, Oracle and/or its affiliates.

50	ID Number for additional person	Please enter the ID number of the additional person.	PER-ID-NUM	Must have account

Service Credits Earned When Starting Service

For some memberships, you may want to add service credits when starting the program. For example, the customer gets three free pay-per-view movies when signing on for cable service. Or a customer receives 500 frequent flier miles for signing up for a combination of gas and electric service.

There are various ways that you can accomplish this. You should work with your implementers to consider the various options to determine the method that best suits your business practice.

- You could use an SA activation algorithm to create a membership and an event for the initial points. Use this method if the points are related to a single type of service agreement and the points are earned automatically when starting service (i.e., without any human decision to be made).
- You could use a membership creation or membership activation algorithm to generate a service credit event automatically. This method assumes that the decision to create the membership has been made and that the free initial points are always earned for this type of membership (i.e., regardless of the type of service created).
- You could use questions and miscellaneous fields for a campaign/package to determine a customer's eligibility for participation in the membership and for the initial free points. A column reference posting algorithm could create the membership and/or the service credit event for the free points based on the answers to the questions.
- Perhaps the initial free points are only earned after the first bill is generated. Use a bill completion algorithm to generate the initial points.

You may think of other plug-in spots that could be used to generate free initial points based on your business needs.

Service Credits Earned Through Billing

For some memberships, you may accumulate points as a result of billed amounts for other services. For example, perhaps your customers earn one frequent flier mile for every $10 spent on the combined electricity, gas and water bills each month.

To accomplish this, you must design an algorithm to be executed at billing time. There are various plug-in spots executed at billing time that you may use, but the recommended plug-in is a post completion algorithm on the customer class. This plug-in is executed after all bill segments are frozen and most of the completion logic has occurred.

Your algorithm should determine the service agreements that contribute to the membership and calculate the service credit amount for those service agreements bill segments.

This algorithm should also consider what to do when bill segments that contributed to the event are canceled. The algorithm provide with the base product CBCM-SC checks to see if any canceled bill segments are referenced on any previous events. If so, it includes the canceled amount on the new event. This may cause the new event to be a negative amount. The assumption is that over time, earned credits will compensate for the negative event amount.

Copyright © 2026, Oracle and/or its affiliates.

For a membership that interfaces information to a third party, it is assumed that the negative event amount is also interfaced.

Service Credits Redeemed Through Billing

For some memberships, your customer may redeem their earned points by receiving a discount on their bill. For example, if your cable customer has earned one free pay-per-view movie, you can give them a credit the next time they get billed for a pay-per-view movie.

The base product has not provided any algorithms to credit a bill based on earned service credits. This section will identify considerations your implementers should follow when designing algorithms to redeem service credits through billing.

The recommendation is to credit the customer's bill by generating an adjustment using a pre-bill completion algorithm. This algorithm's responsibilities are as follows:

- Determine if the appropriate bill segment(s) contain the charges that need to be credited. For example, if the service credit is for a free pay-per-view movie, determine if the customer has been billed for a pay-per-view movie.
- Determine if the customer's current service credit balance for this program. For example, how many free pay-per-view movie credits are left?
- Create an adjustment to credit the appropriate service agreement by the eligible credit amount.
- Update the service credit membership balance by creating a new SC event with a credit for the number of points redeemed. Link the adjustment to the event as a contributed to FT.
- Consider cancel/rebill situations. If a cancel/rebill has occurred, determine if there is a change to the redeemed credits. For example, if the original bill had one pay-per-view movie that was credited and the new bill also has one pay-per-view movie, no change is needed to the service credit balance. If the original bill had more pay-per-view movies than the new bill, perhaps one or more redeemed service credit points should be reinstated. If the original bill had fewer pay-per-view movies than the new bill, perhaps more points should be redeemed.

You may wonder why we don't recommend crediting the customer's bill while generating the bill segment. For example, use pre-processing calculation rule to determine if any points should be redeemed and use a calculation rule to generate a bill calculation line with the credit amount.

The reason for this is that cancel/rebill logic is not straightforward. Algorithms executed during rate application should NOT perform any updates, such as updating the service credit membership balance. The balance should be updated using a bill segment freeze algorithm or a bill completion algorithm.

When a cancellation occurs, the service credit balance should be updated to reinstate the redeemed points. Again, this should occur when the cancellation is frozen or at bill completion time. If you perform a cancel/rebill, the calculation of the rebill segment does not have the up-to-date information about the service credit balance because the reinstatement of the points by the canceled segment has not occurred yet.

Designing Your Rate Options for Capital Credits

The capital credit allocation background process relies on certain data configuration in order to function correctly. This section identifies the required data setup.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Allocating Capital Credits for more information.

- Identifying SQ and Sales Information for Historical Bill Segments
- Designing Bill Factors for Credit Allocation

Identifying SQ and Sales Information for Historical Bill Segments

To allocate capital credits, the background process retrieves billing history for each SA that contributes to the membership for the given fiscal year. The process needs to calculate the service quantity (SQ) amount billed and the sales amount billed for the SA in that year.

Note

Sales Amount. The sales amount refers to the monetary amount billed. For a capital credit allocation, this amount would generally exclude taxes and may exclude other line item amounts from the bill.

In order to calculate the amounts correctly, the background process must determine which bill calculation lines for each bill segment contain the SQ and/or sales information. Characteristics on the bill calculation lines identify which bill lines should be used.

The rest of this section uses examples to illustrate how you may configure your rate options to support this.

- Define Characteristics for SQ and Sales
- Define Calculation Rules
- Define Batch Control Parameters

Define Characteristics for SQ and Sales

Char Type for identifying bill lines that hold **SQ information**

- Char Type: CCA-SQ
- Description: Capital credit allocation usage
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Char Type for identifying bill lines that hold **sales information**

- Char Type: CCA-SALES
- Description: Capital credit allocation sales
- Type of Char: Pre-defined

Copyright © 2026, Oracle and/or its affiliates.

- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Define Calculation Rules

Identify each rate schedule that may be linked to a service agreement that contributes to a capital credit membership.

For each of these rate schedules, identify the calculation rules whose resulting bill calculation line will contain a billable service quantity that should be included in the SQ calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SQ char type (defined above) and a char value of Y.

For each rate schedule, identify the calculation rules whose resulting bill calculation line amount should be included in the sales calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SALES char type (defined above) and a char value of Y.

> **Note**
>
> **Characteristic Information**. The system automatically copies characteristic info from a calculation rule to its resulting bill calculation line if the char type entities include both calculation rule and bill calc line.

Define Batch Control Parameters

The background process to allocate capital credits CPCRALOC receives the char type and char value to identify the bill calculation lines that contain the SQ and sales amounts. Once you have your characteristics defined, update your batch control to include these values as default parameter values.

Designing Bill Factors for Credit Allocation

The capital credit allocation process uses an allocation factor in its calculation. A typical capital credit membership may define multiple subcategories, meaning that allocation amounts are calculated each year for the multiple subcategories. The calculation is the same for each subcategory, but the allocation factor differs.

The process has been designed to calculate the allocation for a single subcategory. If your organization requires allocations calculated for multiple subcategories, the process must be run for each subcategory. The allocation process receives a bill factor as an input parameter. As a result, a different bill factor should be set up to define the allocation factor for each subcategory.

For each subcategory, the allocation factor may differ further for the type of customer. For example, the allocation for a commercial customer may differ from the allocation factor for a residential customer. The allocation background process expects the bill factor for each subcategory to define a characteristic type of revenue class. The process determines each service agreement's revenue class by looking at the value defined on its SA type.

Copyright © 2026, Oracle and/or its affiliates.

Following is an example of bill factors set up for a capital credit membership with two subcategories: transportation and generation.

- Characteristic Type for Allocation Bill Factor
- Bill Factor for Transportation
- Bill Factor for Generation

Characteristic Type for Allocation Bill Factor

Char Type: REV-CLASS

Description: Revenue Class

Type of Char: Pre-defined

Values: (define all the valid revenue class values)

Char Entity: Bill Factor

Bill Factor for Transportation

Bill Factor Id: CCAF-TRANS

Description: Transportation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new transportation allocation factor for each revenue class must be defined)

Bill Factor for Generation

Bill Factor Id: CCAF-GEN

Description: Generation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new generation allocation factor for each revenue class must be defined)

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The characteristic source is characteristic collection.** It is the responsibility of the background process to determine the SA's revenue class and to pass this value into the bill factor routines to retrieve the correct bill factor value.
>
> **Estimating Allocation Factors**. Often the company needs to estimate the allocation factors for the new fiscal year and may adjust the values several times until the calculated allocation amounts are satisfactory. Refer to Allocating Capital Credit for more information.

Partial Retirement

In the cooperative business, it is common to never retire certain capital credit allocation amounts. The amounts that do not retire should be assigned their own subcategory.

When executing the retirement background process, the subcategory to retire may be input to the process. If you have certain subcategories that you do not retire, you would simply run the background process for the subcategories that do retire.

Cooperatives typically retire amounts and transfer the amounts to a beneficiary when a member dies. This is known as "estate retirement". Refer to Service Credits for Capital Credit Memberships for more information. If your business practice designates that certain subcategories of allocated amounts do not get retired, this probably holds true for estate retirement as well. If that is the case, your membership inactivation algorithm should be designed to only retire the appropriate amounts by subcategory.

Interface Membership Information to a Third Party

For some memberships, you may accumulate points for a third party, for example accumulating frequent flier miles for an airline. For these types of memberships, you must interface the event information to the third party.

To interface information to a third party, you may choose one of the following options:

- Design an extract program to interface the information
- Use workflow and notification to interface the information via the XAI tool
- Interface Via an Extract Program
- Other Considerations For Interfacing Info to a Third Party

Interface Via an Extract Program

The service credit event may indicate a batch code and batch run number. Design a program to extract event information to a third party. This extract program would select service credit events marked with its batch code and the current run number.

Copyright © 2026, Oracle and/or its affiliates.

Your service credit event must define a completion algorithm that stamps the appropriate batch code and run number. The base product provides an algorithm type to perform this logic. Refer to SCEC-BT for more information.

Other Considerations For Interfacing Info to a Third Party

Because event information is extracted to a third party, you must consider how to handle adjustments to the event amount. For example, if your event is generated based on the creation of a bill segment, what should happen if that bill segment is cancelled?

You may want to prevent these types of events from getting canceled. Validation like this may be added via a user exit or using an event cancellation algorithm.

> **Note**
>
> **Sample Algorithms**. The product does not provide any base algorithms to prevent an event from being canceled.

You should allow negative event amounts to be created so that this information may also be sent to the third party's system.

Defining Loan Options

The topics in this section describe how to set up the system to enable loan functionality.

> **Note**
>
> **Loans are optional.** The system configuration requirements described in this section are only relevant if your organization loans money to customers.

- The Terms Of A Loan Are Stored On A Service Agreement
- Payoff Balance and Current Balance for Loans
- Booking The Principal Amount Using An Adjustment
- Loan Amortization Schedule Calculation
- Billing For Loans And Interest Calculation
- Paying What Is Owed
- Overpayments On Loans
- Adjusting Loan Amounts
- Writing Off Loans
- Distribution Codes for Loans
- Setting Up The System To Enable Loans

Copyright © 2026, Oracle and/or its affiliates.

The Terms Of A Loan Are Stored On A Service Agreement

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA Type) contains the loan's terms:

- The **loan amount** is held in the service agreement's Total Amount to Bill.
- The **customer's periodic payment amount** is held in the service agreement's Recurring Charge Amount.
- The **number of amortization periods** (e.g., 36 months, 240 months, etc.) is held in the service agreement's Number of Payment Periods.
- If the **interest rate** is the same for all customers with this type of loan service agreement, the interest rate is defined on the service agreement's SA type (using a bill factor). A specific interest rate can be defaulted from a start option contract value. If a specific interest rate applies to the customer, the SA type's interest rate can be overridden by specifying a bill factor value on the customer's service agreement (where the bill factor value contains the specific interest rate for the customer).
- The SA type controls the **periodicity of the bills** (e.g., monthly or bi-weekly).

Because a loan is defined using a service agreement, the typical functionality that is controlled by the service agreement's SA type is supported, including:

- How and when it is billed.
- How payments are booked in the GL (and the payment priority relative to other service agreements).
- How its debt is monitored by credit and collections.
- How late payment charges are calculated.

Loan service agreements are created using Start/Stop just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

> **Note**
>
> **Automatic calculation of periodic payment amount / number of periods.** The system calculates a loan's periodic payment amount or number of payments (whichever is left blank). You can have the system do this on Start/Stop Maintenance (using the **Calculate** button that appears on the start service confirmation window), and on Loan - Main (by clicking the **Calculate** button). Regardless of where you do this, the calculation is performed by an algorithm on the loan's SA type. Refer to the LPDA-SI algorithm type for more information about the base package algorithm.

Payoff Balance and Current Balance for Loans

As described under Current Amount versus Payoff Amount, a loan service agreement's current balance and payoff balance differ during the lifetime of the loan. Current balance contains how

Copyright © 2026, Oracle and/or its affiliates.

much the customer owes to remain current (typically their periodic payment amount), and payoff balance contains the amount the customer would have to pay to payoff the loan (typically the principal balance plus any accrued interest charges).

Unlike other SAs, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). The current balance for a loan is always the amount of the short-term receivables. The payoff balance for a loan is always the net of the short-term receivables and the long-term receivables.

If the SA has a special role of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. For example, when a bill segment is generated for the loan SA, the amount of the periodic payment is transferred from the long-term receivables to the short-term receivables. Don't worry, the examples in the following sections show exactly what these transactions look like.

An operator can see the how the bills, payments and adjustments have affected the GL, current balance and payoff balance using SA Financial History.

The following sections provide examples of how adjustments, bills and payments are recorded in the GL and the subsequent effect on the current and payoff balances. When reading the examples, remember that the payoff balance is always the net of the short-term receivable and the long-term receivable balances.

Booking The Principal Amount Using An Adjustment

When a loan service agreement is activated (i.e., when its status changes from pending start to active), an adjustment is created to book the principal amount. If the customer takes out a loan of 10,000, the adjustment's financial transaction looks as follows:

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated (and an adjustment is created to book the principal)	Long Term Loan Receivable 10,000 Cash <10,000>	0	10,000	0	10,000

This adjustment is issued if:

- The service agreement's SA type indicates a special role of Loan.
- The loan service agreement's Total Amount to Bill contains an amount (i.e., the loan amount).
- The loan service agreement was created using a start option on Start/Stop Maintenance AND the start option references an adjustment type and this adjustment type has been set up as follows:
  - The adjustment type's distribution code should reference the GL account to credit (e.g., Cash).

Copyright © 2026, Oracle and/or its affiliates.

– The adjustment type's FT algorithm reference Payoff Amt = Adj Amt / Current Amt = 0 (booking principal only impacts a customer's payoff balance).

Note that because this financial transaction doesn't have a current amount (the customer doesn't actually owe a current amount yet), there is no need to book anything to the short-term receivables distribution code.

Loan Amortization Schedule Calculation

The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

A loan's amortization schedule is calculated when an operator clicks the **Calculate** button on Loan - Main . Please be aware that when this button is clicked, an algorithm plugged in on the loan SA type actually calculates the amortization schedule (refer to the algorithm type LSCH-SI for more information).

Billing For Loans And Interest Calculation

A bill segment is produced for a loan when its service agreement's account is next billed.

Factors on a loan's SA type controls when a bill segment is produced for a loan. Typically SA types for loan service agreements are set up to use anniversary calendar billing. For this configuration:

- You must indicate the type of anniversary billing in the calendar billing option. Currently, we only support the Anniversary Future Billing (meaning that loans are billed in advance just like a classic home loan is). Refer to Using The Anniversary Method for more information about how this billing method controls the end date of the loan bill segment.
- You must reference an anniversary billing frequency consistent with the recurring charge frequency (e.g., monthly, quarterly, etc.).

To set up for a loan that is billed on a monthly basis, you would define the following fields in SA Type - Billing:

- **Use Calendar Billing**: Anniversary Future Billing
- **Anniversary Bill Frequency**: Monthly
- **Total Bill Amount**: Required
- **Recurring Charge**: Required
- **Recurring Charge Frequency**: Monthly
- **Total Amount To Bill Label**: Loan Amount
- **Recurring Chg Amt Label**: Payment Amount

If your type of loan must be billed on an exact date (for example, always on the 15th of the month) or with an exact number of days between each bill (for example, every 14 days), then your loan should be set up to use the calendar billing option of Use Bill Period. In order for your loan bills to be created on specific dates, the system makes the following assumptions:

- Your bill cycle schedule for the loan's account is defined with the dates that you want the loan to bill and is defined with the window start date equal to the window end date.

Copyright © 2026, Oracle and/or its affiliates.

- You define a bill period schedule corresponding to your bill cycle schedule. Each bill period schedule's bill date should match your bill cycle window start date and each bill period schedule's bill segment end date should be set to the loan period end date.
- Considerations for the first bill. If the loan SA Type's Initial Start Date Option indicates that the first day of the service agreement should be billed, then the loan SA's start date should match the window start date of the next bill cycle schedule for the account. If the loan SA Type's Initial Start Date Option indicates that first day of the service agreement should not be included, then the loan SA's start date should be one day prior to the window start date of the next bill cycle schedule for the account.
- Define your recurring charge frequency to match the frequency of your bill periods.

How the bill segment affects the customer's balance, and how it affects the general ledger are controlled by several algorithms defined on the loan service agreement's SA type and bill segment type:

- The SA type's loan schedule algorithm controls how the loan amortization schedule is calculated.
- The SA type's loan interest charge algorithm controls how interest is calculated.
- The bill segment type's create algorithm controls how the bill lines are constructed.
- The bill segment type's financial algorithm controls how the general ledger is affected by the bill.

The second entry in the following table contains an example of the financial transaction produced by the base package algorithms (note, the first financial transaction in the table was described under Booking The Principal Amount Using An Adjustment).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000
First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95

Several important points are illustrated above:

Copyright © 2026, Oracle and/or its affiliates.

- When a bill segment is produced for a loan service agreement, the following takes place (if you use a bill segment creation algorithm of Create Bill Segment for Loans):
  - The loan SA type's bill segment creation algorithm calls the SA type's loan interest charge algorithm.
  - The base package loan interest charge algorithm calculates simple interest based on: 1) unbilled principal (i.e., the service agreement's payoff balance minus the current balance), 2) the number of billing periods covered by the bill, and 3) the interest rate. Refer to the algorithm type LINT-SI for more information about the base package interest calculation algorithm.

> **Note**
>
> **No interest on interest and no interest on past due amounts.** Just like a classic home loan, the base package algorithms do not calculate interest on interest, nor do they calculate interest on past due amounts. If you want to levy a late payment charge, use the SA type's late payment processing. If your organization calculates interest differently, you must develop your own algorithm(s).

- The SA type's bill segment creation algorithm uses the calculated interest to format the bill segment's bill lines. It creates one bill line to show the amount of interest in the payment, and another bill line to show the amount of principal. The principal amount is equal to the service agreement's periodic payment amount minus the amount of calculated interest.
- The financial transaction illustrated above is created if you use a bill segment financial algorithm of Payoff Amt = Interest / Current Amt = Bill Amount on the loan's bill segment type. The following explains how this algorithm works:
  - The SA's current balance increases by the amount of the loan's periodic payment amount (i.e., its recurring charge amount). In other words, the amount the customer thinks they owe increases by 438.71.
  - The SA's payoff balance increases by the amount of interest. In other words, if the customer wanted to payoff the loan, they'd owe 10,041.66.
  - The *Interest* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of interest and debits it to the SA type's receivable distribution code (long-term receivables) and credits it to the distribution code defined on the interest rate's bill factor (typically interest revenue).
  - The *Transfer* portion of the GL accounting transfers moneys from long-term receivables (i.e., the unbilled principal) to short term receivables (the billed portion of the debt). The amount transferred is equal to the FT's effect on the service agreement's current balance, allowing the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Remember that the payoff balance is the net of the short-term and long-term receivables.

Paying What Is Owed

When a payment is made for a loan:

- The service agreement's payoff amount is reduced by the payment amount.
- The service agreement's current amount is reduced by the payment amount.

Copyright © 2026, Oracle and/or its affiliates.

The events that happen when a customer makes a payment against a loan is controlled by the FT algorithm plugged in on the loan service agreement's payment segment type. We'll use an example to help explain how this algorithm works. The 3 rd entry in the following table illustrates the financial transaction produced when a payment is made (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000
First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95
Payment is made	Affect Cash Cash 438.71 Long Term Loan Receivable <438.71> Transfer Long Term To Short Term: Long Term Loan Receivable 438.71 Short Term Loan Receivable <438.71>	-438.71	-438.71	0	9,602.95 short-term: 0 long-term: 9,602.95

The financial transaction illustrated above is created if you use a payment segment FT creation algorithm of Payoff Amt = Current Amt = Pay Amt on the loan's payment segment type. The following explains how this algorithm works:

Copyright © 2026, Oracle and/or its affiliates.

- The SA's current balance decreases by the amount of the payment amount. In other words, the customer thinks they owe 0 after the payment. Note refer to Overpayments for information about how an overpayment affects the SA's balances and the general ledger.
- The SA's payoff balance decreases by the amount of the payment. In other words, if the customer wanted to payoff their loan, they'd owe 9,602.95.
- The *Cash* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of the payment and debits it to the payment segment type's distribution code (typically cash) and credits it to the SA type's receivable distribution code (long-term receivable).
- The *Transfer* portion of the GL accounting effectively reduces short-term receivables by the FT's effect on the customer's current balance. This reduction is handled by an offsetting increase to long-term receivables (to make up for reduction made when the cash was applied). Again, this differentiation between short-term and long-term receivables allows the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term).

Overpayments On Loans

You can determine whether you want to accept loan overpayments. Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan.

When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Any customer classes for which you want to allow loan overpayments should use an overpayment distribution algorithm that keeps the overpayment on the loan SA.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to zero out the current balance and transfer the amount of the credit from the SA's short-term receivable to long-term receivable. The adjustment may appear on the customer's next bill to show the additional amount paid against the principal.

The algorithm that controls this adjustment to remove the credit on current balance is plugged in on the loan service agreement's SA type and is applied on the SA Type - Payment Freeze system event.

The third and fourth entries in the following table illustrate an overpayment (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000

Copyright © 2026, Oracle and/or its affiliates.

First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95
Payment is made (with an overpayment of 200.00)	Affect Cash Cash 638.71 Long Term Loan Receivable <638.71> Transfer Long Term To Short Term: Long Term Loan Receivable 638.71 Short Term Loan Receivable <638.71>	-638.71	-638.71	-200.00	9,402.95 short-term: <200.00> long-term: 9,602.95
Create adjustment to remove SA's credit.	Transfer Short Term Credit to Long Term: Short Term Loan Receivable 200.00 Long Term Loan Receivable <200.00>	200.00	0	0	9,402.95 short-term: 0 long-term: 9,402.95

In the third financial transaction illustrated above, the billed amount of the payment works essentially the same as that illustrated under Paying What Is Owed. If the Keep Overpayment on Loan SA algorithm is plugged in on the overpayment distribution event on the customer class, the overpayment amount is applied to the loan SA, creating a credit on the SA's current balance. The following explains how this algorithm works:

- If the account has an loan SA and there is an excess credit, the credit is applied to the loan SA (as long as this does not cause the loan SA to have a credit payoff balance).

Copyright © 2026, Oracle and/or its affiliates.

- If there is not a loan SA to which the credit can be applied, the algorithm checks to see if there is an open excess credit SA for the account.
  - If so, the excess credit amount is applied to the excess credit SA.
  - If not, the algorithm creates an excess credit SA and applies the amount to this SA.

The fourth financial transaction illustrated above is created if the Create Adjustment to Remove SA's Credit algorithm is plugged in on the loan's SA type's payment freeze event. The following explains how this algorithm works:

- If the SA's current balance is less than zero, the algorithm creates a frozen adjustment that removes the credit by transferring the credit from the short-term receivable to the long-term receivable. This adjustment ID is captured on the pay segment so the adjustment can be canceled if the payment is later canceled. Note that the adjustment cancel reason used by the system in this case is specified on the Financial Transaction Options Feature Configuration using the Adjustment Cancel Reason For Payment Linked To Adjustment option type.
- The SA's current balance increases by the amount of the credit transfer. In other words, the customer thinks they owe 0 after the transfer.
- The SA's payoff balance doesn't change because the payoff balance is always the net of the short-term and long-term receivables. In other words, if the customer wanted to payoff their loan, they'd still owe 9,402.95.

> **Note**
>
> **Overpayments and interest.** The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

Adjusting Loan Amounts

You would issue ad hoc adjustments if you need to change a loan's payoff and/or current balance outside of the normal billing / payment functions.

An adjustment can:

- Reduce a loan's payoff balance.
- Reduce a loan's current balance (i.e., how much the customer thinks they currently owe).
- Reduce both the loan's payoff and current balance.

For adjustments that affect payoff amount only:

- These adjustments are used to change the principal owed, e.g., if an additional amount is loaned.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = 0 FT algorithm.
- GL lines will be generated to reflect the change to principal.

For adjustments that reduce current amount only:

Copyright © 2026, Oracle and/or its affiliates.

- These adjustments can be used to change the amount that the customer must pay as part of the next bill.
- The adjustment's adjustment type should reference the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) FT algorithm.
- Typically, GL lines are not generated for FTs that only affect the customer's current balance. However, moneys must be transferred from long to short in the amount of the adjustment (as described above under Payoff Balance and Current Balance for Loans).

For adjustments that reduce both payoff and current amount:

- These adjustment types can be used to levy additional charges, such as late fees, or to correct interest calculations.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = Adj FT algorithm.
- GL lines are generated to reflect the change to principal. In addition, GL lines must be generated to transfer money from long to short in the amount of the adjustment (as described above under Payoff Balance and Current Balance for Loans).

> **Note**
>
> Adjustments that affect the principal balance (payoff balance - current balance) affect the term of the loan because interest is based on the principal balance.
>
> **Adjustments can cause credit balances to exist.** If you credit the loan SA, it is possible for the current balance to become negative. You may need to create additional adjustments that affect the current amount, depending on whether the customer needs to pay this amount as part of the next payment.

Writing Off Loans

Loans are written off using the standard write-off processing.

> **NOT_SUPPORTED**
>
> Refer to The Big Picture Of Write Off Processing for background information.

We illustrate the classic financial transactions that transpire to financially write-off a loan to help illustrate important points (these are the fourth and fifth entries in the following table):

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 1000 Cash <1000>	0	10,000	0	10,000 long-term: 10,000

Copyright © 2026, Oracle and/or its affiliates.

First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95
Payment is made (with an overpayment of 200.00)	Affect Cash Cash 638.71 Long Term Loan Receivable <638.71> Transfer Long Term To Short Term: Long Term Loan Receivable 638.71 Short Term Loan Receivable <638.71>	-638.71	-638.71	-200.00	9,402.95 short-term: <200.00> long-term: 9,602.95
Create adjustment to remove SA's credit.	Transfer Short Term Credit to Long Term: Short Term Loan Receivable 200.00 Long Term Loan Receivable <200.00>	200.00	0	0	9,402.95 short-term: 0 long-term: 9,402.95

Copyright © 2026, Oracle and/or its affiliates.

Sync up current with payoff balance	Transfer Long Term To Short Term: Short Term Loan Receivable 9,402.95 Long Term Loan Receivable <9,402.95>	9,402.95	0	9,402.95	9,402.95 short-term: 9,402.95 long-term: 0
Transfer balance to a write-off SA	Transfer From Loan SA: Write Off Xfer Clearing 9,402.95 Long Term Loan Receivable <9,402.95> Long Term Loan Receivable 9,402.95 Short Term Loan Receivable <9,402.95> Transfer To Write Off SA: Bad Loans Expense 9,402.95 Write Off Xfer Clearing <9,402.95> Note, these will cause a balance of 9,402.55 to exist on the write-off service agreement.	-9,402.95	-9,402.95	0	0

The only unusual portion of the last two financial transactions is the impact on short and long term receivables. Please see the examples above under Billing For Loans And Interest Calculation and Paying What Is Owed to understand how any impact to a loan's current balance causes this type of financial transfer to occur.

Distribution Codes for Loans

As explained above under Payoff Balance and Current Balance for Loans, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the

Copyright © 2026, Oracle and/or its affiliates.

general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Both receivables distribution codes are defined on the loan SA type.

In addition, loans have a distribution code used to book interest revenue. The interest revenue distribution code is defined on the loan's bill factor value for a revenue class (defined on the loan's SA type). For example, on the bill factor you can use one distribution code to book interest revenue from the residential revenue class and another distribution code to book interest revenue from the commercial revenue class. In this example, you create two loan SA types, one for residential revenue and the other for commercial revenue.

Loans may also have a bad loan debt (expense) distribution code that is used when writing off a loan. The bad loan debt distribution code is defined on the loan's write-off service agreement type. Refer to Defining Credit & Collections Options for more information.

Setting Up The System To Enable Loans

The above topics provided background information about how loans are supported in the system. The following discussion summarizes the various setup tasks alluded to above.

- Distribution Code
- Adjustment Types
- Adjustment Type Profile
- Algorithms
- Bill Factor
- Customer Class
- Bill Segment Type
- Frequency
- Bill Period
- Bill Cycle Schedule
- Collection, Severance and Write Off Processes
- SA Type
- Start Options

Distribution Code

You must set up the following distribution codes:

- Long term receivables
- Short term receivables
- Interest revenue
- Bad loan debt

Copyright © 2026, Oracle and/or its affiliates.

Adjustment Types

The following adjustment types are needed:

- Activate a loan. This should reference a distribution code associated with cash or the cash equivalent and an FT algorithm of Payoff Amt = Adj / Current Amt = 0.

> **Note**
>
> **Creating Checks for Loan Amounts.** If you want the system to initiate a check to the customer for the loan amount, the loan activation adjustment type should indicate an **A/P Request Type Code**. Refer to Controls The Interface To A/P & 1099 Reporting for more information.

- Remove Credit (Overpayment). This adjustment should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Even though this algorithm indicates that there is no effect on the GL, there is a special exception built in for loan SAs. The special exception creates GL details to transfer the current balance (short-term receivable) to the long-term receivable. Refer to Overpayments for more information.

> **Note**
>
> **Printing Overpayments on Bills**. If you want the overpayment adjustment to appear on customers' bills, turn on **Print by Default** and enter a **Description on Bill** (e.g. "Additional Principal"). For more information, refer to Controls Information Printed On The Bill.

- Adjustment types to perform any of the adjustments described under Adjusting Loan Amounts.

Adjustment Type Profile

Create an adjustment type profile that references the adjustment types used on a loan. Besides the above adjustment types, it should also reference adjustment types to levy late payment charges (if applicable), levy non-sufficient funds charges (if applicable), refund overpayments (if applicable), sync current balance with payoff balance at write-off time, transfer balances to a write-off service agreement, and write-down small balances.

Algorithms

Add the following algorithms:

- Overpayment Distribution. This algorithm is later plugged in on the customer class for the Overpayment Distribution system event. Refer to the algorithm type OVPY-LO-CSA for more information about the base package algorithm.

Copyright © 2026, Oracle and/or its affiliates.

- Bill Segment Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBS-LO for more information about the base package algorithm.
- Bill Segment Financial Transaction Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBF-LO for more information about the base package algorithm.
- Amortization Schedule. This algorithm is later plugged in on the SA type for the Loan Schedule system event. Refer to the algorithm type LSCH-SI for more information about the base package algorithm.
- Interest Calculation. This algorithm is later plugged in on the SA type for the Loan Interest Charge system event. Refer to the LINT-SI algorithm type for more information about the base package algorithm.
- Payment Periods/Payment Amount Calculation. This algorithm is later plugged in on the SA type for the Loan Periods and Amount system event. Refer to the algorithm type LPDA-SI for more information about the base package algorithm.
- Loan SA Payment Freeze. This algorithm has a parameter that must reference the Remove Credit adjustment type defined above. This algorithm is later plugged in on the SA type for the Payment Freeze system event. Refer to the algorithm type STPZ-RMVCR for more information about the base package algorithm.

Bill Factor

You must set up a bill factor that defines the interest rate. If you have different interest rates for different types of loans, you can create a separate bill factor for each or you can use start options to override the interest rate.

On the bill factor's bill factor value, make sure to reference the GL distribution code used to book interest revenue for the revenue class specified on the loan's SA type.

Customer Class

Any customer class on which you want to allow overpayments for a loan must use the overpayment distribution algorithm defined above. The overpayment distribution algorithm keeps the overpayment on the loan SA rather than transferring it to an excess credit SA, allowing a subsequent adjustment to apply the overpayment to the principal balance.

Bill Segment Type

Create a bill segment type that references the bill segment creation algorithm defined above and the FT creation algorithm defined above.

Frequency

Copyright © 2026, Oracle and/or its affiliates.

Create frequency codes to correspond to the frequency of your loans. When setting up your SA types, you must indicate a recurring charge frequency and, if you use the Anniversary Billing Option, you must indicate an anniversary frequency.

Bill Period

If you use the Use Bill Period option, set up a bill period with an appropriate schedule of dates for billing your loan.

Bill Cycle Schedule

If you use the Use Bill Period option, the bill cycle schedule for these types of loans should be defined with an appropriate schedule of dates for billing your loan.

Collection, Severance and Write Off Processes

You should set up the appropriate credit and collections information. Refer to Defining Credit & Collections Options for more information.

SA Type

You must set up a SA type for your loan service agreements (you may need multiple SA types if you have different business rules for different types of loans). The following points describe the minimal requirements for a loan SA type.

- SA Type - Main
- SA Type - Detail
- SA Type - Billing
- SA Type - Rate
- SA Type - SP Type
- SA Type - Adjustment Profile
- SA Type - Credit and Collections
- SA Type - Algorithms

SA Type - Main

Define the following options:

- **Distribution Code** should be a long-term receivable code.
- **Service Type** should references something like "Miscellaneous Service".
- Specify the **Revenue Class** that, together with the interest bill factor, determines the distribution code used to book the loan interest revenue.

Copyright © 2026, Oracle and/or its affiliates.

- **Start Option** should be turned on.
- The Payment Segment Type should reference the Normal Payment. The base package payment segment financial algorithm (Payoff Amt = Current Amt = Pay Amt) used for Normal Payment pay segment types creates the additional GL details to transfer the credit from long-term receivables to short-term receivables if the SA's special role is Loan.
- Turn on **Late Payment Charge** if applicable.
- Define an appropriate **Adj**ustment **Type (Synch Current)** that will cause current balance to be synchronized with payoff balance (if the loan is written off).

SA Type - Detail

Define the following options:

- **Special Role** is Loan.
- Specify the **Interest Bill Factor** set up above. You can use start options to override.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the short-term receivable account defined above as the **Loan A/R Distribution Code**. If you do not want the system to differentiate between short-term receivables and long-term receivables, make the loan A/R distribution code the same as the distribution code (above).

SA Type - Billing

> **NOT_SUPPORTED**
>
> For an overview of some of these options, be sure to refer to Billing For Loans And Interest Calculation for more information.

Define the following options:

- The Bill Segment Type should reference the value created above.
- **Characteristic Premise Req**uired should not be checked. (A loan SA is not a premise-based service. SA types that have this box checked are filtered out of the SA type search when the start method is Start a SA, so users will never be able to start a loan SA that requires a characteristic premise.)
- **Use Calendar Billing** must equal Anniversary Future Billing or Use Bill Period.
- **Bill Period** is required for the Use Bill Period option.
- **Anniversary Billing Frequency** is required for the Anniversary Future Billing option and must equal the periodicity of the bills (monthly, weekly, etc.).
- **Total Bill Amount** is required (it holds the principal).
- **Total Amount To Bill Label** should reference something like "Loan Amount".

Copyright © 2026, Oracle and/or its affiliates.

- **Recurring Charge** is required (it holds the periodic payment amount).
- **Recurring Chg Amt Label** should reference something like "Payment Amount".
- **Recurring Charge Frequency** is required (it defines the periodicity associated with the recurring charge amount) and must be the same as the bill period frequency or the anniversary billing frequency (based on your **Use Calendar Billing** option).

SA Type - Rate

Turn off the **Rate Required** switch as loans do not use rates.

SA Type - SP Type

Turn off the **Service Points Required** switch as loans do not have service points.

SA Type - Adjustment Profile

Adjustment Type Profile should reference the profile set up above.

SA Type - Credit and Collections

The credit and collections information should reference a **Severance Process Template** that simply expires the loan. The **Debt Class** and **Write Off Debt Class** should reference an appropriate value consistent with your credit and collections rules. Refer to Defining Credit & Collections Options for more information.

SA Type - Algorithms

The Loan Schedule, Loan Interest Charge, Loan Periods, and Amounts and Payment Freeze algorithms defined above must be set up.

Start Options

Loans require a start option to define the adjustment type that is used to create the adjustment to book the initial principal amount when the loan is activated. Loan start options can also specify default values for loan amount, payment amount, and number of periods.

Create at least one start option for each loan SA type. The following information should be defined:

- **Adjustment Type** should reference the adjustment type defined above to book principal.
- **Recurring Charge Amount** (Payment Amount) should only be defined if you have standard loan payments.

Copyright © 2026, Oracle and/or its affiliates.

- **Total Amount To Bill** (Loan Amount) should only be defined if you have standard loan amounts.
- **Number of Payment Periods** should be the number of payment periods in the loan (if you have a standard loan period).
- If you want to define a set of standard APRs for a loan SA Type, set up a **Contract Value** on the Rate Info page. The **Bill Factor** should match the interest bill factor specified on the SA Type.

Defining Non-Billed Budget Options

A Non-Billed Budget (NBB) is a payment plan that allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Non-Billed Budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. As the name suggests, bills are not created for the Non-Billed Budget's scheduled payments; customers must remember to make their payments at the scheduled intervals. The topics in this section describe how to design and set up non-billed budgets.

> **Note**
>
> **Non-Billed Budgets are optional.** The system configuration requirements described in this section are only relevant if your organization offers Non-Billed Budgets.

- What Is A Non-Billed Budget?
- The Financial Impact Of Non-Billed Budgets
- Financial Transactions For Unmonitored Non-Billed Budgets
- Designing Non-Billed Budgets
- Non-Billed Budget Recommendation Rule
- Setting Up The System To Enable Non-Billed Budgets

What Is A Non-Billed Budget?

A Non-Billed Budget is a special type of budget or payment plan that encompasses three major elements:

- A set of scheduled payments
- The business rules used to recommend and potentially renew the payment schedule
- The business rules that govern the financial impact on the current and payoff balances of the SAs covered by the payment schedule

Non-Billed Budgets are managed via a service agreement whose SA type has a special role of Non-Billed Budget. If an SA type has a special role of Non-Billed Budget it must have one or more recommendation rules, and SAs of that type are allowed to have payment schedules.

Copyright © 2026, Oracle and/or its affiliates.

The Financial Impact Of Non-Billed Budgets

When you set up the Non-Billed Budget SA type, you can indicate whether the Non-Billed Budget is monitored by the account debt monitor process. The following sections contain examples of financial transactions for Non-Billed Budgets that are monitored by the account debt monitor.

> **Note**
>
> **Unmonitored Non-Billed Budgets.** SAs that are covered by unmonitored Non-Billed Budgets are subject to different financial treatment than those that are monitored. The financial transactions relevant for unmonitored Non-Billed Budgets are discussed later.

- Current Amount For SAs Covered By A Non-Billed Budget
- Scheduled And Actual Payments On The Non-Billed Budget
- Overpayments for Non-Billed Budgets
- Underpayments For Non-Billed Budgets
- Billing For SAs Covered By The Non-Billed Budget
- Distributing Non-Billed Budget Credit
- Stopping an SA Covered By a Non-Billed Budget

Current Amount For SAs Covered By A Non-Billed Budget

As described under Current Amount versus Payoff Amount , the values of the current balance and payoff balance are the same for most financial transactions. One exception is for SAs that are covered by a Non-Billed Budget in which case the current balance is always zero and the payoff balance is always the amount the customer really owes.

When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget, the system creates adjustments for all affected SAs to set the current amount equal to zero. The adjustment type that references the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) algorithm is taken from the SA's SA type.

> **Note**
>
> **Non-Billed Budgets and Open Item Accounts.** If the Non-Billed Budget is for an open item account, no match event is created for the financial transaction that reduces the current amount to zero. This FT must be manually matched if required.

The following example shows the effect of activating a Non-Billed Budget that covers an electric SA with a current balance of 25. The transactions for the electric SA are illustrated on the right and the transactions for the non-billed budget SA are illustrated on the left.

Copyright © 2026, Oracle and/or its affiliates.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				

By setting the current balance for the covered SAs to zero, the SAs are insulated from the regular debt monitoring process. Depending on the Non-Billed Budget recommendation algorithm , the payoff balance can be ignored, divided evenly between the scheduled payments or added to the first scheduled payment.

Activating a Non-Billed Budget has no affect on its own current or payoff balances.

Scheduled And Actual Payments On The Non-Billed Budget

When a scheduled payment is due, an adjustment is created to increase the Non-Billed Budget's current balance by the expected amount. The current balance on the SA can be monitored to ensure that payments are being made on time.

When the payment is made, the Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment. This accumulated credit is transferred to the covered SAs when the next bill for the account is completed.

The following example illustrates scheduled and actual payments for the Non-Billed Budget in the previous example. The amount of the scheduled Non-Billed Budget payments is 10. Note that the first two transactions were described above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10

An algorithm (Process NBB Scheduled Payment) plugged in on the Non-Billed Budget SA type creates the appropriate financial transactions when the scheduled payment is due. The

Copyright © 2026, Oracle and/or its affiliates.

algorithm is called by the Non-Billed Budget Scheduled Payment Processing (NBBPS) background process.

The normal payment processing handles the adjustments created when the payment is made.

> **Note**
>
> **Non-Billed Budget Payment Cancellation.** If a payment is canceled, the financial transaction is reversed.
>
> **Automatic Payments And Non-Billed Budgets.** Users may set up a Non-Billed Budget to use automatic payments by setting up the account's auto pay options. Users may also exclude the Non-Billed Budget from automatic payment if the account is set up for automatic payment. The NBB Scheduled Payment Automatic Payment Create background process calls the Auto Pay Creation algorithm to create the auto payment for a Non-Billed Budget.

Overpayments for Non-Billed Budgets

Typically, payments in excess of the Non-Billed Budget's current balance are credited to an overpayment (excess credit) SA. When the next adjustment is created for a scheduled payment, the credit on the overpayment SA is used to relieve the non-billed budget current balance.

> **Note**
>
> **Overpayment Distribution Algorithm.** The overpayment distribution is a function of the overpayment distribution algorithm plugged in on the account's customer class. We strongly recommend that the Non-Billed Budget SA type be set up so that overpayment is not allowed. Any excess payments should go to an overpayment SA. For more information about overpayment distribution, refer to Overpayment Segmentation.

In the example below, the customer pays 20 for a scheduled payment instead of 10. The non-billed budget SA is illustrated on the right and the overpayment SA is illustrated on the left. The electric SA is not illustrated in the example below because scheduled payments, payments and overpayments have no effect on covered SAs. The first four transactions were illustrated above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Non-Billed Budget SA				Overpayment SA			
Starting balance								
Non-Billed Budget is activated								

Copyright © 2026, Oracle and/or its affiliates.

First scheduled payment is due	10	0	10	0				
Payment	-10	-10	0	-10				
Second scheduled payment is due	10	0	10	-10				
Over-payment	-10	-10	0	-20	-10	-10	-10	-10
Third scheduled payment is due	10	0	10	-20				
Transfer Adjustment	-10	-10	0	-30	10	10	0	0

After the Process NBB Scheduled Payment algorithm creates the next scheduled payment, it looks for a credit amount on the overpayment SA and creates an adjustment to transfer the credit balance (or the amount of the payment if the credit is more than the scheduled payment amount) from the overpayment SA to the non-billed budget SA. The overpayment transfer adjustment type and the overpayment SA type are specified as parameters to the algorithm.

Underpayments For Non-Billed Budgets

An insufficient payment or a canceled payment leaves a current balance on the Non-Billed Budget SA.

In the example below, the customer makes a payment of 7 for the fourth scheduled payment. The example below does not show the overpayment SA (illustrated above). The first eight transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0

Copyright © 2026, Oracle and/or its affiliates.

Payment	-10	-10	0	-10
Second scheduled payment is due	10	0	10	-10
Over-payment	-10	-10	0	-20
Third scheduled payment is due	10	0	10	-20
Transfer Adjustment	-10	-10	0	-30
Fourth scheduled payment	10	0	10	-30
Underpayment	-7	-7	3	-37

The Process NBB Scheduled Payment algorithm creates a trigger to ensure that the current balance is monitored by the account debt monitor. Refer to Credit And Collections And Non-Billed Budgets for more information.

Billing For SAs Covered By The Non-Billed Budget

When the next bill for the account is completed, the credit on the Non-Billed Budget is transferred to the covered SAs. The credit is prorated over the covered SAs according to the relative payoff balances on each SA.

In the example below, the electric SA's bill is 33. The first ten transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0

Copyright © 2026, Oracle and/or its affiliates.

Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over-payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				
Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0

When a bill segment financial transaction is created, the current amount is set to zero for SAs that are covered by the Non-Billed Budget (if you use a bill segment FT algorithm of Payoff Amt = Bill Amt / Current Amt = Amt Due). Though not evident by the name, the Payoff Amt = Bill Amt / Current Amt = Amt Due algorithm does set the current amount to zero for monitored Non-Billed Budgets. (For SAs with other roles, the current amount is equal to the amount due or the recurring charge.)

A bill completion algorithm transfers money from the Non-Billed Budget to the covered SAs (if you plug in the NBB Credit Transfer bill completion algorithm on the Non-Billed Budget SA type). The algorithm type supplied with the base package distributes the credit using the method described in Distributing Non-Billed Budget Credit.

> **Note**
>
> **Canceled Bill Segments.** No new processing occurs when a bill segment is canceled; any credit balance remains on the covered SA.

Distributing Non-Billed Budget Credit

Copyright © 2026, Oracle and/or its affiliates.

Both the NBB Credit Transfer bill completion algorithm type and the Non-Billed Budget SA stop algorithm type supplied with the base package use the same method of distributing a credit from a Non-Billed Budget SA to the covered SAs. The following points describe how the credit is distributed:

- Covered SAs that are already in credit (due to some other circumstance, such as a cancellation and rebill) are excluded from the distribution.
- The distribution to each covered SA will not exceed its total payoff to ensure that none of the covered SAs have a credit balance.
- The credit is prorated over the covered SAs according to the relative payoff balances on each SA.
- The calculation of the payoff balance is adjusted to exclude the current balance to ensure that the credit is prorated over the debt covered by the budget, not any ad-hoc debt for the SA.

> **Note**
>
> The current balance on covered SAs should always be zero. The only exception occurs if an adjustment has been added that directly affected the SA balance. In this case, the distribution assumes that the balance is outside the non-billed budget and needs to be paid separately.

- Any excess credit remains on the Non-Billed Budget SA until the next distribution takes place or until the Non-Billed Budget SA is stopped.
- The type of adjustments created is determined by the **Adjustment Type (Xfer)** specified on the Non-Billed Budget SA type.

The examples in the table below illustrate the points above.

NBB SA Credit	SA 1 Payoff	SA 1 Current	SA 2 Payoff	SA 2 Current	SA 1 Credit Xfer	SA 2 Credit Xfer
-100.00	-100.00	0.00	-200.00	0.00	0.00	0.00
-100.00	150.00	0.00	-50.00	0.00	-100.00	0.00
-300.00	150.00	0.00	50.00	0.00	-150.00	-50.00
-100.00	150.00	0.00	250.00	0.00	-37.50	-62.50
-100.00	150.00	0.00	250.00	50.00	-42.86	-57.14

The first example above shows that covered SAs with a credit balance are excluded from the distribution. Any excess credit remains on the Non-Billed Budget.

The second example shows that one covered SA has a credit balance, so the entire credit is distributed to the remaining SA.

The third example shows the amount distributed to a covered SA does not exceed its payoff balance. Again, any excess credit remains on the Non-Billed Budget SA.

The fourth example illustrates how the credit is prorated based on the payoff balance. The fifth example illustrates the same prorating but with a current balance on one of the SAs (SA 2). (Remember that the prorating excludes any current balance.)

Copyright © 2026, Oracle and/or its affiliates.

The prorated amount is calculated by subtracting the current balance from the payoff balance then multiplying the result by the distribution amount and dividing by the total payoff owing of all covered SAs.

Stopping an SA Covered By a Non-Billed Budget

If a service agreement covered by a Non-Billed Budget is stopped, the system must bring the current balance and payoff balance of the covered SA back in synch. The system creates an adjustment using the Synch Current adjustment type from the SA's SA type.

In the example below, the electric SA's payoff balance is 21. The first twelve transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over-payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				

Copyright © 2026, Oracle and/or its affiliates.

Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0
SA is stopped	21	0	21	21				

> **Note**
>
> In addition to synching the current and payoff balance, the SA being stopped is removed from the covered SAs collection. When the last covered SA is removed from the collection, the Non-Billed Budget is also stopped.

Financial Transactions For Unmonitored Non-Billed Budgets

Some companies have the concept of non-billed budgets where the payments made by the customer are optional. This functionality is implemented as an unmonitored Non-Billed Budget. Unmonitored Non-Billed Budgets allow a customer to make optional prepayments towards a bill.

As explained previously, unmonitored Non-Billed Budgets receive different financial treatment than monitored Non-Billed Budgets. The financial transaction algorithms use the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type to create the appropriate financial transactions. The following table describes the differences in the financial treatment of monitored and unmonitored Non-Billed Budgets.

System Event	Monitored Non-Billed Budgets	Unmonitored Non-Billed Budgets
When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget...	The system creates adjustments for all affected SAs to set the current balance equal to zero.	The current balances for covered SAs are not zeroed. The activate SA and Non-Billed Budget maintenance processing do not create any adjustments if the Non-Billed Budget is unmonitored.
When a scheduled payment is due...	An adjustment is created to increase the Non-Billed Budget's current balance by the expected amount.	There is no change to the Non-Billed Budget's current balance; it is always zero. The scheduled payment processing background process does not execute the NBB process scheduled payment algorithm.
When the payment is made...	The Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment.	Typically the payments are distributed to an excess credit (overpayment) SA. Refer to Distributing Payments for Unmonitored Non-Billed Budgets for more information.

Copyright © 2026, Oracle and/or its affiliates.

When a bill segment financial transaction is created...	The current amount is set to zero for SAs that are covered by the Non-Billed Budget.	The covered SAs' current amounts are equal to their payoff amounts.
At bill completion...	Money from the Non-Billed Budget is transferred to the covered SAs. Customers may receive a bill for information purposes, but they are not required to pay it.	Money from the overpayment SA is transferred to the account's SAs. The customer is still liable to pay the outstanding balance.
When the Non-Billed Budget is stopped or an SA is removed from a Non-Billed Budget...	The system creates adjustments for all affected SAs to synchronize their current balances with their payoff balances, thus removing the zero current balance and replacing it with the actual current balance.	There is no change to the current balances for covered SAs as the balances already reflect the actual current balance.

Unmonitored Non-Billed Budgets also receive different credit and collections treatment. Refer to Credit and Collections and Unmonitored Non-billed Budgets for more information.

- Distributing Payments for Unmonitored Non-Billed Budgets
- Transferring Credit from Unmonitored Non-Billed Budgets

Distributing Payments for Unmonitored Non-Billed Budgets

For Non-Billed Budgets, payments are distributed according to the payment and overpayment algorithms on the customer class. The base package payment distribution algorithm applies a payment first towards any SAs that have overdue or current balances (refer to Distributing A Payment for more information). Since the unmonitored Non-Billed Budget SA doesn't have a current balance, it is not considered by the payment distribution algorithm. If there aren't any SAs with a current balance, the overpayment distribution algorithm handles the remaining credit. You can elect to:

- Apply the overpayment to an excess credit SA. This is the method that we strongly recommend because all financial transactions are then a function of the normal payment, overpayment and billing processes.
- Apply the overpayment to the highest priority SA that is eligible for overpayment (as specified on the SA type). You can use this method to apply the overpayment to the unmonitored Non-Billed Budget SA. If you use this method, you must also set up the system to transfer the credit from the unmonitored Non-Billed Budget.

> **Note**
>
> **Use An Excess Credit SA.** We strongly recommend that payments for unmonitored Non-Billed Budgets are distributed to an excess credit SA. In this case, the Non-Billed Budget is just a shell to hold the covered SAs and recommend a payment schedule; all financial transactions are a function of the normal payment, overpayment and billing processes.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to Overpayment Segmentation for a detailed discussion of overpayment distribution options.

Transferring Credit from Unmonitored Non-Billed Budgets

If you distribute an overpayment to an unmonitored Non-Billed Budget SA (i.e. the unmonitored non-billed budget maintains a credit balance instead of an overpayment SA), you must plug-in a bill completion algorithm on the SA type to transfer the credit balance to the covered SAs at bill completion time. The bill completion algorithm type (BCMP-NB) supplied with the base package transfers the credit balance to the covered service agreements when the bill is completed. Additionally, the **Adjustment Type (Xfer)** on unmonitored Non-Billed Budget SA types should reference a FT algorithm of Payoff Amt = Adj / Current Amt = Adj to ensure that the credit is removed from both the current and payoff balances.

Warning

You must create your own SA stop algorithm type for correctly stopping an unmonitored non-billed budget that maintains a credit balance. The SA stop algorithm that is supplied with the base package does NOT transfer remaining credit from the unmonitored Non-Billed Budget SA. (The base package SA stop algorithm transfers the remaining credit using the overpayment distribution algorithm on the customer type, which you have set up to transfer to back to the unmonitored non-billed budget.)

Designing Non-Billed Budgets

The topics in this section describe functionality that you must consider when designing non-billed budgets.

- Making SAs Eligible For Non-Billed Budgets
- Designing Recommendation Rules

Making SAs Eligible For Non-Billed Budgets

A billable SA may be covered by a Non-Billed Budget when its SA type is flagged as Eligible for Non-Billed Budget.

All SAs that are eligible for non-billed budgets should reference a bill segment type that uses the Payoff Amt = Bill Amt / Current Amt = Amt Due bill segment FT algorithm. This algorithm sets the SA's current amount to zero if it is covered by a monitored Non-Billed Budget.

A list of the SAs covered by a Non-Billed Budget is maintained with the non-billed budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Copyright © 2026, Oracle and/or its affiliates.

Designing Recommendation Rules

Users (and the renewal process) ask the system to recommend the scheduled payments for a Non-Billed Budget. In general, this recommendation process must establish:

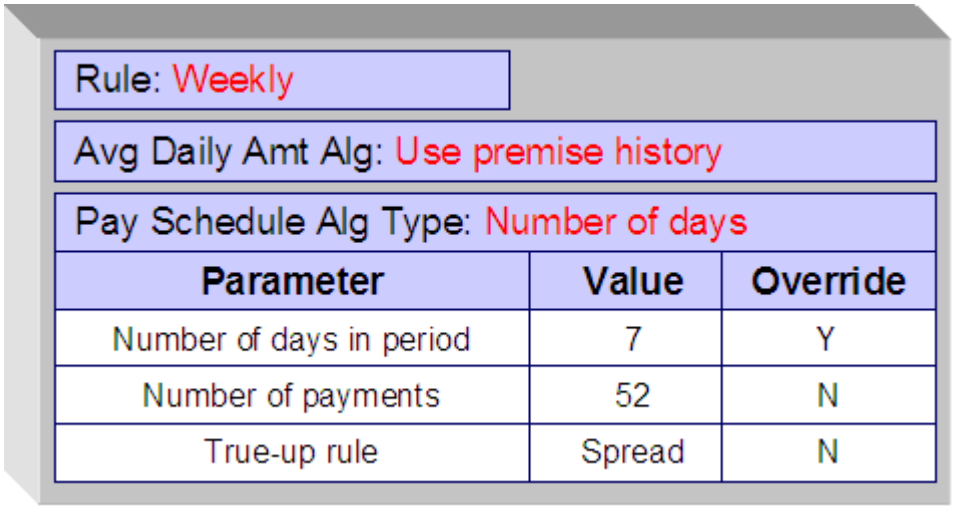
- The amount to be paid
- The dates on which the payments are due

We envision many different types of recommendation rules. For example:

- Recommend 26 scheduled payments to be made on a fortnightly basis that are due on Tuesdays.
- Recommend monthly payments that are due on the nearest workday after the 10th of the month.
- Recommend scheduled payments where the customer pays their annual charges in 10 out of 12 months where the payments are not due in November and December.
- Recommend bi-monthly payments where the payments are due on the first workday following the 5th and 20th of the month.

Additionally, the recommendation rules must determine how to handle any outstanding payoff balances for covered SAs. The true-up rule provided with the base package payment schedule algorithm type can ignore the payoff balance, divide the payoff balance evenly between the scheduled payments, or add the payoff balance to the first scheduled payment.

A recommendation rule comprises three elements:



- An algorithm to calculate an average daily amount (the NBDA-DA algorithm type provided with the base package uses premise billing history)

> **Note**
>
> **Calculating an Amount for Non-utility SAs.** The algorithm type supplied with the base package only handles service-point oriented SAs. For example, the average daily amount algorithm calculates an average daily amount. For non-utility SAs, you must develop the appropriate algorithm types.

- Two algorithm types are provided with the base package to calculate a schedule of payments. NBPS-MON calculates a monthly schedule and NBPS-PS calculates a scheduled based on a specified number of days.
- A collection of default parameter values for the payment schedule algorithm type

A recommendation rule (based on the algorithm types provided with the base package) is illustrated below.

Copyright © 2026, Oracle and/or its affiliates.

Rule: Weekly

Avg Daily Amt Alg: Use premise history

Pay Schedule Alg Type: Number of days

Parameter	Value	Override
Number of days in period	7	Y
Number of payments	52	N
True-up rule	Spread	N

Weekly Payments Recommendation Rule

> **Note**
>
> **Additional Parameters.** Not all of the parameters associated with the weekly payment schedule algorithm type are illustrated. Refer to the NBPS-PS algorithm type for a detail description of the parameters.

The default parameter values for the payment schedule algorithm type may change over time, so the collection contains an effective date. If default values are changed, these changes do not affect Non-Billed Budgets already in effect. Existing Non-Billed Budgets keep the parameter values that were used when the Non-Billed Budget was started.

A user may override the default parameter values for the payment schedule algorithm type to customize the schedule if an override is allowed for a parameter. Additionally, a user may edit the payment schedule details at any time (provided the payment has not yet been processed).

The parameter values used for the recommendation rule are kept with the Non-Billed Budget SA, so that any customized parameter changes can be re-applied to a renewed Non-Billed Budget. For example, the parameter that determines the payment due day may default to the first of the month. To customize the schedule, this value may be changed to the fifth of the month. This amended value is kept with the Non-Billed Budget SA to ensure that the renewed budget follows the same monthly schedule.

> **Note**
>
> Normally parameter values for an algorithm type are kept with the algorithm. Because the parameters may vary for each Non-Billed Budget, the parameter values are kept with the SA in the case of Non-Billed Budgets.

Activating Non-Billed Budgets

You can plug in an algorithm (of type SACR-AT) on the SA Creation system event on the Non-Billed Budget SA type to automatically activate the Non-Billed Budget (i.e. transition it from pending start to active status). If you don't use a SA Creation algorithm to activate the Non-Billed Budget, it is activated the next time the SA activation background process runs.

When a Non-Billed Budget is activated, you can perform special processing using an algorithm plugged in on the SA Activation system event on the Non-Billed Budget SA type. The special processing can be developed to do anything that you would like, for example you could:

- Create a customer contact that with an appropriate letter template can generate a letter to inform the customer of their payment amount and payment schedule.
- Initiate the creation of a payment coupon book for a customer.

The system comes supplied with a sample algorithm type (called SAAT-CC) that simply creates a customer contact to indicate that the Non-Billed Budget is activated.

Renewing Non-Billed Budgets

A Non-Billed Budget can be renewed either manually or via a background process. When the Non-Billed Budget SA is created, the expiration date, renewal date and the recommendation rule used to create the initial budget are kept with the SA. A renewal flag on the Non-Billed Budget SA type controls if a renewal is required, optional or not allowed. If renewal is required, a user must specify a renewal date when creating the service agreement. The renewal date is defaulted on to an SA based on the valued of the **Days Before Expiration for Renewal** field on the SA type.

An algorithm on the SA type can customize the processing required to renew an SA.

The SA renewal background process:

- Executes the SA renewal algorithm (specified on the SA type) when the renewal date is reached (i.e., it is on or before the process date). The base package comes with an algorithm type (SARN-NB) that determines the current recommendation rule for a non-billed budget and executes the associated payment schedule algorithm using the Non-Billed Budget SA-specific parameter values to generate a new schedule. It returns new expiration and renewal dates.
- If the renewal algorithm is successful, the renewal and expiration date fields on the SA are updated with the new values.
- If the renewal process is not successful, a To Do list entry (of type TD-SARN) is created for the account and SA.

The new payment schedule that is returned from the renewal process for a Non-Billed Budget is appended to the current schedule.

A user can manually launch the renewal process for a Non-Billed Budget SA by clicking the **Renew NBB** button on the Non-Billed Budget maintenance page .

Expiring Non-Billed Budgets

Copyright © 2026, Oracle and/or its affiliates.

Non-Billed Budget service agreements may specify an expiration date. The SA expiration background process initiates the stop process for all pending start or active SAs where the expiration date is reached (before or on the process date).

Stopping Non-Billed Budgets

When a Non-Billed Budget stop is initiated, either on request or because it has expired and is not being renewed, the Non-Billed Budget is transitioned to pending stop status. You can plug in an algorithm (of type SAIS-ST) on the SA Stop Initiation system event on the Non-Billed Budget SA type to automatically finalize and stop the SA (i.e. transition it to stopped status). If you don't use a SA Stop Initiation algorithm, the Non-Billed Budget is stopped the next time the SA activation background process runs.

To finalize a pending stop SA, the system first calls the stop SA algorithm plugged-in on the SA Stop system event on the SA type. The stop SA algorithm type (SAST-NB) supplied with the base package:

- Distributes any credit on the Non-Billed Budget to the covered SAs (using the method described in Distributing Non-Billed Budget Credit)
- Distributes any excess credit remaining on the non-billed budget using the overpayment distribution algorithm for the account's customer class and the overpayment transfer adjustment type (specified as a parameter to the algorithm)
- Creates a trigger to cause the account to be reviewed by the account debt monitor
- Creates a customer contact (if the customer contact class and customer contact type parameters are populated)

> **Warning**
>
> If you do not plug in an SA stop algorithm that transfers the credit balance from the non-billed budget to its covered SAs (or an excess credit SA), the stopped Non-Billed Budget may have a credit balance. You must then manually distribute this credit.

After the SA stop algorithm is finished, the SA stop processing performs the following steps if the SA type has a special role of Non-Billed Budget:

- If the Non-Billed Budget is monitored, create adjustments to synchronize the current and payoff balance of covered SAs using the **Adj. Type (Synch Current)** adjustment type from the covered SAs' SA types
- Remove the covered SAs from the Non-Billed Budget
- Remove all the scheduled payments from the non-billed budget
- Create an adjustment to synchronize current and payoff on the Non-Billed Budget SA using the **Adj. Type (Synch Current)** adjustment type from the Non-Billed Budget's SA type

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Synchronizing current and payoff effectively sets the current amount to zero on the Non-Billed Budget SA, as the payoff amount should have been reduced to zero by the distribution and overpayment processing in the algorithm for SA Stop.

> **NOT_SUPPORTED**
>
> Refer to The Lifecycle Of A Service Agreement for more information about how a pending stop SA is stopped and closed.

Automatic Payment and Non-Billed Budgets

If a customer wants to pay their non-billed budget scheduled payments automatically, the account must be set up for automatic payment. In addition, the Non-Billed Budget must indicate that automatic payment is being used.

> **NOT_SUPPORTED**
>
> Refer to How To Set Up Automatic Payment For A Non-Billed Budget for more information.

When this is done, a background process referred to as NBBAPAY creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

> **Note**
>
> You must ensure that your auto pay creation algorithm supports Non-Billed Budget scheduled payments. The APAY-CREATE algorithm type supplied with the base package supports non-billed budget scheduled payments.

Credit and Collections and Non-Billed Budgets

Unless the Non-Billed Budget is unmonitored, the account debt monitor (ADM) monitors a Non-Billed Budget SA's current amount just as it does for any other SA. The scheduled payment algorithm creates a trigger to ensure that the account debt monitor reviews the account the next time it runs. The review date on the trigger record is set to the process business date.

A separate debt class is needed for Non-Billed Budget SA types, thus allowing you to define collection class controls, debt criteria and collection process templates specifically for Non-Billed Budgets. The debt criteria should be set up to trigger a collection process when the arrears amount exceeds $0.01 for more than n payment periods plus the number of grace days that you want to allow.

Copyright © 2026, Oracle and/or its affiliates.

The collection process template can perform any of the events in standard collection processes, such as sending letters to customers and creating severance processes. At a minimum, the collection process template should be set up to start a severance process for all service agreements in the debt class. (Since the debt class is specifically for Non-Billed Budgets, the Non-Billed Budget is the only SA that will be subject to a severance process.)

The Non-Billed Budget severance process template should include the following event types:

- Populate a characteristic on the SA to indicate that the SA is broken. The base package comes supplied with a severance event algorithm type (SVEV-NB) that sets an SA characteristic to indicate that it was "severed".
- Expire Severance Agreement to move the SA to the pending stop state.

When the system subsequently stops the Non-Billed Budget, the system removes the covered SAs from the Non-Billed Budget and synchronizes their current balances with their payoff balances. Since the SAs have current balances again, they are subject to the account debt monitor, which can start subsequent collection processes for any of the SAs that meet the debt criteria for their debt class.

NOT_SUPPORTED

Refer to Stopping Non-billed Budgets for a complete description of the events that occur when a Non-Billed Budget is stopped.

Customers can catch up on their payments and avoid having their Non-Billed Budget broken as long as their current balance doesn't violate the debt criteria for the Non-Billed Budget's collection process.

Credit and Collections and Unmonitored Non-Billed Budgets

If the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type is set to Unmonitored, the NBB Scheduled Payment Processing background process does not create a trigger for the account debt monitor. Additionally, the Non-Billed Budget's current amount is always equal to zero, so it never violates any debt collection criteria. We recommend using a debt class that has the **Eligible for Collection** flag turned off, such as the N/A debt class.

For unmonitored Non-Billed Budgets, the current balance is kept on the covered SAs so they are subject to the account debt monitor and any debt criteria for their SA types' debt classes. For more information, refer to Financial Transactions for Unmonitored Non-Billed Budgets.

Non-Billed Budget Status

A Non-Billed Budget SA's status is just like any other SA's status. In addition, you can use a characteristic to keep an explicit status relevant to the Non-Billed Budget:

- A base package severance event algorithm type (SVEV-NB) creates a characteristic value to indicate if a Non-Billed Budget is "broken" (i.e. stopped as a result of a severance process).
- A base package break Non-Billed Budget algorithm type (NBBR-BRK) creates a characteristic value to indicate if a Non-Billed Budget is "canceled" (i.e. manually stopped by a user).

Copyright © 2026, Oracle and/or its affiliates.

An active Non-Billed Budget implicitly has a "kept" status (i.e. all scheduled payments have been made).

Alerts For Non-Billed Budgets

The system provides alerts to highlight the existence of Non-Billed Budgets. These alerts are important to assist the customer service representatives:

- An alert is displayed if the account has a Non-Billed Budget that is not stopped (e.g., pending start, active or pending stop).
- When a user denies a Non-Billed Budget (for whatever reason), the user should create a customer contact with a given customer contact type. This type of alert prevents the customer from shopping around. An existing alert algorithm type (CC BY TYPCL) can highlight these customer contacts.
- For customers who are permanently forbidden from having a Non-Billed Budget, the user should put a permanent alert on the account.
- Use an algorithm to highlight cancelled or severed non-billed budgets with an entry in the alert zone. The algorithm type to do this is not provided. Use PP BY STATUS and CCAL-WF as examples of how to create this type of algorithm.

> **NOT_SUPPORTED**
>
> For more information about introducing alert conditions on Control Central, refer to Installation Options - Algorithms.

Non-Billed Budget Recommendation Rule

Recommendation rules are used to recommend scheduled payments for Non-Billed Budgets. For information about designing recommendation rules, refer to Designing Recommendation Rules.

To define recommendation rules, navigate to **Admin**, and then **Financial**, and then **NBB Recommendation Rule**, and then **Add.**

Description of Page

Enter an easily recognizable **Recommendation Rule** code and **Description** for each recommendation rule.

Specify the **Average Daily Amount Algorithm** used to calculate the average daily amount for this recommendation rule.

Specify the **Payment Schedule Algorithm Type** used to create the recommended payment scheduled for Non-Billed Budgets that use this recommendation rule. The Payment Schedule Algorithm Type cannot be modified if a Non-Billed Budget SA that is not stopped or cancelled is using this recommendation rule.

Payment Schedule Parameters enables you to define collections of default parameter values for the payment schedule algorithm type that are effective dated. For each collection:

Copyright © 2026, Oracle and/or its affiliates.

- **Effective Date** defines the date on which the collection of parameter values becomes effective.
- **NBB Rule Parameter Value** specifies the default value of each parameter supplied to the algorithm. Note that the payment schedule algorithm type controls the number and type of parameters.
- **Override** indicates whether the user can override the default value for the parameter.

Setting Up The System To Enable Non-Billed Budgets

The above topics provided background information about how Non-Billed Budgets are supported in the system. The topics in this section describe how to set up the system to enable Non-Billed Budget functionality.

> **Note**
>
> **Example Setup.** This section describes typical non-billed budget configurations. Your set up and configuration may differ depending on your business needs. This section is provided for guidance only. Read the descriptions of Non-Billed Budget functionality above to understand the implications of the described setup.

- NBB Distribution Codes
- NBB Adjustment Types
- NBB Adjustment Type Profiles
- NBB Characteristic Types
- NBB Customer Contact Class And Types
- NBB Algorithms
- NBB Debt Class And Collection Process
- SA Types for SAs Covered by NBBs
- NBB Recommendation Rules
- Non-Billed Budget SA Types
- NBB Background Processes

NBB Distribution Codes

You must set up a Non-Billed Budget Clearance distribution code that is used on the Non-Billed Budget SA type to credit non-billed payments.

NBB Adjustment Types

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Non-Billed Budget Financial Transaction Algorithms.** The Non-Billed Budget adjustment types use the standard FT algorithm types that are provided with the base package. If you have not yet defined algorithms for these types in your system, do so before creating the Non-Billed Budget adjustment types.

The following adjustment types are needed:

- Add SA To Non-Billed Budget. This adjustment type should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on **Adjustment Type (Current=0)** on SA types that are eligible for Non-Billed Budgets. Note that this adjustment type is never used if the SA is added to an unmonitored Non-Billed Budget.
- Bill Complete for Monitored Non-Billed Budget. This adjustment type should reference a distribution code used for balance transfer clearing. It should reference a FT algorithm of Payoff Amt = Adj / Current Amt = 0. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are monitored Non-Billed Budgets.
- Synch Balance for Non-Billed Budget. This adjustment type should be set up for **Sync. Current Amount** and should reference a FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). This adjustment type is referenced on the **Adj. Type (Synch Current)** on Non-Billed Budget SA types. It is used when a Non-Billed Budget SA is stopped to synch the current balance with the payoff balance.
- Scheduled Payment. This adjustment type should reference an FT algorithm of Payoff Amt = 0 / Current Amt = Adj Amount (no GL). Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on the Non-Billed Budget process scheduled payment algorithm.
- Overpayment Transfer. This adjustment type should reference a transfer distribution code and a FT algorithm of Payoff Amt = Adj / Current Amt = Adj. This adjustment is referenced on the non-billed budget process scheduled payment algorithm and the stop non-billed budget algorithm. Note that if there is already a transfer adjustment type created in your system, you do not need to create a new one.

If you are setting up an unmonitored Non-Billed Budget that maintains a credit balance (as opposed to maintaining the credit balance on an overpayment SA), you need to create an adjustment type for Bill Complete for Unmonitored Non-Billed Budget. (Refer to Transferring Credit from Unmonitored Non-billed Budgets for more information.) The adjustment type should reference a transfer distribution code and a FT algorithm of Payoff Amt = Adj / Current Amt = Adj. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are unmonitored Non-Billed Budgets.

NBB Adjustment Type Profiles

Create an adjustment type profile for Non-Billed Budgets that references the following adjustment types:

- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)
- Synch balance for Non-Billed Budget

Copyright © 2026, Oracle and/or its affiliates.

- Scheduled payment
- Overpayment transfer

Create an adjustment type profile for eligible SAs that references the following adjustment types:

- Add SAs to monitored Non-Billed Budgets
- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)

> **Note**
>
> **Bill Complete Adjustment Types.** Because the bill complete adjustment types transfer amounts between two SAs, they must be in profiles for both Non-Billed Budget and eligible SA types.
>
> **Overpayment Transfer Adjustment Type.** The overpayment transfer adjustment type created above is used to transfer funds from an excess credit SA to a Non-Billed Budget when the scheduled payment is processed. It is also used to transfer excess funds from a Non-Billed Budget that is being closed to an excess credit SA. The transfer adjustment should therefore be added to an adjustment type profile that is referenced on the excess credit SA type.

NBB Characteristic Types

Create a Non-Billed Budget status characteristic type that specifies Service Agreement as its characteristic entity. The characteristic type should include the following predefined values:

- Non-Billed Budget Canceled
- Non-Billed Budget Severed

NBB Customer Contact Class And Types

Create a Non-Billed Budget customer contact class. The contact class may include the following customer contact types:

- Non-Billed Budget Activate
- Non-Billed Budget Renewal
- Non-Billed Budget Stop

> **Note**
>
> **Customer Contact Letters.** If you want to send letters to your customers when a contact of any of these types is created, you must create an appropriate letter template and attach it to the contact type.

Copyright © 2026, Oracle and/or its affiliates.

NBB Algorithms

You must define the following algorithms:

- On NBB recommendation rule, the Non-Billed Budget Daily Amount Calculation. Refer to the NBDA-DA algorithm type for more information about the base package algorithm.
- On SA type:
  - Non-Billed Budget Process Scheduled Payment. This algorithm has parameters that must reference the Scheduled Payment and Overpayment Transfer adjustment types defined above. Another parameter references an overpayment SA type (that you may need to create if there is not already one in your system). Refer to the NBPA-PS algorithm type for more information about the base package algorithm.
  - Non-Billed Budget SA Renewal. Refer to the SARN-NB algorithm type for more information about the base package algorithm.
  - Break Non-Billed Budget SA. Refer to the NBBR-BRK algorithm type for more information about the base package algorithm.
  - SA Activation - automatically activate SA (if you want to automatically activated Non-Billed Budgets when they are created). Refer to the SACR-AT algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
  - SA Activation - create customer contact (if you want the system to create a customer contact when NBB SAs are activated). Refer to the SAAT-CC algorithm type for more information about the base package algorithm.
  - SA Stop - automatically stop SA (if you want to automatically transition Non-Billed Budgets from pending stop to stop when their stop is initiated). Refer to the SAIS-ST algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
  - SA Stop - Stop Non-Billed Budget. Refer to the SAST-NB algorithm type for more information about the base package algorithm.
  - Bill Completion - Non-Billed Budget Credit Transfer. Refer to the BCMP-NB algorithm type for more information about the base package algorithm.
- On bill segment type, the Bill FT Algorithm (for all SAs that are eligible for NBB). Refer to the BSBF-BA algorithm type for more information about the base package algorithm. Note this is the standard bill FT algorithm type used for common bill transactions. It supports bill FT for non-billed budgets and other SA types. You only need to create it if it doesn't already exist in your system.
- On severance event type, an algorithm for Non-billed Budget Severance. Refer to the SVEV-NB algorithm type for more information about the base package algorithm.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Payment Schedule Algorithm Types.** For Non-Billed Budget payment schedule algorithm types, you need to define the algorithm types (if you add your own algorithm types). You do not need to define algorithms because the parameter values for the algorithm are defaulted on the recommendation rule and stored with the Non-Billed Budget SA. (Normally the algorithm holds the parameter values.) Refer to the NBPS-MON algorithm type for more information about the base package payment schedule algorithm.

NBB Debt Class And Collection Process

Set up a separate debt class, collection class control, collection process template and severance process template for Non-Billed Budgets according to the information in Credit and Collections and Non-Billed Budgets.

SA Types for SAs Covered by NBBs

You must modify the SA type for any SAs that you want to allow to be covered by a Non-Billed Budget.

- Verify that the specified **Bill Segment Type** (on the Billing page) references a financial transaction algorithm to set the current amount to zero for monitored Non-Billed Budgets. The FT creation algorithm type BSBF-BA (i.e., Payoff Amt = Bill Amt / Current Amt = Amt Due) supplied with the base package sets the current amount to zero for SAs that are covered by monitored non-billed budgets, though this is not evident by the name. (For SAs that are not covered by a Non-Billed Budget, the current amount is equal to the amount due or the recurring charge.) Refer to Billing For SAs Covered By The Non-Billed Budget for more information.
- Set the **Eligible for Non Billed Budget** flag (on the Billing page) to Eligible for Non-Billed Budget .
- Populate the **Adjustment Type (Current = 0)** (on the Detail page) to indicate the adjustment to be used to zero out the current amount on the covered SAs when the Non-Billed Budget SA is activated. Use the Add SA To Non-Billed Budget adjustment created above. This adjustment type is only called for SAs that are covered by a monitored Non-Billed Budget.
- Reference an **Adjustment Type Profile** (on the Adjustment Profile page) that includes the Add SA To Non-Billed Budget adjustment type referenced in the **Adjustment Type (Current = 0)** field above.
- If not already specified (for write off), an **Adj. Type (Synch Current)** (on the Main page) is also required. It is used to synchronize (make equal) the current amount with the payoff amount when the SA is removed from (i.e. no longer covered by) a Non-Billed Budget.

NBB Recommendation Rules

Copyright © 2026, Oracle and/or its affiliates.

Set up any NBB Recommendation Rules that you want to be available for your Non-Billed Budget SAs. Use any Non-Billed Budget Daily Amount Calculation algorithms defined above. Also use the Non-billed Budget Monthly Payment Schedule (NBPS-MON) algorithm types and specify the default parameters.

Non-Billed Budget SA Types

You must set up a SA types for your Non-Billed Budget service agreements. You may need multiple Non-Billed Budget SA types if you have different business rules for different types of Non-Billed Budgets, for example, if you have both monitored and unmonitored Non-Billed Budgets or if you support Non-Billed Budgets with different renewal requirements. The following points provide guidelines for creating a non-billed budget SA type.

- SA Type - Main (NBB)
- SA Type - Detail (NBB)
- SA Type - Billing (NBB)
- SA Type - Rate (NBB)
- SA Type - SP Type (NBB)
- SA Type - Adjustment Profile (NBB)
- SA Type - Credit and Collections (NBB)
- SA Type - Algorithms (NBB)
- SA Type - NBB Recommendation Rule (NBB)

SA Type - Main (NBB)

Service Type should reference something like "Miscellaneous Service".

Distribution Code should be the one you set up to book credits for Non-Billed Budgets.

Revenue Class should be set to N/A. (Revenue classes are not applicable because Non-Billed Budgets do not apply a rate and revenue classes are only relevant for SA types that use a rate.)

The **Payment Segment Type** should reference the Normal Payment.

Do Not Overpay should be on. Any excess payments should go to the overpayment SA, not the Non-Billed Budget SA.

Late Payment Charge is not applicable and should not be turned on because Non-Billed Budgets are not billed.

Adj. Type (Synch Current) should reference the Synch Balance for Non-Billed Budget adjustment type created above.

SA Type - Detail (NBB)

- **Special Role** is Non-Billed Budget.

Copyright © 2026, Oracle and/or its affiliates.

- **Adjustment Type (Xfer)** must be populated to indicate the adjustment to be used for transferring accumulated credit from the Non-Billed Budget SA to the covered SAs. This field is not used for unmonitored Non-Billed Budgets.
- **Renewal** may be optional, not allowed, or required depending on your business processes.
- If Renewal is required, specify the **Days Before Expiration for Renewal**.
- **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

SA Type - Billing (NBB)

Non-Billed Budget SAs do not get billed, so the **Eligible for Billing** flag should be off.

Additionally, the **Characteristic Premise Required** should not be checked for Non-Billed Budgets.

SA Type - Rate (NBB)

Non-Billed Budget SAs do not use rates, so the **Rate Required** flag should be off.

SA Type - SP Type (NBB)

Non-Billed Budget SAs do not have service points, so the **Service Points Required** flag should be off.

SA Type - Adjustment Profile (NBB)

Adjustment Type Profile should reference the adjustment type profile for Non-Billed Budgets (set up above).

SA Type - Credit and Collections (NBB)

The credit and collections information should reference a **Severance Process Template** that calls the Non-Billed Budget Severance algorithm created above and expires the Non-Billed Budget SA. The **Debt Class** should reference an appropriate value consistent with your credit and collections rules. Typically, monitored Non-Billed Budgets should be in their own debt class. Unmonitored Non-Billed Budgets should have a **Debt Class** that is not Eligible for Collection.

The **Write Off Debt Class** is not applicable because the Non-Billed Budget contains no debt to be written off. Reference a debt class such as N/A. Refer to Defining Credit & Collections Options for more information.

Copyright © 2026, Oracle and/or its affiliates.

SA Type - Algorithms (NBB)

The SA type algorithms defined above must be set up:

- The Non-Billed Budget Credit Transfer algorithm created above should be specified for the Bill Completion system event (not used on unmonitored Non-Billed Budgets).
- The Break Non-Billed Budget SA algorithm created above should be specified for the Break NBB SA system event.
- The Non-Billed Budget Process Scheduled Payment algorithm created above should be specified for the Process NBB Scheduled Payment system event (not used on unmonitored non-billed budgets).
- The Non-Billed Budget SA Renewal algorithm created above should be specified for the SA Renewal system event.
- If you created the Automatic SA Activation algorithm above, it should be specified for the SA Creation system event.
- The Non-Billed Budget SA Activation algorithm created above should be specified for the SA Activation system event.
- If you created the Automatic SA Stop algorithm above, it should be specified for the SA Stop Initiation system event.
- The Stop Non-Billed Budget algorithm created above should be specified for the SA Stop system event.

SA Type - NBB Recommendation Rule (NBB)

Add the recommendation rules defined above that are valid for SAs of this type. Also, indicate which recommendation rule should be used as the default.

NBB Background Processes

Ensure that the following background processes are scheduled:

- Non-Billed Budget Scheduled Payment Processing (NBBPS)
- Non-Billed Budget Scheduled Payment Automatic Payment Create (NBBAPAY)
- Service Agreement Renewal (SARENEW)
- Stop Expired Service Agreements (SAEXPIRE)

Defining Quotation Options

This section describes tables that must be set up before quotations can be created.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, refer to The Big Picture of Quotations.

- Setting Up SA Types For Quotes
- Setting Up Quote Route Types
- Setting Up Terms and Conditions
- Setting Up Decline Reasons
- Setting Up Customer Classes For Quotes

Setting Up SA Types For Quotes

The topics in this section describe additional setup responsibilities required on SA types that can have proposal service agreements.

Note

Assumption. We have assumed that you've already designed your SA types for the services that you sell. If you haven't done this, refer to Defining Service Agreement Types .

- Enabling The Automatic Generation Of Billing Scenarios
- Enabling The Generation Of Simulated Bill Segments
- Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

Enabling The Automatic Generation Of Billing Scenarios

As described under Proposal SAs Contain Billing Scenarios And Template Consumption, a proposal SA requires billing scenarios before a quote detail can be generated. The system can automatically create billing scenarios when a proposal SA is created. If this is required for your implementation, create a Proposal SA Creation algorithm type, and plug in the appropriate algorithm on each applicable Proposal SA type. Refer to PSAC-CBS for an example algorithm ***(note, this algorithm is not applicable for C2M but may be used as a reference only)***.

Enabling The Generation Of Simulated Bill Segments

As described under Creating Quotes And Quote Details, in order for the system to generate simulated bill segments for a proposal SA, you must plug-in a Proposal SA Bill Segment Generation algorithm on the proposal SA's SA type. Refer to CBSP-AR for an example algorithm that creates a simulated bill segments for each billing scenario linked to the proposal SA by calling rate application.

Copyright © 2026, Oracle and/or its affiliates.

Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

As described under Accepting / Declining Quote Details, in order for the system to create a real SA when a proposal SA is accepted, you must plug-in a Proposal SA Acceptance algorithm on the proposal SA's SA type. Refer to PSAA-PS for an example algorithm that creates a real SA by copying the proposal SA.

> **Note**
>
> **Interval pricing service agreements.** are not supported. PSAA-PS has a parameter for creating interval profiles, time-of-use maps and contract options when the real SA is created. This specific parameter/option is not applicable for C2M.

Setting Up Quote Route Types

Quote route types control how quotes are routed to customers and prospects. To define a quote route type, open **Admin**, and then **Sales & Marketing**, and then **Quote Route Type.**

> **NOT_SUPPORTED**
>
> Refer to Printing Quotes for more information about how quotes are routed to customers and prospects.

Description of Page

Enter a unique **Quote Route Type** and **Description** for every quote route type.

Quote Routing Method controls the type of information that may be defined when the respective **Quote Route Type** is selected on Account - Person Information. The following options are available:

- Postal: Use this method if the routing is via the postal service.
- Fax: Use this method if the routing is via fax.
- Email: Use this method if the routing is via email.

> **Note**
>
> The values for **Quote Routing Method** are customizable using the Lookup table. This field name is QTE_RTG_METH_FLG .

- The next two fields control how quotes that are routed using this method are printed (both in batch and online).

Copyright © 2026, Oracle and/or its affiliates.

- Use **Batch Control** to define the process that creates the flat file that is passed to your quote printing software. Refer to Tec hnical Implementation of Printing Quotes In Batch for more information about these processes.
- Use **Extract Algorithm** to define the plug-in that constructs the "flat file records" that contain the information merged onto quotes routed using this method. Refer to Printing Quotes for more information.

Setting Up Terms and Conditions

As described under Legal Terms and Conditions May Be Specified On SAs , your SA type start options can reference terms and conditions (T&C's) that should be defaulted onto new service agreements (both real and proposal). Each T&C is identified with a terms and condition code. To define a terms and conditions code, open **Admin**, and then **Sales & Marketing**, and then **Terms and Conditions**, and then **Add.**

> **Note**
>
> **T&C print order.** The value of the T&C code controls the order in which the T&C appears on the printed quote. This means you should assign these codes in some type of structured format (e.g., 01...) if you would like them to appear in a certain order.

Description of Page

Enter a unique **Terms and Condition** code and **Description**. Use **Text** to describe the exact terms.

Setting Up Decline Reasons

A proposal SA decline reason must be supplied when a proposal SA is declined. Open **Admin**, and then **Sales & Marketing**, and then **Proposal SA Decline Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Decline Reason** and **Description** for each proposal SA decline reason.

Where Used

Decline reasons are used when a quote detail is declined.

Setting Up Customer Classes For Quotes

An optional plug-in spot exists on customer class where you can introduce additional logic to be executed when a quote is completed for an account that belongs to this customer class. The base package comes supplied with a sample algorithm that creates a workflow process when a quote is completed (refer to the algorithm QTEC-WP for more information).

Copyright © 2026, Oracle and/or its affiliates.

Defining Case Management Options

Case management functionality is a highly configurable tool your organization can use to manage many situations, including (but certainly not limited to) the following:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- an application for new service,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change service providers on a future date,
- the processing of a market message in a deregulated environment,
- ... (the list is only limited by your time and imagination)

Obviously the steps involved in the resolution of the above cases are very different. The topics in this section describe how to configure the system to manage your cases as per your organization's desires.

> **Note**
>
> **Separate module.** The Case Management functionality is associated with a separate module. If the Case Management module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

> **NOT_SUPPORTED**
>
> Refer to Case Management for a description of how end-users use cases.

- The Big Picture Of Cases
- Setting Up Case Management Options

The Big Picture Of Cases

The topics in this section provide background information about how to configure the system to support your case management requirements.

- Case Type Controls Everything
- Scripts and Cases

Copyright © 2026, Oracle and/or its affiliates.

- To Do's and Cases
- Examples of Case Types

Case Type Controls Everything

Whenever a user creates a case, they must specify the type of case (e.g., high-bill complaint, literature request, etc.). The case type controls how the case is handled.

Case types hold the business rules that control cases. Since these business rules can sometimes be quite complicated, setting up case types requires planning and foresight. The topics in this section describe the type of business rules that can be configured on your case types.

- Person / Account / Premise Applicability
- Contact Information Applicability
- Business Object Association
- Additional Information
- Access Rights
- Lifecycle
- Status-Specific Business Rules
- Responsible User Applicability

Person / Account / Premise Applicability

Some types of cases may be person-oriented, others may be premise-oriented, and still others may be account-oriented. For example:

- Cases used to keep track of a literature request would reference the person who requested the literature.
- Cases used to keep track of the inspection of a property would reference the premise being inspected.
- Cases used to keep track of a high-bill complaint would reference the account associated with this bill(s) being disputed.

When you set up a case type, you define if its cases must reference a person, account, and/or premise. Note, any combination of these objects is permitted on a case.

Contact Information Applicability

When a case is created, you may want to keep track of how to contact its originator. For example, you may want to record the originator's email address or phone number. When you set up a case type, you define if contact information is required, optional or not allowed on its cases.

Copyright © 2026, Oracle and/or its affiliates.

Business Object Association

A case type may reference a Business Object, which serves as a link between cases of that type and the options that are associated with the business object.

Additional Information

Some of your cases may require additional information (in the form of characteristics). For example, a high-bill complaint may require at least one bill. When you set up a case type, you can define the additional fields that are required. In addition, you can define default values for these fields.

The case functionality also allows you to require characteristics when a case enters a given state. Refer to Required Fields Before A Case Enters A State for the details.

> **Note**
>
> **Requiring supporting documents.** Because any type of characteristic can be referenced on a case, you can require references to supporting documents by requiring a file location characteristic.

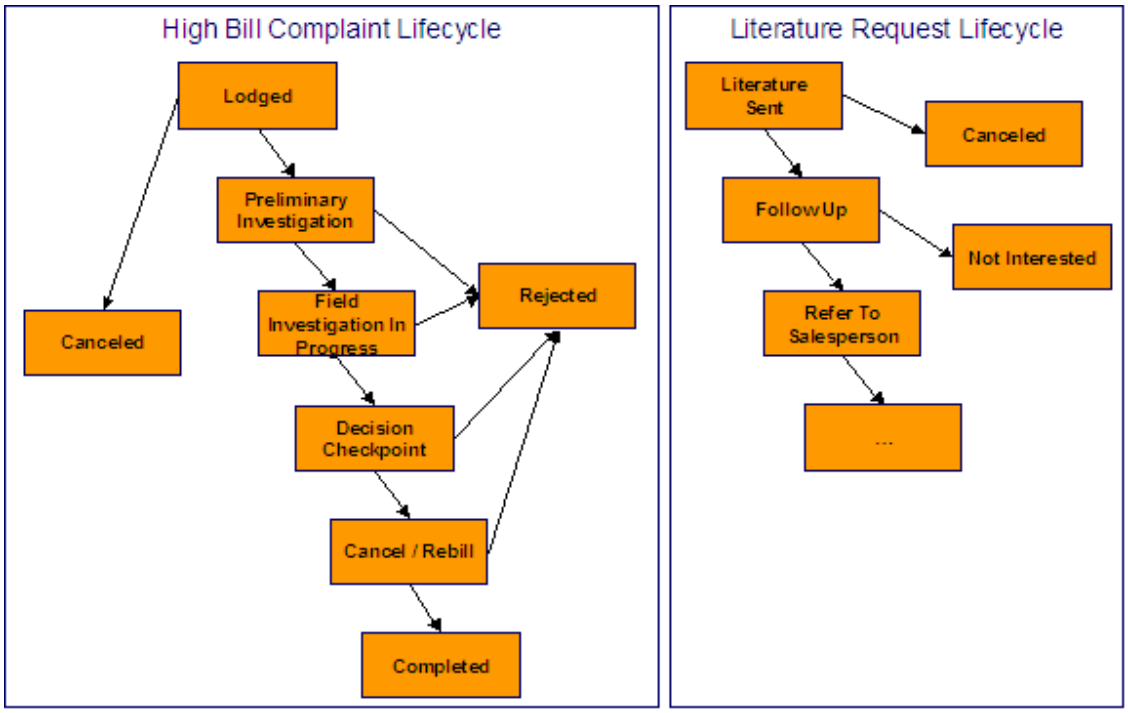
Access Rights

You can take advantage of the system's security to restrict cases of a given type to certain users. For example, you can restrict high-bill complaints to specific user groups.

The following points describe how to implement this type of security:

- Create an application service for each type of case you need to secure
- Define the access modes Add, Inquire and Change for each application service
- Define the applicable application service on each case type
- Link the appropriate user groups to each application service
  - For user groups that are allowed to add cases of a given type, define Add as a valid access mode.
  - For user groups that are allowed to view cases of a given type, define Inquire as a valid access mode
  - For user groups that are allowed to change cases of a given type, define Change as a valid access mode

If you restrict access to a case type's cases, you can further restrict which users can work on cases given the status of the case. Refer to Which Users Can Transition A Case for more information.



Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Restricting access to cases is optional.** If you don't specify an application service on a case type, all users (who have access to the case transaction) may access its cases.

Lifecycle

Many objects in the system have predefined lifecycles whose rules are governed by the base-package and cannot be changed. For example, a service agreement starts out in the Pending Start state and eventually becomes Closed when it's been final billed (and paid). You can't change the system to allow a service agreement to starts its life in the Closed state.

The lifecycle of cases is not governed by the base package. Rather, you define the lifecycle of your cases when you set up their case types. Examine the following diagrams; the one on the left shows the potential lifecycle of a case that manages a high-bill complaint, the one on the right shows the potential lifecycle of a case that manages a customer's literature request.

Potential Lifecycles Of Two Types Of Cases

> **Note**
>
> **Just examples.** The above lifecycles are just examples. When you set up your case types, you must define the valid states for your case type.

The topics that follow describe important concepts that are illustrated in the above diagrams.

- Valid States versus State Transition Rules

Copyright © 2026, Oracle and/or its affiliates.

- Transitory States
- One Initial State and Multiple Final States
- Allowing A Case To Be Reopened
- Make Sure To Have A Canceled State
- Buttons Are Used To Transition A Case From Status To Status
- State Transitions Are Audited
- Reports and Analytics Highlight Productivity

Valid States versus State Transition Rules

The orange boxes in the above diagram show the potential valid states a given case can have. The lines between the boxes indicate the state transition rules. These rules govern the states a case can move to while it's in a given state. For example, the above diagram indicates a high bill complaint that's in the Lodged state can be either Canceled or moved into the Preliminary Investigation state.

When you set up a case type, you define both its valid states and the state transition rules.

Transitory States

You can define a state in a case type as **Transitory** if you do not wish the case to exist in a particular state. For example, let's assume that an algorithm is associated with the Decision Checkpoint state (Enter Processing) that would automatically determine the next state for the case (i.e. Cancel/Rebill or Reject) and also contains logic to transition the case accordingly. In this scenario, you may not ever want the case to exist in the Decision Checkpoint state, so that a user won't ever see a high bill complaint in that state. If the other states were marked as non-transitory, and an error were to occur during the transition from Decision Checkpoint to Cancel/Rebill, the case would roll back any changes to data made in the Cancel/Rebill (Enter Processing) state along with the changes made in the Decision Checkpoint state, and would end up in the Field Investigation In Progress state - the last non-transitory state prior to Decision Checkpoint.

One Initial State and Multiple Final States

When you set up a case type's states, you must pick one as the initial state. The initial state is the state assigned to new cases of a given type. For example, high-bill complaint cases have an initial state of Lodged, whereas literature request cases have an initial state of Literature Sent.

You must also define which statuses are considered to be "final". When a case enters a "final" state, it is complete and no further action is necessary. You might want to think of the "final" states as the potential outcomes of a case. For example, a high-bill complaint has potential outcomes of Completed, Rejected, and Canceled.

The "final" states are used by the system to differentiate between open and closed cases. For example, an alert highlights when the person / account / premise in context has open cases (this alert only exists if you've plugged-in the appropriate installation alert).

Copyright © 2026, Oracle and/or its affiliates.

Allowing A Case To Be Reopened

You can set up your state transition rules to allow a case to be reopened (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure a case type accordingly.

Make Sure To Have A Canceled State

The system does not allow you to delete a case. Therefore, if you want to support logical deletion, you should have a status of Canceled early in a case type's lifecycle. Doing this allows a user to cancel (i.e., logically delete) a case.

> **Note**
>
> **Cancel reason.** You might want to consider setting up your case types to require a cancel reason (in the form of a predefined value characteristic) when a user cancels a case. Refer to Required Fields Before A Case Enters A State for more information.

Buttons Are Used To Transition A Case From Status To Status

When a case is displayed on Case - Main, a separate button is shown for each state into which the case can be transitioned. For example, a high-bill complaint case that is in the Lodged state would show two buttons: **Start Investigation** and **Cancel**. If the user presses the **Start Investigation** button, the case is transitioned to the Preliminary Investigation state. If the user presses the **Cancel** button, the case is moved to the Canceled state.

You may define the text displayed on the button differently for each state transition. This allows the action description to be varied according to the previous status. For example, the button to transition from New to Active may be labeled **Activate**, but the button to change from Closed to Active may be labeled **Reactivate**.

Refer to Which Users Can Transition A Case for instructions describing how to restrict users to specific actions.

State Transitions Are Audited

The system maintains an audit trail whenever a case transitions from one state to another. This audit is shown in the case's log.

Reports and Analytics Highlight Productivity

When you set up a case type's lifecycle, keep in mind that several reports and analytics highlight how long it took cases to transition into a state. For example, you can use a report to see how long it took high-bill complaints to be completed (or initially actioned or ...). Refer to the Reports chapter for the details of case reports.

Copyright © 2026, Oracle and/or its affiliates.

Status-Specific Business Rules

As described in Lifecycle, when you set up a case type, you define the possible states its cases can pass through. The following topics describe business rules that can be configured for each state.

- A Script That Helps A User Work Through A Case
- Required Fields Before A Case Enters A State
- Validation Before A Case Enters A State
- Additional Processing When Entering A State
- Validation Before A Case Exits A State
- Additional Processing When Exiting A State
- Automatic Transition Rules
- Script Launching Option
- Which Users Can Transition A Case Into A State

A Script That Helps A User Work Through A Case

You can define a Business Process Assistant script that helps a user work a case while it's in a given state. For example, when you set up the Preliminary Investigation state for the high-bill complaint case type, you can define a script. A user can then easily launch this script to help them work through a case in this state.

Please keep the following in mind when you're designing how to integrate BPA scripts with your cases:

- You can have a different script for each state. For example, you could develop a script to help a user work on a case while it's in the Preliminary Investigation state and a different script to help them work in a case while it's in the Decision Checkpoint state.
- Rather than make a user launch a script by pressing a hyperlink on the case page, you can have the system automatically launch the script while the case is in a given state. Refer to Script Launching Option for more information.
- You can also have the system automatically launch a script when a user selects a To Do entry. Refer to Launching Scripts When To Do Entries Are Selected for more information.

NOT_SUPPORTED

Refer to Scripts and Cases for more information about how to streamline your case processing with scripts.

Required Fields Before A Case Enters A State

Copyright © 2026, Oracle and/or its affiliates.

You can define additional fields (i.e., characteristics) that are required before a case can enter a given state. For example,

- You can indicate a high-bill complaint must reference at least one bill before it enters the Preliminary Investigation state.
- You can indicate a case must reference a cancel reason before it enters the Canceled state.

You do this by indicating that characteristics (that were optional when the case was added) are required when a case enters a given state.

Validation Before A Case Enters A State

You can define validation that executes before a case can enter a given state. For example, you can indicate the case must have been assigned a responsible user before it can enter the Preliminary Investigation state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Entering A State

You can define additional processing that should happen when a case enters a given state. For example, you can have a letter created when a high-bill complaint case is Rejected. Similarly, you can have a To Do entry created when a high bill complaint enters the Preliminary Investigation state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

You can also incorporate state transitioning logic within routines that are executed when a case enters a state, so that you do not need to rely upon CASETRAN to transition your cases. For example, when the state entry routines of the Preliminary Investigation status for a high-bill complaint are executed, they may be designed to transition the case into either the Rejected or Field Investigation In Progress state without waiting. Note that your Exit Validation and Exit Processing logic, if configured for the case state, will still be executed as part of the state transition. Auto-Transition logic for this state will be ignored during this transition.

Validation Before A Case Exits A State

You can define validation that executes before a case can exit a given state. For example, you might want to check the account's balance is less than a given value before a case can exit a given state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Exiting A State

You can define additional processing that should happen when a case exits a given state. For example, you can have a To Do entry automatically completed when a high bill complaint leaves the Decision Checkpoint state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

Copyright © 2026, Oracle and/or its affiliates.

Automatic Transition Rules

You can define rules that automatically transition a case into a different state. For example, you can indicate a literature request should be transitioned to the Follow Up state 1 week after the literature is sent. Similarly, you can indicate a high-bill complaint should transition to the Decision Checkpoint state after the fieldwork is complete. These rules are held in algorithms that are plugged in on the case type and therefore you can define any type of automatic transition rules.

Cases in a state with automatic transition rules are monitored by the CASETRAN background process. Each time this program runs, the respective automatic transition plug-in is called for each such case and it transitions the case if the condition applies.

> **Note**
>
> **When to execute CASETRAN.** Because your automatic transition rules will be dependent on your business requirements, you need to think carefully about when you run the CASETRAN background process. For example, if you have automatic transition rules that transition a case to a new state when a related field activity is completed, you would want to schedule this job to run after field activities are uploaded. If you have rules to transition a case after a customer pays a deposit, you'd want to schedule this job to run after payments are uploaded. Bottom line - your business rules will dictate the frequency of execution.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. In other words, you don't need to wait for the auto-transition background process to be executed. An indication that the case was auto-transitioned online is displayed right below the action buttons section.

> **Note**
>
> **Auto-Transition Errors.** Online auto-transition is performed recursively committing each successful state transition to the database. It is performed up to 100 times or until an error is encountered during the process. If this happens, auto-transition stops at the last **non-transitory** state into which a successful transition had occurred. Two case log entries will be generated automatically - one containing the message that a transition error has occurred, and a second containing the actual error message. A To Do entry will also be generated automatically upon rollback. The type of this To Do entry will be taken from 1) the Case Transition Exception To Do Type **option** for the **Business Object** associated with the case type, and if this is not populated, 2) the Exception To Do Type indicated on the Case Options Feature Configuration. All of the above error handling is true for both batch and online processing of cases.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Triggering Auto-Transition.** If you have a customized process that affects the state of a case and you want the case to be auto-transitioned right away, i.e. not wait for the next scheduled CASETRAN background process to execute, you can customize that process to trigger auto-transition for the specific case, or you can put the state transition logic into the routines that execute at state entry time.

Script Launching Option

You can define whether the script associated with a given state is to be automatically launched while the case is in that state. The system supports the following options:

- Launch the script only if no script is currently active.
- Always launch the script unless this specific script is currently active.

> **Warning**
>
> With this option, if a script is currently open in the page's BPA script area then it will be automatically closed and the case script will open.

- Do not automatically launch the script.

You do this by plugging-in a Script Launching algorithm for the given state. If no such plug-in is provided the script is not automatically launched.

Which Users Can Transition A Case Into A State

If you have restricted access to a case type, you can further restrict which user groups are allowed to transition a case into specific states. For example, you can control which user group can transition a high bill complaint into the Preliminary Investigation state. The following points describe how this is done:

- Define actions on the application service defined on the case type. You must define an action for each status that you need to secure.
- Define each status's corresponding action. Note, you only need to link a status to an action if it's secured. Any user with access to the case type can perform statuses that aren't linked to actions.
- Define the transition role for each status's valid next status. You can assign valid next statuses to be reachable via system (only), or system and user.
- Define which user groups have access to the actions (i.e., statuses). In addition, these user groups should have access to the Change action.

Responsible User Applicability

Copyright © 2026, Oracle and/or its affiliates.

Some of your cases may require a "responsible user". This is the user who has overall responsibility for the case. When you set up a case type, you define if a responsible user is required, optional or not allowed on its cases.

The following points describe how to set up the system if a responsible user is not required when a case is first created, but is later in its lifecycle:

- Indicate that a responsible user is optional on the case type
- Plug-in either an exit validation or entry validation algorithm on one of the case type's states to require a responsible user at some point in a case's lifecycle

> **Note**
>
> **Address To Do entries to the responsible user.** If you use the base-package algorithm to create a To Do entry when a case enters a given state, you can indicate that the To Do entry should be addressed to the responsible user on the case.

Scripts and Cases

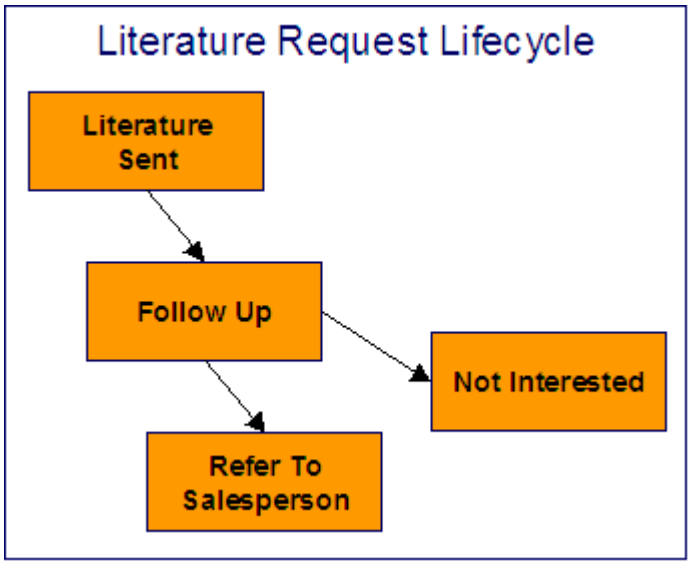
There are three ways Business Process Assistant scripts can be used to manage cases:

- You can create a BPA script to help users create a case. For example, a script can help a user create a new high-bill complaint.
- Using a script to create a case can save a user a lot of time (and training efforts). This is because the script can automatically populate many fields on the case based on answers to questions.

Refer to Initiating Scripts for a description of how end-users initiate scripts.

- You can create a script to help users work on a case when it's in a given state. Refer to A Script That Helps A User Work A Case for more information.
- You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these ToDo entries without assistance. However, you can set up the system to automatically launch a script when a user selects a ToDo entry. For example, consider a ToDo entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this ToDo entry. This script might guide the user through the investigation process (and help them update the case). Refer to Executing A Script When A To Do Entry Is Selected for more information.

To Do's and Cases



The topics in this section provide background information about how to facilitate case management with To Do entries.

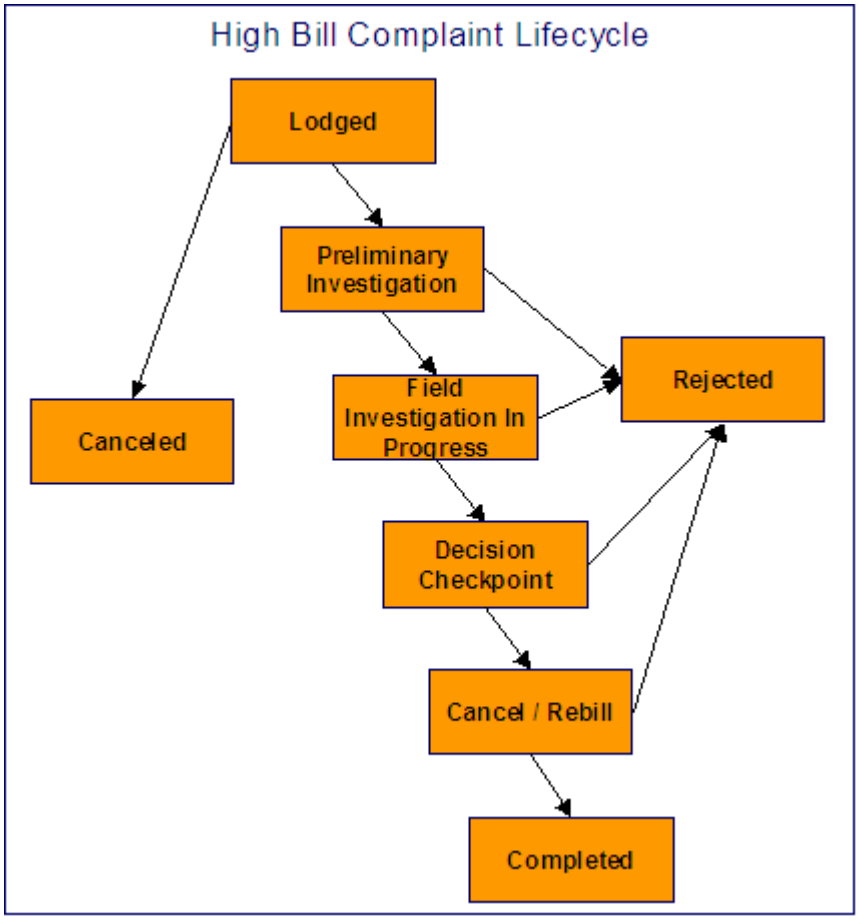
- Creating and Completing To Do Entries
- Launching Scripts When To Do Entries Are Selected
- All To Do Entries Are Visible

Copyright © 2026, Oracle and/or its affiliates.

Creating and Completing To Do Entries

You can configure your case types to create and complete To Do entries when a case enters or exits a state. Let's use the following lifecycle diagram to illustrate a potential use of To Do's:

Let's assume the following:



- You want a To Do entry created when a literature request case enters the Follow Up state. You want this To Do automatically completed when the case enters either the Refer To Salesperson or Not Interested states. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when a case enters the Refer To Salesperson state. You do not want the system to automatically complete this entry (the sales person must manually do this). Note, we refer to this as the "second" To Do entry below.

To implement the above, you would set up a case type as follows:

- Plug-in an entry processing algorithm on the Follow Up status to create the first To Do entry.
- Plug-in an exit processing algorithm on the Follow Up status to complete the first To Do entry.
- Plug-in an entry processing algorithm on the Refer To Salesperson status to create the second To Do entry.

While the case type illustrated above had a single To Do entry "active" at any point in time, you can easily configure a case type to have multiple To Do entries active at any point in time. Let's use the following lifecycle diagram to illustrate this point:

Copyright © 2026, Oracle and/or its affiliates.

Let's assume the following:

- You want a To Do entry created when a high bill complaint is created and you want it completed when the case reaches the Canceled, Rejected or Approved states. This To Do entry could be used by a supervisor to monitor the number of high-bill complaints logged. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when the case enters the Preliminary Investigation state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "second" To Do entry below.
- You want a different To Do entry created when the case enters the Decision Checkpoint state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "third" To Do entry below.

To implement the above, you would set up the case type as follows:

- Plug-in an entry processing algorithm on the Lodged status to create the first To Do entry. Plug-in an entry processing algorithm on the Canceled, Rejected and Completed statuses to complete this entry.
- Plug-in an entry processing algorithm on the Preliminary Investigation status to create the second To Do entry. Plug-in an exit processing algorithm on the Preliminary Investigation status to complete this entry. We elected to use an exit processing algorithm because we only have to plug it in on one status. If we'd used an entry processing algorithm, we would need to plug it in on the 2 statuses into which a Preliminary Investigation status can transition.

Copyright © 2026, Oracle and/or its affiliates.

- Plug-in an entry processing algorithm on the Decision Checkpoint status to create the third To Do entry. Plug-in an exit processing algorithm on the Decision Checkpoint status to complete this entry.

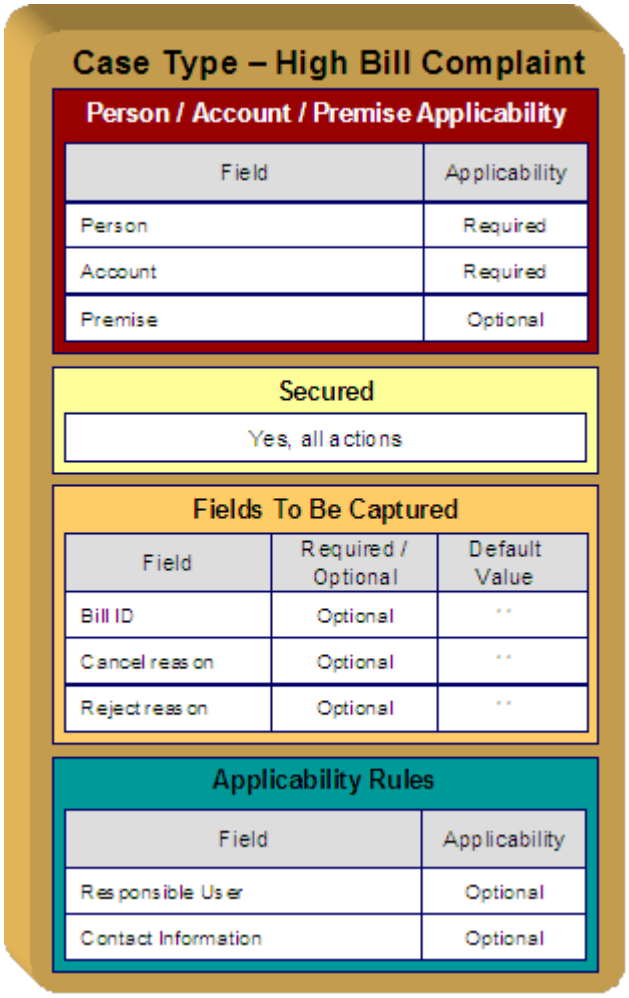
Launching Scripts When To Do Entries Are Selected

You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these To Do entries without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this type of To Do entry. This script might guide the user through the investigation process. Refer to Executing A Script When A To Do Entry Is Selected for more information.

All To Do Entries Are Visible

When a case is displayed on Case Maintenance, the system summarizes the number of To Do entries associated with the case (if you've set up your To Do types appropriately).

Examples of Case Types



The topics that follow provide examples of case types related to several business processes. Use the information in this section to form an intuitive understanding of case types. After attaining this understanding, you'll be ready to design your own case types.

- High Bill Complaint

High Bill Complaint

Some organizations will set up a case to manage a high-bill complaint. The following diagram illustrates how such a case type might look:

Copyright © 2026, Oracle and/or its affiliates.

Case Type – High Bill Complaint

Person / Account / Premise Applicability

Field	Applicability
Person	Required
Account	Required
Premise	Optional

Secured

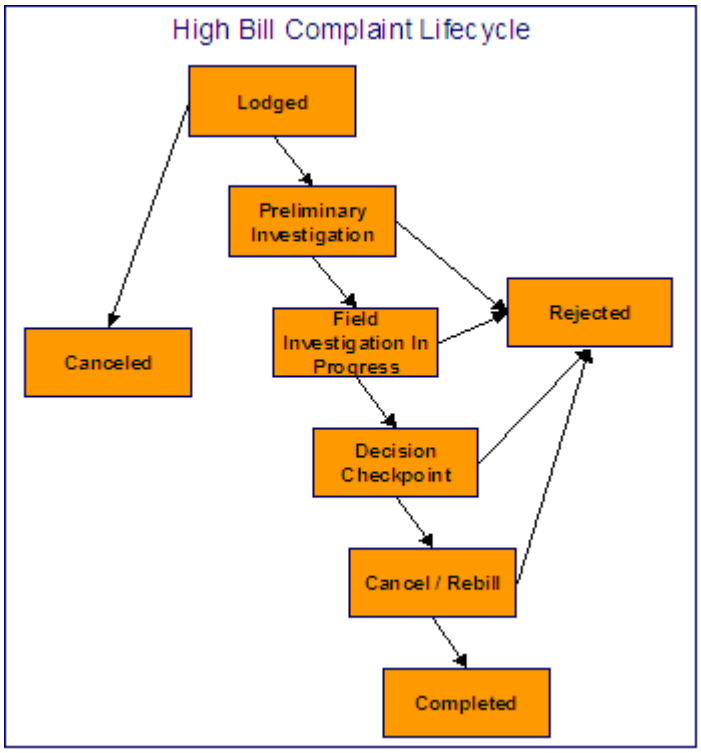
Yes, all actions

Fields To Be Captured

Field	Required / Optional	Default Value
Bill ID	Optional	''
Cancel reason	Optional	''
Reject reason	Optional	''

Applicability Rules

Field	Applicability
Responsible User	Optional
Contact Information	Optional



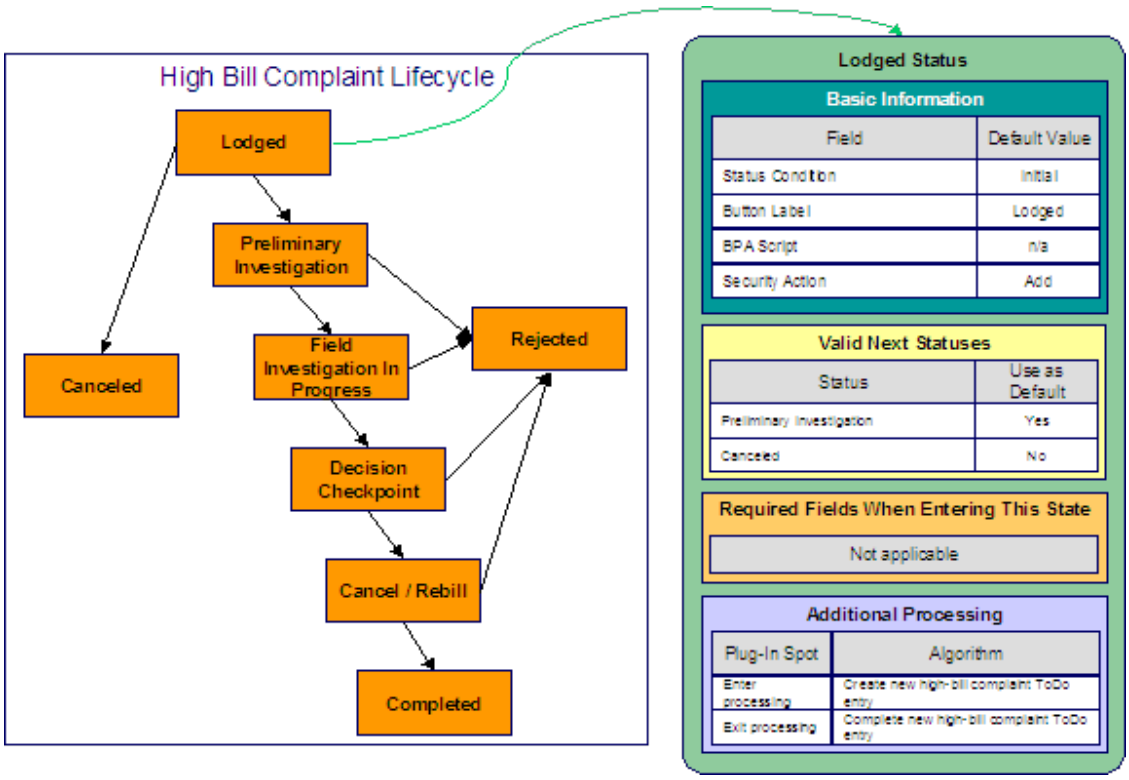
Note the following about the High Bill Complaint case type:

- Notice that we set up the case type to require a person and an account, but premise is optional. This is because a bill can span multiple premises and knowing the premise isn't so important on cases of this type.
- We need to restrict high-bill complaints to specific user groups. This means we need to set up a specific application service for this case type (that has a separate "action" for each status).
- Cases of this type have 3 additional fields over their lifetime. Notice the following:
  - The **Bill ID** characteristic is set up to be optional. This is because we've assumed that sometimes a high-bill complaint case can be lodged when you can't find the bill in question and you still want to log the case.
  - Later in this section, you'll see that we've configured the Preliminary Investigation status to require a **Bill ID** before a case can enter this state.
  - Both the **High Bill Complaint Cancel Reason** and **Reject Reason** are optional. Later in this section, you'll see that we've configured the Canceled and Rejected statuses to require these fields, respectively.
- Cases of this type do not need a **Responsible User** when first created. Later in this section, you'll see how we've configured the Preliminary Investigation status to require a **Responsible User** before a case can enter this state.

Copyright © 2026, Oracle and/or its affiliates.

- Cases of this type do not need **Contact Information**. This was a subjective decision and depends on your organization's philosophy.

The topics that follow describe each of the statuses in a high-bill complaint's lifecycle. We have assumed the following state transition rules:

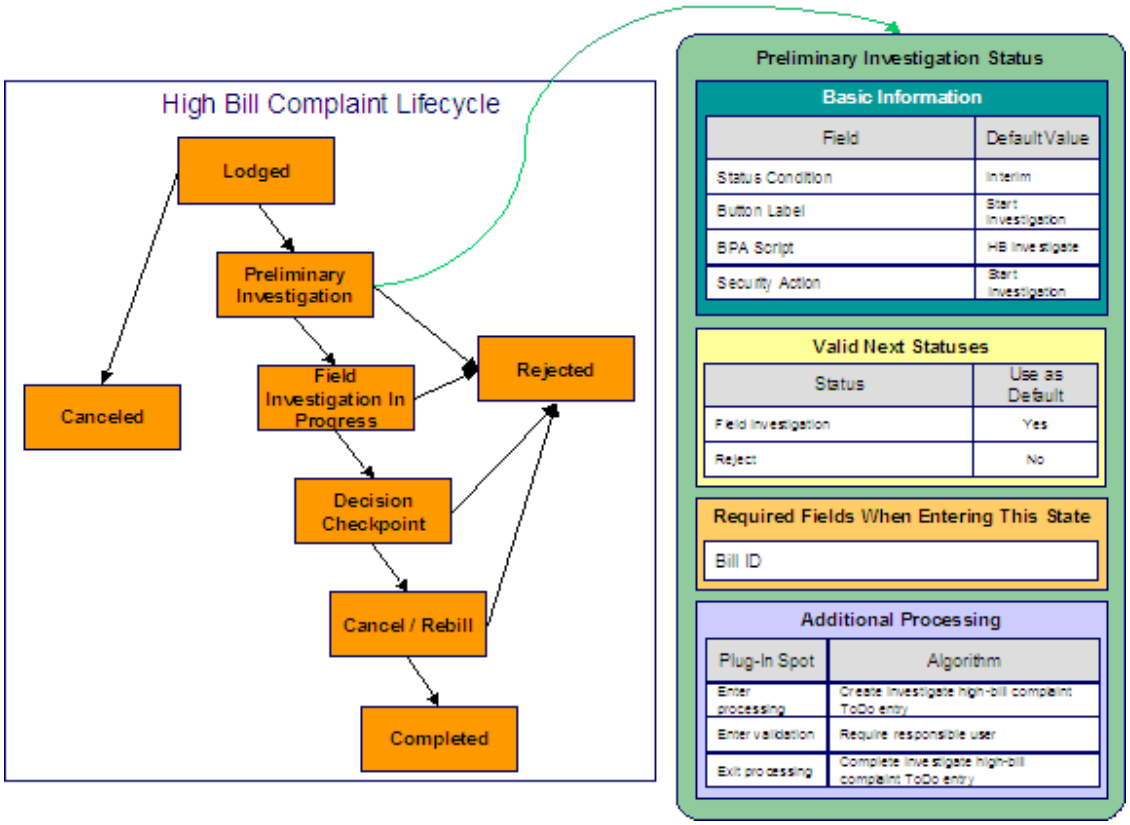


- Lodged High Bill Complaint
- Preliminary Investigation High Bill Complaint
- Field Investigation High Bill Complaint
- Decision Checkpoint High Bill Complaint
- Cancel Rebill High Bill Complaint
- Completed High Bill Complaint
- Rejected High Bill Complaint
- Canceled High Bill Complaint

Lodged High Bill Complaint

The following is an example of the configuration of the Lodged status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



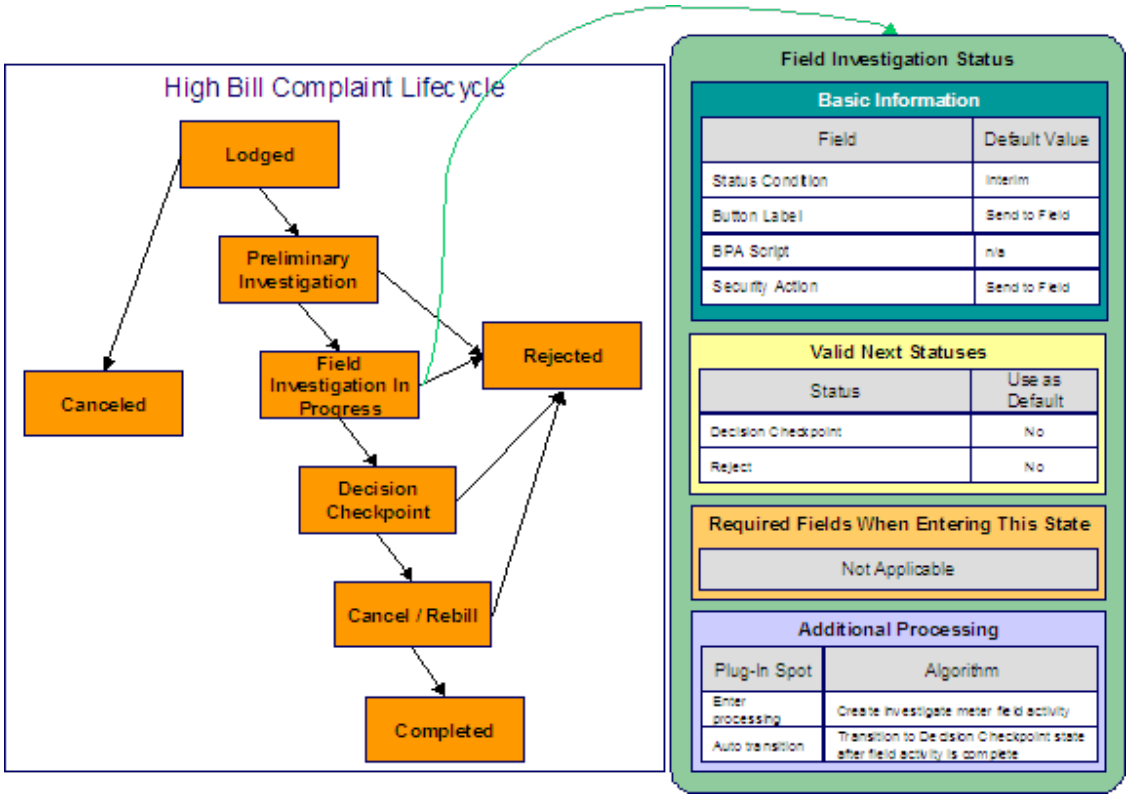
Note the following about this status:

- Lodged is the initial state. The initial state is the state populated on new cases of a given type. Remember that only one status can be defined as the initial state.
- It has a button label even though it's the initial state. The above diagram doesn't allow a user to ever transition a case into this state and therefore there will never be a button with such a label. However, it's a required field just in case you change your business rules.
- We have decided not to use a BPA script to help a user work on a high-bill complaint when it's in this state (this is probably not the best decision as BPA scripts can be quite useful).
- We have associated the Add action with this status. This means that only users with rights to the add action for the application service defined on the case type can add cases of this type.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Canceled and Preliminary Investigation states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Preliminary Investigation High Bill Complaint

The following is an example of the configuration of the Preliminary Investigation status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



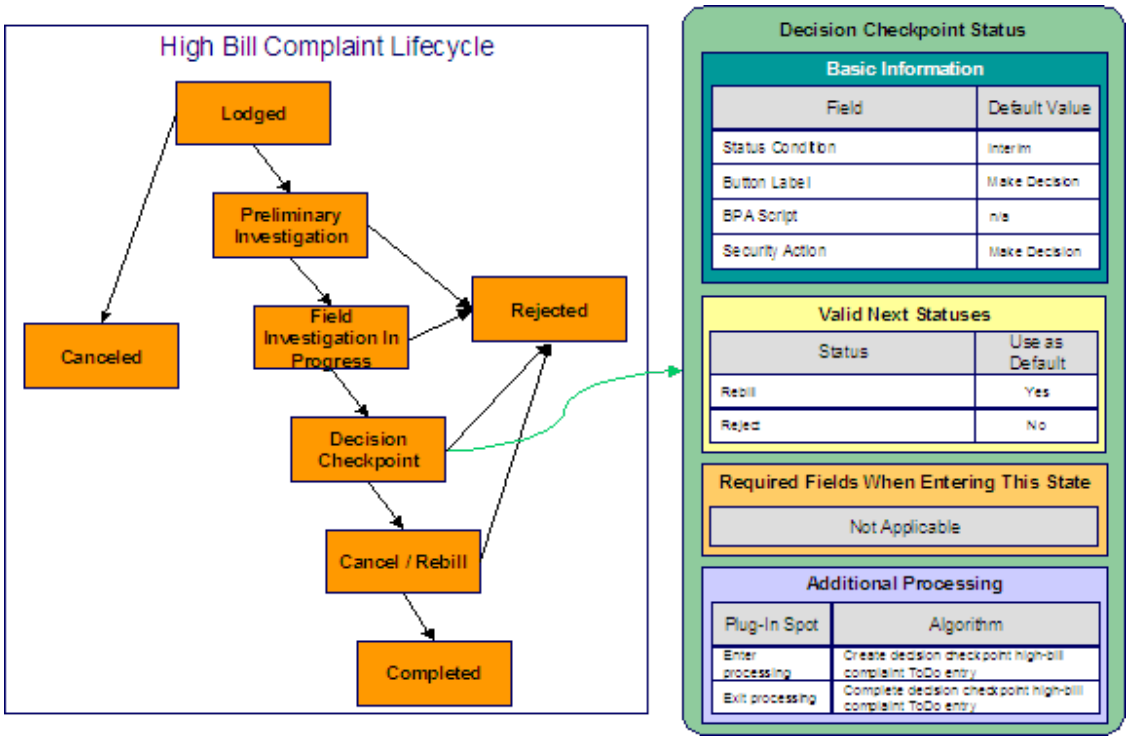
Note the following about this status:

- Preliminary Investigation is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Start Investigation**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Preliminary Investigation state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Start Investigation action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Field Investigation and Rejected states.
- Notice that a **Bill ID** must be specified on the case before it can be moved into this state.
- Notice that the Additional Processing plug-ins do the following:
  - Create and complete a To Do entry when a case enters and exits this state, respectively
  - Require a responsible user before a case can enter this state

Field Investigation High Bill Complaint

Copyright © 2026, Oracle and/or its affiliates.

The following is an example of the configuration of the Field Investigation In Progress status for high bill complaint cases.



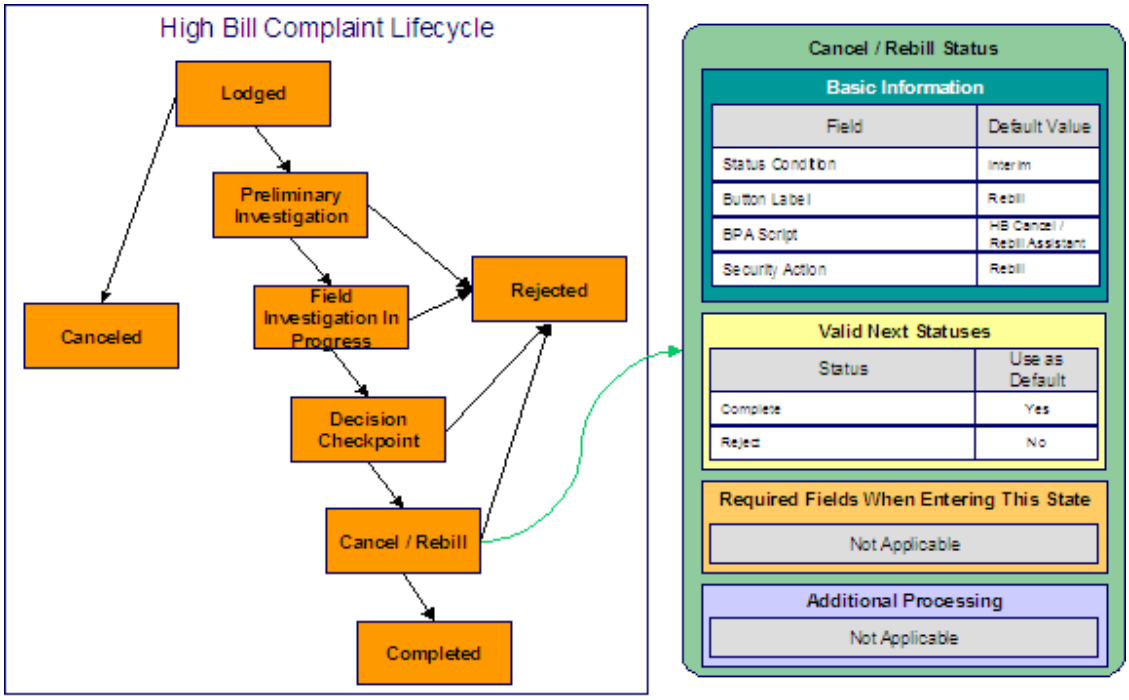
Note the following about this status:

- Field Investigation In Progress is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Send to Field**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Preliminary Investigation state as this is the only state that can transition into the Field Investigation in Progress state.
- We have decided not to specify a BPA script on this status because users don't work cases in this state (see the Additional Processing notes below for why this is the case).
- We have associated the Send to Field action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Decision Checkpoint and Rejected states.
- Notice that the Additional Processing plug-ins do the following:
  - Create a field activity when a case enters this state
  - Cause the case to automatically transition to the Decision Checkpoint state when the field activity is completed

Decision Checkpoint High Bill Complaint

Copyright © 2026, Oracle and/or its affiliates.

The following is an example of the configuration of the Decision Checkpoint status for high bill complaint cases.



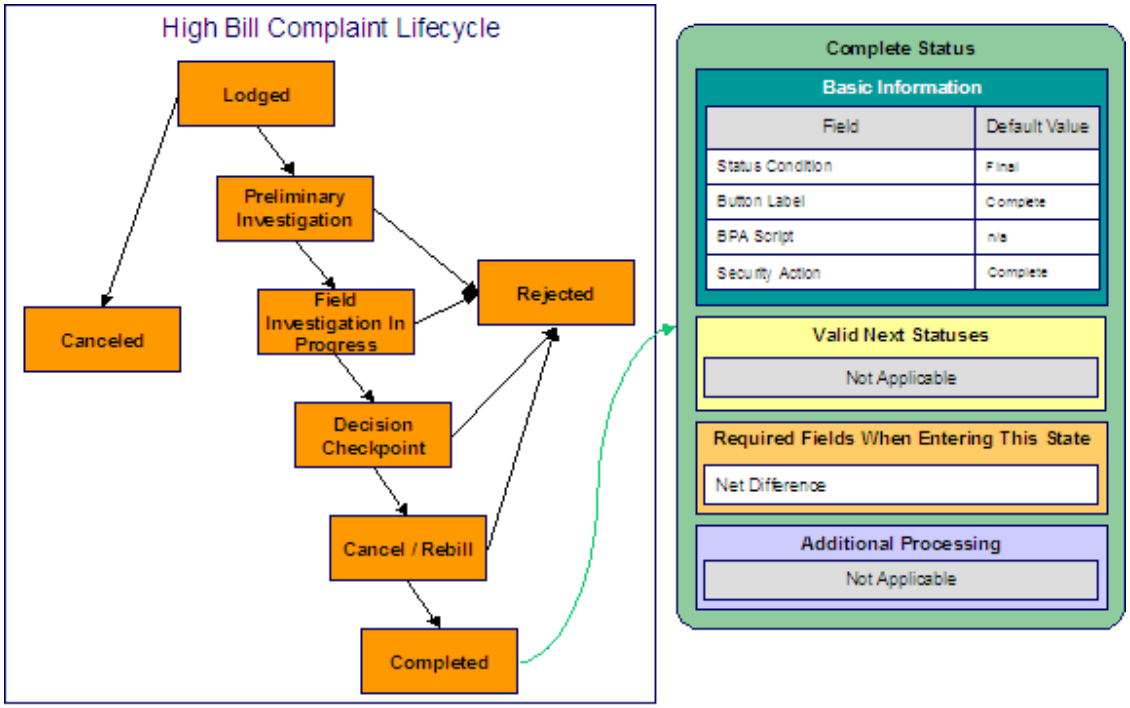
Note the following about this status:

- Decision Checkpoint is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Make Decision**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Field Investigation in Progress state as this is the only state that can transition into the Decision Checkpoint state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Make Decision action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state. Because the system will automatically transition cases into this state when the related field activity is complete, users will probably never press this button (and you may wish to prevent users from pressing this button be restricting security rights to the related action).
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Cancel / Rebill and Rejected states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Cancel Rebill High Bill Complaint

The following is an example of the configuration of the Cancel / Rebill status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



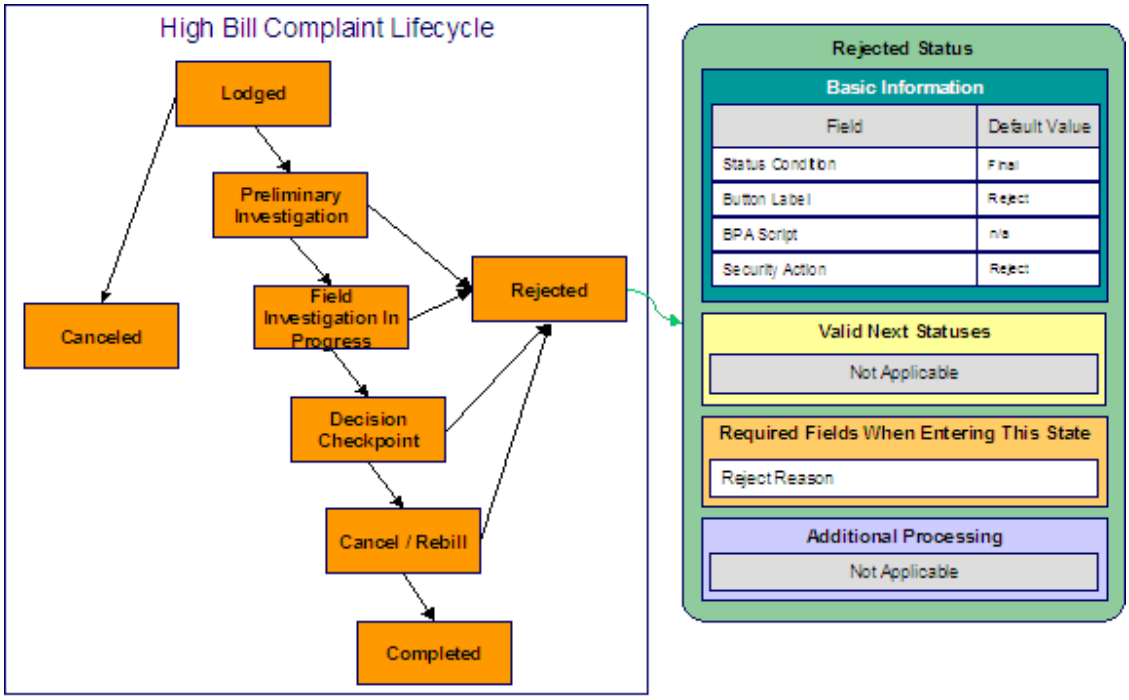
Note the following about this status:

- Cancel / Rebill is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Cancel / Rebill**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Decision Checkpoint state as this is the only state that can transition into the Cancel / Rebill state.
- We have referenced a BPA script that can assist a user in the cancel / rebill efforts.
- We have associated the Rebill action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Completed and Rejected states.

Completed High Bill Complaint

The following is an example of the configuration of the Completed status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



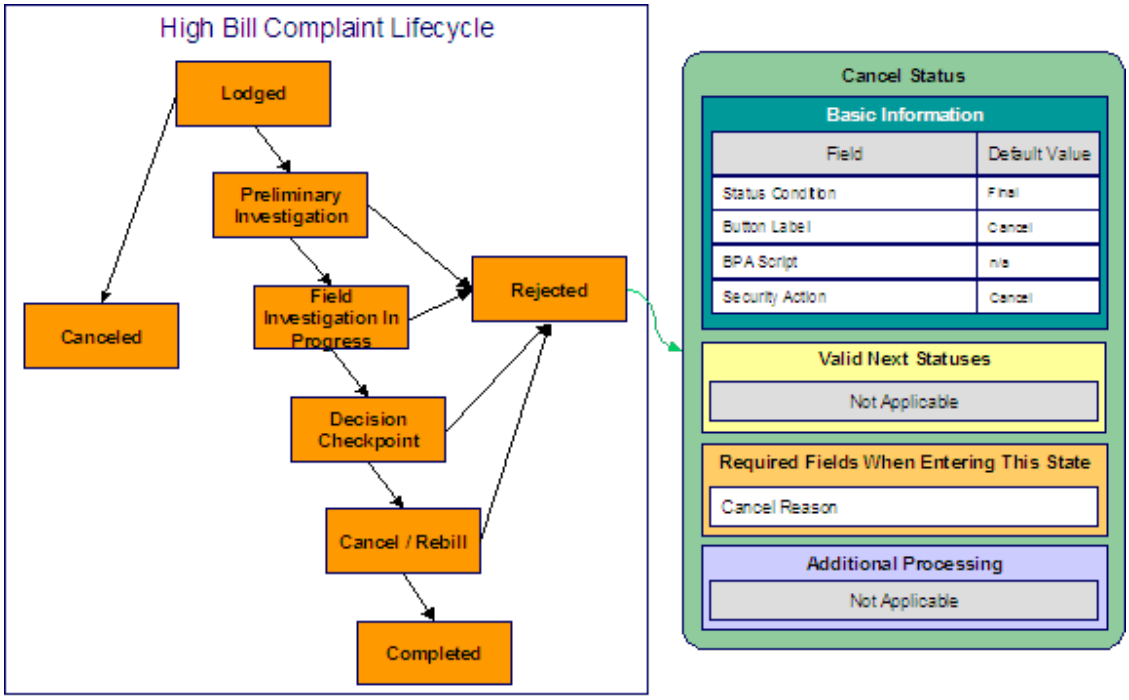
Note the following about this status:

- Completed is a final state (meaning that no further action is necessary).
- It has a button label of **Complete**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Cancel / Rebill state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Complete action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Completed case to be reopened, you would need to define the state into which a Completed case could be transitioned.
- Notice that the **Net Difference** must be specified on the case before it can be moved into this state. This would be the difference to the customer's balance after the cancel rebill took place.

Rejected High Bill Complaint

The following is an example of the configuration of the Rejected status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.



Note the following about this status:

- Rejected is a final state (meaning that no further action is necessary).
- It has a button label of **Reject**. This is the label on the button that a user presses to move a case into this state. This button will appear on cases that are in the Preliminary Investigation, Field Investigation in Progress , Decision Checkpoint and Cancel / Rebill states.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Reject action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Rejected case to be reopened, you would need to define the state into which a Rejected case could be transitioned.
- Notice that a **Reject Reason** must be specified on the case before it can be moved into this state.

Canceled High Bill Complaint

The following is an example of the configuration of the Canceled status for high bill complaint cases.

Copyright © 2026, Oracle and/or its affiliates.

Note the following about this status:

- Canceled is a final state (meaning that no further action is necessary).
- It has a button label of **Cancel**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Cancel action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Canceled case to be reopened, you would need to define the state into which a Canceled case could be transitioned.
- Notice that a **Cancel Reason** must be specified on the case before it can be moved into this state.

Setting Up Case Management Options

The topics in this section describe how to set up the system to enable case management.

> **⚠ Warning**
>
> The following topics assume you thoroughly understand the concepts described under The Big Picture Of Cases.

Installation Options

- Case Info May Be Formatted By An Algorithm
- Alert Info Is Controlled By An Installation Algorithm

Case Info May Be Formatted By An Algorithm

An algorithm may be plugged in on the installation record to format the standard case information that appears throughout the system. Refer to CSIN-DFLT for an example of this algorithm.

This algorithm may be further overridden by a "Case information" plug-in on the Case Type. Refer to C1-CT-INFO for an example of this algorithm.

Alert Info Is Controlled By An Installation Algorithm

An algorithm that is plugged in on the installation record is responsible for formatting the alerts that highlight if the person / account / premise in context has open cases. Refer to CCAL-CASE for an example of this algorithm.

Setting Up Application Services

As described under Access Rights, you can prevent unauthorized users from accessing cases. The following points describe how to implement this type of security:

- Create an application service for each case type that needs to be secured
- Create an action on the application service for each status you need to secure
- Link the valid user groups to the application service and define which actions they can perform
- Define the application service on the case type
- Define the related action for each status on the case type / status

Setting Up Scripts

Copyright © 2026, Oracle and/or its affiliates.

As described under Scripts and Cases, BPA scripts can facilitate the creation and working of cases. Refer to the Defining Script Options for instructions describing how to set up scripts.

Setting Up To Do Types

As described under To Do's and Cases, To Do entries can be used to highlight cases that require user attention.

The following points provide a high-level description of how to create (and complete) To Do entries for a case type:

- Create a To Do type for each different type of To Do entry used during a case's lifecycle
  - On the To Do type, think carefully about the roles whose users can work on the entries
  - Also consider if you would like a BPA script launched when a user selects the entry
- Specify the To Do type on the appropriate entry processing or exit processing algorithm
- If you want the system to automatically complete To Do entries, specify the To Do type on the appropriate entry processing or exit processing algorithm

Please be aware that the case maintenance transaction highlights the number of open and assigned To Do entries linked to the case being displayed on the page. However, the system can only do this if the To Do entries reference a foreign-key characteristic whose foreign key references the case table. If you use the CSEN-TD algorithm to create To Do entries when a case enters a given state, this algorithm will do this for you if:

- You have set up a foreign-key characteristic type whose foreign key references the case table
- In addition, the characteristic type must reference a characteristic entity of To Do Entry

Setting Up Characteristic Types

As described under Additional Information, some of your cases may require additional information (in the form of characteristics). If this is true, you must set up the characteristic types before setting up the case types.

Refer to Setting Up To Do Types for instructions regarding a characteristic type that must be set up in order for the system to know the To Do entries that are associated with a case.

If you use the CSEN-CC algorithm to create customer contacts when a case enters a given state, you should set up a foreign-key characteristic type as follows:

- Its foreign key must reference the case table
- In addition, the characteristic type must reference a characteristic entity of Customer Contact

Setting Up Case Types

The case type maintenance transaction is used to maintain your case types. The topics in this section describe how to use this transaction.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to The Big Picture Of Cases for more information about how a case type encapsulates the business rules that govern a case.

- Case Type - Main
- Case Type - Case Characteristics
- Case Type - Lifecycle

Case Type - Main

Use this page to define basic information about a case type.

Open the case type page by selecting **Admin**, and then **Customer**, and then **Case Type**, and then **Case Type**, and then **Add.**

Note

Recommendation. Before using this transaction, we strongly recommend that you review the Examples of Case Types.

Main Information

Enter a unique **Case Type** code and **Description** for the case type.

Use **Long Description** to provide a more detailed explanation of the purpose of the case type.

If your implementation requires restricting case types by CIS Division, specify a **CIS Division** on the case type.

Person Usage controls the applicability of a person on cases of this type. Select Required if a person must be defined on this type of case. Select Optional if a person can optionally be defined on this type of case. Select Not Allowed if a person is not allowed on this type of case.

Account Usage controls the applicability of an account on cases of this type. Select Required if an account must be defined on this type of case. Select Optional if an account can optionally be defined on this type of case. Select Not Allowed if an account is not allowed on this type of case.

Premise Usage controls the applicability of a premise on cases of this type. Select Required if a premise must be defined on this type of case. Select Optional if a premise can optionally be defined on this type of case. Select Not Allowed if a premise is not allowed on this type of case.

Entity Relationship controls the validation of relationships on cases of this type. ***All*** ensures that the account belongs to the person and that the account and premise are related. ***Person and Account Only*** disables the account and premise validation. ***Premise and Account Only*** disables the person and account validation. ***None*** disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

Copyright © 2026, Oracle and/or its affiliates.

If you need to restrict access to cases of this type to specific user groups, reference the appropriate **Application Service**. Refer to Setting Up Application Services for the details of how to secure access to your cases.

If you are configuring a case type to handle the processing of data defined via a **Business Object**, associating the case type with a business object serves to link the properties of the business object (e.g. BO options) with cases of that type. Refer to Business Objects for further information. In addition, refer to Automatic Transition Rules for information on the role of BO options in case auto-transition errors.

Responsible User Usage controls the applicability of a responsible user on cases of this type. Select Required if a responsible user must be defined on this type of case. Select Optional if a responsible user can optionally be defined on this type of case. Select Not Allowed if a responsible user is not allowed on this type of case. Refer to Responsible User Applicability for more information.

Contact Information Fields

There are three contact information fields: **Contact Person & Method Usage**, **Contact Instructions Usage**, and **Case Phone Usage**. These fields are used to determine whether or not each type of contact information must be entered on case records with this case type. Select Required if the contact information must be entered, select Optional if the user can choose whether or not to include the contact information on this type of case, or select Not Allowed if the contact information cannot be entered on this type of case.

Algorithms

The **Algorithms** grid contains algorithms that control functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Case Information	Optional	We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm. Plug an algorithm into this spot to override the "Case information" algorithm on installation options or the system default "Case information" if no such algorithm is defined on installation options.

Case Type Tree

Copyright © 2026, Oracle and/or its affiliates.

The tree summarizes the case type's lifecycle. You can use the hyperlinks to transfer you to the **Lifecycle** tab with the corresponding status displayed.

Case Type - Case Characteristics

To define characteristics that can be defined for cases of this type, open **Admin**, and then **Customer**, and then **Case Type**, and then **Search** and navigate to the **Case Characteristics** page.

Description of Page

Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on cases of this type. Turn on the **Default** switch to default the **Characteristic Type** when cases of this type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** box is checked. Refer to Required Fields Before A Case Enters A State for a description of how you can make option characteristics required at later stages in a case's lifecycle.

Case Type - Lifecycle

Case types that involve multiple users and multiple potential outcomes have complex lifecycles. Before you can design a case type's lifecycle, it's important that you thoroughly understand the concepts described under Lifecycle and Status-Specific Business Rules. After thoroughly understanding these concepts, we recommend you perform the following design steps:

- Draw a "state transition diagram" as illustrated above under Lifecycle. Keep in mind that if your state transition diagram is complex, your cases will be complex. While some cases warrant complexity, you should always ask yourself if there aren't better ways to achieve the desired results if your first effort results in complexity.
- Determine which characteristics (if any) are required during each stage of a case's lifecycle
- Determine when To Do entries (if any) should be created (and completed) during a case's lifecycle
- Determine additional validation (if any) that should be executed before a case enters and exits each state
- Determine additional processing (if any) that should transpire when a case enters or exits each state
- Determine if scripts are warranted to help users work the cases and, if so, design the scripts for each applicable state

When the above tasks are complete, you will be ready to set up a case type's lifecycle.

Open the Lifecycle page by selecting **Admin**, and then **Case Type**, and then **Case Type**, and then **Search** and navigate to the **Lifecycle** page.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> You can navigate to a status by clicking on the respective node in the tree on the Main tab. You can also use the hyperlinks in the Next Statuses grid to display a specific status in the accordion.

Main Information

The **Status** accordion contains an entry for every status in the case type's lifecycle.

Use **Status** to define the unique identifier of the status. This is NOT the status's description, it is simply the unique identifier used by the system.

Use **Description** to define the label that appears on the lifecycle accordion as well as the status displayed on the case.

Use **Script** to reference a BPA script that can assist a user work on a case while it's in this status. Refer to A Script That Helps A User Work Through A Case for the details.

Use **Access Mode** to define the action associated with this status. This field is disabled if an application service is not specified on the Main page. Refer to Access Rights for the details of how to use this field to restrict which users can transition a case into this state.

Use **Batch** to specify a batch control that will auto-transition the case. Any case in a status configured with a batch control will be transitioned when the batch job runs (rather than when CASETRAN is executed). For this purpose, batch process C1-CSTRS (**Case Scheduled Transition**) is supplied with base package, which will execute all Exit Status logic for the current status, and Enter Status logic for the destination status. You may choose to create a batch process with your own transition logic.

> **Note**
>
> If you wish to defer transitioning a case in a particular status until the batch process on your case type status is executed, you should not populate an Auto-Transition algorithm on that status. Otherwise, CASETRAN will transition the case according to your Auto-Transition logic.

Use **Comment** to describe the status. This is for your internal documentation requirements.

Use **Sequence** to define the relative order of this status in the tree on the Main page.

Use **Status Condition** to define if this status is an Initial, Interim or Final state. Refer to One Initial State and Multiple Final States for more information about how this field is used.

Use **Transitory State** to indicate whether a case should ever exist in this state. Only Initial or Interim states can have a transitory state value of No.

The **Alert Flag** is used to indicate whether or not an alert should be displayed for customers with cases in the state. (The alert is shown via the base package Installation - Alert algorithm.)

Algorithms

The **Algorithms** grid contains algorithms that control important functions for cases of this type. You must define the following for each algorithm:

Copyright © 2026, Oracle and/or its affiliates.

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Description
Auto Transition	This algorithm is executed to determine if a case that's in this state should be transitioned into another state. Refer to Automatic Transition Rules for the details.
Enter Processing	This algorithm holds additional processing that is executed when a case is transitioned into this state. You can also specify state transition logic within Enter Processing routines. Refer to Additional Processing When Entering A State for the details.
Enter Validation	This algorithm holds validation logic that executes before a case can enter a given state. Refer to Validation Before A Case Enters A State for the details.
Exit Processing	This algorithm holds additional processing that is executed when a case is transitioned out of this state. Refer to Additional Processing When Exiting A State for the details.
Exit Validation	This algorithm holds validation logic that executes before a case can by transitioned out of a given state. Refer to Validation Before A Case Exits A State for the details.
Script Launching	This algorithm sets the script launching option for the script associated with a given state, if any. Refer to Script Launching Option for the details.

Next Statuses

Use the **Next Statuses** grid to define the statuses a user can transition a case into while it's in this state. Refer to Valid States versus State Transition Rules for more information. Please note the following about this grid:

- Use **Action Label** to indicate the verbiage to display on the action button used to transition to this status.
- **Sequence** controls the order of the buttons that appear on Case - Main. Refer to Buttons Are Used To Transition A Case Into A State for more information.
- **Use as Default** controls which button (if any) is the default button.
- **Transition Condition** may be configured to identify a common transition path for cases of this type in the current state. This transition condition may then be referenced across multiple case types. You'll need to add values to Look Up table field **TR_COND_FLG** that fit the typical transitions for your case types (e.g. Ok, Error, etc.).

By assigning the transition condition value to a given "next status", you can design your Enter State transition or Auto-Transition logic to utilize those flag values *without specifying a status*

Copyright © 2026, Oracle and/or its affiliates.

particular to a given case type. Thus, similar logic may be used across a range of case types to transition a case into, for example, the next Ok state for the case's current status.

- **Transition Role** controls whether only the System or both System and User have the ability to transition a case into a given "next status".
- You can use the status description hyperlink to open the Status accordion to the respective status.
- When you initially set up a case type, none of the statuses will reside on the database and therefore you can't use the search to define a "next status". We recommend working as follows to facilitate the definition of this information:
  - Leave the Next Statuses grid blank when you initially define a case type's statuses
  - After all statuses have been saved on the database, update each status to define its Next Statuses (this way, you can use the search to select the status).

Required Characteristics

Use the **Required Characteristics** grid to define characteristics that are required when a case enters this state. Only Optional characteristics defined on the main page appear in this grid. Refer to Required Fields Before A Case Enters A State for more information.

Defining Umbrella Agreement Options

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

> **Note**
>
> **Separately module.** The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to Turn Off A Function Module for more information.

- The Big Picture Of Umbrella Agreements
- Setting Up Umbrella Agreement Options
- Umbrella Agreements Configuration Examples

Copyright © 2026, Oracle and/or its affiliates.

The Big Picture Of Umbrella Agreements

The topics in this section provide background information about how to configure the system to support your umbrella agreement requirements.

- Renewable Umbrella Agreements
- Terms Of Service Covered Entities
- Overriding Rate Terms

Renewable Umbrella Agreements

When defining your umbrella agreement types, you must determine if umbrella agreements of this type are renewable. If so, you must set the renewal flag on the UA type to Renewable and determine the number of days prior to the end date of the umbrella agreement that the renewal process should start.

In addition, you must decide on your renewal procedure and design an appropriate renewal algorithm. You may use one of the sample renewal algorithms provided by the system.

- The sample algorithm URNW-TD creates a To Do entry. Using this algorithm you can direct the To Do entry to an appropriate role to determine if the umbrella agreement should be renewed. If the umbrella agreement is associated with an account management group, the To Do entry could be assigned to a role defined for that AMG.
- The sample algorithm URNW-CA creates a case. Using this algorithm you can create an appropriate case to help track the steps required for renewing an umbrella agreement.

If the base algorithms do not provide the logic your organization needs, you may create a new algorithm.

> **Note**
>
> It is the responsibility of the renewal algorithm to change the renewal date as per the business requirements. If renewal requires manual review, the algorithm should reset the date to blank. If the algorithm can determine a new renewal date, the date should be changed to the appropriate value.

Terms Of Service Covered Entities

For each terms of service type you design, consider whether or not a TOS created for this type should reference one or more entities in the system that are "covered" by the terms of service. Following are some examples of covered entities:

- A special contract is created for all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement used for this contract, you want the user to link the person record representing the McDonalds corporate entity as a covered entity for the TOS.

Copyright © 2026, Oracle and/or its affiliates.

- An umbrella agreement is created for a large customer with several types of services. Perhaps you want to group the services in the contract based on type of service. The service type may be set up as a covered entity.

The covered entities could also be used to denote eligibility. Refer to Linking To A UA For A Group Of Premises for an example of using the covered entity collection for eligibility.

The covered entities are actually characteristics. You must define the desired characteristic types if they do not already exist. In this case, they would be foreign key characteristic types. The characteristic types that you want to use must reference a characteristic entity of TOS covered entity.

A terms of service record may only reference covered entity types that you designate on the Terms of Service type record. When designing the covered entities that are allowed for TOS records of a given type, you may also configure the Terms of Service type to indicate that one or more covered entity types are required.

Refer to Terms Of Service Type - Main for more information.

Overriding Rate Terms

If your organization has business rules that require a service agreement's rate terms to be overridden, you can accomplish this using umbrella agreements and terms of service records. There are two levels of overriding that are possible:

- Override rate schedule
- Override other terms on the rate, including contract riders, contract terms and tax exemptions

To override any rate terms, the service agreement must be linked to a terms of service record that references a template service agreement. In addition, you must configure settings in the system to indicate whether or not overriding of terms is allowed.

- The SA type for the customer's service agreement indicates whether or not the rate schedule may be overridden using the rate source flag.
  - If the rate source value is Check TOS First, then SA, when applying the rate, the system determines if the SA is linked to a TOS effective at the time of the bill with a template SA. If so, the rate schedule on the template SA is used.
  - If the rate source value is Check SA Only, when applying the rate, the always uses the rate schedule on the customer's SA (regardless of whether or not the SA is linked to a TOS effective at the time of the bill with a template SA).
- If any bill factor on one of calculation rule indicates that it is eligible for tax exemptions, contract terms or contract riders, the terms of service usage flag on the bill factor indicates where the system should look for the appropriate value. The flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

The following table illustrates the different scenarios possible when configuring your bill factors and the resulting behavior. The term "standard behavior" in the tables below indicate that the standard behavior as described in Defining Bill Factors is followed.

	TOS Usage	Template SA	Customer SA	BF Char Source

Copyright © 2026, Oracle and/or its affiliates.

Contract Rider Applicability is checked	Check TOS First, then SA	Found	Not checked	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed.
		Not Found	Found	If source = SA, the customer SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
		Not Found	Not Found	N/A
	Check TOS Only	Found	Not checked	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
		Not Found	Not checked	N/A
	Check SA Only	Not checked	Standard behavior	

	TOS Usage	Template SA	Customer SA	BF Value Source	BF Char Source
Value in Contract Term is checked	Check TOS First, then SA	Found	Not checked	Template SA	N/A
		Not Found	Found	Customer SA	N/A
		Not Found	Not Found	Bill Factor Value (based on Char Source)	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
	Check TOS Only	Found	Not checked	Template SA	N/A

Copyright © 2026, Oracle and/or its affiliates.

		Not Found	Not checked	Bill Factor Value (based on Char Source)	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
	Check SA Only	Not checked	Standard behavior		

	TOS Usage	Template SA	Customer SA	BF Value Source
Tax Exemption is checked	Check TOS First, then SA	Found	Not checked	Template SA
		Not Found	Found	Customer SA
		Not Found	Not Found	No value
	Check TOS Only	Found	Not checked	Template SA
		Not Found	Not checked	No value
	Check SA Only	Not checked	Standard behavior	

Note that proration logic is followed for the above functionality as expected. For example, imagine that a bill factor with Value in Contract Terms is proratable and the TOS usage value is Check TOS First, then SA. If the template SA has a contract value that is only in effect for the first 10 days of a bill, that value is used for the first 10 days and the remaining days in the bill take the value from the SA (if applicable) or the bill factor value as per the table rules above.

> **Note**
>
> When designing your terms of service type, you must indicate whether a template service agreement is optional, required or not allowed. When the template SA is required, the user setting up the TOS record for this TOS type must link the correct service agreement as the template SA. If a new template service agreement is required, the new SA must be created first.

Setting Up Umbrella Agreement Options

The topics in this section describe how to set up umbrella agreement options.

- Configure SA Types for Umbrella Agreements
- Configure Bill Factors for Umbrella Agreements
- Configure A Campaign To Link An SA To A Terms Of Service
- Setting Up Umbrella Agreement Types
- Setting Up Terms Of Service Types
- Setting Up Terms of Service Cancel Reasons

Copyright © 2026, Oracle and/or its affiliates.

Configure SA Types for Umbrella Agreements

For each type of service agreement that may be linked to a terms of service record, you must configure the Rate Source for the SA type to indicate if the rate should always be taken from the service agreement (Check SA Only) or if the rate should be taken from the terms of service record for the service agreement, if any (Check TOS First, then SA).

NOT_SUPPORTED

Refer to Overriding Rate Terms for more information.

Note

The rate source is only visible on SA type if the Contract Management module is not turned off.

Configure Bill Factors for Umbrella Agreements

For each bill factor that has a value in contract term, contract rider applicability or tax exemption applicability, you must indicate where the system should look for a value when a service agreement is linked to a terms of service with a template SA and where this bill factor is referenced by the rate being applied. Using the terms of service usage flag, tell the system to Check TOS Only, Check SA Only or Check TOS First, then SA.

NOT_SUPPORTED

Refer to Overriding Rate Terms for more information.

Note

The terms of service usage flag is only visible on bill factor if the Contract Management module is not turned off.

Configure A Campaign To Link An SA To A Terms Of Service

The system provides a pair of column reference algorithm types that support linking a new service agreement to an existing terms of service record via an order. The pair includes a validation algorithm type CRVL-SATOS and a posting algorithm type CRPS-SATOS.

In order to take advantage of this functionality, you must:

Copyright © 2026, Oracle and/or its affiliates.

- Create an algorithm for each of the above algorithm types. Only one algorithm is needed for each algorithm type because there are no parameters for either one.
- Setup a unique column reference for the terms of service ID column reference code and plug in the new validation and posting algorithms on the record.
- For campaigns whose orders link a new service agreement to an existing umbrella agreement, make sure to define a miscellaneous field for the terms of service ID. Note, the miscellaneous field must reference the column reference that you setup above.

Based on your business practice, you may want to further configure your campaign / package for linking a service agreement to an existing terms of service. Refer to Linking A Service Agreement To A TOS Through Orders for more information.

Setting Up Umbrella Agreement Types

The umbrella agreement type transaction is used to maintain your UA types. The topics in this section describe how to use this transaction.

- Umbrella Agreement Type - Main
- Umbrella Agreement Type - Algorithms

Umbrella Agreement Type - Main

Open **Admin**, and then **Umbrella Agreement**, and then **Umbrella Agreement Type**, and then **Add** to define basic information about an umbrella agreement type.

Description of Page

Enter a unique **Umbrella Agreement Type** code and **Description** for the UA type.

Use **Renewal** to indicate whether an umbrella agreement of this type is Renewable or Not Renewable. For renewable UA types, indicate the **Renewal Days Before Expiration**. The renewal date for umbrella agreements of this type are calculated based on this number of days before the end date.

Use the characteristics collection to define characteristics that can be defined for umbrella agreements of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on umbrella agreements of a given type. Turn on the **Default** switch to default the **Characteristic Type** when umbrella agreements of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible on an umbrella agreement record. Refer to *Setting Up Characteristic Types & Their Values* for more information.

Enter the valid **Terms of Service Type**s that may be referenced for umbrella agreements of this type.

Copyright © 2026, Oracle and/or its affiliates.

Umbrella Agreement Type - Algorithms

Open **Admin**, and then **Umbrella Agreement**, and then **Umbrella Agreement Type**, and then **Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Description
UA Renewal	Algorithms of this type are executed by the UARENEW background process when an umbrella agreement has reached its renewal date. Only one renewal algorithm is allowed for a given UA type.

Setting Up Terms Of Service Types

The terms of service type transaction is used to maintain your Terms of Service types. The topics in this section describe how to use this transaction.

- Terms Of Service Type - Main
- Terms Of Service Type - UA Types

Terms Of Service Type - Main

Open **Admin**, and then **Umbrella Agreement**, and then **Terms of Service Type**, and then **Add** to define basic information about terms of service types.

Description of Page

Enter a unique **Terms of Service Type** code and **Description** for the TOS type.

Use **Template SA Usage** to indicate whether a template SA is Optional, Required or Not Allowed. Refer to Overriding Rate Terms for more information about using template SAs.

Use the characteristics collection to define characteristics that can be defined for terms of service records of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on terms of service records of a given type. Turn on the **Default** switch to default the **Characteristic Type**

Copyright © 2026, Oracle and/or its affiliates.

when terms of service records of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible on a terms of service record. Refer to *Setting` Up Characteristic Types & Their Values* for more information.

Use the **Covered Entities** collection to define the types of entities that are "covered" by terms of service records of this type. Refer to Terms Of Service Covered Entities for more information

> **Note**
>
> **Characteristic Types.** You can only choose characteristic types defined as permissible for TOS covered entity. Refer to *Setting Up Characteristic Types & Their Values* for more information.

Terms Of Service Type - UA Types

Open **Admin**, and then **Umbrella Agreement**, and then **Terms of Service Type**, and then **Add** and navigate to the **UA Types** page.

Description of Page

Enter the valid **Umbrella Agreement Type**s that may reference this terms of service type.

Setting Up Terms of Service Cancel Reasons

Whenever a terms of service record is canceled, a cancel reason must be specified. Open **Admin**, and then **Terms of Service Cancel Reason** to specify such cancellation reasons.

Description of Page

Enter an easily recognizable **Terms of Service Cancel Reason** and **Description** for the terms of service cancellation reason.

Umbrella Agreements Configuration Examples

This section provides examples of how you would configure the system to support various business scenarios.

- Linking A Service Agreement To A TOS Through Orders

Copyright © 2026, Oracle and/or its affiliates.

Linking A Service Agreement To A TOS Through Orders

As described in Configure A Campaign To Link An SA To A Terms Of Service, the system has provided a pair of column reference algorithms to enable your users to link a new service agreement to an existing terms of service record (and its umbrella agreement) when starting service via the order transaction.

When designing your campaign and packages to use this option, consider the scenarios where you may use this to determine whether or not you require additional configuration. The following topics describe some possible scenarios.

- Linking To A UA For A Given Account
- Linking To A UA For A Group Of Premises

Linking To A UA For A Given Account

Imagine that you would use this logic when an important customer is starting additional service and has an existing umbrella agreement for other services that the new service should be added to. The user creating the order is probably the account manager for that account and would know the correct terms of service record to link the new service to.

For this scenario, you do not need to provide any "help" to the user to indicate that linking to a TOS is an option or to help select the correct TOS. You simply need to ensure that the campaign that would be used by this account manager to start service for the important customer simply includes a question / miscellaneous field to link the SA to the terms of service.

Linking To A UA For A Group Of Premises

Imagine you have created an umbrella agreement for a group of premises that are not actively managed by a specific user. For example, perhaps there are several apartment complexes that have negotiated a special rate with your company. When new customers sign up for service at a premise that belongs to one of these apartments, the user should be informed that there is a special contract for this premise. The user may also need help selecting the correct terms of service record. To accomplish this logic, you must define additional algorithms to help your users.

For example, perhaps your standard campaign for residential electric customers includes a package to be used by premises linked to one of these apartment buildings and should only be eligible to one of those premises. You must create an eligibility algorithm for this package. Its logic could be designed based on the following assumptions:

- The qualifying premises are linked to a parent premise
- The parent premise is linked to the appropriate terms of service record in its covered entity collection

The eligibility algorithm checks to see if the order's premise is linked to a parent premise that is referenced on a terms of service record for an umbrella agreement that is currently in effect. It could also be restricted to search for a specific umbrella agreement type or terms of service type if appropriate.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The campaign for this scenario must include a question / miscellaneous field to link the SA to the terms of service. It should be configured with an applicability of only applicable on package. The package that is used to include the SA into the terms of service for the apartment complex would include this question / miscellaneous field.

Once the user chooses this package, user is prompted to provide the correct terms of service record via the question / miscellaneous field. To help the user, you should create a column reference retrieval algorithm to default the correct terms of service record for this premise. It would use the same logic as the eligibility algorithm described above. In other words, it would find the parent premise for this premise and then find the terms of service record covered entity collection includes this parent premise and whose umbrella agreement is currently in effect.

Reports Addendum

This chapter is an addendum to the general Defining and Designing Reports chapter.

- Configuring the System to Invoke Oracle Analytics Publisher Enterprise Real-Time
- Configuring the System for Batch Bill Print
- Description of Sample Reports

Configuring the System to Invoke Oracle Analytics Publisher Enterprise Real-Time

In order to invoke Oracle Analytics Publisher Enterprise from within the system, it must be configured. This topic describes the steps at a high level that are required to configure your system to enable BI Publisher.

- Specify Reporting Tool Options
- Reporting Tool Algorithm
- Interface with Oracle Analytics Publisher Enterprise Batch Scheduler

Specify Reporting Tool Options

The following information should be defined on Reporting Tool Options table:

- **Reporting Server** is the web server URL where the reporting tool is installed.
- **Reporting Folder** defines the name of the directory on the Oracle BI Publisher server where reports are located. The system's reporting tool algorithm constructs the URL to open Oracle Analytics Publisher Enterprise based on the information provided on Reporting Options. The same folder name should be used as a report folder in Oracle Analytics Publisher Enterprise where reports are published.

Copyright © 2026, Oracle and/or its affiliates.

Reporting Tool Algorithm

The base product provides an installation algorithm plug-in spot called Reporting Tool. This plug- in spot should contain an algorithm that invokes the reporting tool real-time. The corresponding algorithm type, called algorithm reference: F1-BIPR-INV, invokes Oracle Analytics Publisher Enterprise.

This algorithm relies on information defined in the Reporting Options table: the reporting server and folder names for accessing the reporting tool. The algorithm constructs several strings, for example, the URL of the Analytics Publisher, information about the report being requested and user info in the format expected by Oracle Analytics Publisher Enterprise. The Java program returns the correct URL to the browser. The browser then opens an Analytics Publisher Enterprise window with the appropriate URL.

To use the algorithm reference: F1-BIPR-INV algorithm type to invoke Oracle Analytics Publisher Enterprise, perform the following steps:

1. Create an algorithm for this algorithm type.
2. In the installation options, add an entry to the algorithm collection with an algorithm entity of Reporting Tool and indicate the algorithm created in the previous step.

Interface with Oracle Analytics Publisher Enterprise Batch Scheduler

Presently the base product does not provide support for batch jobs with Oracle Analytics Publisher. Please use Oracle Analytics Publisher directly in order to schedule reports to run in batch.

Configuring the System for Batch Bill Print

This section describes the steps for configuring the applications to print bills in batch.

- Configure Oracle BI Publisher for Batch Bill Print
- Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

Configure Oracle BI Publisher for Batch Bill Print

> **Note**
>
> Using BI Publisher for bill print is only supported with on-premises implementations. Cloud service implementations must use a 3rd party bill print system.

1. Configure the Oracle BI Publisher Scheduler to allow report job submission.

> **Note**
>
> Refer to the Oracle Fusion Middleware Administrator's Guide for Oracle Business Intelligence Publisher for more information.

Copyright © 2026, Oracle and/or its affiliates.

2. Ensure that the CI_BILLPR report artifacts (CI_BILLPR.rtf, CI_BILLPR.xdo, CI_BILLPR.xdm) are deployed to corresponding BI Publisher catalog folder:

Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

1. Go to **Admin**, and then **Reporting**, and then **Reporting Options** and configure the following values:
   - **Reporting Server from Browser** should point to the correct BI Publisher Server URL; for example, `http://<hostname>:port`
   - **Reporting Folder** is the name as the Catalog Folder in BI Publisher where CI_BILLPR is located; for example, CCB
   - **Reporting Engine User ID** is the BI Publisher User ID.
   - **Reporting Engine Password** is the BI Publisher Password.
2. Create a custom Bill Route Type Extract Algorithm using the C1-BLEX-BIP Algorithm Type. Ensure that the following algorithm soft parameters are set:
   - **Output Directory** is the directory in BI Publisher server where the generated output files will be placed, for example. `/tmp/`
   - **Report Absolute Path** is the path where CI_BILLPR.xdo is located in the BI Publisher Catalog, for example, `/CCB/CI_BILLPR/CI_BILLPR.xdo`
   - **Report Format** is the format of the generated output files; for example, `pdf`
   - **Report Code** is the CI_BILLPR report code; for example, CI_BILLPR
3. **Go to Admin Menu, B, Bill Route Type** and configure the corresponding Bill Route Type (such as, `POSTAL`) to use the RTTYPOST Batch Control and the custom Bill Route Type Extract Algorithm.

Description of Sample Reports

This section provides an overview of each sample report supplied with Oracle Utilities Customer Care and Billing that may be found in the demonstration database. They may be used by your organization as they are or as a starting point for creating a new report.

> **Note**
>
> **Account Security**. The sample reports provided with the product do NOT incorporate account security. If a user has been given security to view the report, then all the data in the report is available for viewing.

Active Severance Processes - CI_ACSVPR

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01.
End Date	P_TO_DT	End date to use for reporting active severance processes. If not defined to date is set to the current date.

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR

> **Note**
>
> Using BI Publisher for bill print is only supported with on-premises implementations. Cloud service implementations must use a 3rd party bill print system.

Parameters

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Parameter Code	Description
CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'.
First Bill	**P_FROM_BILL_ID**	First Bill Id to print for the Bill Range.
Last Bill	**P_TO_BILL_ID**	Last Bill Id to print for the Bill Range.
Batch Code	**P_BATCH_CD**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected.
Batch Number	**P_BATCH_NBR**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected.
Extract Algorithm	**P_EXTRACT_ALG**	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected.

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

Billed Revenues by Rate - CI_BILREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Copyright © 2026, Oracle and/or its affiliates.

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Condition (Open, Closed)	P_COND_FLG	If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases.

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)

Copyright © 2026, Oracle and/or its affiliates.

2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Case Statistics for a Given Status - CI_CSESGS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type/Status	P_CASE_STATUS_CD	This is the desired Case Type and Status that will be reported on.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Collection Summary - CI_CLLSUM

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	If from date is not set, the default is one month prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user, it is set to one month after the current date

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days.
End Date	P_TO_DT	End date to use for reporting customer contacts. If not defined, End Date is set to the current date.
Customer Contact Class / Type	P_CC_TYPE_CD	Specify a Customer Contact Class / Type to restrict the report output to a specific class / type.

Report Description

Copyright © 2026, Oracle and/or its affiliates.

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

Parameter	Parameter Code	Description
Service Type	P_SERVICE_TYPE	Service type used to restrict the report to premises with services of this type.

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

> **Note**
>
> If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

GL Accounting Summary - CI_GLACSM

Copyright © 2026, Oracle and/or its affiliates.

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report.

Report Description

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

> **Note**
>
> Generating letters in batch is not supported yet.

Parameters

Parameter	Parameter Code	Description
Batch Switch	P_BATCH_SW	For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'.

Copyright © 2026, Oracle and/or its affiliates.

Customer Contact	P_CC_ID	References the customer contact associated with the main customer linked to the account.

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the installation options. The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the installation options.

%2 is Person Id stored on the Customer Contact.

Open Cases By Type - CI_CSEOPN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type	P_CASE_TYPE_CD	If specified, only cases of this type are included in the report.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.

Copyright © 2026, Oracle and/or its affiliates.

First Bucket High Limit	P_B1_LIMIT	Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user it is set to the current date

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Copyright © 2026, Oracle and/or its affiliates.

Receivables Aging - CI_RCVAGA

Parameters

Parameter	Parameter Code	Description
Cutoff Date	P_CUTOFF_DATE	The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days.
First Bucket High Limit	P_B1_LIMIT	High limit of first bucket.
Second Bucket High Limit	P_B2_LIMIT	High limit of second bucket.
Third Bucket High Limit	P_B3_LIMIT	High limit of third bucket.

Report Description

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days.

Copyright © 2026, Oracle and/or its affiliates.

End Date	P_TO_DT	Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_TAX_ACCTY_CHAR	Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts.

Report Description

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Parameter Code	Description
ToDo Entry Status	P_ENTRY_STATUS_FLG	Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and assigned To Do entries.
ToDo Type	P_TD_TYPE_CD	Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or assigned entry.

Report Description

The report shows open and assigned To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or assigned). If you don't specify a status, all open and assigned To Do entries will appear on this report.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / assigned state will appear on this report.

> **Note**
>
> **Graphs.** The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm RPTV-UASUMM to check these conditions.

Parameter	Parameter Code	Description
Umbrella Agreement	P_UA_ID	Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed.

Copyright © 2026, Oracle and/or its affiliates.

Account Management Group	P_AMG	Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group.
Umbrella Agreement Characteristic Type	P_CHAR_TYPE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4).
Umbrella Agreement Characteristic Value	P_CHAR_VALUE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value.
Number of Days Before Expiration	P_EXPIRE_IN_X_DAYS	Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration.

Report Description

This report provides summary information about one or more umbrella agreements.

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

The estimate for the unbilled portion is calculated as (Bill Amount / Number of Days in the Bill Period) * Number of Unbilled Days for the Accounting Period.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for $150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as 150/31*21 = $101.61.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only

Copyright © 2026, Oracle and/or its affiliates.

estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

> **Note**
>
> **Performance Consideration.** If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Defining Overdue Processing Options

The system periodically monitors how much your customers owe to ensure they haven't violated your collection rules. When a violation is detected, the system initiates the appropriate activities (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). The topics in this section describe how to configure the system to manage your overdue processing requirements.

> **Note**
>
> The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with algorithms that support collecting on overdue bills. If your organization practices balance-forward accounting (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under Defining Credit & Collections Options.

> **Warning**
>
> Setting up this module is as challenging as your organization's collection rules. If you have simple rules, the set up process will be straightforward. If your rules are complicated (e.g., they differ based on the type of customer, the age of debt, the type of service, etc.), your setup process will be more challenging.

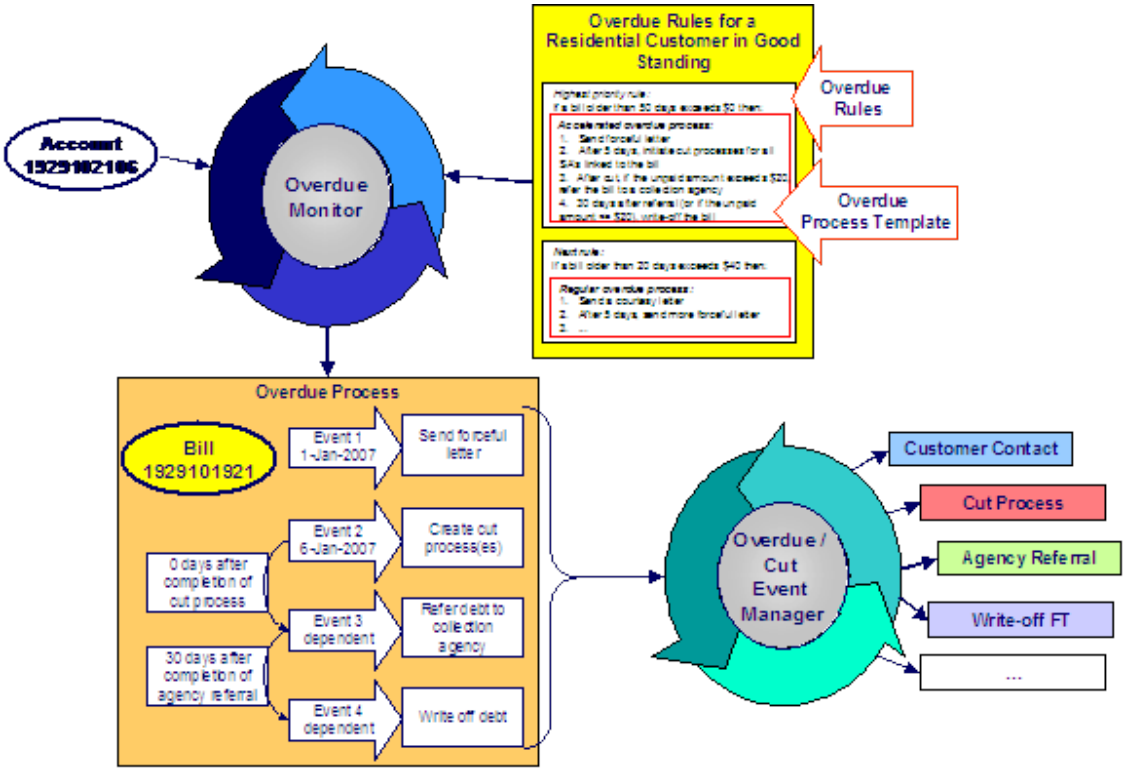
- Creating Overdue and Cut Procedures



Case Study - Collecting On Overdue Bills

The following topics introduce a case study that describes how overdue processing can be used to collect on overdue bills. This is just an example as virtually every aspect of overdue processing is configurable. Use this case study to familiarize yourself with the overdue processing core concepts.

- Monitoring Overdue Bills
- Cutting Service Agreements

Monitoring Overdue Bills

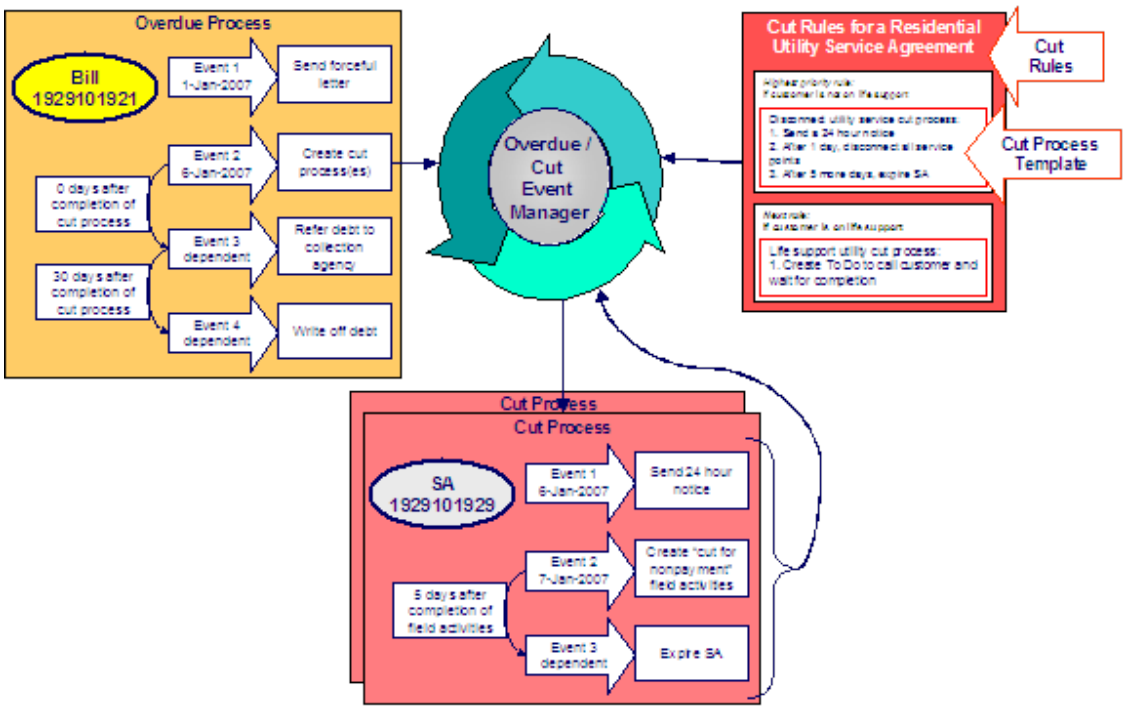
The following diagram illustrates the objects and processes involved with collecting overdue bills.

There are many important concepts illustrated above:

Copyright © 2026, Oracle and/or its affiliates.

The Overdue Monitor checks if your accounts have bills that violate your overdue rules	The Overdue Monitor is a background process that periodically reviews your account's financial obligations. Note well: every account belongs to a collection class. There are two types of collection classes: those whose accounts are monitored by the Account Debt Monitor, and those that are monitored by the Overdue Monitor. This chapter describes the Overdue Monitor.
Overdue rules define when and how unpaid bills are collected	An account's collection class overdue rules have algorithms that monitor an account's financial obligations. These algorithms are invoked by the Overdue Monitor when it's time to review an account's obligations. These algorithms can contain any type of criteria. However, most are defined using a combination of a threshold age and monetary amount. For example, a classic algorithm would check if a bill has unpaid financial transactions more than 20 days old that exceed $50. In the case of bill-oriented collection, the monitoring algorithms look at each of the account's bills to determine if they are paid. Note, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. If a monitoring algorithm finds an unpaid bill, it can check if it old enough (and large enough) to be considered a violation. When you set up a monitoring algorithm, you define the type of overdue process that should be created when an overdue bill is detected. You do this by defining the appropriate "overdue process template".
An overdue process template defines how to handle an overdue bill	An overdue process template contains one or more overdue event types. These define the number and type of events that are created to prod the customer to pay. For example, you might set up an overdue process template with event types to send a series of letters followed up by a call. The overdue process template has contains the rules defining when events are activated. The specific action that's performed by an overdue event is controlled by the Activation algorithm defined on its event type. Refer to Overdue Event Type - Main for a list of the various Activation algorithms delivered with the base package.

Copyright © 2026, Oracle and/or its affiliates.



Multiple objects can be associated with a single process	The above diagram shows a single bill linked to an overdue process. It should be noted that an overdue process is capable of referencing multiple bills (or other objects). Note well: while a single overdue process can reference many overdue objects, all such objects must be of the same type. For example, you cannot commingle bills and service agreements under a single overdue process. The type of object managed by an overdue process is defined on its overdue process template.
If a customer pays the bill, the overdue process is cancelled	If an overdue bill is paid, the overdue process is canceled real-time. You control if and how an overdue process is cancelled by setting up the appropriate rules on the overdue process template.
The Overdue / Cut Event Manager activates and triggers overdue events	The Overdue / Cut Event Manager is a background process that activates overdue events on the appropriate date. On this date, the event's Activation algorithm(s) are called. This Overdue / Cut Event Manager also has the responsibility of recursively activating later events that are dependent on the completion of earlier events.
Events can be activated real-time	Overdue Process - Main has a button that allows users to activate (and recursively trigger) overdue events online / real-time. This means you don't have to wait for a batch job to activate events.
Overdue events can wait for related activities to complete	As described above, an overdue event's Activation algorithm can create virtually any object. What wasn't explained is that the event can be set up to wait for the ancillary object to finish before it completes. For example, an event can create a To Do entry and wait for it to complete before the next event is triggered. You can introduce plug-ins to create and wait on virtually any object. While an overdue event is in the Wait state, the Overdue / Cut Event Manager monitors the state of the related object(s). When the related object completes, the event is transitioned to the Complete sate (thus triggering dependent overdue events). Please see Some Events Wait For Something Before Completing for more information.

Cutting Service Agreements

An overdue process may contain an overdue event that creates a cut process(es). A cut process is used to cut (i.e., stop) a service agreement. The following diagram illustrates the objects and processes involved with cutting a service agreement.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Cut processes aren't required.** It's quite conceivable to design an overdue process that doesn't cut service. For example, the overdue process may just contain an event that creates a case and the case manages the collection activities.

An overdue process may contain an overdue event that cuts (i.e., stops) service	If an overdue process's bill remains unpaid, one of the latter overdue events typically creates one or more cut processes. A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement.
Cut rules define how to sever service agreements	The system allows you to define rules to control the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ... The cut rules are defined on the service agreement's SA type. This allows different rules for different types of service agreements.

Copyright © 2026, Oracle and/or its affiliates.

Overdue events can "wait" for related activities to complete	When an overdue event creates cut process(es), it typically enters the Wait state. It enters this state as it is waiting for the cut process(es) to complete before it can itself complete. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related cut process(es). When the cut process(es) complete, the system transitions the originating overdue event to the Complete state (thus triggering dependent events).
A cut process template defines how to cut a service agreement	Cut processes and events are created using a cut process template. A cut process template defines the actions involved in cutting a given type of service agreement. A cut process template usually contains several cut events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received. An Activation algorithm controls the specific action associated with a cut event and therefore an event can do practically anything. Refer to Cut Event Type - Main for a list of the various Activation algorithms delivered with the base package.
Cut events are also managed by the Overdue / Cut Event Manager	The same background process that manages the activation of overdue events manages cut events. This means you only have to submit one batch job to activate and trigger both overdue and cut events.
Events can be activated real-time	Cut Process - Main has a button that allows users to activate (and recursively trigger) cut events online / real-time. This means you don't have to wait for a batch job to activate events.
Cut events can "wait" just like overdue events	Cut events support the ability to wait for something to complete just like overdue events. For example, if a cut event creates a field activity, it enters the Wait state. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related field activities. When the field activities complete, the system transitions the originating cut event to the Complete state. And, just like for overdue events, the notion of a cut event creating something and then waiting for it to complete is not limited to field activities. For example, you could have a cut event create a To Do entry and wait for it to complete before the next event is triggered. Please see Some Events Wait For Something Before Completing for more information.

Copyright © 2026, Oracle and/or its affiliates.

After a service agreement is stopped, it will be final billed	Many cut processes are configured so their last cut event expires the service agreement. What happens at expiration depends on the type of service agreement. However, eventually the service agreement is transitioned into the Stopped state. When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.
If a customer doesn't pay their final bill, the final bill will be processed using a different type of overdue process	Final bills only differ from ongoing bills in that the service agreements associated with the bill's FTs are not active. This means that there is nothing to cut. This means that the type of overdue process used to handle a "final" bill should differ from that used to handle "ongoing" bills. As described above, overdue rules define how unpaid bills are handled (both ongoing and final). We recommend configuring your overdue rules to use different overdue process templates for final versus ongoing bills.
The last overdue event typically causes the debt to be written off	Ultimately, if the overdue and cut events fail to inspire payment, the debt will be written off. The method used to write-off a bill is controlled by an overdue event Activation algorithm.

How Does The Overdue Monitor Work?

This section describes how the Overdue Monitor background process C1-ADMOV) uses your overdue rules to collect overdue debt.

This process has an optional input parameter for CIS Division. It can be used if you implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

> **Note**
>
> **Recommendation.** We recommend that you familiarize yourself with the concepts described in the case studies before reading this section.
>
> **Collecting overdue bills.** The examples in the following section frequently refer to how the Overdue Monitor is configured for an organization that collects on unpaid bills. It should be noted that these are just examples as the Overdue Monitor can be used to collect on virtually anything (if you create the appropriate plug-in algorithms).

- Different Overdue Rules For Different Customers
- Overdue Rules Are Embodied In Algorithms
- When Is An Account Monitored?

Copyright © 2026, Oracle and/or its affiliates.

- Collection Class Defines If And How Accounts Are Monitored

Different Overdue Rules For Different Customers

The Overdue Monitor uses rules to control how it monitors an account's debt. The system allows you to define different rules for different combinations of collection class, division and currency code. For example,

- You probably have different collection rules for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different rules applied to each jurisdiction's debt. The **CIS division on each customer's account** defines the jurisdictional rules applied to the account's debt.
- You probably have different collection rules for different customer segments. For example, bills for large customers might be overdue if they are more than 10 days late, whereas small customers might have 24 days. You differentiate your customers in respect of the overdue via the **collection class on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

The above means that every combination of CIS division, collection class, and currency code can have different rules. The following matrix is used to illustrate a sample organization's rules (note, we assume a single currency and therefore avoid the third dimension):

Account's Division	Account's Collection Class: Commercial Customer	Account's Collection Class: Residential Customer
North	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 45 days, create the commercial 45 days late overdue process. Next Priority: If a bill exists with unpaid FT's > $100 that is older than 30 days, create the commercial 30 days late overdue process.	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 50 days, create the accelerated overdue process for residential customers. Lower Priority: If a bill exists with unpaid FT's > $25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.
South	...	...

Notice that there can be multiple criteria for each cell in the matrix. What differentiates one criteria from another is its priority. The higher priority criteria will be compared first. If the debt violates the criteria, the overdue process is initiated and no further comparisons are performed.

Overdue Rules Are Embodied In Algorithms

Your organization's overdue rules are defined in algorithms plugged in on Collection Class Overdue Rules (in the Overdue Monitor Rule system event). When the Overdue Monitor analyzes an account, it uses the rules associated with the account's collection class, CIS

Copyright © 2026, Oracle and/or its affiliates.

division and currency code. To analyze an account, it simply invokes these algorithms in sequence order, i.e., the lower the sequence, the higher its priority.

An Overdue Monitor Rule algorithm has two responsibilities:

- it determines if an account violates its overdue rules,
- if so, it creates one or more overdue processes using an overdue process template

When Is An Account Monitored?

The Overdue Monitor determines if an account violates your overdue rules at least every X days, where X is defined on the Customer Class - Controls associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, the Overdue Monitor examines an account's debt as follows:

- X days after an account's bill due date (X is defined in the field Credit Review Grace Days on customer class control).
- If a payment is canceled with a cancellation reason that indicates non-sufficient funds.
- If a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to Breaking A Bill Oriented Payment Arrangement for more information.
- If a pay plan is broken. Refer to The Pay Plan Monitor for more information.
- If a match event is added, changed or deleted.
- When a written off bill is reversed.

> **Note**
>
> **Additional events.** Your implementation can have other events trigger the analysis of an account by the Overdue Monitor. To do this, add logic to insert a row on the CI_ADM_RVW_SCH table when the event occurs. This row simply references the account ID to be reviewed and the desired review date.

Collection Class Defines If And How Accounts Are Monitored

As described above, every account references a collection class. The collection class defines if and how its accounts are monitored. There are three options:

- The accounts are monitored by the Account Debt Monitor
- The accounts are monitored by the Overdue Monitor (this is described in this chapter).
- The accounts are not monitored for overdue debt.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Migration.** If you plan to migrate from the Account Debt Monitor (ADM) method of collection to the Overdue Monitor method, a special Overdue Monitor algorithm (C1-ACT-CSW) has been supplied that will skip accounts that are eligible for review by the Overdue Monitor if they have an active collection, severance or write-off process. This algorithm should be plugged in the applicable Collection Class Overdue Rules so that it will be invoked first. This allows accounts with active ADM-oriented collection activities to work themselves through the system. When an account no longer has any active ADM-oriented activities, monitoring responsibilities will be assumed by the Overdue Monitor.

The Big Picture Of Overdue Processes

As described above, the Overdue Monitor subjects your accounts to overdue rules. If a rule is violated, an overdue process is created. The topics in this section provide background information about overdue processes.

- How Are Overdue Processes Created?
- The Components Of An Overdue Process
- Experimenting With Alternative Overdue Process Templates
- Overdue Process Information Is Overridable
- Original and Unpaid Amounts
- Overdue Processes Are Highlighted Elsewhere
- How Are Overdue Processes Cancelled?
- Overdue Processes Are Created From Templates
- The Big Picture Of Overdue Events
- The Big Picture Of Cut Processes
- Cut Events Are Like Overdue Events
- Write Offs Are Implemented Using Overdue Events
- Calendar vs Work Days

How Are Overdue Processes Created?

As described above, the system creates an overdue process when an account violates your overdue rules. In addition, a user can manually create an overdue process at their discretion.

The Components Of An Overdue Process

The following topics describe the major components of an overdue process.

- Overdue Objects

Copyright © 2026, Oracle and/or its affiliates.

- Overdue Events
- Overdue Log

Overdue Objects

When an overdue process is created, the system links the overdue object(s) to the process. For example, if an overdue bill is detected, the bill is linked to the overdue process.

When you set up an overdue process template, you define the type of object it collects on by defining the foreign key characteristic type used to reference the object. For example, when you set up an overdue process template to collect on bills, you define a foreign key characteristic type that references the bill object.

Overdue Events

An overdue process has one or more overdue events. These events are the actions designed to encourage the customer to pay. For example, you might set up overdue events that:

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to seize the customer's assets)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring overdue process templates. When the system creates an overdue process, it copies the events defined on the specified template.

It's important to note that all overdue events are created when the overdue process is created. A separate background process, the Overdue / Cut Event Manager, is responsible for activating, monitoring, and triggering overdue events. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a cut process, refer debt to a collection agency, write-off debt, etc.).

Overdue Log

Every overdue process has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When the process is created, a log entry is created to describe why the process was started.
- When an overdue event is activated, a log entry is created. These entries frequently contain a foreign key to the object that the event created so that users can easily drill down to the object from the log. For example, if an event creates a To Do entry, the To Do entry's foreign key is placed on the log and this allows a user to drill down on the log entry to see the To Do entry.
- When a process is canceled, a log entry is created to describe the circumstances of the cancellation (e.g., manual versus automated).

Copyright © 2026, Oracle and/or its affiliates.

- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.
- ...

Many of the base-package algorithms involved in overdue processing insert log entries so that a thorough audit trail is maintained. These algorithms have been designed to allow you to control the verbiage in each log entry by defining the desired message number using an algorithm parameter.

The log is viewable on the Overdue Process - Log page.

> **Note**
>
> **More than just an audit trail.** The log entries are more than just an audit trail. The system makes use of the log entries to know what it did. For example, when an overdue event needs to monitor the state of the To Do entries that it created, it uses the log to determine the identity of these To Do entries.

Experimenting With Alternative Overdue Process Templates

The system allows you to determine the efficacy of proposed overdue process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing overdue process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" overdue process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Overdue Processing Feature Configuration for every champion template. Each option's value defines:
  - the "champion" overdue process template code
  - the "challenger" overdue process template code
  - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing overdue process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, your implementation's Overdue Rule Plug-In may include logic to use the challenger template X% of the time rather than the champion template. The sample plug-in provided in the base product, called C1-CB-CR-RAT, includes this logic.

Copyright © 2026, Oracle and/or its affiliates.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination)

Overdue Process Information Is Overridable

"Overdue process info" is the concatenated string of information that summarizes an overdue process throughout the user interface. The base-package logic constructs this string by concatenating the following information:

- The description of its overdue process template
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your overdue process templates. This design allows some / all overdue process templates to have an override info string.

Original and Unpaid Amounts

There are two amounts associated with each overdue object linked to an overdue process: its Original Amount and its Unpaid Amount. These amounts are used throughout overdue processing.

You control how these amounts are calculated by defining the appropriate algorithm on your overdue process templates. For example, you can plug in a base-package algorithm (C1-CUAOA) if you collect on overdue bills and the original amount is the amount of financial transactions linked to the bill, and the unpaid amount is the sum of financial transactions that are not linked to balanced match events.

> **Note**
>
> The system captures a history of an overdue process's unpaid amounts. Refer to How to Capture Arrears History for more information.

Overdue Processes Are Highlighted Elsewhere

The topics in this section describe how other parts of the system highlight the existence of overdue and cut processes.

Copyright © 2026, Oracle and/or its affiliates.

- Alert Zone
- Credit and Collections Zone
- Account Activity History Zone

Alert Zone

If you plug-in the appropriate alert algorithm (C1-OD-PROC) on the Installation record, alert(s) will be shown for active overdue processes in the Alert Zone that appears in the Sidebar and on Control Central - Account Information.

Credit and Collections Zone

The Credit and Collections zone on Control Central - Account Information shows active overdue and cut processes.

Account Activity History Zone

The Account Activity History Zone on Control Central - Account Information shows pending and waiting events and inactive processes.

How Are Overdue Processes Cancelled?

A user may cancel an overdue process at their discretion, online / real-time using Overdue Process - Main.

The system will automatically cancel an overdue process when the object(s) associated with the overdue process are sufficiently paid. Exactly when the system checks if an overdue process should be cancelled is dependent on your organization's billing and accounting rules. For example, if you practice open-item accounting, you'd want to analyze an account's active overdue processes whenever a match event is added, changed or deleted (as match events are the only objects that impact if debt is considered paid in an open-item world). The base-package supports this specific example. If you need additional events to check if an overdue process should be canceled (e.g., the creation of a pay plan), a base-package change MAY be necessary. Please check with customer support if you have questions.

Two algorithms plugged-in on the overdue process template handle the cancellation:

- The Cancel Criteria algorithm is responsible for determining if an overdue process should be canceled. Algorithms of this type analyze the outstanding debt on the objects linked to the overdue process and indicate whether a process can be cancelled.
- The Cancel Logic algorithm is responsible for actually canceling the process. The logic involved in cancellation can be quite sophisticated as canceling an overdue process can result in the cancellation of its pending events and cut processes.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Why two algorithms?** The reason two algorithms are involved in cancellation is because we want the cancellation logic to be encapsulated in one place so it can be called during both manual and automated cancellation.
>
> **Different logic for different templates.** Because both the Cancel Criteria and Cancel Logic algorithms are plugged-in on the overdue process's template, you can have different cancellation criteria and logic for different templates.

Overdue Processes Are Created From Templates

As described above, you set up overdue process templates to define the types of events and when they are executed. When an overdue process is created, its events are created by copying the event types from an overdue process template. The remaining topics in this section provide background information to assist you in setting up your templates.

The Big Picture Of Overdue Events

This section describes the various types of overdue events and their lifecycle.

- How Are Overdue Events Created?
- Overdue Events Can Do Many Things
- Overdue Event Information Is Overridable
- Overdue Event Lifecycle

How Are Overdue Events Created?

Overdue events are created as follows:

- The Overdue Monitor invokes Overdue Monitor Rules to periodically check your accounts (refer to Overdue Rules Are Embodied In Algorithms for how this works). An Overdue Monitor Rule creates an overdue process when an account violates your overdue rules. The overdue process has one or more overdue event(s). The number and type of events is controlled by the overdue process template specified on the Overdue Monitor Rule.
- Users can create an overdue process manually on Overdue Process - Main. To do this, they specify an overdue process template. The number and type of overdue events is defaulted from the template.
- An overdue event may be manually added to an existing overdue process by a user on Overdue Process - Events.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Bottom line.** Most overdue events are created by the system when it creates an overdue process for delinquent obligations. If you need to create an ad hoc overdue event, you can either create an overdue process whose template contains the desired event OR link the desired event to an existing process.

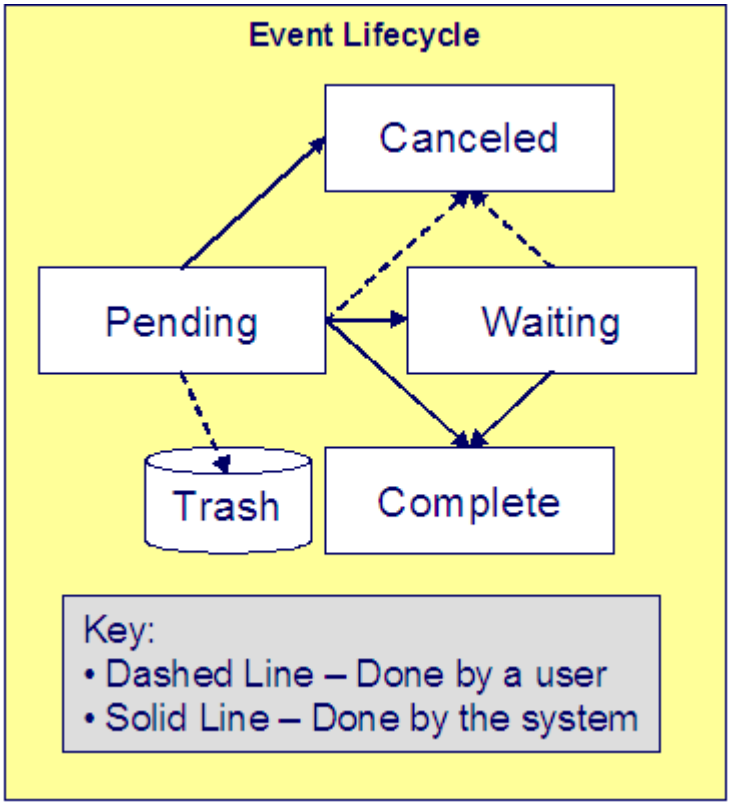
Overdue Events Can Do Many Things

An overdue event can perform a wide number of activities as the logic is embodied in an algorithm. The following points describe how this works:

- Every overdue event references an overdue event type.
- The overdue event type, in turn, references an Event Activation algorithm.
- The Event Activation algorithm is invoked when the event is triggered.

Overdue Event Information Is Overridable

"Overdue event info" is the concatenated string of information that summarizes an overdue event throughout the system. The base-package logic constructs this string by concatenating the following information:



- The event type's description
- The event's status
- If it's pending:
  - If the event has a trigger date, the number of days until it's triggered plus the verbiage day(s) from today
  - Otherwise, the verbiage dependent on other events
- If it's waiting, the number of days, hours and minutes that it's been waiting
- If it's canceled, the cancel reason code's description
- If it's complete, the number of days, hours and minutes that it's been complete

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your event types. This design allows some / all event types to have an override info string.

Overdue Event Lifecycle

The following diagram shows the possible lifecycle of an overdue event:

Copyright © 2026, Oracle and/or its affiliates.

Overdue events are initially created in the Pending state. An event can take myriad paths after it's created; it all depends on how you've configured the system. The following topics describe an event's lifecycle:

- How and When Events Are Activated
- Activating Events Should Add a Log Entry
- Holding Events
- Some Events Wait For Something Before They Activate
- How Are Events Canceled

How and When Events Are Activated

An overdue event contains the date is should be activated; this is referred to as its trigger date. On this date, the Overdue / Cut Event Manager (a background process (C1-ODET)) invokes the Event Activation algorithm plugged-in on the event's event type. The Event Activation algorithm, in turn, will decide on the state in which to leave the overdue event (e.g., it may transition it to the Complete state or the Waiting state).

If a user can't wait for the Overdue / Cut Event Manager real-time, they can click a button on Overdue Process - Main to activate (and recursively trigger) events online / real-time.

You control how an event's trigger date is populated by configuring the overdue process template. You are given two choices when you link an event type to an overdue process template:

- You can indicate the event should be assigned a trigger date when it is first created. You'd use this approach on the first event and events with no dependencies on earlier events. The following points describe how to configure the overdue process template to do this:

Copyright © 2026, Oracle and/or its affiliates.

- Indicate the event type is NOT dependent on other events, and
- Define the number of days after the process's creation to use when calculating the trigger date.

- You can indicate the event should be assigned a trigger date only after earlier events are Complete. This technique should be used whenever you have an event that is only executed after other events are Complete. The following points describe how to configure the overdue process template to do this:
  - Indicate the event is dependent on other events, and
  - Define the number of days after the completion / cancellation of all dependent event(s) that the trigger date should be set to. The Overdue / Cut Event Manager sets the trigger date on such an event when it detects that all of its dependent events are complete / canceled.

> **Note**
>
> **Calendar vs Workdays.** When an overdue event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to Calendar vs. Work Days for more information.

Activating Events Should Add a Log Entry

As described above, an overdue process has a log holding a history of meaningful events in the process's life. Most Event Activation algorithms will add an entry to the process's log.

These log entries are more than just an audit trail as they also reference the objects that are created during activation. For example, if an activation algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

Holding Events

You can prevent a pending event with a trigger date on / before the current date from activating by plugging-in a Hold Event Activation plug-in on the overdue process template. This might prove useful, for example, if you want to suspend an overdue process while a case used to investigate the assertion of a customer is outstanding. Then, when the case closes, the overdue process can start up where it left off.

This technique would prove useful, for example, if your users can grant ad hoc suspend periods (e.g., if a customer wants a few extra days to pay before a cutoff). To do this, create a case type that has two states: Open and Close. Make sure to set up the Open state to have an automatic transition algorithm to close the case after X days. Then, all a user has to do is create a case of this type when they want to provide a suspend period. When the suspend period is over and payment isn't received, the case will close and the overdue process will start up where it left off.

Some Events Wait For Something Before They Activate

Copyright © 2026, Oracle and/or its affiliates.

Consider this scenario - you want an overdue event to create a To Do entry so a user can authorize the next phase of an overdue process. When this event activates, the event's activation algorithm will create a To Do entry, but it will NOT transition the event to complete. Rather, the overdue event will exist in the waiting state. While in the waiting state, the Overdue / Cut Event Manager will monitor the state of the To Do entry. When the To Do entry completes, the original overdue event can transition to the complete state and then latter dependent events can be triggered. The following points describe how to configure the system to support this type of event:

- The event type's Event Activation algorithm should behave as follows:
  - It creates the object on which the overdue event waits.
  - It must link this object to the overdue process by creating a log entry where the prime-key of the related object is referenced (in a foreign-key characteristic). This log entry should also reference the event.
  - It should leave the overdue event in the waiting state.
- The event type must have a Monitor Waiting Event algorithm. This algorithm is invoked each time the Overdue / Cut Event Manager executes. If the related object has transitioned to a "final" state, the originating overdue event is transitioned to the complete state (and then latter dependent events are triggered).

> **Note**
>
> **Bottom line.** Two algorithms must be set up on an overdue event type to implement waiting functionality: an Event Activation algorithm that creates the monitored object and a Monitor Waiting Event algorithm to check on the state of the monitored object. The Overdue / Cut Event Manager has the dual responsibility of activating the event and monitoring its related object for completion (and then triggering the dependent events when it completes).

While the above example illustrated how an overdue event could create and then monitor a To Do entry, you can use this functionality to create and monitor any object that has an initial and final state. If the base package does not contain the algorithms you need, simply develop new ones using the base-package algorithms as examples.

How Are Events Canceled

A pending event will be cancelled automatically by the system when the overdue process is canceled. Refer to How Are Overdue Processes Cancelled for more information.

A user may cancel a pending or waiting event at their discretion.

Regardless of what triggers the cancellation, the Cancel Logic algorithm plugged in on the overdue event type handles the cancellation. This allows you to introduce additional cancellation logic should the need arise. Please note that the base package cancel algorithms insert a log entry when a user manually cancels an event.

The Big Picture Of Cut Processes

Copyright © 2026, Oracle and/or its affiliates.

While not required, many overdue processes will contain one or more events that will cut (i.e., stop) service. When such an event activates, it creates a "cut process". A cut process is very similar to an overdue process; the major difference is that a cut process is linked to a specific service agreement (the one being cut), whereas an overdue process is linked to the object(s) in arrears.

The topics in this section provide background information about cut processes.

- How Are Cut Processes Created?
- Overdue Events Wait For The Cut Process To Conclude
- Cut Processes Exist Under An Overdue Process
- The Components Of A Cut Process
- Cut Process Information Is Overridable
- How Are Cut Processes Cancelled?
- Cut Processes and Events Are Created From Templates

How Are Cut Processes Created?

The activation of an overdue event can create one or more cut processes.

In addition, a user can manually create a cut process at their discretion using Cut Process - Main.

Overdue Events Wait For The Cut Process To Conclude

Overdue events that create cut processes are perfect examples of events that wait for the object they create to complete before they, in turn, complete. After the cut process concludes, the originating overdue event will complete thus triggering its dependent events.

Cut Processes Exist Under An Overdue Process

It's important to note that a cut process exists in respect of an overdue process. In other words, you can't create a cut process without referencing a parent overdue process. There are two reasons why:

- A cut process's overdue process defines the objects in arrears. It is these objects that are monitored to determine if the cut process (and overdue process) can be cancelled.
- The log associated with a cut process's overdue process contains the history of the cut process(es) and their events; there is no log specific to a cut process.

The Components Of A Cut Process

Cut processes are simpler than overdue processes as they simply contain one or more "cut events". These events are the service agreement-specific actions designed to encourage the customer to pay. For example, you might set up cut events that:

- Create field activities to cut service

Copyright © 2026, Oracle and/or its affiliates.

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to manage a customer with life support issues)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring cut process templates. When the system creates a cut process, it copies the events defined on the related template.

It's important to note that all cut events are created when the cut process is created. The Overdue / Cut Event Manager is responsible for activating the cut events at the appropriate time. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, create a field activity, etc.)

Cut processes do not have their own log as their history is maintained on the parent overdue process's log.

Cut Process Information Is Overridable

"Cut process info" is the concatenated string of information that summarizes a cut process throughout the system. The base-package logic constructs this string by concatenating the following information:

- Its cut process template's description
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected on the cut process's overdue process

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your cut process templates. This design allows some / all cut process templates to have an override info string.

How Are Cut Processes Cancelled?

A user may cancel a cut process at their discretion, online / real-time using Cut Process - Main.

The system will automatically cancel a cut process when the overdue process is cancelled.

Regardless of what triggers the cancellation, the Cancel Cut Process algorithm plugged in on the cut process's template handles the cancellation.

If a cut process is canceled and the cut process's events created field activities, the cancel logic embodied in the algorithm can be quite sophisticated. Refer to Field Activities To Cut And Reconnect Service for an example.

Cut Processes and Events Are Created From Templates

Copyright © 2026, Oracle and/or its affiliates.

When a cut process is created, its cut events are created by copying a cut process template's event types. Cut events follow the same lifecycle and possess the same behavior as overdue events.

Cut Events Are Like Overdue Events

Cut events almost identical to overdue events. The major difference is that cut events exists under a cut process and therefore are oriented towards the cut process's service agreement. The following topics describe other differences between cut events and overdue events.

- Field Activities To Cut and Reconnect Service
- A Cut Event Expires Service Agreements (and May Trigger Final Billing)

Field Activities To Cut and Reconnect Service

A cut process that's created for a service agreement whose service can be severed will typically contain a cut event that creates field activity(s) to cut service. The base-package cut event activation algorithm will create field activities for the service points linked to the service agreement being cut. The type of activity is defined on the field activity type profile defined on each service point's SP type. Please see C1-CE-CR-FA for the exact details of the base-package algorithm.

If the cut process is canceled after field activity(s) are created and before the cut process completes, different activities can transpire. The specifics of what happens are controlled by a Cancel Logic algorithm plugged in on the cut process template. The following points summarize how a base-package algorithm (C1-CP-DWFA) works:

- It assembles all Pending, Held and Complete cut for nonpayment field activities (FA) created by the cut process (these are defined in the overdue process's log).
- Each FA is processed as follows:
  - If the FA is Pending or Held and it is not linked to a field order (i.e., it hasn't been dispatched):
    - The FA is cancelled
    - An entry is added to the overdue process log to indicate the cancellation
  - If the FA is Pending or Held and it is linked to a field order (i.e., it has been dispatched):
    - A To Do entry is created (the To Do Type is defined on the algorithm)
  - If the FA is Complete and the Cut Process's SA is pending start or active (i.e., it hasn't been expired yet):
    - Reconnect field activity(s) are created for every service point that had a cut for non-payment field activity. The type of activity is defined on the field activity type profile defined on each service point's SP type.

A Cut Event Expires Service Agreements (and May Trigger Final Billing)

The last cut event is typically set up with an activation algorithm that expires the cut process's service agreement. If earlier cut events created "cut for non-payment" field activities, these

Copyright © 2026, Oracle and/or its affiliates.

field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point.

> **Note**
>
> **Final billing.** When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).

Write Offs Are Implemented Using Overdue Events

The system has been designed to allow overdue events on the original overdue process to write-off the objects being collected. Refer to Writing Off Bills for a case-study explaining how to do this.

Calendar vs Work Days

When you set up your overdue and cut process templates, you supply information that controls how each event's trigger date is calculated. You have two options:

- You can say that an event's trigger date can only be populated after earlier, dependent events are complete. For example, the 2 nd event (cut service) is triggered 2 days after the 1 st event is complete (48 hour warning letter).
- You can say that an event's trigger date is populated when the process is first created. You simply define the number of days after the start of the process when each such event should be triggered. For example, the 2 nd event (send cutoff warning) can be triggered 7 days after the start of the process.

In addition to the above, an option defined on the Feature Configuration for Overdue Processing plays a part in the calculation of an event's trigger date:

- If you set the option to use calendar days, the trigger date of events will be set to the first workday on / after the calculated date. For example, if you indicate that the 2 nd event is triggered 7 days after the 1 st event, the system will add 7 days to the 1 st event's completion date. It then checks if this is a workday (and not a holiday); if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.
- If you set the option to use workdays, the trigger date will be calculated by counting workdays. For example, if you indicate that the 2 nd event is triggered 7 days after the 1 st event, the system will count 7 workdays and set the trigger date accordingly.

> **Note**
>
> **Account's division controls the work calendar.** The system uses the above information in conjunction with the work calendar associated with the account's division to determine workdays.

Bill-Oriented Collection - Advanced Topics

The topics in this section provide information on features designed to facilitate the collection of overdue bills.

- Miscellaneous Bill-Oriented Collection Topics
- Writing Off Bills
- Bill-Oriented Payment Arrangements

Miscellaneous Bill-Oriented Collection Topics

The topics in this section provide background information about a variety of bill-oriented collection topics.

- Highlights Of The Sample Overdue Monitor Rule Algorithm
- Holding A Process's Events
- Bill Info Shows Unpaid and Write-off Amounts

Highlights Of The Sample Overdue Monitor Rule Algorithm

A base-package Overdue Monitor Rule algorithm exists to support many different types of overdue rules (see C1-CB-CR-RAT). Keep in mind that multiple such algorithms can be plugged in on Collection Class Overdue Rules. When the Overdue Monitor analyzes an account, it calls these algorithms until there are no more to invoke (or until an algorithm tells it that there is nothing more to check). The following points describe its various options:

- **Different rules based on credit ratings.** You can set up algorithms to only be applied to accounts with a credit rating <= a given value. We anticipate such algorithms will be used in conjunction with other such algorithms to apply different rules based on the customer's credit rating.
- **Different rules based on an account or service agreement characteristic.** You can set up algorithms to only be applied if an account or one of its service agreements has a given characteristic type and value effective within the last X days. For example, you could set up an algorithm that would process an account if it had a broken payment arrangement service agreement within the last 365 days (broken payment arrangement service agreements are marked with a given char type and value). You could set up a different algorithm that treated strategic customers more leniently (given that the definition of "strategic" could be held in an account or service agreement characteristic).
- **Skipping a bill if it has a future postpone date.** You can set up algorithms to ignore an unpaid bill if it has a "postpone date" that's in the future. This date would be defined on the bill using an ad hoc characteristic. The characteristic type is defined as a parameter on the algorithm.
- **Special process for bills with disputed debt.** You can set up an algorithm to create a given type of overdue process if the bill has disputed debt. By "disputed debt", we mean a bill with a financial transaction that's linked to an unbalanced match event that's marked as Disputed.

Copyright © 2026, Oracle and/or its affiliates.

- **Special process for bills with credit balances.** You can set up an algorithm to create a special overdue process if the bill's total charges are negative (i.e., a credit bill). Such bills should be very unusual as we strongly recommend that credit bills should have their credit balance applied to an overpayment service agreement during bill completion.
- **Different rules when all service agreements are inactive.** You can set up an algorithm that should only be applied if all service agreements are inactive. We anticipate this can be used to differ the type of overdue process as if an account does not have active service agreements; there is nothing to stop to encourage them to pay.
- **Different rules based on age and amount of a bill.** You can set up an algorithm to create different types of overdue processes based on the age and amount of the bills.

> **Note**
>
> **You are not limited by the base-package's rules.** If your implementation requires options that are not supported by the base-package algorithm, simply develop your own.

Holding A Process's Events

Refer to Holding Events for a description of how to prevent the activation of an overdue / cut processes events while a given condition is true. The condition is defined in an algorithm so you can set up the system to prevent event activation for practically any condition. For example, you might want to hold event activation while the bill's account has an active case (e.g., a user might set up a case to conduct an ad hoc investigation of billing discrepancies). When the case closes, you'd want the process to start up where it left off.

Bill Info Shows Unpaid and Write-off Amounts

The base-package Bill Information algorithm (plugged in on the Installation record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the unpaid and write-off amounts of each bill.

Writing Off Bills

The topics in this section provide background information on how to write off bills.

- After Service Is Cut, Write-Off Oriented Events Can Commence
- Collection Agency Referrals
- Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event
- Small Amount Write-Downs
- Bill Info Shows Written Off Amounts
- Online Write Off Of Bills Is Performed On Bill-Main
- Online Reversal Of Written Off Bills Is Performed On Bill-Main
- Write Offs And Overdue Process Cancellation

Copyright © 2026, Oracle and/or its affiliates.

- An Alert Can Show Written Off Bills

After Service Is Cut, Write-Off Oriented Events Can Commence

After the last service agreement has been stopped, overdue events to manage the write-off of the overdue process's bill(s) should be triggered. Please note that a separate overdue process is NOT created to manage write-offs. Rather, events associated with the original overdue process will handle the write-off activities.

Collection Agency Referrals

Before debt is written off, many implementations refer the unpaid bills to a collection agency. The following points describe how to implement this.

- Set up an overdue event type with an activation algorithm that refers an overdue process's bill(s) to a collection agency.
- When such an event is activated, the system creates a Collection Referral record for a collection agency. The specific agency to which the debt is referred is controlled by the event type's activation algorithm. The sample algorithm simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must develop your own algorithm.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to Setting Up Collection Agencies for more information.
- If the collection agency is successful in obtaining the funds, a payment will be added. If the payment satisfies the cancel criteria defined on the overdue process template's cancellation plug-in, the overdue process will cancel. When an overdue process is cancelled, the cancel criteria on the overdue process's template are executed. We strongly recommend plugging in an algorithm that will cancel collection agency referrals when an overdue process is cancelled.
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you set up your overdue process template to have an event that creates a collection agency cancellation X days after the referral. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).
- Collection agencies are notified of the cancellation of a referral by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithms that make and cancel collection agency referrals insert rows in the overdue process's log to audit these events.

Copyright © 2026, Oracle and/or its affiliates.

Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event

Most overdue process templates will be configured to contain an event that writes-off the unpaid balance of bills.

> **Note**
>
> **Processing is redirected to another algorithm.** The base-package overdue event activation algorithm that writes off bills simply redirects the call to the Write-Off Bill algorithm plugged in on the account's Collection Class Overdue Rules. The reason for this redirection is because users can manually write-off a bill (using Bill - Main) and when they do this, we want to invoke the same logic as when an overdue process writes-off a bill.

The base-package Collection Class Overdue Rules - Write-Off Bill algorithm determines the amount that should be written off for each distribution code on each unpaid financial transaction. It then creates a separate adjustment for each service agreement where the lines on the adjustment contain the amount to be written off for each distribution code. If the unpaid financial transactions are not linked to a match event, the write-off adjustments plus the unpaid financial transactions will be linked to a new match event. If the unpaid financial transactions were linked to an unbalanced match event, the write-off adjustments will be added to the existing match event (thus making it balanced).

If partial payments were made against a bill, the amount written off will be prorated in light of the partial payments. For example, if 20% of a bill had been paid, 80% of each distribution code will be written off.

For example, assume the original bill's FT looked as follows (note, if the bill has multiple service agreements this will need to be done for each SA's FT's):

- Debit A/R $110.00
- Credit Flat Charge Revenue ($50)
- Credit Usage Revenue ($50)
- Credit City Tax Payable ($5)
- Credit State Tax Payable ($5)

Assume the customer had made a partial payment of $11 and it was matched to this FT. At write-off time, the system will create an adjustment whose adjustment lines will cause each distribution code to be written off by 90% (100% - $11 / $110). For example:

- Debit Flat Charge Revenue (or some W/O Expense) $45
- Debit Usage Revenue $45
- Debit City Tax Payable $4.50
- Debit State Tax Payable $4.50
- Credit A/R $99

This adjustment will then be linked to the original match event on which the payment was linked (thus making it Balanced).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithm that writes off bills inserts a row into the overdue process's log for each bill written off.

Small Amount Write-Downs

Many organizations will write-down a bill whose value is small early in an overdue process. The base-package overdue event activation algorithm has parameters to support this requirement (this algorithm allows you to write-off an overdue process's bill(s) if their value is less than a threshold amount).

If your organization writes-down small amounts differently than large amount, simply set up an overdue event type to reference such an activation algorithm and position it in the appropriate place in the overdue process template.

Bill Info Shows Written Off Amounts

The base-package Bill Information algorithm (plugged in on the Installation record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the amount written-off for each bill.

Online Write Off Of Bills Is Performed On Bill-Main

If a bill's account is associated with a Collection Class Overdue Rule that has a Write Off Bill algorithm, a button appears on Bill - Main if the bill hasn't been written off. When clicked, the Write Off Bill algorithm is invoked to write-off the bill.

Online Reversal Of Written Off Bills Is Performed On Bill-Main

If a bill's account is associated with a Collection Class Overdue Rule that has a Write Off Bill algorithm, a button appears on Bill - Main if the bill has been written off. When clicked, the Write Off Bill algorithm is invoked (in reversal mode). The algorithm cancels the write-off adjustments (thus making the bill payable again). It also schedules the account for review by the Overdue Monitor the next time it runs.

Write Offs And Overdue Process Cancellation

It should be stressed that writing-off a bill may cause an overdue process to be canceled because the bill's FT will be linked to a balanced match event (note, the specific cancel criteria are in a plug-in so this is not a hard rule).

The following points highlight interesting aspects of bill write-off and overdue process cancellation:

Copyright © 2026, Oracle and/or its affiliates.

- If a user writes off a bill real time and the bill has an Active overdue process, the process's cancel criteria will be invoked. This typically results in the cancellation of the overdue process.
- If an overdue event writes off a bill, the state of the process depends on your cancel criteria and where the overdue event is positioned in the overdue process. For example,
  - Imagine an overdue process that has an overdue event that writes offs small amounts of debt early in the process. If such a process is applied against bill with a small amount of debt, the process will be canceled (when the event activates).
  - Contrast this to an overdue process where the last event writes off the bill. Because there are no other events to activate, the process will complete (i.e., it will not be canceled).

An Alert Can Show Written Off Bills

A base-package Control Central Alert algorithm (C1-WO-BILL) can be set up to highlight if the account in context has written off bills. This algorithm is plugged in on the Installation record.

Bill-Oriented Payment Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

> **Note**
>
> **Nomenclature.** Some organizations refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the payment arrangement closes and the customer's bills only contain charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

- Creating Payment Arrangements
- Installment, Payoff and Current Amounts
- Breaking A Bill-Oriented Payment Arrangement
- Online Breaking
- Online Canceling

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

Copyright © 2026, Oracle and/or its affiliates.

- It holds debt.
- It is periodically billed (thus creating unmatched bill segment financial transactions).
- When a payment is received, the payment segment financial transactions are matched to the bill segment financial transactions.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent bills at the inception of the payment arrangement.

When you transfer debt from the overdue bills to a PA SA, transfer adjustments are created to transfer debt from the delinquent SAs to the PA SA. Match events are created to link the "transfer from" adjustments to the original unpaid financial transactions (FT). When all FT's on a bill are linked to balanced match events, the bill is no longer considered overdue and any active overdue process (and its related cut processes) will be cancelled. Refer to How Are Overdue Processes Canceled for more information.

> **Note**
>
> **Use the Payment Arrangement Transaction.** Use the Payment Arrangement - Bill Oriented to set up bill-oriented payment arrangements. This transaction creates a PA SA, transfers overdue bills to it, and sets up the installment amount. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

> **Warning**
>
> If you do not understand the difference between payoff balance and current balance, refer to Current Amount versus Payoff Amount.

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, there will be no overdue bills. If the customer neglects to pay bills containing charges associated with the payment arrangement, an overdue process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the bills whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes $500 and they want to pay this off in 10 installments, you'd set up the installment amount to be $50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their bills, you can transfer additional bills to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a

Copyright © 2026, Oracle and/or its affiliates.

customer who is paying off $500 with 10 installments of $50 would have an initial payoff balance of $500 and a current balance of $0. After the first bill, the PA SA would still have a payoff balance of $500, but its current balance would be $50. When the customer pays, the PA SA's payoff balance would fall to $450 and its current balance would return to $0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff $1,000 of debt in $10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed ($50 for new debt and $10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays $60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Breaking A Bill-Oriented Payment Arrangement

If a customer neglects to pay a bill, an overdue process is created. If the bill contains charges from a payment arrangement, you'll want to "break" the payment arrangement. By "break", we mean cancel the arrangement and reinstate the debt under the originating bills. To do this, you must configure the cut process template used to cut the PA SA to contain a cut event that breaks the payment arrangement.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Processing is redirected to another algorithm.** The base-package cut event activation algorithm that breaks a payment arrangement simply redirects the call to the Bill-Based Payment Arrangement algorithm plugged in on the account's Collection Class Overdue Rules. The reason for this redirection is that users can manually break a payment arrangement (using Payment Arrangement - Bill Oriented). When they do this, we want to invoke the same logic as when a cut event activation algorithm breaks a payment arrangement.

The base-package Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm does the following:

- Creates "cancel adjustments" for all unpaid financial transactions associated with the payment arrangement (e.g., billed, but not paid installments).
- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement. When these are cancelled, the original bills will become unpaid (and the debt will be rather old by this point).
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop and expires it (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the bills that contributed debt to it (the oldest bills are paid off first). This relief will occur via transfer adjustments from the PA SA to the original SAs.
- Note, if there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), an error is issued as we don't handle new debit on a payment arrangement.
- Inserts a characteristic on the PA SA to indicate that it has been broken (you might want to use this to cause more strict overdue rules to be applied to accounts with broken payment arrangements).
- Marks the account so it will be reviewed by the Overdue Monitor the next time it runs.

> **Note**
>
> **The PA SA must final bill before it closes.** It's important to note that the PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the Overdue Monitor next runs, it will analyze the account's reinstated bills. We recommend setting up a Collection Class Overdue Rule - Overdue Monitor Rule algorithm that has more stringent rules if the account has a broken payment arrangement within the last X days. The base-package algorithm (C1-CB-CR-RAT) supports this type of processing.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Log entry.** The base-package overdue event activation algorithm that breaks a payment arrangement SA inserts a row into the overdue process's log.

Online Breaking

A user can click a button on the Payment Arrangement - Bill Oriented page to break a payment arrangement real time. When clicked, the Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm is called to break the payment arrangement. This is the same algorithm called when a cut event break a payment arrangement.

Online Canceling

A user can click a button on the Payment Arrangement - Bill Oriented page to cancel a payment arrangement real time. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken. The "broken" characteristic type / value can be used to apply stricter rules to the account when it's next reviewed by the Overdue Monitor.

Creating Overdue and Cut Procedures

Your overdue procedures define how your organization collects overdue debt. Your cut procedures define how your organization cuts (i.e., stops) service agreements when collection attempts fail. In this section, we describe how to set up the data that controls these procedures.

> **Warning**
>
> There are numerous ways to design your overdue and cut procedures. Some designs will result in easy long-term maintenance; others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your overdue and cut procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

- Designing Your Overdue Procedures
- Set Up Tasks
- Setting Up Overdue Processing

Copyright © 2026, Oracle and/or its affiliates.

Designing Your Overdue Procedures

The design of your overdue procedures is an iterative process. Over time, you will develop skills that will allow you to skip some steps. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the overdue processing control tables.

Account's Division	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

> **NOT_SUPPORTED**
>
> For more information about how the information in this matrix is used to monitor your customers' debt, refer to How Does The Overdue Monitor Work.

- Your Divisions Are Frequently Preordained
- Designing Your Collection Classes
- Designing Overdue Monitoring Rules
- Designing Overdue Process Templates and Event Types
- Designing Cut Process Templates and Event Types

Your Divisions Are Frequently Preordained

An account's division defines the jurisdiction whose rules govern the account. For example, an account's division controls how its payments are distributed, if / how late payment charges are levied, etc. Divisions have typically been designed in advance of designing your overdue rules.

In our example, we assume you have two divisions: North and South.

Account's Division	Account's Collection Class:	Account's Collection Class:
North		
South		

Designing Your Collection Classes

Multiple collection classes are needed when your organization has different overdue rules and / or procedures based on the type of customer. If all customers are treated the same way, you'll have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

For example, for commercial/industrial customers, you probably don't worry until they owe you more than, say, $100 after 20 days. For residential customers, you probably don't worry until

Copyright © 2026, Oracle and/or its affiliates.

they owe you more than, say, $5 after 20 days. In this situation, you will have at least two collection classes: one for commercial/industrial customers, the other for residential customers.

In our example, we assume you have two collection classes: Residential and Commercial/ Industrial.

Account's Division	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
North		
South		

> **Note**
>
> There are two very different ways to monitor your accounts for overdue debt. This chapter describes the method referred to as Overdue Processing. Refer to Collection / Severance / Write Off for a description of the other method. We anticipate that most organizations will only use a single method. If your organization opts to use both methods, you will need to set up the corresponding collection classes.

Designing Overdue Monitoring Rules

At this point, we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

> **Note**
>
> **Single currency.** We've assumed that your implementation works in a single currency. If this is not true, you will need to add a 3rd dimension that will have a value for each currency code.

Each cell will contain the rules that the Overdue Monitor uses to determine if an account has overdue debt. These rules will eventually be configured using one or more algorithms on Collection Class Overdue Rules.

Account's Division	Account's Collection Class: Residential	Account's Collection Class: Commercial/Industrial
North		
South		

> **Note**
>
> If the Overdue Monitor encounters an account whose collection class and division does not have overdue rules set up, it will issue an error.

Copyright © 2026, Oracle and/or its affiliates.

Determining the rules in each cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For residential debt (regardless of division) we have the following rules:
  - Highest priority. If a bill exists with unpaid FT's > $0 that is older than 50 days, create the "accelerated overdue process" for residential customers. We'll talk more about this process later.
  - Medium priority. If the account's has a broken payment arrangement within the last 60 days with an unpaid bill > $0 that is older than 20 days, create the "broken payment arrangement overdue process".
  - Lower priority. If a bill exists with unpaid FT's > $25 that is older than 25 days, create the "courtesy reminder overdue process" for residential customers. We'll talk more about this overdue process later.
- For commercial-industrial debt (regardless of division) we have the following rules:
  - Highest priority. If a bill exists with unpaid FT's > $0 that is older than 45 days, create the "commercial 45 days late overdue process". We'll talk more about this process later.
  - Medium priority. If the account's credit rating is < 550 and has an unpaid bill > $0 that is older than 20 days, create the "risky commercial customer overdue process".
  - Lower priority. If a bill exists with unpaid FT's > $100 that is older than 30 days, create the "commercial 30 days late overdue process". We'll talk more about this overdue process later.

Given the above, our matrix will look as follows:

Account's Division	**Account's Collection Class:** Residential	**Account's Collection Class:** Commercial/Industrial
North	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 50 days, create the accelerated overdue process for residential customers. Medium Priority: If the account has a broken payment arrangement within the last 60 days with an unpaid bill > $0 that is older than 20 days, create the broken payment arrangement overdue process. Lowest Priority: If a bill exists with unpaid FT's > $25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.	Highest Priority: If a bill exists with unpaid FT's > $0 that is older than 45 days, create the commercial 45 days late overdue process. Medium priority. If the account's credit rating is < 550 and has an unpaid bill > $0 that is older than 20 days, create the risky commercial customer overdue process. Lowest Priority: If a bill exists with unpaid FT's > $100 that is older than 30 days, create the commercial 30 days late overdue process.
South	Same as above	Same as above

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **The rules are limited by your imagination (and business requirements).** While the base-package Overdue Monitor Rule algorithm (C1-CB-CR-RAT) supports the above scenarios, we'd like to stress these are just examples. Your implementation can operate using very different rules by either configuring the base-package algorithm (it has many parameters that you can use to tailor your rules) OR by introducing a new algorithm. Refer to Highlights Of The Sample Overdue Monitor Rule Algorithm for the options delivered with the base-package.

Designing Overdue Process Templates and Event Types

The following table shows a sample overdue process template for one of the rules in the Residential / North cell in the previous section's matrix.

Overdue Process Template	Overdue Event Type	When Triggered
Accelerated overdue process for residential customers	Old debt letter	At inception of process
	Cut active service agreements	10 days after inception
	Reduce customer's credit rating	10 days after inception (i.e., at the same time the cut process is created)
	Write down small debt	0 days after completion of the cut process(es)
	Refer debt to collection agent	0 days after attempting the small write down (this means that either the small write-down or the agency referral will take place as if the write-down is successful, the bill's FTs will be matched to balanced match events and the overdue process will stop)
	Cancel collection agent referral	45 days after referral
	Write-off debt	0 days after collection agent cancellation

You should create a similar table for each of the distinct overdue process templates in your matrix.

At this point, you've designed the distinct overdue process templates. Next, you'll need to design the algorithms that control their overdue processes:

- A template's Calculate Unpaid and Original Amount algorithm calculates the original and unpaid amounts of the objects being collected by a process. These values are used throughout the overdue processing module.
- A template's Cancel Criteria algorithm is executed to determine if a process should be cancelled. Refer to How Are Overdue Processes Cancelled for the details.
- A template's Cancel Logic algorithm is executed to cancel a process. Refer to How Are Overdue Processes Cancelled for the details. Please note that the logic embodied in this

Copyright © 2026, Oracle and/or its affiliates.

type of algorithm can be sophisticated because it is responsible for stopping an ongoing process's activities (e.g., this could involve cancelling field activities or cases). Cancellation algorithms are also responsible for inserting log entry(s).

- A template's Hold Event Activation algorithm is invoked to determine if the Overdue / Cut Event Manager should suspend the activation of the process's events.
- A template's Information algorithm is invoked to construct the override "info string".

Next, extract each unique event type from the above table:

Overdue Event Type	Action
Old debt letter	Create a customer contact
Cut active service agreement(s)	Start a cut process for every active SA with an unpaid FT on the bill
Reduce customer's credit rating	Insert an account credit rating history record
Write down small debt	Create write-down adjustments if unpaid debt is less than $x
Refer debt to collection agent	Create a collection agency referral
Cancel collection agent referral	Cancel the collection agency referral
Write off unpaid debt	Create adjustments to write-off unpaid debt

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of each event type:

- The event type's Event Activation algorithm(s) are executed by the Overdue / Cut Event Manager on its trigger date. The following points describe the logic embodied in such an algorithm:
  - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to Overdue Events Can Do Many Things for the details.
  - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to Some Events Can Wait for the details.
  - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to Activating Events Should Add A Log Entry for the details.
- The event type's Cancel Logic algorithm(s) are invoked when an event is cancelled. The following points describe the logic embodied in such an algorithm:
  - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
  - Any ancillary actions that take place during cancellation.
  - How the log entry(s) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to monitor a waiting event. These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the override "info string".

Copyright © 2026, Oracle and/or its affiliates.

Once you've designed each event type's algorithms, you're ready to design your cut processes.

Designing Cut Process Templates and Event Types

While not required, many overdue processes will contain an overdue event that cuts (i.e., stops) service (in the hopes that stopping service will inspire the customer to pay). When such an event activates, it creates one or more cut process(es).

The system allows you to control if and how service is cut by setting up Cut Process Rule algorithms on your SA types. This allows different rules for different types of service agreements. In addition, because these rules are embodied in algorithms, a given SA type can have conditional logic that controls the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...

> **Note**
>
> **If a service agreements of a given type should never be cut.** If you have certain SA types that should never be cut, do NOT define an algorithm in the SA type's Cut Process Rule .

Determining your Cut Process Rules can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For service agreements associated with metered service, we have the following rules:
  - Highest priority. If the customer has life support requirements, create "cut process in light of life support" process.
  - Lowest priority. Otherwise, create a "metered service" cut process.
- For service agreements associated with charitable contributions, create an "expiration only" cut process.

Once you've determined if / how each SA type is cut, you need to design your cut process templates (you'll need one for each unique method of cutting a service agreement). The following table shows the cut process templates referenced above. Adjacent to each process are its events and an indication of when they are triggered.

Cut Process Template	Event Number	Cut Event Type	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Metered service	10	Letter - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0

Copyright © 2026, Oracle and/or its affiliates.

	40	Expire service agreement	20	10
Cut process in light of life support	10	Generate delinquent life support customer To Do entry (seeking approval for the cut)	N/A - first event	0
	20	Letter - 72 hour disconnect for non-payment warning	10	0
	30	Generate impending life support cutoff To Do entry to C&C rep	20	3
	40	Field activity - cut for non-payment	30	0
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Expiration only	10	Expire service agreement	N/A - first event	

At this point, you've designed the distinct cut process templates. Next, you'll need to design the algorithms that control the lifecycle of their cut processes:

- A template's Cancel Logic algorithm is executed to cancel a process. In addition to cancelling the event, these algorithms are also responsible for inserting log entry(s).
- A template's Information algorithm is invoked to construct the override "info string".

Next, extract each unique event type from the above table:

Cut Event Type	Action
48-hour warning letter	Create a customer contact - 48-hour warning letter (letters are created via customer contacts)
72-hour warning letter	Create a customer contact - 72-hour warning letter
Disconnect for non payment	Create a cut for non-payment field activity
Permission to start a cut process for a life support customer	Create To Do seeking permission to send 72 hour letter
Permission to create a cut field activity for a life support cutoff	Create To Do seeking permission to issue a cut field activity
Service has been disconnected letter	Create a customer contact - service cut letter
Expire service agreement	Expire service agreement

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of their events:

Copyright © 2026, Oracle and/or its affiliates.

- The event type's Event Activation algorithm(s) are executed by the Overdue / Cut Event Manager on its trigger date. The following points describe the logic embodied in such an algorithm:
  - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to Cut Events Can Do Many Things for the details.
  - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to Some Events Can Wait for the details.
  - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to Activating Events Should Add A Log Entry for the details.
- The event type's Cancel Logic algorithm(s) are invoked when an event is cancelled. The following points describe the logic embodied in such an algorithm:
  - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
  - Any ancillary actions that take place during cancellation.
  - How the log entry(s) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to monitor a waiting event. These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the override "info string".

Set Up Tasks

The above topics provided background information about how overdue processing works. The following discussion summarizes the various set up tasks.

- Cut Event Types
- Cut Process Templates
- SA Type - Cut Process Rules
- Overdue Event Types
- Overdue Process Templates
- Collection Classes
- Collection Class Overdue Monitor Rules
- Feature Configuration
- Overdue and Cut Event Cancellation Reasons
- Collection Agencies
- Alert To Highlight Active Overdue Processes
- Bill-Oriented Collection - Additional Set Up

Copyright © 2026, Oracle and/or its affiliates.

Cut Event Types

You will find that most of the time spent setting up your cut event types is spent setting up the objects that are referenced on the cut event type algorithms. For example, if you use the base-package algorithms, you may need to set up the following:

- The various "types" for the objects created by the plug-ins. For example, if a cut event type creates a To Do entry, you must supply the desired To Do type.
- Foreign key characteristic types that are used to reference the ancillary objects in the log entries (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- Messages that are used to define the verbiage in the log entries. For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each cut event type algorithm. Refer to Cut Event Type - Main for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the cut event types.

Cut Process Templates

After your cut event types exist, you can set up your cut process templates. You will find that most of the time spent setting up your cut process templates is spent setting up the objects that are referenced on the cut process template algorithms. Refer to Cut Process Template - Main for the supported system events.

SA Type - Cut Process Rules

After you've created your cut process templates, you can set up the algorithms that hold your cut process rules. These are plugged-in on SA Type - Algorithm in the Cut Process Rule system event.

Overdue Event Types

You will find that most of the time spent setting up your overdue event types is spent setting up the objects that are referenced on the overdue event type algorithms. For example, if you use the base-package algorithms, you will set up the following:

- The various "types" for the objects created by the plug-ins. For example,
  - If an overdue event type creates a To Do entry, you must set up the To Do type.

Copyright © 2026, Oracle and/or its affiliates.

  - If an overdue event type creates a customer contact, you must set up the customer contact type.
  - If an overdue event type writes off debt, you must set up the adjustment types.
  - Etc.
- Foreign key characteristic types that are used to reference the ancillary objects in the log entries (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- Messages that are used to define the verbiage in the log entries. For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each overdue event type algorithm. Refer to Overdue Event Type - Main for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the overdue event types.

Overdue Process Templates

After your overdue event types exist, you can set up your overdue process templates. You will find that most of the time spent setting up your overdue process templates is spent setting up the objects that are referenced on the overdue process template algorithms. Refer to Overdue Process Template - Main for the supported system events.

Collection Classes

Set up collection classes as per your overdue procedures. Make sure to indicate that these collection classes use the Overdue collection method (only accounts linked to collection classes designated as using the Overdue collection method or processed by the Overdue Monitor).

Collection Class Overdue Monitor Rules

After your overdue process templates exist, you can set up your Overdue Monitor Rules. These rules are algorithms plugged in on Collection Class Overdue Rules. You will find most of the time spent setting up these algorithms is spent setting up the objects referenced on the base-package algorithm.

Feature Configuration

You must set up a Feature Configuration to define parameters that control various overdue processing options.

The following points describe the various **Option Types** that must be defined:

Copyright © 2026, Oracle and/or its affiliates.

- Trigger Date: Y-Workdays, N-Calendar Days. This option controls how the system computes the trigger dates on overdue and cut events. Enter Y if the system should use workdays. Enter N if the system should use calendar days. Refer to Calendar vs Work Days for the details.
- Payment Arrangement Type (B/S/A). This option indicates whether your implementation uses the Balance-Oriented Payment Arrangements (value **S**), Bill-oriented Payment Arrangements (value **B**) or both (value **A**). The value governs the navigation path for the payment arrangement lines in the Account History and Credit & Collection zones.
- Champion Template$Challenger Template$Percentage(1-100). You need only set up options of this type if your implementation implements Champion / Challenger functionality. Options of this type are entered in the format ABnnn where A is the overdue process template of the champion template, B is the overdue process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The overdue monitor uses this option to override the champion overdue process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

Overdue and Cut Event Cancellation Reasons

Overdue events can be cancelled automatically and manually (at the discretion of a user). Regardless of the method of cancellation, a cancellation reason must be supplied. You set up your overdue event cancellation reasons using Overdue Event Cancellation Reason - Main and Cut Event Cancellation Reason - Main.

Collection Agencies

If you refer debt to collection agents, you must set up your collection agencies.

Alert To Highlight Active Overdue Processes

If you want an alert to appear if the account has active overdue processes, you must configure an appropriate Control Central Alert algorithm (C1-OD-PROC). This algorithm is plugged in on the Installation record.

Bill-Oriented Collection - Additional Set Up

The topics in this section provide information on additional set up requirements if you collect on unpaid bills.

- One Bill Per Match Event
- Bill-Based Payment Arrangements
- Bill-Based Write-off
- Alert To Highlight Written Off Bills
- Open-Item Bill Amount Plug-In

Copyright © 2026, Oracle and/or its affiliates.

One Bill Per Match Event

As mentioned earlier, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. To determine a bill's outstanding amount, FTs from different bills cannot be commingled on the same match event (but it's OK for a bill's FTs to be on multiple match events). If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill. However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate.

The following Open-Item algorithm types have been provided by the base package to help enforce this rule:

- The Distribute by Bill Due Date Payment Distribution algorithm (C1-PYDS-BDU).
- The match by Bill ID Payment Distribution Override algorithm (C1-PDOV-PYBL).
- The FT cancellation FT Freeze algorithm (C1-CFTZ-COFT).

If any of your customized plug-ins and processes create match events, it is important that these too enforce this rule. You may want to refer to the base package algorithms as an example of how to do this.

Bill-Based Payment Arrangements

If you set up payment arrangements for unpaid bills, you must configure the Bill-Based Payment Arrangement algorithm and plug it in on your Collection Class Overdue Rules.

It's important to set up the adjustment types used during payment arrangement creation to NOT print on bills. This is because the base-package algorithm will match the adjustments used to transfer debt to the payment arrangement with the adjustment used to reduce the payment arrangement's current amount by the amount of the transfer if all adjustment types are set up to not print.

Bill-Based Write-off

If you write-off unpaid bills, you must set up the following:

- Set up the adjustment type that will be used to write-off an unpaid financial transaction. This adjustment type must be configured as follows:
  - **Adjustment Amount Type** must be Calculated Amount
  - Its distribution code is irrelevant as a separate calculation line will be created for each distribution code on the FT's that is written off and these lines will reference the appropriate distribution code.
  - It must reference an adjustment type char type / value that identifies it as one used to write-off a bill's FTs
  - The following algorithms must be defined on the adjustment type:
- The Generate Adjustment system event must reference an algorithm that has the responsibility of determining how to write-off a FT. This algorithm should be determining the FT's GL details and creating a separate adjustment calculation line for each GL detail. The base package is supplied with a sample algorithm that does this (C1-ADJG-WO).

Copyright © 2026, Oracle and/or its affiliates.

- The Adjustment Financial Transaction system event should reference an algorithm that impacts current, payoff and the GL by the amount being written off.
  - The distribution codes referenced on the financial transactions must be set up with a characteristic that holds the distribution code used to write-off the original amounts. For example,
    * Distribution codes used to record tax liabilities will typically reference the same distribution code for write-off (most organizations reverse tax liabilities at write-off time)
    * Distribution codes used to record revenue will typically reference a write-off distribution code used to record a write-off expense.
    * Distribution codes used to record receivables will typically not reference a write-off distribution code because receivables are implicitly written off when revenue and tax liabilities are written off.
  - Set up an adjustment cancellation code used when a users reverses a written-off bill (reversal involves canceling the write off adjustments).
  - Set up a Write Off Bill algorithm and plug it in on your Collection Class Overdue Rules. This algorithm will reference the adjustment type described in the previous point.

Alert To Highlight Written Off Bills

If you want an alert to appear if the account has bills with written-off debt, you must configure an appropriate Control Central Alert algorithm (C1-WO-BILL). This algorithm is plugged in on the Installation record.

Open-Item Bill Amount Plug-In

You must set up the algorithm that computes the original, unpaid, and write-off amounts of your open-item bills. This algorithm is called by other algorithms when these amounts are needed. This algorithm is plugged-in on Installation in the Determine Open Item Bill Amounts spot.

Setting Up Overdue Processing

The topics in this section describe how to set up the control tables to implement your overdue processing.

- Setting Up Overdue Event Types
- Setting Up Overdue Process Templates
- Setting Up Cut Event Types
- Setting Up Cut Process Templates
- Setting Up Collection Class Overdue Rules
- Setting Up Overdue Event Cancellation Reasons
- Setting Up Cut Event Cancellation Reasons

Setting Up Overdue Event Types

An overdue event type encapsulates the business rules that govern a given type of overdue event. Open **Admin**, and then **Credit & Collection**, and then **Overdue Event Type**, and then **Add** to set up overdue event types.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Overdue Events.

Description of Page

Enter a unique **Overdue Event Type** code and **Description** for the overdue event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the overdue event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel an overdue event. Refer to How Are Events Canceled for the details.
Event Activation	Required	This algorithm is executed to activate an overdue event on its trigger date. Refer to Overdue Events Can Do Many Things and How and When Events Are Activated for the details.
Event Information	Optional - only used if you want to override an overdue event's info string	This algorithm is executed to construct an overdue event's override info string. Refer to Overdue Event Information Is Overridable for the details.

Copyright © 2026, Oracle and/or its affiliates.

Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Overdue / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details.

Setting Up Overdue Process Templates

An overdue process template encapsulates the business rules that govern a given type of overdue process. Open **Admin**, and then **Credit & Collection**, and then **Overdue Process Template**, and then **Add** to set up overdue process templates.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Overdue Processes.

Description of Page

Enter a unique **Overdue Process Template** and **Description** for the overdue process template.

Collecting On Object defines the type of object managed by this overdue process. This field actually references a foreign key characteristic type that references the managed object. For example, if this overdue process template manages overdue bills, you'd reference a foreign key characteristic that references the bill object.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Calculate Unpaid & Original Amount	Required	This algorithm is executed to calculate the unpaid and original amounts of the objects associated with the overdue process. These amounts are shown on the overdue process page and in the base-package overdue info string.

Copyright © 2026, Oracle and/or its affiliates.

Cancel Criteria	Required	This algorithm is executed to determine if an overdue process can be cancelled. Refer to How Are Overdue Processes Cancelled for the details.
Cancel Logic	Required	This algorithm is executed to cancel an overdue process. Refer to How Are Overdue Processes Cancelled for the details.
Hold Event Activation Criteria	Optional - only used if overdue processes of this type can be suspended while some condition is true	This algorithm is executed to determine if the activation of overdue and cut events should be suspended. Refer to Holding Events for the details.
Overdue Process Information	Optional - only used if you want to override an overdue process's info string	This algorithm is executed to construct an overdue process's override info string. Refer to Overdue Process Information Is Overridable for the details.

The **Event Types** control the number and type of overdue events linked to an overdue process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the overdue event types appear in the scroll.
- **Overdue Event Type.** Specify the type of overdue event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the overdue process. Refer to How and When Events Are Activated for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
  - **Sequence** is system-assigned and cannot be specified or changed.
  - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Cut Event Types

A cut event type encapsulates the business rules that govern a given type of cut event. Open **Admin**, and then **Credit & Collection**, and then **Cut Event Type**, and then **Add** to set up cut event types.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review Cut Events Are Like Overdue Events.

Copyright © 2026, Oracle and/or its affiliates.

Description of Page

Enter a unique **Cut Event Type** code and **Description** for the cut event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the cut event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut event. Refer to How Are Events Canceled for the details.
Event Activation	Required	This algorithm is executed to activate a cut event on its trigger date. How and When Events Are Activated for the details.
Event Information	Optional - only used if you want to override a cut event's info string	This algorithm is executed to construct a cut event's override info string. Refer to Cut Event Information Is Overridable for the details.
Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Cut / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details.

Setting Up Cut Process Templates

A cut process template encapsulates the business rules that govern a given type of cut process. Open **Admin**, and then **Credit & Collection**, and then **Cut Process Template**, and then **Add** to set up cut process templates.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review The Big Picture Of Cut Processes.

Description of Page

Copyright © 2026, Oracle and/or its affiliates.

Enter a unique **Cut Process Template** and **Description** for the cut process template.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut process. Refer to How Are Cut Processes Cancelled for the details.
Cut Process Information	Optional - only used if you want to override a cut process's info string	This algorithm is executed to construct a cut process's override info string. Refer to Cut Process Information Is Overridable for the details.

The **Event Types** control the number and type of events linked to a cut process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the cut event types appear in the scroll.
- **Cut Event Type.** Specify the type of cut event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the cut process. Refer to How and When Events Are Activated for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
  - **Sequence** is system-assigned and cannot be specified or changed.
  - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Collection Class Overdue Rules

Collection class overdue rules contain algorithms that impact accounts associated with a given collection class, division and currency code are managed. Open **Admin**, and then **Credit & Collection**, and then **Collection Class Overdue Rules**, and then **Add** to set up collection class overdue rules.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Recommendation.** Before using this transaction, we strongly recommend that you review Different Overdue Rules For Different Customers.

Description of Page

Enter the **Collection Class**, **CIS Division** and **Currency Code** to which the rules apply.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
  The following table describes each **System Event**.

System Event	Optional / Required	Description
Bill-Based Payment Arrangement	Optional - only specified if your implementation uses bill-oriented payment arrangements	This algorithm is executed to handle the creation, breaking and canceling of a Bill-Oriented Payment Arrangements.
Overdue Monitor Rule	Required	This algorithm is invoked by the Overdue Monitor to analyze an account's debt. Refer to How Does The Overdue Monitor Work for the details. If you have multiple rules (and therefore multiple algorithms), please take care when assigning the sequence number, as the Overdue Monitor will invoke these rules in sequence order.
Write Off Bill	Option - only specified if your implementation writes-off bills	This algorithm is executed to handle the write-off and write-off reversal of a bill. Refer to Writing Off Bills.

Setting Up Overdue Event Cancellation Reasons

An overdue event cancel reason must be supplied before an overdue event can be canceled. Open **Admin**, and then **Credit & Collection**, and then **Overdue Event Cancel Reason** to define overdue event cancellation reasons.

Description of Page

Enter an easily recognizable **Overdue Event Cancel Reason** and **Description** for each cancellation reason.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Cut Event Cancellation Reasons

A cut event cancel reason must be supplied before a cut event can be canceled. Open **Admin**, and then **Credit & Collection**, and then **Cut Event Cancel Reason** to define cut event cancellation reasons.

Description of Page

Enter an easily recognizable **Cut Event Cancel Reason** and **Description** for each cancellation reason.

Defining Prepaid Metering Options

The topics in this section describe how to set up the system to enable prepaid metering functionality.

> **Note**
>
> **Prepaid metering is optional.** The system configuration requirements described in this section are only relevant if your organization offers prepaid metering service.

- The Big Picture of Prepaid Metering
- Setting Up The System To Enable Prepaid Metering

The Big Picture of Prepaid Metering

Prepaid metering allows customers to pay for energy before it is actually used.

- How Does Prepaid Metering Work?
- Debit Meter vs Credit Meter
- Prepaid Metering Transactions Result in Adjustments
- Interfacing Prepaid Transactions
- Prepaid Transactions Can Go Into Suspense

How Does Prepaid Metering Work?

A traditional electronic prepaid metering system typically operates at three levels:

- Meters that are installed at the customer's home. These meters dispense energy up to the amount that the customer prepaid.

Copyright © 2026, Oracle and/or its affiliates.

- Vending stations located at the utility's offices or designated payment agencies. These stations/agencies sell prepaid credits to customers.
- Master stations that group vending stations together for administration, reporting and control purposes. Master stations communicate information - e.g. customer information, tariff changes, etc - to the vending stations. The vending stations, in turn, report detailed customer sales and other transaction information to the master station.

A prepaid customer goes to a vendor and purchases credits for their meter to dispense energy. The vendor has knowledge of the customer and the rate that the customer is paying. The vendor issues the credits in any of the following forms: a prepaid card, a token (to be inserted into the meter) or a series of numbers (to be keyed into the meter).

Debit Meter vs Credit Meter

Prepaid meters are commonly referred to as debit meters. Billed meter types are also called credit meters. A meter's state of being 'credit' or 'debit' translates to a specific meter configuration. Having this property set at the meter configuration level enables meters to be switched between 'credit' and 'debit' if needed.

Prepaid credits may be purchased for either new premises or existing premises. In the latter case, the existing premise could initially have a typical 'credit' meter. In this case, fieldwork may be involved in getting the meter switched from 'credit' to 'debit' (prepaid).

Prepaid Metering Transactions Result in Adjustments

There could be numerous types of prepaid transactions. But the most common types are prepaid sales and cancellations.

A sale or cancellation transaction includes a total amount that usually includes tax. In order to post to the general ledger, the prepaid transaction must result in a financial transaction. Moreover, separate GL entries must be created for the breakdown of revenue and tax. In some cases, it may also be necessary to calculate the usage from the revenue amount.

Calculated Adjustments are used to book revenue from these types of transactions. A base Generate Adjustment algorithm is available to let rate application generate the appropriate GL calculation lines and calculate the corresponding usage, if needed.

Prepaid adjustments do not affect a customer's balance.

Interfacing Prepaid Transactions

An adjustment upload batch process exists for uploading prepaid transactions that result in adjustments. Refer to Interfacing Adjustments From External Sources for more information.

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to Defining Prepaid Metering Options for more information.

Prepaid Transactions Can Go Into Suspense

Copyright © 2026, Oracle and/or its affiliates.

A prepaid transaction goes into suspense if a prepaid SA could not be determined for any of the following reasons:

- The badge number on the transaction is not a valid meter in the system
- The badge number on the transaction is a valid meter in the system, but is:
  - Not linked to a prepaid meter configuration type
  - Not linked to a non-closed, non-canceled prepaid SA

This can be a common occurrence because of the likelihood that transactions get uploaded prior to meter installation/exchange or service agreement information being updated in the system.

When this situation happens, you probably still want to recognize the revenue by posting an adjustment to a suspense SA that you designate. Refer to the base sample Get Prepaid SA Using Badge Number (C1-SABYBADGE) algorithm for an example of how the suspense SA is specified.

A batch process exists for automatically resolving suspense adjustments. Refer to How Are Suspense Adjustments Resolved for more information.

Setting Up The System To Enable Prepaid Metering

The following sections describe the steps in setting up control information for prepaid metering.

- Meter Types
- Characteristic Types
- Algorithms
- Rate
- Adjustment Types
- Adjustment Type Profiles
- Service Agreement Types
- Bill Cycle
- Vendor Information

Meter Types

Prepaid meters are set up just like any other meter - i.e. the meter must reference a meter type and the meter's configuration must reference a meter configuration type.

To set up prepaid meter types you must do the following:

- Define the meter configuration types that will be used for recording prepaid usage. Mark each of these configuration types as Prepaid . Define one register with the appropriate UOM (e.g. kWh).
- Define the meter types that will be used for prepaid metering. For each meter type, associate one of the Prepaid meter configuration types that you defined. You can also mark each meter type as Prepaid Capable.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Base logic does not require the meter type to be marked as Prepaid Capable. The Prepaid indicator on the meter configuration type is used to identify prepaid meters.

Characteristic Types

The following characteristic types are needed if you are going to upload prepaid transactions as adjustments and need the system to determine the prepaid SA given a prepaid meter's badge number.

Refer to Setting Up Characteristic Types for more information.

- Prepaid Entity Characteristic Type
- Badge Number Characteristic Type

Prepaid Entity Characteristic Type

Create a characteristic type that identifies whether an SA Type is used for prepaid metering. For example:

- Characteristic Type = <code>
- Description = Prepaid Entity
- Char Entities = SA Type
- Subclass = predefined list
- Values = Y, N

Badge Number Characteristic Type

Create a characteristic type for specifying a badge number. For example:

- <code>
- Description = Badge Number
- Char Entities = Adjustment, Adjustment Type
- Subclass = Adhoc

Algorithms

The following algorithms need to be set up in order to store prepaid transactions in the system.

Refer to Setting Up Algorithms for more information.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> The following sections describe basic set up needed for uploading 'sale' and 'cancellation' types of prepaid transactions. Your implementation team may have to define additional specific algorithms types for any other prepaid transaction type that you need to upload into or store in the system.

- Calculation Rule - Calculation Algorithm
- Adjustment Type - Generate Adjustment
- Adjustment Type - Determine SA
- Adjustment Type - Resolve Suspense
- Adjustment Type - Adjustment Information
- Installation - Adjustment Information

Calculation Rule - Calculation Algorithm

Create an algorithm of type Determine Percent Given Total (C1-PCTGVNTOT) specifying your parameter values for UOM / TOU / SQI.

Create an algorithm of type Back Into Revenue (C1-BACKINREV) specifying your parameter values for UOM / TOU / SQI.

Adjustment Type - Generate Adjustment

Create an algorithm of type Adjustment Generation - Apply Rate (ADJG-RT), specifying your prepaid rate and parameter values for UOM / TOU / SQI.

Adjustment Type - Determine SA

Create an algorithm of type Get Prepaid SA Using Badge Number (C1-SABYBADGE), specifying your badge number characteristic type, prepaid characteristic type and suspense SA ID (i.e. SA to which the adjustment needs to post when a valid prepaid SA is not found).

Adjustment Type - Resolve Suspense

Create an algorithm of type Cancel Suspense Adjustment (C1-CANSUSADJ) specifying the following:

- Badge number characteristic type
- Prepaid entity characteristic type
- Prepaid adjustment type
- Adjustment cancel reason

Copyright © 2026, Oracle and/or its affiliates.

If you want this algorithm to create to do entries for adjustments that have been in suspense for too long, specify additional parameter values for number of days and to do type and to do role (optional).

Adjustment Type - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Installation - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Rate

In order to generate separate calculation lines for the revenue and tax breakdown of the prepaid amount, you need to set up a prepaid rate with components that calculate revenue amount and tax amount given just a total amount.

Create a rate schedule with the following components:

- Tax Calculation Rule
  - Calculation Rule Type = Calculation Algorithm
  - Value Type = Percentage
  - Value Source = Bill Factor
  - Bill Factor = your tax bill factor
  - Calculation Algorithm = the one created for algorithm type C1-PCTGVNTOT. Refer to Calculation Rule - Calculation Algorithm for information.
  - Distribution Code = *your distribution code for tax liability*
- Revenue Calculation Rule
  - Calculation Rule Type = Calculation Algorithm
  - Derive SQ = checked
  - Value Type = Unit Charge
  - Value Source = Bill Factor
  - Bill Factor = your rate/kWh bill factor
  - UOM/TOD/SQI to use for the resulting calculated usage, for example kWh
  - RC Cross Reference = indicate the sequence for the tax calculation rule (above)
  - Calculation Algorithm = the one created for algorithm type C1-BACKINREV. Refer to Calculation Rule - Calculation Algorithm for information.
  - Distribution Code = your distribution code for revenue

Copyright © 2026, Oracle and/or its affiliates.

Adjustment Types

You must define an adjustment type for each type of transaction that you want to store in the system. Refer to Setting Up Adjustment Types for more information.

For prepaid sales and cancellation transactions, you need to define calculated adjustment types. In addition, plug-in the following algorithms:

- Adjustment FT Creation - GL Only algorithm - so that transaction amounts do not affect the customer's balance. Specify calc lines as the source for adjustment distribution codes.
- Generate Adjustment
- Determine SA
- Resolve Suspense, if applicable.
- Adjustment Information, if applicable

Adjustment Type Profiles

Create appropriate adjustment type profiles for your prepaid service agreements.

Service Agreement Types

You must create a prepaid SA Type for each unique CIS Division. Each SA Type must be set up as non-billable and requiring a characteristic premise. The SA Types must also indicate that they are used for prepaid by specifying a prepaid entity characteristic value.

Bill Cycle

Create at least one bill cycle that will be used for prepaid accounts. This bill cycle should not have a schedule defined.

Vendor Information

A vendor could be a vending station, payment agency or master station.

You must create a person for each of your vendors. Information about the vendor may include names, an address, phone numbers, etc.

Any other miscellaneous information about the vendor can be stored as characteristics on the person.

Hierarchical relationships between vendors can be established through characteristics. For instance, a vending station's person record may contain a foreign key characteristic that points to the master station that the vending station reports to.

Defining Conservation Program Options

Oracle Utilities Customer Care and Billing allows you to define conservation (or energy efficiency) programs and provide rebates to customers.

- The Big Picture of Conservation Programs
- GL Accounting Example
- Setting Up Conservation Programs

The Big Picture of Conservation Programs

The purpose of using conservation programs is to provide rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy. To redeem their rebates, customers have to submit a rebate application to the utility with receipts, and the utility has to administer and report on the programs.

Admin and transaction objects are provided in the product to support the definition of conservation programs (admin data) and the subsequent rebate claims (transaction data). Portals and BPA scripts are used to maintain the conservation programs and rebate claims. Adjustments are used to recognize the expense and to process refunds.

The following sections discuss the maintenance objects that support this functionality.

- Conservation Program Maintenance Object
- Conservation Program Rebate Definition Maintenance Object
- Rebate Claim Maintenance Object
- Rebate Claim Line Maintenance Object

Conservation Program Maintenance Object

A conservation program is an admin maintenance object (MO) used to support the definition of a conservation program. It holds rules that control how the claims for a conservation program are managed. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- A business object option Display Statistics Service Script is provided for business objects of this type. The script plugged into this option retrieves information displayed on the **Conservation Program Statistics Zone**.
- A business object option Display Statistics UI Map is provided for business objects of this type. This is the map used on the **Conservation Program Statistics Zone** to display statistics.
- A separate maintenance object is provided to capture rebate definitions for a conservation program

Copyright © 2026, Oracle and/or its affiliates.

- Logs are not provided.
- The standard characteristics collection is provided.

> **NOT_SUPPORTED**
>
> For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-CPROG.

Conservation Program Rebate Definition Maintenance Object

A conservation program has rebate definitions that define the rebate amounts and energy savings for different types of products. The superset of such lines is the "rebate matrix". Each row in the matrix defines the rebate and presumed energy savings for a product purchased by the consumer. If your organization wishes to use this maintenance object (MO), you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- The Rebate Definition table can be used to capture information for rebate claim lines such as, appliance type, refund amount, energy savings, and applicable manufacturers and models.
- Logs are not provided for the Rebate Definition.
- A characteristics collection is not provided.

> **NOT_SUPPORTED**
>
> For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-RDEF.

Rebate Claim Maintenance Object

When a customer files a claim for a rebate, a rebate claim will be created. The rebate claim maintenance object (MO) is used to support the definition of a claim. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- Depending on the utility's requirements, you can specify single or multiple items on the Rebate Claim. A separate maintenance object is provided to capture rebate claim lines for a rebate claim.
- The standard characteristics collection is provided.
- A log is provided. This can be used to track approval information for the claim, to capture adjustments created as the claim is processed, etc.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-RCLAIM.

Rebate Claim Line Maintenance Object

A rebate claim has a rebate claim line for each product eligible for a refund. You use the rebate claim line maintenance object (MO) to create a rebate line. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- SA (service): The SA table is the real service SA. There is a separate SA under which the rebate adjustments are stored.
- Logs are not provided for Rebate Claim Line
- The standard characteristics collection is provided.

NOT_SUPPORTED

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin**, and then **Database**, and then **Maintenance Object**, and then **Search** and view the MO C1-REBLN.

GL Accounting Example

The following table shows the financial transactions that are issued when processing energy conservation rebates. This example shows the financial transactions when a customer files a claim for a dishwasher and insulation.

Notice how the expense adjustments are atomized:

- Separate adjustments are created to expense each item individually.
- A single adjustment is created for the A/P check request.

Event	GL Accounting
Rebate adjustment is created - dishwasher	Rebate Expense 35 A/P <35>
Rebate adjustment is created - insulation	Rebate Expense 45.45 A/P <45.45>
A/P check request issued	A/P 80.45 Cash <80.45>

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Conservation Programs

Conservation Programs allow administrators to create and maintain conservation programs for which customer can submit rebate claims. To set up a conservation program, open **Admin**, and then **Customer**, and then **Conservation Program**, and then **Add.**

> **NOT_SUPPORTED**
>
> For additional information on working with rebate claims, see Rebate Claims.

The topics in this section describe the base-package zones that appear on the Conservation Program portal.

- Conservation Program List Zone
- Conservation Program Zone
- Rebate Definition Zone
- Rebate Claim Statistics Zone

Conservation Program List Zone

The Conservation Program List zone lists every conservation program. The following functions are available:

- Click a broadcast button to open other zones that contain more information about the adjacent conservation program.
- Click the Add link in the zone's title bar to add a new conservation program.

This zone displays the following for each conservation program defined in the system:

- Conservation Program Information (Description, Status, Start Date, End Date)
- The number of Complete Claims
- The total Complete Claims Amount
- The number of Incomplete Claims
- The Statistics Date/Time is the date that the statistics were last calculated

Use the following procedure to create a new conservation program:

- Select **Admin**, and then **Customer**, and then **Conservation Program**, and then **Add** or click **Add** on the title bar of the Conservation Program List zone.
- Enter basic information about the conservation program in the **Main** section, including:
  - Conservation Program code
  - Description
  - Start Date/End Date
  - Statistic Update Frequency (in hours)

Copyright © 2026, Oracle and/or its affiliates.

- Enter **Financial Information** about the conservation program, including:
  - CIS Division
  - SA Type
  - A/P Adjustment Type
  - A/P Taxable Adjustment Type
- Enter **Approval Information** about the conservation program, including:
  - Approval To Do Type
  - Duplicate Claim To Do Role
  - Approval Levels and Threshold Amounts
- Click **Save.** To return to the Conservation Program portal without saving the new program, click **Cancel.**

To view a specific conservation program, click the broadcast icon for the conservation program you wish to view. The remaining zones in the Conservation Program portal open displaying details about the selected conservation program.

Conservation Program Zone

You use the Conservation Program zone to view and maintain individual conservation program. The Conservation Program zone displays the following information about the selected conservation program:

- Basic information about the conservation program, including
  - Conservation Program
  - Description
  - Start Date/End Date
  - Statistic Update Frequency (in hours)
  - Status
- Financial Information about the conservation program, including
  - CIS Division
  - SA Type
  - A/P Adjustment Type
  - A/P Taxable Adjustment Type
- Approval Information about the conservation program, including
  - Approval To Do Type
  - Duplicate Claim To Do Role
  - Approval Levels and Threshold Amounts

Please see the zone's help text for information about this zone's fields.

- Conservation Program Status
- Conservation Program Actions
- Editing Conservation Programs

Copyright © 2026, Oracle and/or its affiliates.

- Deleting Conservation Programs
- Activating Conservation Programs
- Deactivating Conservation Programs
- Setting the Status of Conservation Programs to Pending

Conservation Program Status

The Status of a conservation program indicates the current state of the program within the system. Valid statuses include:

- **Pending** indicates the program is pending. This is the initial state of a conservation program when first created.
- **Active** indicates the conservation program is currently active.
- **Inactive** indicates the conservation program is currently inactive.

Conservation Program Actions

You can perform a number of actions on a conservation program, including:

- **Edit:** Used to edit a conservation program
- **Delete:** Used to delete a conservation program
- **Activate:** Used to activate a pending or inactive conservation program
- **Refresh Statistics:** Used to refresh the statistics of an active conservation program
- **Deactivate:** Used to deactivate a pending or active conservation program
- **Pend:** Used to change the status of an active or inactive conservation program to Pending

The actions available are based on the current status of the conservation program. The table below summarizes the actions available at each status.

Status	Valid Action
Pending	Edit, Delete, Activate, Deactivate
Active	Edit, Refresh Statistics, Deactivate, Pend
Inactive	Activate, Pend

Editing Conservation Programs

Use the following procedure to edit an active or pending conservation program:

- Click **Edit.**
- Edit the details of the conservation program as needed.
- Click **Save.**

Copyright © 2026, Oracle and/or its affiliates.

Deleting Conservation Programs

Use the following procedure to delete a conservation program:

- Click **Pend** to change the status of the conservation program to Pending (if needed).
- Click **Delete.**
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the conservation program, click **Cancel.**

Activating Conservation Programs

To activate an inactive or pending conservation program, click **Activate.**

Deactivating Conservation Programs

To deactivate an active or pending conservation program, click **Deactivate.**

Setting the Status of Conservation Programs to Pending

To set the status of an active or inactive conservation program to Pending, click **Pend.**

Rebate Definition Zone

You use the Rebate Definition zone to add, view, and edit rebate definitions associated with a conservation program. A rebate definition defines the types of rebates allowed for a specific conservation program. The Rebate Definition zone displays the following details for each claim line:

- Rebate Definition
- Status (Active or Inactive)
- Rebate Amount per Unit
- Icons to Edit, Delete, and Activate/Deactivate rebate definitions
- Adding Rebate Definitions
- Editing Rebate Definitions
- Deleting Rebate Definitions
- Activating Rebate Definitions
- Deactivating Rebate Definitions

Copyright © 2026, Oracle and/or its affiliates.

Adding Rebate Definitions

Use the following procedure to add a rebate definition:

- Click **Add** in the title bar of the Rebate Definition zone.
- Enter a Description of the rebate definition.
- Select the **Product** for the rebate definition from the dropdown list.
- Select the **Service Type** for the rebate definition from the dropdown list.
- Enter the **Rebate Per Unit Amount** for the rebate definition.
- Enter the **Rebate Unit of Measure** for the rebate definition.
- Select the **Expense Adjustment Type** for the rebate definition from the dropdown list.
- Enter the **Presumed Energy Savings** for the rebate definition.
- Select the **Presumed Energy Savings** Unit of Measure for the rebate definition from the dropdown list.
- Enter the **Manufacturer** and **Model** for each item eligible to be submitted as a rebate claim line.
- To upload manufacturer/model information from a comma-separated-values file, click **CSV File to Upload.**
  - Click **Browse** on the File Upload dialog, and browse to the file to be uploaded.
  - Click **Upload.**
- Click **Save.** To return to the Rebate Definition zone without adding the rebate definition, click **Cancel.**

Editing Rebate Definitions

Use the following procedure to edit a rebate definition:

- Click the edit icon for the rebate definition you wish to delete.
- Edit the details of the claim line as appropriate.
- Click **Save**. To return to the Rebate Definition zone without changing the rebate definition, click **Cancel.**

> **Note**
>
> You can edit a rebate definition only when it is Active.

Deleting Rebate Definitions

Use the following procedure to delete a rebate definition:

Copyright © 2026, Oracle and/or its affiliates.

- Click the delete icon for the rebate definition you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the rebate definition, click **Cancel.**

Activating Rebate Definitions

To activate an inactive rebate definition, click the **Activate** button for the rebate definition you wish to activate.

> **Note**
>
> You can only activate rebate definition that is currently Inactive.

Deactivating Rebate Definitions

To deactivate an active rebate definition, click the **Deactivate** button for the rebate definition you wish to deactivate.

> **Note**
>
> You can only deactivate rebate definition that is currently Active.

Rebate Claim Statistics Zone

You use the Rebate Claim Statistic zone to view statistics for submitted rebate claims based on the current conservation program. This zone displays the following:

- Conservation Program
- Statistics Date/Time
- Statistics Charts
- Statistics Graphs

Statistics Graphs

This zone displays statistics for submitted rebate claims using the following charts:

- **Statistics by Status:** A pie chart that displays the number and percentage of claims for each status.
- **Statistics by Month:** A line chart that displays the number of claims completed each month.

Copyright © 2026, Oracle and/or its affiliates.

- **Statistics by Product:** A pie chart that displays the total value, percentage, and number of claim lines completed for each product.
- **Statistics by Claim Age:** A line and bar chart that displays the number of new claims per month (line graph) and the number of claims per age grouping (bar graph).

To refresh statistics, click **Refresh Statistics** on the title bar of the Rebate Claim Statistics zone.

Defining Open Market Options

- Markets
- Market Participants

Markets

- Understanding Market
- Configuring Market

Understanding Market

The Market object is used to define a deregulated market which is a geographical area operating with a set of rules to manage premises and/or customers for a service type. Separate market instances are created for each geographic area and service type, e.g. Gas New York (GNY), Electric New York (ENY), Electric United Kingdom (EUK).

Each deregulated market has participants (Service Providers) operating within that market. Different types of Service Providers are grouped into Market Relationship Types. There are Service Providers that manage the customer at a premise - e.g. Local Distribution Company, Energy Service Provider (Retailer, Supplier) and some that manage the meter at a premise (Meter Operator, Data Aggregator). Service Providers can operate across several deregulated markets (e.g. Retailers) and they can enter and exit markets independently. Start and End dates are provided to manage Service Providers entering and exiting markets.

Service Provider types can be managed by the market object and others can be managed by Market Provider Configuration. Recommended Market Relationship types managed by the Market object are Meter Owners, Meter Aggregators. There may be markets where no Service Providers are managed by the Market object, even where Meter Owners are present. For example when Meter Owners don’t change.

Service Provider types managed by the Market Provider Configuration are recommended for Retailer and Distributor Market Relationship Types. This option provides greater flexibility for market transactions to be sent to service providers based on the market and billing options.

> **Note**
>
> Refer to Market Provider Configuration for Service Providers that are managed for each Market Billing Option.

Copyright © 2026, Oracle and/or its affiliates.

Markets that manage a provider of last resort or fall back service provider will configure the market Fall Back Service Provider, the start and end dates allow a solution to determine who the current Fall Back Service Provider is. Not all markets have a Fall Back Service Provider.

Configuring Market

This portal is used to display and maintain a Market.

Refer to Understanding Market for more information.

To maintain markets, open **Admin**, and then **Open Market**, and then **Market**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Market Participants

- Understanding Market Participants
- Configuring Market Participants

Understanding Market Participants

Market Participants are participants in a deregulated environment. Relationships between market participants are defined in a particular market record. Refer to Understanding Markets for more information.

Each market participant can be associated to an external system which is used to define the messages that can be sent to that market participant and how each message is sent.

Configuring Market Participants

This portal is used to display and maintain market participants.

Refer to Understanding Market Participants for more information.

You can access the portal by selecting **Admin**, then **Open Market**, then **Market Participant**.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Participants List:** This zone lists all market participant records. Broadcast a record to display the details of the selected record.
- **Market Participant:** This zone provides information about the selected market participant.
- **Market Participant Characteristics**: This zone lists characteristics defined for the market participant.
- **Market Contracts**: This zone lists market contracts where the market participant is either the Buyer or Seller.
- **Processing Method List:** This zone provides the list of processing methods defined for the market participant.
- **Translation Method List:** This zone provides the list of translation methods defined for the market participant.

Copyright © 2026, Oracle and/or its affiliates.

- **Inbound BOs Send By Service Provider:** This zone lists inbound business objects that are sent by this market participant. The identification is driven by the business object having a Business Object Option of type "Sent By Service Provider" that references the current market participant.

Defining Consumer Contract Options

The topics in this section describe how to set up the system to enable consumer contract functionality.

- Understanding Consumer Contracts
- Understanding Consumer Products
- Configuring Consumer Contract Type
- Configuring Consumer Contract Milestone Type
- Configuring Consumer Product
- Configuring Consumer Product Version
- Configuring Consumer Product Rule
- Configuring Consumer Product Component
- Configuring Consumer Contract Rule

Understanding Consumer Contracts

Consumer contracts record customer relationships. These relationships can encompass multiple services, multiple sites and multiple accounts. For example a consumer contract can be for a customer's gas and electricity supply at a single site or for a customer’s water supply at multiple sites.

A consumer contract can relate to one or more consumer product versions. A consumer product version records values that are common to all consumer contracts related to that consumer product version. A consumer product version also records rules that are applied by customer service requests to set up a new consumer contract or change an existing consumer contract. These rules can for example create service agreements or stop service agreements. Refer to Understanding Consumer Products for more details. A consumer contract’s consumer contract products record the links between the consumer contract and consumer product versions.

Note a consumer contract relates to consumer product versions not to consumer products. The consumer product version linked to a consumer contract is the version of the required consumer product that is applicable for that consumer contract. This could for example be the consumer product version that is effective for the date the consumer contract was agreed.

Consumer contracts group together service agreements. The relationship between a consumer contract and a service agreement is recorded in the service agreement by linking the service agreement to one of the contract’s consumer contract products. A consumer contract can record details that are common for all of the related service agreements.

All consumer contracts have a consumer contract type. A consumer contract type limits which consumer products are valid for a consumer contract of that type. Note the consumer products that are eligible are further limited by the consumer product's eligibility criteria. Refer to Understanding Consumer Products for more details.

Copyright © 2026, Oracle and/or its affiliates.

A consumer contract can have milestones where a milestone is a date that is significant to the contract. Milestones can optional trigger an action. Refer to Understanding Consumer Contract Milestones for more details.

- Understanding Consumer Contract Milestones

Understanding Consumer Contract Milestones

Dates that are significant to a consumer contract can be recorded as consumer contract milestones. A consumer contract milestone can optionally trigger an action. For example, a consumer contract milestone could record the date when a fixed-priced period ends and trigger a change to the consumer contract when this date is reached. Another example is a consumer contract milestone that sends a notification to the customer one month prior to the end of the fixed-priced period.

A consumer contract milestone can relate to one or more of the contract's consumer contract products. A contract's consumer contract products record the links between the consumer contract and consumer product versions. In the example above of a consumer contract milestone recording the date when a fixed price period ends, the consumer contract milestone would be related to the consumer contract period whose consumer product version has the fixed priced period.

Each milestone has a consumer contract milestone type. The consumer contract milestone type indicates whether or not a milestone is executable, that is whether or not it triggers an action. For executable milestones, the action to be performed is derived from the consumer contract milestone type.

A consumer contract milestone's executable status can be: Pending, Processed, Not Executable or Canceled. Not Executable indicates that the milestone does not have a related action and Canceled indicates that the milestone is no longer applicable.

The Perform Consumer Contract Milestone Actions (C1–CCMP) batch process executes a consumer contract milestone's actions. This batch process selects the consumer contract milestones whose milestone date is today or in the past and whose executable status is Pending. The batch process performs the **Perform Action** algorithms defined on the milestone's Consumer Contract Milestone Type business object. Once a consumer contract milestone's actions have been performed, the batch process changes its executable status to Processed.

> **Note**
>
> This batch process is built using the Plug-in Driven Background Processes framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. Adjust the batch parameters according to your custom logic, if needed.

The base product provides a **Contract Milestone Type (BO) – Perform Action** algorithm that sends customer notification. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Contract Milestone Type (BO) – Perform Action** algorithm entity in the application.

Understanding Consumer Products

Copyright © 2026, Oracle and/or its affiliates.

Consumer products record attributes and rules that are used for consumer contracts. A consumer product can for example record attributes for:

- The duration of a fixed-priced period
- The amount of a contractual change, such as an exit fee
- Prices

These attributes can be used when setting up a new consumer contract or changing an existing contract. They could also be used to display details when a product is being selected or to include details in correspondence with customers.

A consumer product's rules are used to set up new consumer contracts and to change existing consumer contracts.

A consumer product's attributes and rules are recorded in the consumer product's version. Refer to Understanding Consumer Product Versions for more details.

Consumer product eligibility criteria can be used to determine which consumer products that are eligible in particular circumstances. For example a consumer product could be eligible only when autopay is being used. Consumer product eligibility criteria are optional. If a consumer product has eligibility criteria then the consumer product is eligible or not depending on the criteria. If however a consumer product does not have eligibility criteria then the consumer product is always eligible. The next sections provide more information on this functionality.

- Understanding Consumer Product Eligibility Criteria
- Understanding Consumer Product Versions
- Understanding Consumer Product Rules
- Understanding Consumer Product Components
- Understanding Consumer Product Component Eligibility Criteria
- Understanding Consumer Contract Rules

Understanding Consumer Product Eligibility Criteria

A consumer product eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Eligibility Operand**. The value of these characteristics are populated by the Operands algorithms that are defined on the related Consumer Contract Type's business object. The base product provides **Consumer Contract Type (BO) – Operands** algorithm that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Type (BO) – Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product eligibility criteria rule.

Copyright © 2026, Oracle and/or its affiliates.

The comparison results define what action should be taken when the criteria rule is applied. If the comparison is true or false, the result can be that the consumer product is eligible, the consumer product is not eligible or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product is eligible, the consumer product is not eligible, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Product Versions

A consumer product version records the product attributes and rules that are applicable for consumer contracts related to the consumer product version.

> **Note**
>
> Consumer contracts relate to consumer product versions not to consumer products. The addition of a new consumer product version will not affect existing consumer contracts.

For a consumer contract that is created or changed using a customer service request, the consumer product version is determined using the Determine Version algorithm defined on the Consumer Product business object. The base package provides an algorithm type that determines the effective consumer product version by comparing the version's offer effective date and the date the new contract or contract change was agreed. Alternative custom algorithms could use one or more of the consumer product version's offer effective date, service effective date, offer end date, service end date and consumer product version selection. To see the list of available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Determine Version** algorithm

Consumer products have two kinds of rules: consumer product rules and consumer contract rules. Consumer product rules are used to perform configurable services for a consumer product version. For example, a consumer product rule can determines the fallback product to use when a contract's product is no longer eligible. Consumer contract rules are used to set up new consumer contracts and make changes to existing consumer contracts. For example, a consumer contract rule can be used to create or stop a service agreement.

Consumer product rules relate directly to a consumer product version. Consumer contract rules are organized into groups using consumer product components. The consumer product components can be linked together into a hierarchy. The consumer product version records the consumer product component at the top of the hierarchy.

A consumer product version's attributes are recorded either as consumer product version characteristics or as consumer product component characteristics. Examples of attributes are: the duration of a fixed-price period and the amount of an exit fee.

Consumer product component eligibility criteria determine whether a consumer product component is applicable. The product attributes retrieved or consumer contract rules applied for a consumer product version will vary depending on the consumer product component eligibility criteria rules.

Understanding Consumer Product Rules

Consumer product rules are standard and custom rules that perform actions for a consumer product version. A consumer product rule class defines the type of action that is performed. A consumer product rule class is recorded in the consumer product version for each related

Copyright © 2026, Oracle and/or its affiliates.

consumer product rule. The base product provides the following consumer product rule classes:

- Determine Fallback Product
- Determine If Reapplication Required

A consumer product rule typically includes the following details:

- Basic information about the consumer product rule, including its name, description and detailed description. This is standard information for most consumer product rules.
- Specific parameters used by the consumer product rule.

The base product provides the following consumer product rules:

- **Determine Fallback Product**: A rule that determines the fallback product using a consumer product class recorded in the rule.
- **Determine if Product should be Reapplied:** A rule that determines if reapplication is necessary by deriving the current consumer product component eligibility criteria operands for the consumer product and comparing these with the previous operand values.

Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product Rule (BO) – Apply Rule** algorithm entity in the application.

Understanding Consumer Product Components

Consumer product components group together product attributes and consumer contract rules.

Consumer product component eligibility criteria rules can be created for a consumer product component. These eligibility rules will determine if a consumer product component's product attributes are applicable and if a consumer product component's consumer contract rules are applied. A consumer product version could, for example, have one consumer product component that is eligible when a customer is on autopay and another consumer product component that is eligible when a customer is not on autopay.

A consumer product component can, optionally, have one or more child consumer product components. This allows consumer product components to be organized into a hierarchy. If a consumer product component is not eligible, any child consumer product components will also not be eligible.

Understanding Consumer Product Component Eligibility Criteria

A consumer product component eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product component eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Comp Eligibility Operand**. The value of these characteristics are populated by the **Contract Operands** and **Location Operands** algorithms defined on the Consumer Product business object. The base product provides a **Consumer Product (BO) – Contract Operands** algorithm type that sets a characteristic value to indicate if the customer is

Copyright © 2026, Oracle and/or its affiliates.

or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Contract Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product component eligibility criteria rule.

The comparison results define what action should be taken when the criteria rules is applied. If the comparison is true or false, the result can be that the consumer product component should be applied, the consumer product component should not be applied or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product component should be applied, the consumer product component should not be applied, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Contract Rules

Consumer contract rules are standard and custom rules that perform actions to set up a new consumer contract or change an existing consumer contract which is related to the consumer product version. A consumer contract rule could for example create a new service agreement.

Consumer contract rules are grouped together by consumer product components. Consumer product components determine if and when a consumer contract rule will be applied. Refer to Understanding Consumer Product Components for more details.

Consumer contract rules are applied by a customer service request when a consumer contract is being created or changed. Different consumer product rules can be applied at different stages of the customer service request and for different changes. The consumer product component defines a consumer contract rule usage that determines when a consumer contract rule is applied.

The base product provides the following consumer contract rule usages:

- On Activation – Add: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products that have been added.
- On Activation - Remove: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products whose end date time has been set.
- On Completion – Add: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products that have been added.
- On Completion – Remove: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products whose end date time has been set.
- Service Location - Add: The consumer contract rules are performed when any action required to add a service point or registration point to a contract, such as field work or a market process, has been performed.
- Service Location – Remove: The consumer contract rules are performed when any action required to remove a service point or registration point from a contract, such as field work or a market process, has been performed.

The base product provides **Consumer Contract Rule (BO) – Apply Rule** algorithms that add a service agreement and that add a consumer contract milestone. Additional algorithms may

Copyright © 2026, Oracle and/or its affiliates.

exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Rule (BO) – Apply Rule** algorithm entity in the application.

Configuring Consumer Contract Type

This portal is used to display and maintain a Consumer Contract Type.

A Consumer Contract Type defines the Consumer Products that are valid for the type of contract. It also defines the information that is used in determining product eligibility.

Refer to Understanding Consumer Contracts for more information.

To maintain consumer contract types, open **Admin**, and then **Consumer Contract**, and then **Consumer Contract Type**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Contract Milestone Type

This portal is used to display and maintain a Consumer Contract Milestone Type.

A Consumer Contract Milestone Type defines milestone dates that can be recorded and whether an action should be performed for the type of milestone.

Refer to Understanding Consumer Contract Milestones for more information.

To maintain consumer contract milestone types, open **Admin**, and then **Consumer Contract**, and then **Consumer Contract Milestone Type**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Product

This portal is used to display and maintain a Consumer Product, including the consumer product's versions and eligibility rules.

Refer to Understanding Consumer Products for more information.

To maintain consumer products, open **Admin**, and then **Consumer Contract**, and then **Consumer Product**.

This is a standard All-In-One Portal.

Refer to the Consumer Product zone's embedded help text for more information.

This portal also shows zones for Consumer Product Versions and Consumer Product Eligibility.

Configuring Consumer Product Version

Copyright © 2026, Oracle and/or its affiliates.

This portal is used to display and maintain a Consumer Product Version.

Refer to Understanding Consumer Product Versions for more information.

To maintain consumer product versions, open **Admin**, and then **Consumer Contract**, and then **Consumer Product Version**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Product Rule

This portal is used to display and maintain a Consumer Product Rule.

Refer to Understanding Consumer Product Rules for more information.

To maintain consumer product rules, open **Admin**, and then **Consumer Contract**, and then **Consumer Product Rule**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuring Consumer Product Component

This portal is used to display and maintain a Consumer Product Component, including child consumer product components, eligibility rules and related consumer product versions.

Refer to Understanding Consumer Product Components for more information.

To maintain consumer product components, open **Admin**, and then **Consumer Contract**, and then **Consumer Product Component**.

This is a standard All-In-One Portal.

Refer to the Consumer Product Component zone's embedded help text for more information.

This portal also shows zones for Consumer Product Component Eligibility and Related Consumer Product Versions.

Configuring Consumer Contract Rule

This portal is used to display and maintain a Consumer Contract Rule.

Refer to Understanding Consumer Contract Rules for more information.

To maintain consumer contract rules, open **Admin**, and then **Consumer Contract**, and then **Consumer Contract Rule**.

This is a standard All-In-One Portal.

Refer to the embedded help text for more information.

Configuration

This section contains additional configuration topics for Oracle Utilities Customer to Meter and Oracle Utilities Customer Care and Billing.

- Configuring Zones
- Content Migration Assistant (CMA) Addendum
- To Do Lists Addendum
- Background Processes Addendum
- Security Addendum
- Defining Converted COBOL Program Options
- Advanced Search Options

Configuring Zones

Many zones in Oracle Utilities Customer Care and Billing do not require configuration by your implementation team. For example, the base package is shipped with the Account Financial History zone that appears on the Control Central - Account Information portal. This zone does not require configuration because its zone type has no configurable options (i.e., its behavior is static).

Other zones require configuration before they can be used because their behavior is dynamic. The topics in this section provide tips and techniques on how to configure zones in Oracle Utilities Customer Care and Billing.

NOT_SUPPORTED

Refer to The Big Picture of Portals and Zones in the *Oracle Utilities Application Framework Administration Guide* for a description of portal and zone functionality.

- Configuring Timeline Zones

Configuring Timeline Zones

A timeline zone is a zone that may be configured on the account or customer information tabs of Control Central. This type of zone contains one or more "lines" where each line shows when significant events have occurred. For example, you can set up a timeline zone that has two lines: one that shows when payments have been received from a customer, and another that shows when bills have been sent to the customer.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

For a complete description of the numerous features available on a timeline zone, refer to Timeline Zone`.

Configuration is required to enable a timeline zone. A timeline zone is made up of one or more algorithms where each algorithm returns “events” for a certain type of record (payment or bill for example). The product delivers several algorithm types for the timeline zone to include “events” for many different transactions in the product. Each algorithm type uses the Account or Person in context to retrieve the related information.

- Refer to Configuring Timeline Zones in the framework portion of the administration guide for information about the type of detail each event may return. The base provided algorithm types include many parameters to allow the implementation to configure much of this information as desired.

Many of the algorithms support supplying a BPA script to launch when a user clicks on an event on a timeline. Be sure to review each algorithm type to see what types of events support a BPA script. For each event, determine if your business practice warrants the development of a BPA script.

After configuring the algorithms per your business needs, the following additional steps are needed:

- Set up a zone that references these algorithms. The zone will reference the **F1-TIMELINE** zone type.
- Link the zone to the appropriate portal(s) (e.g., Control Central - Account Information or Control Central - Customer Information).
- Update your users' portal preferences and security rights so they can see the zone in the desired location on the portal(s).

You can set up many timeline zones. For example,

- You might want different zones to appear on a portal depending on the type of user. For example, you might want one timeline for billing clerks, and a different one for customer service representatives.
- For aesthetic reasons, you might want multiple simple timeline zones to appear on a given portal rather than one complex timeline zone.
- You might want to set up context specific timeline zones. For example, you might want to have one timeline zone that is premise-oriented and another that is person-oriented.

Content Migration Assistant (CMA) Addendum

This section is an addendum to the general Content Migration Assistant section in the *Oracle Utilities Application Framework Administration Guide*. This section assumes that you are familiar with the concepts of Content Migration Assistant (CMA).

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> CMA is designed to migrate configuration data only. Since base product data should be updated only through product patching mechanisms, CMA cannot currently be used to migrate master/transactional data that contains system-generated primary keys, such as customer account or billing information.

This addendum describes Content Migration Assistant (CMA) functionality that is specific to Oracle Utilities Customer Care and Billing.

The following sections provide information about what is provided in the C1-owned base package:

- Base Package Migration Plans
- Base Package Migration Request
- Wholesale and Piecemeal Migrations
- Processing Notes for Specific Objects

Base Package Migration Plans

The C1-owned base package provides a large number of migration plans to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration plans:

1. Navigate to **Admin**, and then **Implementation Tools**, and then **Migration Plan**, and then **Search**.
2. Enter “C1” in the **Migration Plan** field.
3. **Click Refresh**.
4. Select a migration plan in the search results list. The details of the selected migration plan are displayed in the Migration Plan portal.

> **Note**
>
> The C1-owned base package plans can also be used as a basis for custom migration plans. To create a custom migration plan, select a plan to base the custom migration plan on, click the Duplicate button, and define the custom plan to meet the implementation’s requirements as described in Defining a Migration Plan in the *Oracle Utilities Application Framework Administration Guide*.

Base Package Migration Request

The C1-owned base package provides two migration request to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration requests:

1. Navigate to **Admin**, and then **Implementation Tools**, and then **Migration Request**, and then **Search**

Copyright © 2026, Oracle and/or its affiliates.

2. Enter "C1" in the **Migration Request** field.
3. Click **Refresh.**
4. Click the **Copy and Sync Control Data** link in the search results list.

The details of the migration requests are outlined below. Please use the Migration Request portal to view additional details about this migration request.

Base Admin Data Migration Request

- **Migration Request:** C1-AdminBasic
- **Description:** Base Admin Data
- **Detailed Description:** Base Admin Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

Copy and Sync Control Data Migration Request

- **Migration Request:** C1-CopyControlTables
- **Description:** Copy and Sync Control Data
- **Detailed Description:** Copy and Sync Control Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

For additional information about these migration plans, see Base Package Migration Plans.

> **Note**
>
> The C1-owned base package request can also be used as a basis for custom migration requests. To create a custom migration request, select the base package request, click the Duplicate button, and define the request as to meet the implementation's requirements as described in Defining a Migration Request in the *Oracle Utilities Application Framework Administration Guide*.

Wholesale and Piecemeal Migrations

There are two general types of migrations used with the Content Migration Assistant: wholesale migrations and piecemeal migrations.

- Wholesale Migrations
- Piecemeal Migrations

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administration data from one environment to another. For example, a wholesale migration might be used when migrating admin data from a development or test environment to a production environment. For more on this type of migration, see Types of Migrations in the *Oracle Utilities Application Framework Administration Guide*.

The following is a high-level overview of the steps involved when executing a wholesale migration.

Copyright © 2026, Oracle and/or its affiliates.

1. Process the “F1-SchemaAdmin” (FW Foundation) migration request (This request contains migration plans for Field, Lookup, Char Type, Currency Code and FK Ref).
2. Process the “C1-AdminBasic” migration request. This includes copies of framework migration plans (including plans for Business Objects, Algorithms, and Feature Configurations) from the “F1-FrameworkAdmin” migration request, as well as independent base package C1-owned wholesale migration plans which can be run first.
3. Process any of the other delivered framework-based (F1-owned) migration requests as needed (except for the “F1-FrameworkAdmin” migration request which is already incorporated in #2)
4. Process the “C1-CopyControlTables” migration request. This includes base package C1-owned wholesale migration plans with dependency on “C1-AdminBasic” migration request.

Piecemeal Migrations

Piecemeal (or "non-wholesale" or “targeted”) migrations are used when migrating a small portion (or piece) of configuration and/or administration data from one environment to another. For example, a piecemeal migration might be used when migrating groups and rules from a development or test environment to a production environment. For more on this type of migration, see Types of Migrations in the *Oracle Utilities Application Framework Administration Guide*.

The C1-owned base package does not contain piecemeal migration plans for Oracle Utilities Customer Care and Billing.

Processing Notes for Specific Objects

The following limitations apply to certain Oracle Utilities Customer Care and Billing objects when using Content Migration Assistant:

- An Issuing Center object references a User. If this user does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- A Case Type object references an Application Service. If this service does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- Collection Agency and Service Provider objects reference a Person. If this person does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- Service Provider and Tender Source objects reference a Service Agreement. If this service agreement does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- If your migrateable object includes log tables, you may add your log entity to the characteristic type F1-MGO. You should also mark the log table as a “Non-Migrateable Table” in the Maintenance Object options.
- Transactions are applied in an unspecified order (and probably in order numerically by a randomly generated ID value). CMA only looks at "hard" constraints when determining what to put into the same transaction. Any "soft" constraints such as characteristics and algorithm parameters that might have FK references to other objects are not processed by CMA. Unless the migration plan ensures that related items go into the same transaction, they will end up in different ones, and must need to apply again and again until eventually all gets applied.

Copyright © 2026, Oracle and/or its affiliates.

To Do Lists Addendum

This section is an addendum to the general To Do Lists chapter. This addendum describes the To Do functionality that is specific to Oracle Utilities Customer Care and Billing.

- Assigning A To Do Role

Assigning A To Do Role

As described in To Do Entries Reference A Role, each To Do entry requires a role. To Do entries created in Oracle Utilities Customer Care and Billing may attempt to assign a role based on an account management group or division if it is applicable to the type of data related to the To Do entry.

As described in The Big Picture of To Do Lists, users are informed that something requires their attention by entries that appear in a To Do List. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error (meter read cannot be found).
- This bill segment that's in error, in turn, triggers the creation of a To Do entry.
- The To Do entry is assigned a role. A role is one or more users who can look at / work on the entry.
- When users view a To Do List, they only see entries addressed to roles to which they belong.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to Setting Up Account Management Groups for more information.

By assigning an AMG to an account, you are telling the system to address this account's To Do list entries to the roles defined on the AMG (note, each To Do type can have a different role defined for it on an AMG).

You can optionally use division to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you may have a division called California Operations and assign this to accounts located in California. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the California Operations division. Refer to Setting Up CIS Divisions for more information.

A To Do Pre-Creation installation options plug-in is provided to determine the appropriate To Do Role for an account based on AMG and division setup. If plugged in, the logic to determine To Do role for an account is performed whenever a To Do entry is created. Refer to C1-TDCR-DFRL for further details on how this plug-in works.

Copyright © 2026, Oracle and/or its affiliates.

NOT_SUPPORTED

Refer to To Do Entries Reference A Role for the details of how an initial role is assigned to To Do entries.

Background Processes Addendum

This chapter is an addendum to the general Defining Background Processes chapter. This addendum describes the background processes that are provided with Oracle Utilities Customer to Meter.

- How To Set Up A New Extract Processes
- Choosing Which Records Are Selected
- The Big Picture of Sample & Submit

How To Set Up A New Extract Processes

Several background processes delivered with the system are used to interface information out of the system. The topics in this section describe when and how to introduce an additional extract process.

- Setting Up Meter Read Extracts
- Setting Up Automatic Payment Extracts

Setting Up Meter Read Extracts

You will need a meter read extract for every mechanism your company uses to route meter read requests to the software that handles your meter reading requests. For example:

- You will need a meter read extract to interface records to your handheld device software. The MDL process delivered with the system is intended to be used to handle this function. This process will have to be populated to format the output records in keeping with the needs of your meter reading software.
- If you interface some meter read requests to automatic meter reading software, you will need a new meter read extract process.

If you need additional meter read extract processes, set up the following information:

- Add a new batch control record. Populate the fields as follows:
- **ID.** Assign an easily recognizable unique ID for the meter read extract process.
- **Description.** Enter a description of the meter read extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use Route Type to define the meter read extract process to be used for each route type.
- It may be necessary to register the process with your scheduler software.

Copyright © 2026, Oracle and/or its affiliates.

Setting Up Automatic Payment Extracts

You will need an automatic payment extract for every mechanism your company uses to route automatic payment requests to a financial institution / clearing house. For example:

- You will need an automatic payment extract to interface records to the Automated Clearing House (ACH) if you allow customer to pay via credit card or direct debit from a checking account. The **APAYACH** and C1-APACH processes delivered with the system are intended to be used to handle this function.

If you need additional automatic payment extract processes, set up the following information:

- Add a new batch control record. Populate the fields as follows:
- **Batch Process.** Assign an easily recognizable unique ID for the automatic payment extract process.
- **Description.** Enter a description of the automatic payment extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use Auto Pay Route Type to define the auto pay extract process to be used for each route type.

Choosing Which Records Are Selected

The system is delivered with some background processes that utilize the **Select Records** plug-in spot to select the records to be processed. It is important to note that these background processes do not utilize the Process Records plug-in spot. This logic is hardcoded as these background processes are some of the core system functions such as billing and collections. This functionality provides flexibility in choosing which records are processed, but not how they are processed.

The background processes delivered with the system optionally selects records based on CIS Division. One example is the batch control (BILLING) and algorithm (C1-BILL-SR). The background process and select records algorithm work as a pair. The batch control defines the parameter to be used by the select records algorithm. The algorithm defines the thread strategy, key fields, and makes the batch control parameter available to be used in the SQL algorithm parameter.

Customizing Which Records Are Selected

There are two ways to customize what is provided with the system.

If your organization processes records using the same criteria as the samples delivered in the system, in this case CIS Division, simply create a custom batch control for each CIS Division and specify the corresponding parameter value.

If your organization processes records using different criteria, the following points summarize the steps needed to implement a new background process using plug-ins for the specific functionality:

- Duplicate an existing batch control
- Remove the batch parameter not relevant to your organization and replace with the relevant batch parameter. Note: only the batch parameters associated with selecting records should be removed or updated. Parameters uses to process records must remain.

Copyright © 2026, Oracle and/or its affiliates.

- Duplicate the plug-in script associated with the select records algorithm type. Modify the script to pass the new batch parameter(s) to bind variables and remove those that are no longer batch parameters.
- Duplicate the select records algorithm type and associate with the new script.
- Create an algorithm for the new algorithm type. The SQL parameter value should be copied from the original algorithm type's algorithm parameter value and modified to make use of the newly added bind variables. (**Note:** Do not change the fields selected or their order.)
- Update the batch control to use the new select records algorithm.

The Big Picture of Sample & Submit

Sample and Submit refers to the ability to create Activity Requests. This is functionality that enables an implementer to design an ad-hoc batch process using the configuration tools.

Some examples of such processes are:

- Send a letter to customers that use credit cards for auto pay and the credit card expiration date is within 30 days of the current date.
- Stop auto pay for customers that use credit cards as the form of payment if the credit card has already expired. Notify the customer that their auto pay agreement has been terminated and that they need to call to reinstate.
- Select auto pay accounts that have more than X non-sufficient fund penalties, stop the auto pay agreement and notify the customer.

> **Note**
>
> The terms *activity request* and *sample & submit request* may be used interchangeably.

- Activity Request Type Defines Parameters
- Preview A Sample Prior To Submitting
- Credit Card Expiration Notice
- Defining a New Activity Request
- Setting Up Activity Request Types
- Maintaining Sample & Submit Requests

Activity Request Type Defines Parameters

For each type of process that your implementation wants to implement, you must configure an activity request type to capture the appropriate parameters needed by the activity request.

Preview A Sample Prior To Submitting

Copyright © 2026, Oracle and/or its affiliates.

To submit a new activity request, a user must select the appropriate activity request type and enter the desired parameter values, as applicable.

After entering the parameters, the following actions are possible

- Click **Preview** to see a sample of records that satisfy the selection criteria for this request. This information is displayed in a separate map. In addition, the map displays the total number of records that will be processed when the request is submitted. From this map you can **Save** to submit the request, go **Back** to adjust the parameters or **Cancel** the request.
- Click **Cancel** to cancel the request.
- Click **Save** to skip the preview step and submit the request.

When an activity request is saved, the job is not immediately submitted for real time processing. The record is save in the status Pending and a monitor process for this record's business object is responsible to transition the record to Complete.

As long as the record is still Pending, it may be edited to adjust the parameters. The preview logic described above may be repeated when editing a record.

The actual work of the activity request, such as generating customer contact records to send letters to a set of customers, is performed when transitioning to Complete (using an enter processing algorithm for the business object).

Credit Card Expiration Notice

The base product supplies a sample process to find customers that use credit cards for auto pay and their credit card expiration date is within *X* days of the current date.

To this functionality the following configuration tasks are needed:

- Define an appropriate customer contact class and type to use.
- Define appropriate activity request Cancellation Reasons. Cancellation reasons are defined using a customizable lookup. The lookup field name is C1_AM_CANCEL_RSN_FLG.
- Define an activity request type for the business object C1-NotifyExpiringCreditCardTyp . You may define default parameter values for the number of days for expiration and customer contact class and type.

Defining a New Activity Request

To design a new ad-hoc batch job that users can submit via Sample and Submit, first create a new Activity Request Type business object. The base product BO for the activity type C1-NotifyExpiringCreditCardTyp may be used as a sample.

The business object for the activity request includes the functionality for selecting the records to process, displaying a preview map for the user to review and to perform the actual processing. The base product BO for the activity request C1-NotifyExpiringCreditCardReq may be used as a sample. The following points highlight the important configuration for this business object:

- Special BO options are available for the activity request BOs to support the Preview Sample functionality.

Copyright © 2026, Oracle and/or its affiliates.

  - Activity Request Preview Service Script. This script is responsible for retrieving the information displayed when a user asks for a preview of a sample of records.
  - Activity Request Preview Map. This is the map that is invoked to display the preview sample results.
- The enter algorithm plugged into the Complete state is responsible for selecting all the records that satisfy the criteria and processing the records accordingly.

Setting Up Activity Request Types

Activity Request Types define the parameters to capture when submitting an activity request through Sample and Submit. To set up an activity request type, open **Admin**, and then **Customer**, and then **Activity Request Type**, and then **Add.**

The topics in this section describe the base-package zones that appear on the Activity Request Type portal.

- Activity Request Type List
- Activity Request Type

Activity Request Type List

The Activity Request Type List zone lists every activity type. The following functions are available:

- Click a broadcast button to open other zones that contain more information about the adjacent activity type.
- Click the Add link in the zone's title bar to add a new activity type.

Activity Request Type

The Activity Request Type zone contains display-only information about an activity request type. This zone appears when an activity request type has been broadcast from the Activity Request Type List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the activity request type.
- Click the **Delete** button to start a business process that deletes the activity request type.
- Click the **Duplicate** button to start a business process that duplicates the activity request type.
- State transition buttons are available to transition the activity request type to an appropriate next state.

Please see the zone's help text for information about this zone's fields.

Maintaining Sample & Submit Requests

Copyright © 2026, Oracle and/or its affiliates.

Use the Sample and Submit transaction to view and maintain pending or historic activity requests. Navigate using **Menu**, and then **Tools**, and then **Sample & Submit Request**, and then **Search.**

- Sample & Submit Request Query
- Sample & Submit Request Portal

Sample & Submit Request Query

Use the query portal to search for an existing sample & submit request. Once a request is selected, you are brought to the maintenance portal to view and maintain the selected record.

Sample & Submit Request Portal

This portal appears when a sample & submit request has been selected from the Sample & Submit Request Query portal.

The topics in this section describe the base-package zones that appear on this portal.

- Sample & Submit
- Sample & Submit Log

Sample & Submit

The Sample & Submit zone contains display-only information about an activity (sample & submit) request. The following functions are available:

- Click the **Edit** button to modify the parameters. Refer to Preview A Sample Prior to Submitting for more information.
- If the activity request is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Please see the zone's help text for information about this zone's fields.

Sample & Submit Log

This is a standard log zone.

Security Addendum

This chapter is an addendum to the general Defining Security and User Options chapter. This addendum describes security functionality that is specific to Oracle Utilities Customer Care and Billing.

- Implementing Account Security
- Masking Sensitive Data
- Encrypting Sensitive Data

Copyright © 2026, Oracle and/or its affiliates.

- Data Privacy Addendum

Implementing Account Security

> **Caution**
>
> This section assumes you understand The Big Picture of Row Security.

When you create an account, you must define which users can access the account's information. For example,

- If you have customers in two geographic territories, you may need to restrict access to accounts based on the office that manages each territory. For example, only users in the northern office may manage accounts in the northern territory.
- If you have industrial and residential customers, you may need to restrict access to these different customer segments based on the skill set of the users. For example, some users are skilled in dealing with industrial customers, while others are skilled in dealing with residential customers.

By granting a user access rights to an account, you are actually granting the user access rights to the account's bills, payment, adjustments, orders, etc.

> **NOT_SUPPORTED**
>
> Refer to If You Do Not Practice Account Security for setup instructions if your organization doesn't practice account security.

> **Note**
>
> **Account security may also affect persons and premises.** Refer to Persons Can Also Be Secured for how access to person information is also restricted by account security. Refer to Premises Can Also Be Secured for how access to premise information is also restricted by account security.

The topics in this section describe how to implement account security.

- Persons Can Also Be Secured
- Premises Can Also Be Secured
- Data Becomes Invisible When Access Is Restricted
- Restricted Transactions
- Account Security Case Studies
- The Default Access Group
- If You Do Not Practice Account Security

Copyright © 2026, Oracle and/or its affiliates.

Persons Can Also Be Secured

It's important to be aware that persons can also be secured as a result of "account security". It works like this:

- If a person is linked to at least one account, users will not be allowed access to the person (or the person's related information) unless they have access to at least one of the person's accounts.
- If a person is not linked to any accounts (a rare situation), any user may access the person.

> **Note**
>
> **How are persons linked to accounts?** A person is linked to an account when an account is created using the methods described under How To Add A New Customer From Control Central and Order User Interface Flow. In addition, you may manually link and unlink persons from account using the Account - Person page.

Premises Can Also Be Secured

It's important to be aware that premises can also be secured as a result of "account security". It works like this:

- If a premise is linked to at least one account, users will not be allowed access to the premise (or the premise's related information) unless they have access to at least one of the premise's accounts.
- If a premise is not linked to an account (a rare situation), then all users may access the premise.

> **Note**
>
> **How are premises linked to accounts?** A premise is indirectly linked to an account. For the purpose of access restriction, we deem a premise as being linked to an account if at least one of its service points is linked to at least one of the account's service agreements.

Data Becomes Invisible When Access Is Restricted

The following summarizes the impact of a user not having access to an account:

- Account Security and Control Central
- Account Security and Searches (and Maintenance Pages)
- Account Security and To Do Lists

Copyright © 2026, Oracle and/or its affiliates.

- Account Security and Control Central
- Account Security and Searches (and Maintenance Pages)
- Account Security and To Do Lists

Account Security and Control Central

This section summarizes the impact of account security and searching:

- Searches are affected as follows:
- An account will only be visible if a user has access to the account's access group.
- Persons that are not linked to accounts will be visible to all users.
- If a person is linked to an account, the person will only be visible if the user has access to at least one of the person's accounts.
- Premises that are not linked to accounts will be visible to all users unless secured with the Premise/SP installation option and the user's associated CIS Divisions and the premise has a CIS Division.
- If a premise is linked to an account, the premise will only be visible if the user has access to at least one of the premise's accounts.
- The alerts that highlight the existence of "multiple relationships" are not impacted by account security. Specifically:
  - The 'Person has multiple accounts' alert will appear if the selected person is linked to multiple accounts, even if the user doesn't have access to every account. Note well, the person couldn't have been selected if the user didn't have access rights to at least one account.
  - The 'Premise has multiple accounts' alert will appear if the selected premise is linked to multiple accounts, even if the user doesn't have access to every account. Note well, the premise couldn't have been selected if the user didn't have access rights to at least one account.
- Only accounts to which the user has access will be displayed in the person tree.
- Only accounts to which the user has access will be displayed in the account tree.
- All other pages contain information related to the current account context. The current account context can never reference an inaccessible account and therefore these pages are not impacted by account security.

> **Note**
>
> The user must have access rights to search for and view an account. If your implementation wishes to allow users to search for all accounts without validating the user's access rights, this can be configured by setting up the **Search All Account** option type on the Customer Information Options Feature Configuration

Account Security and Searches (and Maintenance Pages)

Searches are the gateway to the information that appears on maintenance pages. In general, account-related information is suppressed when a user doesn't have access rights to the

Copyright © 2026, Oracle and/or its affiliates.

account. This suppression is true for rows that directly reference an account AND for rows that indirectly reference an account. For example:

- A user can only see bills associated with accounts to which they have access rights.
- A user can only see financial transactions associated with service agreements that are, in turn, associated with accounts to which they have access rights.

> **Note**
>
> **Person and premise searches are also impacted.** Keep in mind that information will be suppress from both person and premise-oriented searches if the person / premise is related to accounts. Refer to Persons Can Also Be Secured for how access to person information is also restricted by account security. Refer to Premises Can Also Be Secured for how access to premise information is also restricted by account security.

Account Security and To Do Lists

Account security does NOT impact the information that appears in a user's To Do list. Rather, we have assumed that your To Do roles (and the users assigned to these roles) are consistent with your account security requirements. This can result in anomalies. For example, it's possible for a supervisor to assign a bill segment error to a user who doesn't have access to the bill segment's account. This user will then see the related To Do entry in their Bill Segments In Error To Do list. However, when they drill down on the entry, account security will manifest itself (i.e., the user won't be able to display the bill segment that's in error). This happens because the drill down causes the bill segment search logic to execute. This logic inhibits the selection of bill segments if the user can't access the related account.

To minimize these anomalies, we recommend the following:

- Setup To Do Roles consistent with your Data Access Roles.
- Setup Account Management Groups that are consistent with your Access Groups.
- Setup default To Do Roles on your Account Management Groups for each To Do type.

Restricted Transactions

The following table lists all transactions that have some type of account security. The following notation is used to describe the type of account security:

- **Account-oriented.** This notation is used if the respective transaction uses basic account security (i.e., the user must belong to at least one data access role that has access to the account's access group in order to see the information).
- **Person-oriented.** This notation is used if the respective transaction uses person-oriented account security. Refer to Persons Can Also Be Secured for more information.
- **Premise-oriented.** This notation is used if the respective transaction uses premise-oriented account security. Refer to Premises Can Also Be Secured for more information.
- None of the above. Some unusual transactions have unusual implementations of account security. These are described below.

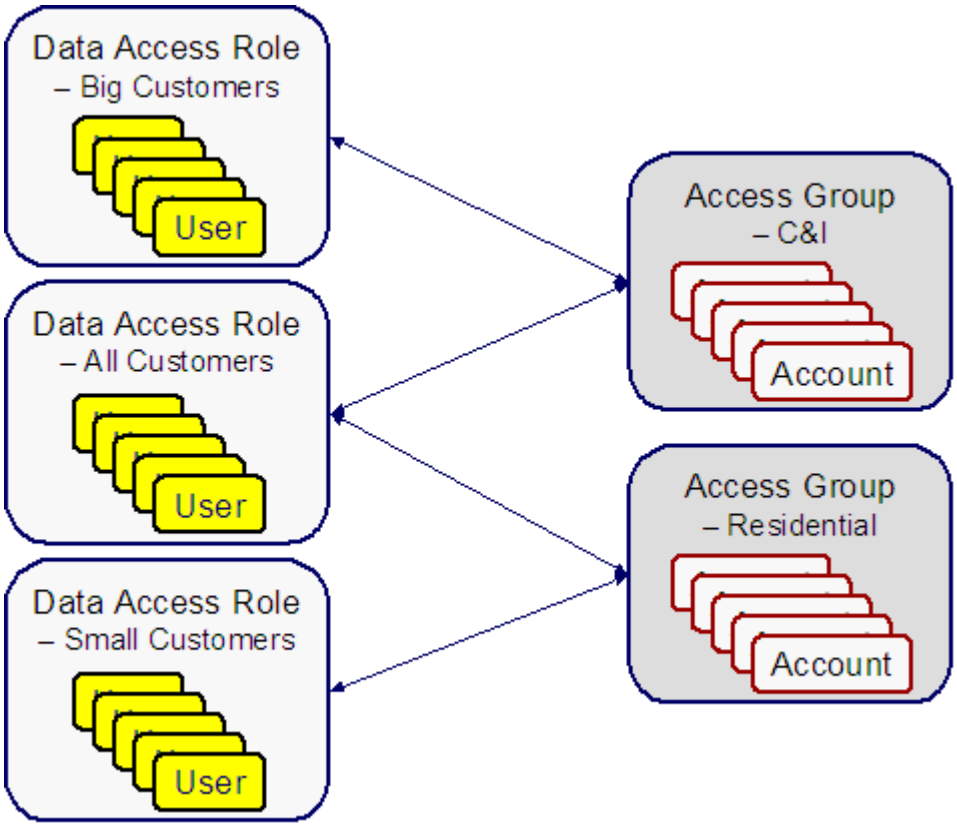
Payment	Account-oriented
Payment Arrangement	Account-oriented
Payment Arrangement for Bills	Account-oriented
Payment Event	The user must have access to ALL accounts linked to the payment event.
Payment Event Quick Add	The user must have access to ALL accounts linked to the payment event(s).
Payment Quick Add	Account-oriented
Payment / Tender Search	Account-oriented
Person	Person-oriented
Premise	Premise-oriented
Premise Management	Premise-oriented
Quote	Account-oriented
SA Billing History	Account-oriented
SA Cash Accounting Balance	Account-oriented
SA Financial History	Account-oriented
SA Relationship	Account-oriented
Service Agreement	Account-oriented
Service Credit Event	The user must have access to ALL accounts linked to the service credit membership that has the service credit event.
Service Credit Membership	The user must have access to ALL accounts linked to the service credit membership.
Service Provider SA Relationship	Account-oriented
Severance Process	Account-oriented
Start/Stop	Account-oriented
Statement	The user can see the statement if they have access to at least one account on the statement's statement construct.
Statement Construct	The user can see the statement if they have access to at least one account on the statement construct.
Terms of Service	Account-oriented (User must have access to at least one account linked to the SA collection in the TOS.)
TOU Map	Account-oriented (for SA-specific TOU maps)
Umbrella Agreement	Account-oriented (User must have access to at least one account linked to the SA collection in the UA's TOS.)
Write Off	Account-oriented
Write Off Process	Account-oriented

Account Security Case Studies

Copyright © 2026, Oracle and/or its affiliates.

The topics in this section contain examples of how to implement account security. Use these examples to form an intuitive understanding of these objects. Once this intuition is obtained, you'll be ready to design the account security objects for your own company.



- Securing Accounts Based On Customer Class
- Securing Accounts Based On Region

Securing Accounts Based On Customer Class

Assume the following security requirement exists:

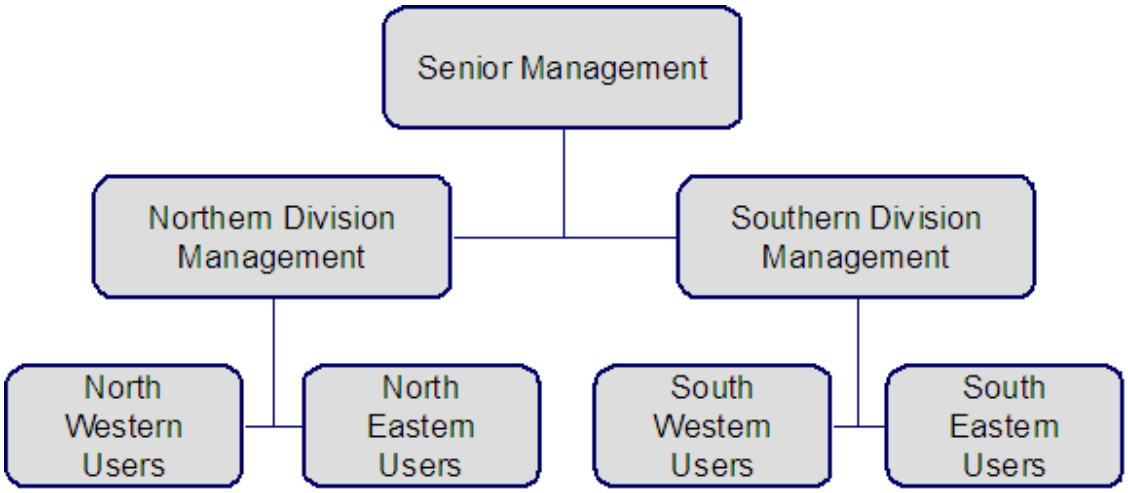
- You have two broad groups of accounts:
- Residential accounts.
- Commercial / Industrial accounts.
- Users can be classified as have one of the following access rights:
  - May access all accounts.
  - May only access residential accounts.
  - May only access commercial / industrial accounts.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Notice the following about the above:

- There are 2 access groups because access to accounts is based on whether the account is considered to be residential or commercial/industrial.

Copyright © 2026, Oracle and/or its affiliates.

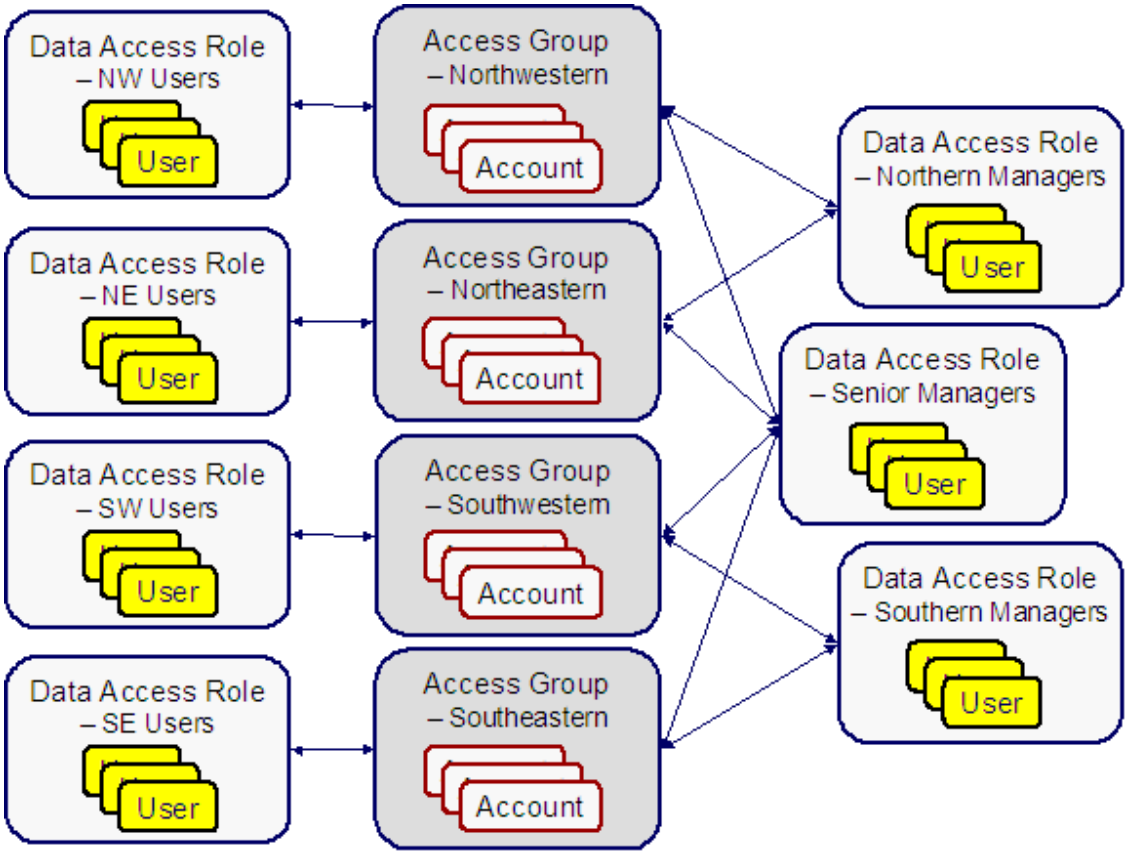


- The Big Customers data access role is only linked to the C&I access group.
- The Small Customers data access role is only linked to the Residential access group.
- The All Customers access role is linked to both the C&I and Residential access groups. Users with this role can therefore access all accounts.

Securing Accounts Based On Region

Assume that accounts are classified as belonging to one of the following regions:

- Northwestern
- Northeastern
- Southwestern
- Southeastern



Assume the following company hierarchy exists:

- Senior Management has access to all customers
- Northern Division Management has access to all customers in the Northwestern and Northeastern divisions.
- Southern Division Management has access to all customers in the Southwestern and Southeastern divisions.
- Northwestern Users have access to all customers in the Northwestern division.
- Northeastern Users have access to all customers in the Northeastern division.
- Southwestern Users have access to all customers in the Southwestern division.
- Southeastern Users have access to all customers in the Southeastern division.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Copyright © 2026, Oracle and/or its affiliates.

Notice the following about the above:

- There are 4 access groups because access to accounts is based on the region in which they are located (and there are 4 regions).
- There are 7 data access roles because each component of every layer of the access hierarchy requires a separate data access role.

The Default Access Group

There are two ways an access group can be assigned to an account:

- The base package will default an account's access group based on the user who adds the account. It uses the user's default access group to do this.
- If you can conceive of a rule to assign an appropriate access group to a newly added account, you can have your programming staff introduce a user exit to the account row program to implement this rule. For example, a user exit could be developed that assigns an access group to an account based on its customer class. The name of the user-exit is AFTER-MOVE-CORR-ADD and the name of the account row program is CIPCACCR.

> **Warning**
>
> Regardless of the method used to assign an account's access group, please be aware that the user who adds an account must have access to this access group.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> **Subsequent changes to an account's access group.** A user may change an account's access group to any access group to which they have access.

If You Do Not Practice Account Security

If you do not restrict access to accounts (i.e., all users can access all accounts), you must set up one access group and one data access role and then indicate all users are part of this role. You should also define the access group as the default access group on all of your users (so that new accounts are all labeled with this access group).

Masking Sensitive Data

Refer to Masking Data for instructions describing how to configure the system to mask sensitive data like a customer's social security number or bank account number. If your implementation intends to mask any of the information that appears in the Customer Information Zone please navigate to this zone's documentation for special instructions.

Encrypting Sensitive Data

The product provides support for encrypting certain sensitive data, which may be necessary if your implementation wants to meet security standards such as those for credit card transactions, as specified by the Payment Card Industry Security Standards Council.

Please be sure that you are familiar with the information documented in Database Encryption and Masking before reading further.

The remaining details in this section provide information about the fields in the product that support encryption along with the suggested configuration for the **Encryption** feature configuration entry if your implementation opts to encrypt the data.

Note that as described in the above link, the recommended method to use for defining encryption keys is through a key ring. This method supports key rotation. For implementations that are using the keystore for defining keys, refer to Moving from Keystore to Key Ring for information about adopting the recommended method.

External Account ID and Credit Card Number Encryption

If your implementation would like to encrypt credit card IDs, the following entry should be added to the Encryption feature configuration so that the data stored in the External ID column on the Account Automatic Payment table is encrypted:

table='CI_ACCT_APAY', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID'

table='CI_APAY_CLR_STG', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID'

table='CI_PEVT_DTL_ST', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID'

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> All configurations must share the same key ring.

> **Note**
>
> - A customer's bank account ID or credit card number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the customer's bank account ID or credit card number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base product provides an Encrypt Account Auto Pay External Account Id Column Reference Value algorithm type for this purpose.
> - A field encryption feature configuration option needs to be configured for each schema field (in a CLOB / XML field) that represents a customer's bank account ID or credit card number in any of your implementation schemas. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key ring.

If your implementation is integrated with a self-service application and one time payment details are captured in Person Self-Service Payment Option (C1_PER_SS_PAYOPT), the product supports encryption of the Credit Card Number and External Account ID fields on this table. In addition, the product supports a hash representation of this fields for searching purposes. To encrypt Credit Card Number and External Account ID, add the following entries to the Encryption feature configuration:

- **table='C1_PER_SS_PAYOPT', field='CREDIT_CARD_NBR', encryptedField='ENCR_CREDIT_CARD_NBR',hashField='HASH_CREDIT_CARD_NBR'**
- **table='C1_PER_SS_PAYOPT', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID', hashField='HASH_EXT_ACCT_ID'**

Bank Account Number Encryption

If your implementation would like to encrypt the bank account number stored on the back account table, the following entry should be added to the Encryption feature configuration:

table='CI_BANK_ACCOUNT', field='ACCOUNT_NBR', encryptedField='ENCR_ACCOUNT_NBR'

MICR ID Encryption

The product provides support for encrypting MICR ID associated with payments. In addition, the product supports capturing a hash representation of this field for searching purposes. This field is captured on three tables and entries should be added to the Encryption feature configuration for each as follows:

- **table='CI_PEVT_DTL_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**
- **table='CI_PAY_TNDR_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**

Copyright © 2026, Oracle and/or its affiliates.

- **table='CI_PAY_TNDR', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**

> **Note**
>
> All configurations must share the same key ring.

Person ID Number Encryption

The product provides support for encrypting an identifier associated with a person. In addition, the product supports capturing a hash representation of this field for searching purposes. Because the ID collection on Person includes an ID type, your implementation may decide to encrypt all IDs captured for the person or may choose to only encrypt IDs of one or more specific ID types. If you want to encrypt multiple ID types, you must configure a field encryption option type for each ID type. The following shows an example of an encryption feature configuration entry for encrypting an ID with the type “SSN”:

table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN’

table='CI_ENRL_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN’

> **Note**
>
> All configurations must share the same key ring.

> **Note**
>
> - The Person ID Number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the Person ID Number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base package provides an Encrypt Column Reference Value algorithm type for this purpose.
> - A field encryption feature configuration option needs to be configured for each schema field (in a CLOB / XML field) that represents a Person ID Number in any of your implementation schemas. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key ring.

Company ID Encryption

The product provides support for encrypting the Company ID that is populated into automatic payment extract files. If your implementation would like to encrypt company IDs on the Auto Pay Route Type table (CI_APAY_RT_TYPE), the following entry should be added to the Encryption feature configuration:

table='CI_APAY_RT_TYPE', field='CO_ID', encryptedField='ENCR_CO_ID'

Copyright © 2026, Oracle and/or its affiliates.

In addition, if your implementation allows Company ID overrides by CIS Division, the following entry should be added to the Encryption feature configuration so that the Company ID on the CIS Division Route Type table (C1_CIS_DIV_RTYP) is encrypted.

table='C1_CIS_DIV_TRYP', field='OVRD_CO_ID', encryptedField='ENCR_OVRD_CO_ID'

- Managing Encrypted Data

Managing Encrypted Data

The sections in this topic extend the information described in the framework documentation's Managing Encrypted Data topic.

Initially Encrypting Data

The current supported configuration for encryption is using the key ring. For implementations using this configuration, performing initial encryption on all the fields defined in the encryption feature configuration, the information on how to encrypt this data for the first time is described in the framework documentation topic Initially Encrypting Data

In addition, if you have encrypted data defined in a Column Reference on the Order table, you will also need to run this background process:

- C1-ECRVL: Encrypt Legacy Column Reference Values

For backwards compatibility, the product continues to support the legacy method of encryption using keystore. This is not recommended as it doesn't support key rotation. Legacy batch controls supplied to support this method of encrypting will no longer supported in an upcoming release.

Moving from Keystore to Key Ring

The framework documentation topic Moving from Keystore to Key Ring describes the basic steps to take to start using key ring to define your encryption keys rather that a keystore. For Customer Care and Billing implementations, the following additional steps are needed.

- Previously, it was documented that you did not need entries in feature configuration for encrypting the External Account ID field on the Auto Pay Clearing Staging table (CI_APAY_CLR_STG) or the Payment Event Upload Staging table (CI_PEVT_DTL_ST). Moving forward, configuration is needed for these tables as described in External Account ID and Credit Card Number Encryption.
- Previously, it was documented that you did not need entries in feature configuration for encrypting the Person ID Number on the Order Person ID table (CI_ENRL_PER_ID) table. Moving forward, configuration is needed for these tables as described in Person ID Number Encryption.

Data Privacy Addendum

This section is an addendum to the general Data Privacy chapter. This addendum describes Object Erasure functionality that is specific to Oracle Utilities Customer to Meter.

- Customer Erasure
- The Person MO Controls Customer Erasure
- Persons, Accounts And Service Agreements Are Obfuscated
- Configuring The System For Customer Erasure

Copyright © 2026, Oracle and/or its affiliates.

- Notifying External Systems About Customer Erasure

Customer Erasure

A customer's personal information can be erased from the system under certain circumstances - the most common of which is when the information is no longer necessary for the original purposes of which it was collected and processed. This is usually the case when a customer's accounts have been closed for some time and there is no other activity for that customer.

Erasure can be triggered automatically (e.g. as service agreements go into a final state) or manually (e.g. when a customer calls in to request for erasure).

- Automatic Trigger Of Customer Erasure
- Manual Trigger Of Customer Erasure

Automatic Trigger Of Customer Erasure

A person's eligibility for erasure can be automatically evaluated when key events occur on that person's accounts. These events include:

- Adding a service agreement
- Closing a service agreement
- Canceling a service agreement
- Reactivating a service agreement
- Accepting a proposal service agreement
- Declining a proposal service agreement
- Reopening a proposal service agreement
- Deleting a proposal service agreement
- Monitoring SA Triggers For Customer Erasure

Monitoring SA Triggers For Customer Erasure

The base product provides an MO Audit algorithm, Monitor SA Manage Erasure Events (C1-SAMNGEREV) that implementations need to plug in on the Service Agreement (SA) MO to enable automatic triggering of erasure.

Note that this algorithm simply creates a General Process record for the Person. This technique allows the system to perform the erasure evaluation (i.e. in the Manage Erasure Schedule algorithm) in batch. This is to minimize the number of times that the Manage Erasure Schedule algorithm is executed for the same Person. For instance, if the customer had one SA closed, another one canceled and another SA created, the erasure evaluation will only be executed once (i.e. when the C1-MNERP batch process runs) even if there were three SA events for that person.

The Manage Erasure Schedule for Person (C1-MNERP) plugin-driven batch process is provided to process the General Process records for managing person erasure. The Process Record algorithm on this batch process invokes the Manage Object Erasure (F1-ManageErasureScheduleDriver) business service. Refer to the C1-MNERP batch control in the application for more details.

Copyright © 2026, Oracle and/or its affiliates.

Manual Trigger Of Customer Erasure

A customer may call in to request an agent to erase them from the system.

The base product provides a Trigger Customer Erasure (C1-TrgCustEr) BPA script that users can configure as a favorite script in their User Preferences.

This script assumes that the user retrieves the Person before running the script – meaning, the Person is already in the current context. The script pulls in the Person ID and renders the information on the map, which also captures Erasure Date, Erasure Reason and Comments as additional inputs.

A Confirm action will invoke the same Manage Erasure Schedule processing that is executed in automatically triggered person erasures. If the customer is eligible for erasure, the Person and its associated Account(s) and Service Agreement(s) will be scheduled for erasure on the designated Erasure Date. Otherwise, an error will be displayed, indicating ineligibility for erasure.

Refer to the Trigger Customer Erasure (C1-TrgCustEr) BPA script in the application for more details about this script.

The Person MO Controls Customer Erasure

A customer's eligibility for erasure is evaluated at the Person level. This means that only the Person maintenance object will specify a Manage Erasure Schedule algorithm. Eligibility criteria in this algorithm will check the status of the Person's Account(s) and Service Agreement(s) to determine whether or not these objects can be erased. Object Erasure Schedule records are added/updated/discarded, based on the outcome of the eligibility check.

- Manage Erasure Schedule Algorithm: Person Erasure Evaluation

Manage Erasure Schedule Algorithm: Person Erasure Evaluation

The base product supplies a Maintenance Object - Manage Erasure Schedule algorithm – i.e. Person Erasure Evaluation (C1-PEREREVAL) that determines Person Erasure eligibility based on the status of the service agreements (SAs). If all SAs are in some final state - e.g. Closed, Canceled - the Person is deemed eligible for erasure and the corresponding Object Erasure Schedule records are added. Otherwise, the Person is deemed ineligible for erasure. If a person that is already scheduled for erasure happens to have new activity - e.g. started a new SA, reactivated a Closed SA - any existing Object Erasure Schedule records for that Person and its Account(s) and SA(s) will be discarded.

Persons, Accounts And Service Agreements Are Obfuscated

The following sections describe the erasure processing for Person, Account and Service Agreement information.

- Purge Versus Obfuscate
- Person, Account and Service Agreement Erasure BOs
- Person, Account and Service Agreement Obfuscation Algorithms

Copyright © 2026, Oracle and/or its affiliates.

Purge Versus Obfuscate

Purging involves physical deletion of a record. On the other hand, obfuscation involves updating certain fields in the table that are considered personally identifiable information (PII) – e.g. name, address, etc. The values of these fields are updated to blank or some value that is no longer identifiable to a person – e.g. the random-generated primary key of the Person record.

Base-supplied Person, Account and SA erasure logic performs obfuscation on the root tables of these maintenance objects (MOs). The reasons are:

- Purging could have impacts to external systems
- Purging might cause orphan data or invalid foreign key references within the system

However, base logic does purge most of the data in these MOs' child tables.

Refer to the next sections for details on each object's obfuscation processing.

Person, Account and Service Agreement Erasure BOs

The base product provides the following Object Erasure Business Objects (BOs):

- Person Erasure: C1-ErasureSchedulePerson
- Account Erasure: C1-ErasureScheduleAccoun
- Service Agreement Erasure: C1-ErasureScheduleSA

All are child BOs of the Erasure Root parent BO - F1-ErasureScheduleRoot. These BOs are delivered plugged in on their corresponding maintenance objects.

Refer to the Business Object configuration in the application for more details.

Person, Account and Service Agreement Obfuscation Algorithms

The Person, Account and Service Agreement Erasure business objects include an Enter algorithm (on the Erased state) that is responsible for obfuscating data in the maintenance object's tables. The following sections describe each algorithm.

- Person Obfuscation
- Account Obfuscation
- Service Agreement Obfuscation

Person Obfuscation

The Person Erasure (C1-ErasureSchedulePerson) BO is delivered with an enter algorithm on the Erased state - C1-PEROBJERS.

This algorithm performs the following:

- On the Person root table:
  - Updates the Address1, City and Postal fields with the PER_ID value.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> These fields are search fields and are thus indexed.

  - Deletes the contents of the Person Data Area (CLOB) field, if the algorithm is configured to do so.
- Deletes all records in the Person Seasonal Address table
- Deletes all records in the Person Identifier table
- In the Person Name table:
  - The primary name is retained and the name value is replaced with the PER_ID value.

> **Note**
>
> Deletion of the primary name makes the Person record and its Account and SA records unsearchable through the user interface - e.g. via Control Central search.

  - All other names are deleted
- Deletes all records in the Person Phone table
- Deletes all records in the Person Contact table
- Deletes all records in the Person-to-Person table
- Deletes all records in the Person Self-Service Payment Option table
- Deletes all records in Person Characteristic table, if the algorithm is configured to do so.
- Deletes all records in the Attachment table that are linked to the Person, if the algorithm is configured to do so.

Account Obfuscation

The Account Erasure (C1-ErasureScheduleAccount) BO is delivered with an enter algorithm on the Erased state - C1-ACCTOBFS.

This algorithm performs the following:

- In the Account root table:
  - Removes the link to the Mailing Premise Id
  - Clears contents of the Account Data Area
  - Deletes the contents of the Account Data Area (CLOB) field, if the algorithm is configured to do so.
- Deletes all Account Person records except the main Person.

> **Note**
>
> Deletion of the ‘main’ person makes the Account unsearchable through the user interface - e.g. via Control Central search.

- Updates the main Person's Address Source to Person

Copyright © 2026, Oracle and/or its affiliates.

- Deletes all records in the Person Address Override table
- Deletes all records in the Account Auto Pay table
- Deletes all records in the Account Alerts table
- Deletes all records in the Account Messages table
- Deletes all records in the Account Credit Rating History table
- Deletes all records in the Account Debt Monitor Review Schedule table
- Deletes all records in the Non-Cash Deposit table
- Deletes all records in the Budget Review table
- Deletes all records in the Notification Preferences table and its child tables
- Deletes all records in Account Characteristic table, if the algorithm is configured to do so.
- Deletes all records in the Attachment table that are linked to the Account, if the algorithm is configured to do so.

Service Agreement Obfuscation

The Service Agreement Erasure (C1-ErasureScheduleSA) BO is delivered with an enter algorithm on the Erased state - C1-SAOBFSCTN.

This algorithm performs the following:

- On the SA root record:
  - Removes the link to the Characteristic Premise.
  - Deletes the contents of the SA Data Area (CLOB) field, if the algorithm is configured to do so.
- Deletes all records in the SA/SP table and its child tables: SA/SP Field Activity and SA/SP Characteristics.
- Deletes all records in SA Characteristic table, if the algorithm is configured to do so.
- Deletes all records in the Attachment table that are linked to the SA, if the algorithm is configured to do so.
- Deletes all records in the SA Notification Preferences table and its child tables.

Configuring The System For Customer Erasure

The following are the steps to enable Customer Erasure:

- Plug in the Manage Erasure Schedule - Person Erasure Evaluation algorithm on the Person MO.
- Configure the Erasure Period option on each of the Person, Account and SA MOs.

> **Note**
>
> Note: The values for all three MOs should be the same, to ensure the Erasure Dates are the same on the resulting Object Erasure Schedule records.

- Plug in the Monitor SA Manage Erasure Events (C1-SAMNGEREV) Audit algorithm on the SA MO.

Copyright © 2026, Oracle and/or its affiliates.

- If using the Trigger Customer Erasure (C1-TrgCustEr) script to manually trigger person erasure:
  - Configure values for the Erasure Reason lookup field DP_CUST_ERS_RSN_FLG.
  - Configure the C1-TrgCustEr BPA script as a Favorite Script in User Preferences.

Notifying External Systems About Customer Erasure

When CCB is integrated with a meter data management system (such as Oracle Utilities Meter Data Management) and the Person and SA syncs are used to synchronize Contact and Usage Subscription information with corresponding Person and SA information, the meter data management needs to be notified when such information is already erased in CCB.

The following sync request BO schemas include a Customer Erased switch:

- MDM2 Person Sync Request: C1-MDM2PersonSyncRequest
- MDM2 SA Sync Request: C1-MDM2SASyncRequest

Logic on these BOs sets this switch to true if the related Person/SA has an Object Erasure Schedule record that is in the Erased state.

The meter data management system can use this switch to trigger its own erasure processing for Contact and Usage Subscription information. For an example, refer to the Data Privacy documentation for Oracle Utilities Meter Data Management.

Refer to the Business Object configuration in the application for more details.

Defining Converted COBOL Program Options

The topics in this section describe the transaction that allows you to define the metadata for converted COBOL programs within the current environment's database.

> ⚠ **Caution**
>
> Updating converted COBOL Programs requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience.

- Converted COBOL Program - Main

Converted COBOL Program - Main

Use this transaction to define converted COBOL program user exits for your system. Navigate to this page using **Admin**, and then **System**, and then **Converted COBOL Program**, and then **Search.**

Description of Page

The following describes fields that are relevant to defining the user exit code that a converted COBOL Program should use:

Program Component ID represents the internal ID that is given to the converted COBOL program component.

Program Com Name is the physical name of the converted COBOL program component.

Copyright © 2026, Oracle and/or its affiliates.

Template is the template used to generate the converted COBOL program component.

Location ID *(for development purposes)*

Table *(for development purposes)*

User Exit Program. Specify if you have written user exit code for this converted COBOL program component.

Development Status Flag. Options include Note Generated and Not Regeneratable.

Short Comments provides a short description of the converted COBOL program component.

Long Comments provides more details of the converted COBOL program component.

The **Variable Information** grid (including Variable Name, Occurrence, Variable Sequence, Variable Value, and Variable Alternate Value) is *for development purposes only*.

Advanced Search Options

The product offers an option to perform expanded / fuzzy searching in Control Central Search by Name and Address. The option is only available if your implementation has appropriately configured your database for fuzzy searching.

Refer to the DBA guide in the installation guide for details on setting up the database to support fuzzy searching. Note that there are some implementations where fuzzy searching will not be possible. For example, it's only available for implementations using the Oracle database. Additionally, not all languages are supported. Refer to the Oracle Database documentation for more information about fuzzy searching.

If your implementation has configured its database to enable fuzzy searching, you must also set up a Feature Configuration to indicate that feature is supported. Find the Feature Configuration record for the **General System Configuration** feature type. (It may need to be defined if it does not exist). Choose the option type **Enable Expanded Results** and define a value of **Y**.

Integration

Oracle Utilities Customer to Meter a provides tools to facilitate the integration other systems. This section provides technical information needed by your implementers to accomplish this.

- CTI-IVR Integration
- Call Summary and Call Tagging Integration
- Analytics Integration Overview
- Self-Service Integration
- Defining DataConnect Options
- Business Flags
- Customer Engagement
- Oracle Fusion Customer Experience Cloud Service Integrations
- Customer Profile Insights

Copyright © 2026, Oracle and/or its affiliates.

- Customer Relationship Management Integration
- RightNow Knowledge Integration
- External Applications
- Configuring Master Data Synchronization
- Oracle Utilities Operational Device Management
- Analytics Integrations
- Oracle Utilities Analytics Visualization
- Oracle Utilities Network Management System
- Oracle Utilities Customer Program Cloud Service
- Asset Management System Integration
- Oracle Customer Experience for Utilities
- Oracle Utilities Data Intelligence
- Message Formats
- Data Import - Message Driven Bean Configuration
- Creating Application Links in External Applications

CTI-IVR Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system. The interface provides the following functionality:

- The ability to launch Control Central for a particular account ID or phone number from an external application
- The ability to accept the next call, as dictated by the CTI software,
- The ability to perform an outbound phone call from within Oracle Utilities Customer Care and Billing

This document provides technical information needed by your implementers to fully integrate with your CTI/IVR system.

- CTI-IVR Integration Configuration
- Launching The System From an External Application
- Receiving the Next Caller in the Queue
- Initiating an External Call

CTI-IVR Integration Configuration

The integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system requires the setup of master configuration data that controls the Next Caller and Automated Dialer functions.

To set up the CTI/IVR integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration**. You are brought to an all-in-one portal with options

Copyright © 2026, Oracle and/or its affiliates.

to add/edit the CTI/IVR Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Launching The System From an External Application

The following section describes possible options to launch the system from an external system.

- Launching The Application Using a URL

Launching The Application Using a URL

You launch the application using a URL. With this option you can set the system to launch a script upon startup. You can also indicate to the system to automatically load an appropriate page (if this information is not part of the script).

The application includes a simple sample html page that can launch CCB Control Central Search by Phone Number or by Central Search Account Id. The page is called CTISample.HTM and is located in /cm_templates.

> **NOT_SUPPORTED**
>
> Refer to Launching A Script When Starting The System for further information.

Receiving the Next Caller in the Queue

If your CTI-IVR system allows users to request the next caller waiting in a queue, the system provides a mechanism to integrate with this functionality.

A BPA script called **Get Next Caller (C1-GtNxtClrC)** is available that can be used to request the next call waiting in an inbound queue managed by a CTI application.

When the **Get Next Caller** BPA is executed, it launches the **CTI Get Next Caller** and **Launch CTI** processing scripts that are defined in the CTI/IVR Integration master configuration. Your implementation creates the **CTI Get Next Caller** script that retrieves the next account in the queue. The base product supplies a sample **Launch CTI** BPA script that launches Control Central using the **C1-CCByAcct** BPA script and passing in the account that was returned by the **CTI Get Next Caller** script.

- Customize Integration to Your Next Caller Function

Customize Integration to Your Next Caller Function

Your implementation needs to create a **CTI Get Next Caller** processing script that will responsible for getting the next account in the queue, based on your integrated CTI application. The base-supplied **Launch CTI** processing script can be used to navigate to Control Central with the next caller’s account passed in.

Copyright © 2026, Oracle and/or its affiliates.

In order to integrate the next caller functionality with your CTI-IVR system, perform the following steps:

- Create your custom **CTI Get Next Caller** service script that retrieves the next account from the queue.
- Create a **Launch CTI** BPA script if your business rules require additional logic and/or need to launch a different page in the system..
- Plug in the **CTI Get Next Caller** and **Launch CTI scripts** on the CTI/IVR Integration master configuration.

Initiating an External Call

This section describes the automated dialer functionality provided with the system as well as information about integrating with your own automated dialer.

- Overview of Automated Dialer
- Technical Implementation of Automated Dialer
- Customize Integration to Your Automated Dialer Software
- Customize Automated Dialer User Interface

Overview of Automated Dialer

In order to initiate a call to a customer from within the system, a context menu item **Go To Automated Dialer** is available on the Person context menu. To call a customer displayed in the current context, choose this option from the person context menu and a window appears, showing a list of phone numbers defined for that person.

Select the desired phone number and click **Dial**.

> **Note**
>
> **Context Entry Secured**. The navigation key for this window automatedDialer refers to an application service to facilitate application security. If your installation does not support an integration with external dialer software, configure the security settings to ensure that users do not have access to the application service for this context entry.

Technical Implementation of Automated Dialer

The popup window is implemented as a BPA script (**C1-LAutoDial**) that calls a configurable **Automated Dialer** BPA script that is responsible for retrieving and displaying person contacts and phone numbers (i.e. if the installation option is set to Use Legacy Person Phone and Email feature configuration option is set to 'Y'). The **C1-AutoDial** sample script provided with the system integrates to any soft phone protocol handler that launches a dialer based on overriding the "tel:" protocol from a browser, for example, Cisco IP Communicator. It launches a UI map to display the person contacts and phone numbers (i.e. if the feature option is set).

Phone Dialer Configuration

Copyright © 2026, Oracle and/or its affiliates.

If your implementation chooses to use the functionality provided with the system and integrate with a soft-phone dialer, plug in the base-supplied **C1–AutoDial** script in the CTI/IVR Integration master configuration.

Customize Integration to Your Automated Dialer Software

In order to integrate with a different automated dialer software application, your implementers must create your own **Automated Dialer** BPA script, to call your specific dialer.

- Copy the **C1-AutoDial BPA** script and make the appropriate changes to integrate with your automated dialer (e.g. change the protocol from “tel:” to “callto:”.
- Plug in your custom Automated Dialer script on the CTI/IVR Integration master configuration.

Customize Automated Dialer User Interface

Your implementation may choose to display a different user interface for the **Go To Automated Dialer** function than the one provided with the system. For example, perhaps there is more information that you would like to display in addition to the person's name and phone numbers. In order to do this, your custom **Automated Dialer** script needs to invoke a custom UI map that you create as follows:

- Copy the base-supplied **C1-AutomatedDialer** UI map and make the necessary changes.
- Invoke your custom UI map from your custom **Automated Dialer** .

Call Summary and Call Tagging Integration

Call Summary and Call Tagging uses Generative Artificial Intelligence and integration with a third-party Computer Telephony Integration (CTI) application to automatically summarize and categorize call transcripts, providing customer service agents an overview of the call. Agents can review and edit the summary and tags before saving them directly to the customer contact.

> **Note**
>
> Call Summary and Call Tagging is only available with Oracle Utilities Customer Cloud Service and Oracle Utilities Customer Care and Billing Cloud Service.

See Creating Customer Contacts Using Call Summary and Call Tagging in the *Business User Guide* for more information how users work with Call Summary and Call Tagging.

This section provides details related to implementation of Call Summary and Call Tagging, including:

- Integrating With a CTI Application
- Configuring Characteristic Types and Customer Contact Types with Characteristic Tags
- Enabling the Service Guide Zone

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> Call Summary and Call Tagging relies on generative AI models that must be deployed as part of your cloud service implementation. Please contact your Oracle Customer Success Manager if you wish to use Call Summary and Call Tagging.

- Integrating with a CTI Application
- Configuring Characteristic Types and Customer Contact Types with Characteristic Tags
- Enabling the Service Guide Zone

Integrating with a CTI Application

This section provides an overview of the process to integrate a third-party Computer Telephony Integration (CTI) vendor with Call lSummary and Call Tagging, utilizing the Service Guide SDK JavaScript library. By integrating CTI, your agents can use enhanced Call lSummary and Call Tagging features such as:

- Incoming call notifications
- Call control management, including muting, holding, and ending calls
- Access to call transcripts and summaries

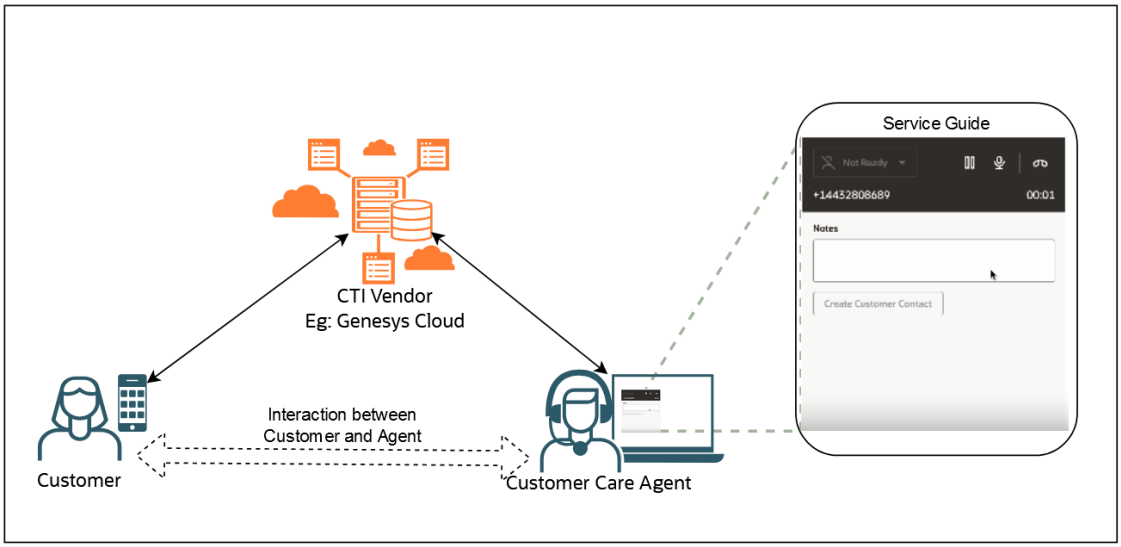
> **Note**
>
> Oracle does not endorse specific CTI vendors or provide implementation instructions for third-party applications. This document focuses on the integration points supported by the Service Guide SDK, detailing relevant events and APIs. Hosting third-party applications is beyond the scope of this guide.

This section contains the following:

- Understanding Computer Telephony Integration
- Prerequisites and Technical Requirements
- Configuring the CTI iFrame
- Integrating the Service Guide SDK in the Partner Application

- Understanding Computer Telephony Integration
- Prerequisites and Technical Requirements
- Configuring the CTI iFrame
- Integrating the Service Guide SDK in the Partner Application

Understanding Computer Telephony Integration



Computer Telephony Integration (CTI) is a technology that integrates computer software and telecommunication systems seamlessly. It connects a phone system to a computer, enabling users to manage phone functions directly from their desktop.

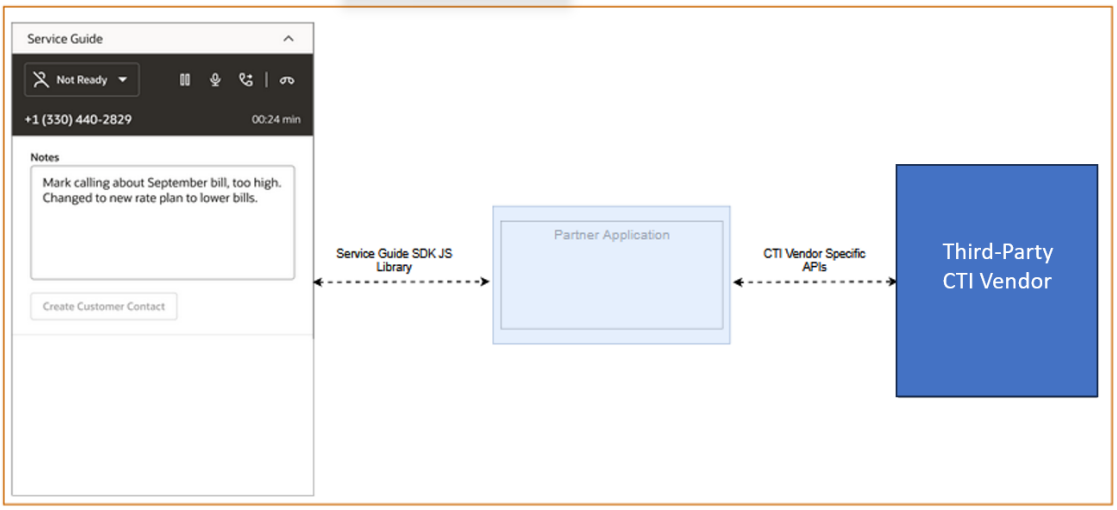
Copyright © 2026, Oracle and/or its affiliates.

With CTI, customer calls that come into the service center are routed through a CTI system and sent to an available agent. The CTI provider facilitates this process by identifying callers, providing access to customer details, and offering call control features directly from the agent's desktop. Call controls include incoming call notifications, call control options during a call (such as hold or mute), and the ability to obtain a text transcript of the call, if supported by the CTI vendor.

This image illustrates a basic flow where a call to the utility is routed via the CTI vendor and handled by an agent. The CTI provider identifies the caller, enables the agent to view customer details, and enables the agent to mute the call, put the call on hold, or transfer the call.

Figure CTI Integration Flow Example

Prerequisites and Technical Requirements



Call Summary and Call Tagging facilitates integration with third-party CTI vendors through a partner application. Oracle provides the Service Guide SDK JavaScript library for communication between the Call Summary and Call Tagging application and the CTI partner application, which runs as an invisible iFrame.

The CTI iFrame serves as a container for embedding the partner application, which is a web application developed by utility system administrators. This application communicates with the CTI backend using vendor-specific APIs to deliver the required functionality.

This image illustrates the technical components of the solution:

Copyright © 2026, Oracle and/or its affiliates.

Figure Technical Components

Before completing the steps in this guide, complete the following tasks:

1. Select a CTI vendor that meets your needs. The vendor should support both incoming and outbound calls and provide API support for accepting calls from the web application.
2. Verify that you can invoke the CTI vendor APIs.
3. Develop the partner application as a web-based solution that can be made available over https.

Configuring the CTI iFrame

After you have created your partner application, you must gather the following information, which is used to configure the application inside of the Call Summary and Call Tagging feature:

- The URL of the partner application page
- The window domain of the final page with which the partner application is loaded

URL of the Partner Application

You must provide the URL for the partner application page that will be embedded in Call Summary and Call Tagging as part of the CTI iFrame. This should include any static query parameters that the partner application expects.

Call Summary and Call Tagging appends the **`crmDomain`** query parameter to this URL, which is the window location of the Call Summary and Call Tagging application. For example:

```
https://opav12345.getway.mycti.cloud/crm/embeddableApp.html?
enableFrameworkClientId=true&dedicatedLoginWindow=true
```

Copyright © 2026, Oracle and/or its affiliates.

This example shows an iFrame URL that is used by Call Summary and Call Tagging for loading the partner application, where, `crmDomain=<Service-Guide-window-location>` is appended by Call Summary and Call Tagging.

```
https://opav23abc5a4z.getway.mycti.cloud/crm/embeddableApp.html?
enableFrameworkClientId=true&dedicatedLoginWindow=true&crmDomain=
```

Window Domain of the Final Page

You must provide the window domain, including the protocol, host and port number, of the final page with which the partner application will be loaded. The window domain may not be same as the hostname present in the iFrame URL above, as the final window may be loaded after multiple redirections. This is common when using authentication providers, and can result in a window location that is different than the initial URL. For example:

```
https://apps.usawest.mycti.cloud
```

- CTI iFrame Considerations
- Avoiding CORS Errors

CTI iFrame Considerations

When configuring the CTI iFrame, consider the following issues.

iFrame Not Visible to Agent

The CTI iFrame is not visible to the end user. Only the controls provided by Service Guide are available to the agent. However, the CTI iFrame can open any necessary windows to perform necessary operations, such as logging a user into the CTI system to establish an authenticated session with the CTI backend.

Permissions

The CTI iFrame includes the permissions listed here. These permissions allow Service Guide to handle phone calls using the browser.

```
camera *; microphone *; autoplay *; hid *
```

When prompted, agents must accept and provide these permissions in order to allow Service Guide to handle a customer call.

> **Note**
>
> Agents might have to disable pop-up blockers in their browser if the partner application uses a pop-up window for authentication purposes.

Authenticated Requests

An important aspect of CTI integration is to allow agents to make authenticated requests to the CTI system. CTI systems typically use authentication and authorization to establish a valid user login and allow the system to make appropriate API calls on behalf of the logged-in agent.

Copyright © 2026, Oracle and/or its affiliates.

Utilities can provide a window for agents to log into the CTI system, however, Oracle recommends setting up a Single Sign On (SSO) with the Oracle Customer Cloud Service application so that a single user login is recognized when an agent accesses various systems.

> **Note**
>
> Refer to your CTI vendor documentation for information about allowing API access for agents and SSO setup.

Avoiding CORS Errors

In order to embed your partner application as an <iFrame> inside Call Summary and Call Tagging, you must set up appropriate headers to avoid Cross Origin Resource Sharing (CORS) errors from browsers.

Specifically, the partner application should be set up as follows:

```
Set only "Content-Security-Policy: frame-ancestors <Service Guide Base URL>"
response header.

DO NOT SET "X-Frame-Options" response header.
```

This setup applies to the partner application and any other domains to which a request gets redirected during the initial load. When the partner application is loaded and Single Sign On (SSO) is set up, the partner application may redirect browsers to an authentication provider's URL and domain, which might differ from the partner application's domain. The browser redirects occur inside the iFrame, therefore, any such domains should follow the above recommendation to ensure successful load and redirect in the iFrame embedded in Call Summary and Call Tagging.

If the authentication provider does not allow the SSO redirect window to be embedded, the partner application can open a separate login window. The agent can then sign in using CTI system credentials or credentials for other providers that utility has configured. Once the sign in is performed and a successful authenticated session is established, this window can be closed (programmatically) and CTI initialization can proceed.

> **Note**
>
> Contact your Oracle Support team if you need assistance identifying the `<Service Guide Base URL>` for your environment.

Integrating the Service Guide SDK in the Partner Application

The partner application you implement could be a normal HTML/Javascript application. To communicate with the Call Summary and Call Tagging feature, you must inject a Javascript library, called Service Guide SDK, into your partner application. Additionally, you must:

- Invoke the APIs required for the integration, or
- Listen for necessary events

Copyright © 2026, Oracle and/or its affiliates.

The integration between Call Summary and Call Tagging and the partner application is a frontend-to-frontend integration through the javsascript SDK library.

You can import the library in the HTML page of the partner application using either method shown below.

Import Using Script Tag

Code example:

```
<script type=“module" src="https://static.oracle.com/cdn/service-guide-sdk/
<version-number>/service-guide-sdk.umd.js" onload="onSdkLoad()"></script>
        <!-- Once the above script is loaded, SDK class will be available
under window.OUSG.ServiceGuideSdk variable. -->
<script>
      function onSdkLoad() {
         const sdkInstance = new window.OUSG.ServiceGuideSdk({...});
         // You can now use "sdkInstance" variable for referring to SDK
instance.
      }
</script>
```

Once the script is loaded, SDK can be instantiated using the class available at **`window.OUSG.ServiceGuideSdk`**.

Import as Module using Dynamic Import

Code example:

```
const sdkUrl = 'https://static-stage.oracle.com/cdn/service-guide/service-
guide-sdk/<version-number>/service-guide-sdk.esm.js';
const {ServiceGuideSdk} = await import(sdkUrl);
const sdkInstance = new ServiceGuideSdk({...});
// You can now use "sdkInstance" variable for referring to SDK instance.
```

Using requirejs

Code example:

```
<!--
          First load the requirejs from appropriate source -->
<script
    id="requirejs"
    src="https://requirejs.org/docs/release/2.3.7/minified/require.js"
></script>

<!-- Now load SDK using require-js -->
<script type="module">
  const sdkUrl = 'https://static-stage.oracle.com/cdn/service-guide/service-
guide-sdk/<version-number>/service-guide-sdk.esm.js';

  require([sdkUrl], (OUSG) => {
     const sdkInstance = new OUSG.ServiceGuideSdk({...});
     // You can now use "sdkInstance" variable for referring to SDK instance.
```

Copyright © 2026, Oracle and/or its affiliates.

```
  });
</script>
```

SDK Initialization

Once the SDK library is loaded, the partner application must create an instance of the SDK by initializing it with the appropriate parameters. Call Summary and Call Tagging will add a "`crmDomain`" query parameter while loading the partner application in an iFrame. This parameter should be used while initializing SDK.

Code example:

```
// Read "crmDomain" query parameter from the window location
let url = window.location.search;
let segments = url.replace('?', '&').split('&');
const parentDomain = decodeURIComponent(segments.find(segment =>
(segment.indexOf('crmDomain') >= 0)).split('=')[1]);

//Initialize Service Guide SDK
const sdkInstance = new ServiceGuideSdkClass({
    serviceGuideDomain: parentDomain,
    isCtiInstance: true, // Most important to set
    options: {application: 'cti'} // This is also an important parameter to
include while initializing the SDK to let Service Guide know which
application the notification is coming from.
});

// You can now use "sdkInstance" variable for referring to SDK instance.
// You can also set the SDK instance on the window object in case you need to
access it later:
// window.serviceGuideSdk = sdkInstance;
```

- Operations and Events

Operations and Events

The Service Guide SDK provides two types of APIs:

1. Operations
2. Events

- Operations
- Events

Operations

When the partner application needs the Call Summary and Call Tagging feature to perform an action or send data, it must invoke an `Operation` on the SDK.

For example, the partner application wants to notify an agent, via the Service Guide zone, that it has received an incoming call. This requires the partner application to invoke the `callReceived` operation.

Available operations include:

Copyright © 2026, Oracle and/or its affiliates.

- ctiInitialized
- agentStatusUpdated
- callReceived
- initiatedCallSession
- endCallSession
- callMuted
- callUnmuted
- callOnHold
- callResumed
- transcriptReceived
- callWrappedUp
- loggedOut

To indicate that these operations are targeted towards the Service Guide interface, the operations are added under the "Ui" namespace of the SDK. Below is an example code for invoking an operation:

```
// SDK loading and initialization code as demonstrated before.

// Finish rest of the CTI specific setup
// initCti(...); //illustration purpose only

// After all initialization is done, notify Service Guide of it
// (Assuming the SDK instance is named "serviceGuideSdk")

serviceGuideSdk.Ui.ctiInitialized();

// This can also be done in some async callback if your setup needs an
asynchronous handling
// Assuming getAuthToken is an asynchronous function that returns auth token
for a logged in user.

getAuthToken(async (authToken) => {
    // assuming CTI vendor has a `ctiSdk` library that provides a client
initialization code

    await ctiSdk.ApiClient.initialize(authToken); // Another asynchronous
processing

    // At this point all CTI initialization is done, notify Service Guide.

    serviceGuideSdk.Ui.ctiInitialized();
});

...

/* Another example */
// Assuming CTI vendor has below API for subscribing to a client that invokes
the provided callback when a customer call is received.

ctiSdk.ApiClient.Interaction.subscribe(async (callData) => {
```

Copyright © 2026, Oracle and/or its affiliates.

```
    // Invoke "callReceived" operation on Service Guide SDK's "Ui" module.

    serviceGuideSdk.Ui.callReceived({
        data: {
            phoneNumber: calData.ani,
            callId: callData.id
        }
    });
});
```

Operation: ctiInitialized

This table provides details of the ctiInitialized operation:

Operation Component	Details
Description	This is the first operation the partner application invokes to notify Service Guide that the application is ready to handle CTI functionalities. It should be invoked after initial setup of the partner application is complete, which includes: • Setting up communication channels and websocket connections • Initializing various SDKs, including the Service Guide SDK • Completing all other initialization code
Payload	None
Parameter Description	Not Applicable
Notes	Service Guide expects this operation to be called when the partner application is loaded to confirm that it is ready to handle call center operations. If Service Guide does not receive a response within a predetermined time, it reloads the partner application iFrame. If the partner application can't be loaded after 3 attempts, Service Guide assumes the Partner Application is down and abandons attempts to load it. Service Guide notifies the agent about the failure to load the partner application.

Operation: agentStatusUpdated

This table provides details of the agentStatusUpdated operation:

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Description	This operation is used by the partner application to notify Service Guide of the agent's availability to take an incoming call. The Service Guide displays one of these agent statuses, depending upon the payload when the operation is invoked: • Ready • Not Ready When an agent is actively handling a call, the status is Not Ready. Be aware that the partner application must invoke this operation to notify Service Guide when the agent should be moved to Not Ready status. Depending on the CTI vendor, this could be an explicit notification that the vendor sends to the partner application or it could be done by the partner application in response to when a call is connected.

Payload	`{`
	`  data: {`
	`  isAgentReady: boolean`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**isAgentReady**: Whether the agent is currently ready to receive calls.
Error Parameter Description	If the Partner Applications receives an error while updating the agent status, it notifies Service Guide about the error by including an "error" object in the payload instead of including a "data" object. The error object has the following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occured. Possible values: – "**READY_STATUS_UPDATE_FAILED**" – "**NOT_READY_STATUS_UPDATE_FAILED**"
Notes	None

Operation: callReceived

This table provides details of the callReceived operation:

Operation Component	Details
Description	When an incoming call is received from the CTI vendor and sent to the partner application, invoke this operation to notify Service Guide about the incoming call.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details

Payload	`{`
	`  data: {`
	`  phoneNumber: string,`
	`  callId: string`
	`  }`
	`}`

Parameter Description	**phoneNumber**: Incoming customer phone number. **callId**: A unique identifier representing the new incoming call session.
Notes	None

Operation: initiatedCallSession

This table provides details of the initiatedCallSession operation:

Operation Component	Details
Description	To be invoked when the new call session is established with the customer in response to an incoming call. Note that the agent will not explicitly accept an incoming call, but must be automatically connected to the call using auto-answer capabilities. Depending upon the CTI vendor, this could be an explicit setting in the CTI backend, or the Partner Application might be required to invoke an explicit vendor API to accept the call when it is received. Service Guide does not display Accept or Reject options for the agent. In response to this operation, Service Guide will render the call controls that are needed for the agent to interact with the active call session.

Payload	`{`
	`  data: {`
	`  phoneNumber: string,`
	`  callId: string,`
	`  connectedTime: integer | string | Date`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Parameter Description	**phoneNumber**: Customer phone number. **callId**: A unique identifier representing the newly established call session. **connectedTime**: An optional parameter representing the start of the conversation. If present, it can be an integer representing UNIX timestamp OR a String representing datetime in ISO-8601 OR a javascript Date object.
Error Parameter Description	If the partner applications receives an error while establishing the call session with the customer and agent, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**CONNECT_FAILED**".
Notes	Both the callReceived and initiatedCallSession operations expect a callId parameter. This is required because a CTI vendor might not generate a new call identifier until a call is connected. Therefore, the call identifier might not be available when the callReceived operation is invoked. The "connectedTime" paramater can be used if the call was already in progress via another CTI software before the Service Guide window was opened. In this case, it is useful to send the timestamp from the beginning of the conversation so that Service Guide can correctly reflect the call length instead of starting the timer from 0.

Operation: endCallSession

This table provides details of the endCallSession operation:

Operation Component	Details
Description	The Partner Application can invoke this operation when the call is disconnected from the CTI vendor. Note that if the agent disconnects the call in the Service Guide interface, this operation should be invoked when the call is actually disconnected by the CTI vendor in response to the Agent disconnect request.

Payload	`{`
	`  data: {`
	`  callId: string,`
	`  callDuration: number (optional)`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Parameter Description	**callId**: A unique identifier for the call session that ended. **callDuration**: Optional call duration in seconds.
Error Parameter Description	If the partner applications receives an error while disconnecting the call session, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**DISCONNECT_FAILED**".
Notes	None

Operation: callMuted

This table provides details of the callMuted operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to mute an ongoing call was successfully processed. This operation can also be used to notify Service Guide if the call was externally muted so that Service Guide can update itself.

Payload	`{`
	`  data: {`
	`  callId: string`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**callId:** A unique identifier for the call that was muted.
Error Parameter Description	If the partner applications receives an error while muting the call, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**MUTE_FAILED**".
Notes	None

Copyright © 2026, Oracle and/or its affiliates.

Operation: callUnmuted

This table provides details of the callUnmuted operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to un-mute an ongoing call was successfully processed. It can also be used to notify Service Guide if the call was externally un-muted so that Service Guide can update itself.

Payload	`{`
	`  data: {`
	`  callId: string`
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Parameter Description	**callId:** A unique identifier for the call that was un-muted.
Error Parameter Description	If the partner applications receives an error while unmuting the call, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**UNMUTE_FAILED**".
Notes	None

Operation: callOnHold

This table provides details of the callOnHold operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to put the call on hold was successfully processed. It can also be used to notify Service Guide if the call was externally put on hold so that Service Guide can update itself.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details

Payload	```
	{
	    data: {
	       callId: string
	    },
	
	    error: object<{
	         isError: boolean,
	         message: string }> (optional)
	    }
	}
	``

Parameter Description	**callId:** A unique identifier for the call that is placed on hold.
Error Parameter Description	If the partner applications receives an error while putting the call on hold, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**HOLD_FAILED**".
Notes	None

Operation: callResumed

This table provides details of the callResumed operation:

Operation Component	Details
Description	This operation should be invoked to notify Service Guide that a request to resume a call that was previously put on hold was successfully processed. It can also be used to notify Service Guide if the call was externally resumed so that Service Guide can update itself.

Payload	```
	{
	    data: {
	       callId: string
	    },
	
	    error: object<{
	         isError: boolean,
	         message: string }> (optional)
	    }
	}
	``

Parameter Description	**callId:** A unique identifier for the call that is resumed.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Error Parameter Description	If the partner applications receives an error while resuming the call that was previously put on hold, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**RESUME_FAILED**".
Notes	None

Operation: transcriptReceived

This table provides details of the transcriptReceived operation:

Operation Component	Details
Description	This operation should be invoked in response to the request transcript event to send the text transcript of the call. The partner application should request the transcript from the CTI backend via CTI-specific APIs. It is not necessary to fetch the transcript from the CTI backend at the point when the call ends. If the appropriate CTI vendor APIs are available, a real-time transcript can be collected during the call and held in front-end memory, which then can be used at the end of the call.

Payload	`{`
	`  data: {`
	`  agentTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional),`
	
	`  customerTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional),`
	
	`  combinedTranscripts: array<{`
	`  channel: string,`
	`  text: string,`
	`  offsetMs: number }> (optional)`
	
	`  },`
	
	`  error: object<{`
	`  isError: boolean,`
	`  message: string }> (optional)`
	`  }`
	`}`

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details
Parameter Description	**agentTranscripts:** An array of collected text transcripts for the agent's side of the conversation. Each element consists of the `channel` , `text` and `offsetMS`. **customerTranscripts:** An array of collected text transcripts for Customer's side of conversation. Each element consists of the `channel` , `text` and `offsetMS`. **combinedTranscripts:** An array of collected text transcripts for the whole conversation. Each element consists of the `channel` , `text` and `offsetMS`. **channel:** Either `'internal'` or `'external'` **text:** Actual speech to text transcript **offsetMs:** Offset in milliseconds from the conversation start time.
Error Parameter Description	If the partner applications receives an error while collecting the call transcript from CTI backend, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**TRANSCRIPTION_FAILED**".
Notes	Either **only** `combinedTranscripts` **OR both** agentTranscripts and customerTranscripts must be included in the payload. The `channel` property should have one of these values, based on who the conversation owner is: **`channel='internal'`** All elements of `agentTranscripts` OR those elements in `combinedTranscripts` that belong to agent. **`channel='external'`** All elements of `customerTranscripts` OR those elements in `combinedTranscripts` that belong to customer.

Operation: callWrappedUp

This table provides details of the callWrappedUp operation:

Operation Component	Details
Description	To be invoked when the call wrap up has been completed on the CTI side and the Service Guide UI should be notified so that it can reset itself, making the agent available for the next call.

Copyright © 2026, Oracle and/or its affiliates.

Operation Component	Details

Payload	<pre>{
	  data: {
	  callId: string
	  },
	  error: object<{
	  isError: boolean,
	  message: string
	  }> (optional)
	}</pre>

Parameter Description	**callId:** A unique identifier for the call for which the wrapup was done.
Error Parameter Description	If the partner applications receives an error while capturing the wrap up information on CTI side, it can notify Service Guide about the error by including the "**error**" object in the payload instead of including the "data" object. Error object has following properties: • **isError**: Boolean representing whether or not an error occurred. • **message**: An error code representing the type of error that occurred. Possible values are "**WRAPUP_FAILED**".
Notes	None

Operation: loggedOut

This table provides details of the loggedOut operation:

Operation Component	Details
Description	This operation should be invoked in response to the "logout" event to notify the Service Guide that the partner application has finished performing any cleanup in response to the "logout".
Payload	None
Parameter Description	Not Applicable
Notes	None

Events

When the Call Summary and Call Tagging user interface needs to request data or perform an action in the CTI backend, it raises an SDK Event that the Partner Application must listen for.

For example, when an agent puts a call on hold in the Call Summary and Call Tagging user interface , the application would raise an event to request that the Partner Application place the call on hold. Similarly, when agent requests to summarize the call, the application requests the text transcript from the Partner Application by raising an event.

The Partner Application listens for these events and performs the requested action, typically using CTI-provided APIs, and responds by invoking appropriate operations with the requested data.

Supported events include:

Copyright © 2026, Oracle and/or its affiliates.

- serviceGuideCti:agent:status:update
- serviceGuideCti:call:disconnect
- serviceGuideCti:call:mute
- serviceGuideCti:call:unmute
- serviceGuideCti:call:hold
- serviceGuideCti:call:resume
- serviceGuideCti:request:transcript
- serviceGuideCti:call:wrapUp
- serviceGuideCti:agent:logout

To streamline the event emitting mechanism and provide a consistent way to respond to these events, the Service Guide SDK is defined as an instance of the `EventEmitter` class. Additionally, all of these events are wrapped inside a single event that is emitted by the SDK and targeted to the CTI iFrame. Implementers can listen for a single event and inspect the event details to know which specific event has been requested.

> **Note**
>
> To minimize data entry errors, the Service Guide SDK already defines the string constants for these event names so that implementers don't need to enter the specific names.

This example shows how to handle events using an SDK instance that was initialized in an earlier code snippet and shows how to invoke another operation on the SDK in response to an event:

```
// SDK Loading and Initialization code
...

// Assuming the SDK instance is named "serviceGuideSdk"

// Read all CTI specific event names
const events = serviceGuideSdk.getCtiSdkEvents();

// "serviceGuideSdk.getSdkEventName()" gives the single, wrapper event name.
// Since the SDK is an "EventEmitter" instance, you can directly call ".on()"
function to subscribe to it.

serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(), async ({eventName,
payload}) => {

    // "eventName" will contain the actual name of the event listed above
that was emitted by Service Guide.

     switch (eventName) {

          case events.updateAgentStatus: // Refers to the constant defined by
Service Guide SDK for the "serviceGuideCti:agent:status:update" event.
               // Assuming CTI vendor has below API
               if(payload.data.isAgentReady) {
                 try {
```

Copyright © 2026, Oracle and/or its affiliates.

```
                    const response = await
ctiSdk.ApiClient.markUserReady({...});
                    if(response.ok) {
                       // Now let Service Guide know that the agent status has
been updated to "ready"
                       serviceGuideSdk.Ui.agentStatusUpdated({ data:
{isAgentReady: true} });
                    }
                  } catch (error) {
                    // Error occurred while updating the agent status in the
backend. Let Service Guide know with an error payload.
                    serviceGuideSdk.Ui.agentStatusUpdated({ error: {isError:
true, message: 'READY_STATUS_UPDATE_FAILED'} });
                  }
                } else {
                  try {
                    const response = await
ctiSdk.ApiClient.markUserBusy({...});
                    if(response.ok) {
                       // Now let Service Guide know that the agent status has
been marked as "busy"
                       serviceGuideSdk.Ui.agentStatusUpdated({ data:
{isAgentReady: false} });
                    }
                  } catch (error) {
                    // Error occurred while updating the agent status in the
backend. Let Service Guide know with an error payload.
                    serviceGuideSdk.Ui.agentStatusUpdated({ error: {isError:
true, message: 'NOT_READY_STATUS_UPDATE_FAILED'} });
                  }
                }
                break;

           case events.disconnectCall:
                     // disconnect the call and invoke "endCallSession"
operation to let Service Guide know.
                break;

           case events.requestTranscript:
                // Assuming CTI vendor has below API to get Agent transcript
                const agentTranscript = await
ctiSdk.ApiClient.getInternalTranscript(payload.data.callId);

                // Assuming CTI vendor has below API to get Customer
transcript
                const customerTranscript = await
ctiSdk.ApiClient.getExternalTranscript(payload.data.callId);

                // map the CTI provided transcript in to the necessary format
that Service Guide understands,
                // i.e. an array of elements containing "text", "offsetMs" and
"channel" properties

                const mappedAgentTranscript =
mapToOperationFormat(agentTranscript);
                const mappedCustomerTranscript =
```

Copyright © 2026, Oracle and/or its affiliates.

```
mapToOperationFormat(customerTranscript);

               // Provide the transcript to Service Guide as part of
"transcriptReceived" operation
               serviceGuideSdk.Ui.transcriptReceived({
                    data: {
                        agentTranscripts: mappedAgentTranscript,
                        customerTranscripts: mappedCustomerTranscript
                    }
               });
               break;
          ...
     }
});

// You can also take modularized approach and define multiple "handlers" to
handle specific event

serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(),
handleAgentStatusUpdate);
serviceGuideSdk.on(serviceGuideSdk.getSdkEventName(),
handleTranscriptGeneration);
...

// and define individual handlers above as
const handleAgentStatusUpdate = async ({eventName, payload}) => {
    if (eventName === events.updateAgentStatus) {
        ... // update agent status and let Service Guide know.
    }
});

const handleTranscriptGeneration = async ({eventName, payload}) => {
    if (eventName === events.requestTranscript) {
        ... // Retrieve the transcripts and send them to Service Guide.
    }
});
```

Event: serviceGuideCti:agent:status:update

This table provides additional details about the serviceGuideCti:agent:status:update event:

Description	Payload	Parameter Description	Notes

This event is raised when an agent updates their status to Ready or Not Ready, indicating whether they are ready to receive another call.
The Partner Application should call the appropriate CTI-specific API to mark the agent's presence as defined in the payload.
	`{`
	`  data: {`
	`  isAgentReady: boolean`
	`  }`
	`}`
		isAgentReady:
		Whether the agent is ready to receive calls.
			The partner application should respond to this event by invoking "**agentStatusUpdated**" operation. This should be done after receiving a confirmation from the CTI backend that the update was successful, otherwise invoke it with an error payload.

Copyright © 2026, Oracle and/or its affiliates.

Event: serviceGuideCti:call:disconnect

This table provides additional details about the serviceGuideCti:call:disconnect event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent disconnects the call.	`{ data: { callId: string } }`	**callId:** A unique identifier representing the call session that needs to be disconnected.	The partner application should respond to this event by invoking "**endCallSession**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually disconnected, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:mute

This table provides additional details about the serviceGuideCti:call:mute event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent wants to mute their audio on the call.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be muted.	The partner application should respond to this event by invoking "**callMuted**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually muted, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:unmute

This table provides additional details about the serviceGuideCti:call:unmute event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent wants to reconnect their audio after it has been muted.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be un-muted.	The partner application should respond to this event by invoking "**callUnmuted**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually unmuted, otherwise invoke it with an error payload.

Copyright © 2026, Oracle and/or its affiliates.

Event: serviceGuideCti:call:hold

This table provides additional details about the serviceGuideCti:call:hold event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent places the customer on hold.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be placed on hold.	The Partner Application should respond to this event by invoking "**callOnHold**" operation. This should be done after receiving a confirmation from the CTI backend that the call was actually placed on hold, otherwise invoke it with an error payload.

Event: serviceGuideCti:call:resume

This table provides additional details about the serviceGuideCti:call:resume event:

Description	Payload	Parameter Description	Notes
This event is raised by Service Guide when the agent removes the hold placed on the call.	`{ data: { callId: string } }`	**callId:** A unique identifier for the call to be resumed.	The partner application should respond to this event by invoking "**callResumed**" operation. This should be done after receiving a confirmation from the CTI backend that the call that was previously put on hold was actually resumed (hold was lifted), otherwise invoke it with an error payload.

Event: serviceGuideCti:request:transcript

This table provides additional details about the serviceGuideCti:request:transcript event:

Copyright © 2026, Oracle and/or its affiliates.

Description	Payload	Parameter Description	Notes

This event is raised by Service Guide when an agent requests the call transcript.	{
	data: {
	callId: string
	}
	}
		callId:
		A unique identifier for the call to be answered.
			The Partner Application should respond to this event by invoking "**transcriptReceived**" operation. This should be done after collecting the relevant transcript from the CTI backend. If for some reason, the transcript cannot be collected, the partner application should invoke the operation with an error payload.

Event: serviceGuideCti:call:wrapUp

This table provides additional details about the serviceGuideCti:call:wrapUp event:

Description	Payload	Parameter Description	Notes

After ending the call, when the agent finishes the after-call work and is ready to move to the next call, this event allows the partner application to capture any after-call work details (wrap up) in the CTI backend.
Depending upon the CTI Vendor, this might not be a mandatory operation. Utilities should handle this event after consulting the CTI Vendor documentation.
	{
	data: {
	callId: string,
	agentNotes: string,
	tags: array<string>
	}
	}
		callId: A unique identifier for the call for which the wrapup should be done.
		agentNotes: Any notes an agent might have collected during the call. This is included to capture any after-call notes (if the CTI Vendor makes it mandatory). This is optional and may or may not be present.
		tags: An array of strings representing the call topics that the agent wants to capture as part of wrap up. These are optional and may or may not be present.
			The partner application should respond to this event by invoking "**callWrappedUp**" operation. This should be done after receiving a confirmation from the CTI backend that the wrapup update was successful. If the update was not successful, the partner application should invoke the operation with an error payload.

Event: serviceGuideCti:agent:logout

This table provides additional details about the serviceGuideCti:agent:logout event:

Copyright © 2026, Oracle and/or its affiliates.

Description	Payload	Parameter Description	Notes
This event is raised when an agent logs out of the Service Guide. The partner application may wish to perform cleanup as part of logout or it may wish to perform a logout of its own to end the authenticated session it may have established at the beginning. This event should be used to initiate that logout and cleanup process.	None	Not Applicable	The Partner Application should respond to this event by invoking "**loggedOut**" operation, only after necessary cleanup was done. Service Guide application will wait a certain amount of time to let the partner application finish the cleanup. The partner application must invoke the "**loggedOut**" operation within that time. If not done, Service Guide will assume that the cleanup was already done and will proceed to complete the logout process on the Service Guide side.

Configuring Characteristic Types and Customer Contact Types with Characteristic Tags

The tags generated by the Call Summary and Call Tagging functionality are based on characteristic types to which the "Characteristic Tag" characteristic entity has been assigned.

In order to apply tags (characteristic types) to customer contacts, the appropriate characteristic types must be created and configured on the appropriate customer contact types. This involves the following:

1. In the **Characteristic Type** portal, add the following **Characteristic Entities** to any characteristic types to be used as tags:
   - Customer Contact
   - Characteristic Tag
2. In the **Customer Contact Type** portal, add the appropriate characteristic types to each customer contact type.

For example, if your implementation includes a "General Inquiry" customer contact type as well as "Billing Inquiry", "Payments", and "Rates" tags (characteristic types), you would do the following:

1. Created "Billing Inquiry", "Payments", and "Rates" characteristic types. The Value Type for tag characteristic values must be "Adhoc Value"
2. Add the "Customer Contact" and "Characteristic Tag" characteristic entities to each characteristic type created in step 1.
3. Create a "General Inquiry" customer contact type.

Copyright © 2026, Oracle and/or its affiliates.

4. Add the "Billing Inquiry", "Payments", and "Rates" characteristic types to to the "General Inquiry" customer contact type.

See Characteristic Types, Setting Up Customer Contact Types, and Customer Contact Tags for more information.

Enabling the Service Guide Zone

To enable access to the **Service Guide** zone, add the Service Guide Zone (C1-SVCGUIDE) application service to the appropriate user groups.

Analytics Integration Overview

Oracle Utilities Customer to Meter provides tools to facilitate the integration with Oracle Utilities Analytics.

- Analytics Configuration

Analytics Configuration

This section describes functionality provided for integrating with Oracle Utilities Analytics (OUA).

- **Customer Analytics Configuration Portal**

  Oracle Utilities Customer to Meter provides a Customer Analytics Configuration portal that holds information on the customer analytics configuration activities. This portal provides a summary of how much configuration has been set up, and also provides links and guidelines for the areas that need configuration, at the minimum, to successfully extract data from Oracle Utilities Customer Care and Billing to OUA. The following provides more information about this functionality.

  1. **Customer Analytics Configuration Details** – These data load parameters are used to extract, load, and transform data from Oracle Utilities Customer Care and Billing to Oracle Utilities Analytics. These parameters are used to identify and/or filter data when loading them into the data warehouse. Refer to the *Oracle Utilities Customer Care and Billing* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each extract parameter.
  2. **Bucket Configuration List** – This is a summary of the bucket configurations that are needed to classify and group extracted data within Oracle Utilities Analytics. The bucket configurations provide the ability to readily report and analyze data by buckets, or groups. Refer to the *Oracle Utilities Customer Care and Billing* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each bucket configuration supported by Oracle Utilities Customer Care and Billing.

- **Characteristic Mapping**

  Oracle Utilities Customer Care and Billing has identified the objects for which characteristic extraction is supported. This includes mapping the source characteristic entity to thetarget dimension, and defining which target columns are allowed to be mapped for which target dimension. The following table shows the supported mapping.

Object	Supported Target Dimension	Supported Target Columns

Copyright © 2026, Oracle and/or its affiliates.

Account Characteristic	**Account Dimension**	**User Defined Fields 6 - 15**
Person Characteristic	**Person Dimension**	**User Defined Fields 1 - 6**
Premise Characteristic	**Premise Dimension**	**User Defined Fields 6 - 18**
Premise Characteristic	**Address Dimension**	**User Defined Fields 7 - 16**
Service Agreement Characteristic	**Service Agreement Dimension**	**User Defined Fields 9 - 19**

Meter Analytics Configuration Portal

The Meter Analytics Configuration portal holds information on the meter data analytics configuration activities. This portal provides a summary of how much configuration has been set up, and also provides links and guidelines for the areas that need configuration, at the minimum, to successfully extract data from Oracle Utilities Meter Data Management to OUA. The following provides more information about this functionality.

- **Analytics - Oriented Master Configuration:** These data load parameters are used to extract, load, and transform data from Oracle Utilities Meter Data Management to Oracle Utilities Analytics. They are used to identify and/or filter data when loading them into the data warehouse. Refer to the *Oracle Utilities Meter Data Management* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each extract parameter
- **Analytics - Oriented Extendable Lookup List:** The meter data analytics related Extendable Lookup Business Objects are listed in this section. It provides a navigation link to the extendable Lookup Maintenance portal where the lookup values can be configured. Refer to the *Oracle Utilities Meter Data Management* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on meter data analytics related extendable lookups.
- **Service Point Configuration List:** This lists the service point types within the system and indicates for each whether or not the meter analytics configuration has been setup. It provides a navigation link to the service point type where the necessary configuration can be setup or modified. Refer to the *Oracle Utilities Meter Data Management* section in the ***Configuring Oracle Utilities Analytics*** chapter of the *Oracle Utilities Analytics Administration Guide* for further information.

Batch Controls

Batch Code	**Name / Description**
D1-SPSDL	**Service Point Snapshot Download**
D2-DUGDL	**Usage Subscription Usage Group Download**
D2-MVREF	**Materialized View Refresh**
D2-USGDL	**Service Point Usage Snapshot Download**
D2-UUSDL	**SP Unreported Usage Snapshot Download**
D2-VEEDL	**SP VEE Exception Snapshot Download**

Self-Service Integration

The following sections describe functionality provided for the integration with self-service applications such as Oracle Utilities Customer Self Service and Oracle Utilities Digital Self Service.

- About Self-Service Tasks
- Setting Up Self-Service Task Configuration
- Maintaining Self-Service Tasks
- Self-Service Start/Stop/Transfer Overview
- Self-Service Start/Stop/Transfer Operations
- Configuring Rate Compare Usage Adjustment Profiles

About Self-Service Tasks

Self-service tasks hold information about self-service operations that customers initiate from an integrated self-service application, such as Oracle Utilities Customer Self-Service and Oracle Utilities Digital Self Service.

A few examples of self-service tasks are:

- One time payments
- Account verification
- Start/Stop requests
- Auto pay setup
- Creating customer meter readings

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supported self-service operations.

The following sections highlight self-service integration functionality.

- Self-Service Task Type Defines Self-Service Task Behavior
- Creating Self-Service Tasks

Copyright © 2026, Oracle and/or its affiliates.

Self-Service Task Type Defines Self-Service Task Behavior

Each type of self-service operation has specific processing requirements.

Self-service task type controls how a self-service task is processed. It defines the business object to use when creating the self-service task record. The business object defines the lifecycle of self-service task record.

The self-service task type can also specify common configuration data, such as settings for error handling.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

Setting Up Self-Service Task Configuration

- Self-Service Integration Configuration
- Defining Self-Service Task Types

Self-Service Integration Configuration

The integration with a self-service application such as Oracle Utilities Customer Self Service or Oracle Utilities Digital Self Service requires the setup of master configuration data that controls the processing of your self-service operations.

To set up self-service integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration.** Two master configurations are required:

- **CCB Self Service Integration:** This master configuration is used for the integration of customer data with a self service application.
- **MDM Self Service Master Configuration:** This master configuration is used for the integration of meter data with a self service application.

Refer to the embedded help for more details on how each section in these records is configured.

Defining Self-Service Task Types

A self-service task type defines properties that control how a self-service task is processed.

Refer to About Self-Service Tasks for an overview of service task functionality.

To maintain the types applicable to your product, open **Menu**, and then **Self-Service**, and then **Self-Service Task Type.**

This is a standard All-in-One portal.

The information captured on the self-service task type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Copyright © 2026, Oracle and/or its affiliates.

Maintaining Self-Service Tasks

This section describes the functionality supported for viewing and maintaining self-service tasks.

Refer to About Self-Service Tasks for an overview of self-service task functionality.

Navigate using **Menu**, and then **Self-Service**, and then **Self-Service Task**, and then **Search**. You are brought to a query portal with options for searching for self-service tasks.

Once a self-service task record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Self-Service Task** zone provides basic information about a self-service task. Refer to the embedded help for more information.

Self-Service Start/Stop/Transfer Overview

> **Warning**
>
> This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

The Start Stop Transfer Tasks (C1-StartStopTransferTasks) inbound web service is used by the self-service application to support the following start/stop/transfer transactions:

- New Service
- Add Service
- Stop Service
- Transfer Service

Distinct action method roles represent each type of transaction:

- Self-Service New Service
- Self-Service Add Service
- Self-Service Stop Service
- Self-Service Transfer Service

At the beginning of the start/stop/transfer process, the action method role is used to identify the type of transaction. It is determined using the Request Mode (Start/Stop/Transfer), the New Customer indicator (Yes/No) and the New Account indicator (Yes/No):

- If Request Mode is 'Start', the Action Method Role is 'Self-Service New Service' if either the New Customer or the New Account indicator is 'Yes'. If both New Customer and New Account indicators are 'No', Action Method Role is 'Self-Service Add Service'.
- If Request Mode is 'Stop', the Action Method Role is 'Self-Service Stop Service'
- If Request Mode is 'Transfer' , the Action Method Role is 'Self-Service Transfer Service'.

Configuration information are maintained using Self-Service Task Type and Customer Service Type. Self-Service Task Type defines the self-service task BO to be used. Customer Service Request Type defines the customer service request BOs used to persist data, and the controls

Copyright © 2026, Oracle and/or its affiliates.

used throughout the transaction. Refer to the "Enhanced Start, Stop, and Transfer Service Configuration Options" section of the digital self-service user guide for more about the controls.

At the beginning of the transaction, configuration information are determined and a self-service start/stop/transfer task is created. The same service task is used for the entire transaction. The service task is used to store the information received from the self-service application and operation processing results. It will remain in Pending status until the transaction is finalized. When the transaction is finalized, the service task is transitioned out of the Pending status and the collected information are persisted.

The following is the expected sequence of IWS operation calls per type of transaction:

New Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details - operation is called if customer exists (Person ID is available).
3. Service Eligibility
4. Process Other Person
5. Clear Other Person
6. Determine Services To Start
7. Validate Start SP Selection
8. Service Questions
9. Process Services To Start
10. Deposit Assessment
11. Start Service Finalization

Add Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details
3. Service Eligibility
4. Determine Services To Start
5. Validate Start SP Selection
6. Service Questions
7. Process Services To Start
8. Deposit Assessment
9. Start Service Finalization

Stop Service

1. Retrieve Request Type Details
2. Retrieve Service-Related Customer Details
3. Determine Services To Stop
4. Retrieve Services To Stop
5. Validate Stop Service Agreement Selection
6. Service Questions

Copyright © 2026, Oracle and/or its affiliates.

7. C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations.dita#C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations
8. Stop Service Finalization

Transfer Service

1. Retrieve RC1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operations.dita#C1_98SelfServiceIntegration_Self_Service_Start_Stop_Transfer_Operationsequest Type Details
2. Retrieve Service-Related Customer Details
3. Service Eligibility
4. Determine Services To Start
5. Validate Start SP Selection
6. Service Questions - operation is called with Question Placement Group is 'Start Service'
7. Process Services To Start
8. Deposit Assessment
9. Determine Services To Stop
10. Retrieve Services To Stop
11. Validate Stop Service Agreement Selection
12. Service Questions - operation is called with Question Placement Group is 'Stop Service'
13. Process Services To Stop
14. Transfer Service Finalization

Self-Service Start/Stop/Transfer Operations

> **Warning**
>
> This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

Retrieve Request Type Details

This operation is used to retrieve the following configuration information at the beginning of the start, stop and transfer transaction:

- Action Method Role
- Action Method
- Self-Service Task Type
- Customer Service Request Type
- Person/Business Controls
- Start Service Controls
- Stop Service Controls

Action Method Role is determined based on the Request Mode, New Customer indicator and New Account indicator inputs. The Action Method Role is used to determine the Action Method. The Action Method defines the Self-Service Task Type and Customer Service

Copyright © 2026, Oracle and/or its affiliates.

Request Type configuration. Note that the Self-Service Task Type and Customer Service Request Type can differ by CIS Division and/or Customer Class. The Self-Service Task Type defines the self-service task BO to be used. The Customer Service Request Type defines the customer service request BOs used to persist data, and the controls used throughout the transaction. Controls determine the behavior of the self-service application UI, operations, and service task processing. Succeeding operations expect the Self-Service Task Type and Customer Service Request Type as inputs.

Person/Business Controls are based on the input person/business flag. Start Service Controls are returned if the input Request Mode is either 'Start' or 'Transfer'. Stop Service Controls are returned if the input Request Mode is either 'Stop' or 'Transfer'.

Time Zone is returned as part of the Start Service and Stop Service Controls. It comes from one of the following sources:

1. Customer Service Request Type
2. Premise - Input premise if available. Otherwise, premise linked to the input account's most recent service.
3. Installation Options

Retrieve Service-Related Customer Details

This operation is used to retrieve the following service-related information for the input account and/or person:

- Name
- Mailing Address
- Contact Details

If the input account is populated, the input person is either the account owner (main customer) or a guest who was invited by the owner. Name, Mailing Address and Contact Details are based on the account's main customer. If input account is not populated, Name, Mailing Address and Contact Details are based on the input person. Phone and email contact information are always returned. Other contact types are returned based on the corresponding control.

This operation also uses the Should Prompt For ID controls to determine if ID should be prompted for the input account and/or person. If the input account is populated, the account's main customer is used. Otherwise, the input person is used. If ID should be prompted, the valid ID Types controls are returned for input person.

Finally, this operation indicates if a non-final self-service start/stop/transfer task exists for the input account.

Service Eligibility

This operation determines if a customer is eligible to start service. It is used when starting new service, adding service, or transferring service. If the customer is eligible, a new self-service start/stop/transfer task is created where the input customer information and the results of processing performed throughout the transaction are persisted. The service task will remain in Pending status until it is transitioned by the finalize operation. Abandoned service tasks are discarded automatically via a monitor algorithm on the Pending status. The service task ID is returned as well as the customer's eligible and ineligible accounts.

The Retrieve Request Type Details operation that determines configuration information should be called before this operation can be used.

Copyright © 2026, Oracle and/or its affiliates.

When starting new service for new customer (input person is not populated), the Check For Existing Person Algorithm control is used to determine if an existing person in the system matches the input name, ID, and contact information. If a match is found, the operation returns a match indicator, and no further processing is performed.

When starting new service or adding new service, person identity checks may be performed based on the ID check controls. The Should Prompt For ID controls are used to determine if ID should be prompted for the input person. This is the same step performed in the Retrieve Service-Related Customer Details operation and both should have the same result. It is necessary to do this step in this operation because the result from the Retrieve Service-Related Customer Details operation is not persisted.

The Start Service Eligibility Algorithms control determines eligibility. It uses the input information to this operation, the ID check results, and the ID prompt result. This control also determines the customer's eligible and ineligible accounts.

Process Other Person

This operation process additional persons when starting new service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. Eligible persons are persisted on the service task. Ineligible persons may be persisted based on the service task based on the Other Person Eligibility controls. Each person's eligibility is returned as output. Note that any additional persons that are currently in the self-service start/stop/transfer task are replaced with the input when this operation is called.

The Search For Person Algorithm control is used to find an existing person in the system that matches the input name, ID, and contact information. The search result (Match / No Match / Ambiguous Match) is returned as output. If the search resulted in an ambiguous match, the person is skipped. Person identity checks may be performed based on the ID check controls.

For new a new person, eligibility is based on ID check results. Note that if ID check is not performed, the person is considered eligible. Only eligible new persons are persisted on the service task. The Other Person Eligibility control determine the eligibility of an existing person. It is either based on ID check or a set of utility-specific eligibility algorithms. Eligibility based on ID check is evaluated the same way as a new person. Existing persons that are eligible are persisted on the service task. Existing persons that are ineligible are persisted on the service task if the Other Person Processing control is set to 'Review'.

Clear Other Person

This operation removes any additional persons that are currently in the pending self-service start/stop/transfer task.

Determine Services To Start

This operation determines the SP-based services to start at premise when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the Determine Services To Start Algorithm control to get a list of SA to start for SPs at the premise for the input start date. This information is stored in the service task's start service details. Note that SA and SP information currently in the service task are replaced when this operation is called. The operation returns the determined SPs along with badge number of the meter currently installed on the SP.

Note that the start date must be within the range defined by the start service controls. The range is calculated as follows:

- Start Date Low Limit = Current Date + Lead Days

Copyright © 2026, Oracle and/or its affiliates.

- Start Date High Limit = Start Date Low Limit + Maximum Start Days in Future control

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Also, weekends and holidays based on the Work Calendar control are skipped when incrementing the Start Date Low Limit.

Validate Start SP Selection

This operation uses the Validate SPs To Start Algorithms controls to validate the selected SPs where service is being started if Start Level control is 'Individual Services'. It is used when starting new service, adding service, or transferring service. The SP-based services to start at the premise should be determined before this operation can be used.

Service Questions

This operation uses the Read Questions algorithm on the CS request type BO to retrieve the applicable service questions when starting new service, adding service, stopping service, or transferring service. The SP-based services to start at a premise and/or the SP-based services to stop for an account should be determined, and a pending self-service start/stop/transfer task already exist before this operation can be used.

Note that when transferring service, this operation is called for two scenarios - start service and stop service. The operation uses the input Question Placement Group to distinguish between these calls. Question Placement Group is used to logically group questions, based on where the questions are shown on the user interface.

- If Question Placement Group is 'Start Service', the questions are filtered using the input premise and SPs.
- If Question Placement Group is 'Stop Service', the questions are filtered using the input premise only. Any further filtering (e.g. SP Type) will be done by the calling system using the applicability list that is returned for each question.

When invoking the algorithm, the input account and SPs are used. If the input Question Placement Group is 'Stop Service' and Stop Level control is 'Account', all premises in the service task's stop details are used. Otherwise, the input premises are used.

Process Services To Start

This operation marks which of the SPs and SP-based SAs previously determined by the Determine Services To Start operation will be started based on the input premise or SPs when starting new service, adding service, or transferring service. If Start Level control is 'Premise' all SPs and SAs are marked. If Start Level control is 'Individual Services' only the input SPs and its SAs are marked.

This operation also process response to start service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for start, set an SA's start option, or add non SP-based SAs to the services being started.

All services being started are validated using Validate Service To Start Algorithms control.

Deposit Assessment

This operation determines the deposit requirements when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the deposit controls and the customer information in the service task to determine if deposit is required. If deposit is required, the deposit amount is calculated using the Recommendation Algorithm associated with the Deposit SA Type control's deposit class. The deposit required

Copyright © 2026, Oracle and/or its affiliates.

indicator and deposit amount are persisted on the service task and returned as output. The Allow Pay In Full control is also returned as output.

If the deposit is required, the operation returns deposit installation options collection. Each entry has two attributes:

- Number of Installments
- Installment Amount

Number of Installments is based on the Number of Installments control. The corresponding Installment Amount is the deposit amount divided by the Number of Installments. Note that Installment Amount must be greater than or equal to the Minimum Installment Amount control an option to be included in the collection. If Allow Pay In Full control is 'true', the following entry is included in the collection:

- Number of Installments = 1
- Installment Amount = Deposit Amount

The operation will fail if deposit is required and not one deposit installation option can be determined.

Start Service Finalization

This is the final operation called when starting new service or adding service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP). Refer to the self-service task BO (C1-SSStartStopXferServiceTask) for more information.

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Determine Services To Stop

This operation uses the Determine Services To Stop Algorithm control to determine the SP-based services to stop for an account at a given stop date when stopping service or transferring service. It returns number of premises that have stoppable services.

This operation can be called read-only mode. This mode is used by the self-service application to determine if stop service is available as an option to the user. When not in read-only mode, a self-service start/stop/transfer task containing the determined SP-based services is created if one doesn't exist (initial call when stopping service). The service task will remain in Pending status until it is transitioned by the finalize operation. The ID of the newly created service task

Copyright © 2026, Oracle and/or its affiliates.

is returned as output. If service task already exists (transferring service or stop date is changed when stopping service), the service task ID is passed to this operation and its stop details are replaced with the determined SP-based services.

Note that the stop date must be within the range defined by the stop service controls. The range is calculated as follows:

- Stop Date Low Limit = Current Date + Lead Days
- Stop Date High Limit = Stop Date Low Limit + Maximum Stop Days in Future control

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Note that weekends and holidays based on the Work Calendar control are skipped when incrementing the Stop Date Low Limit.

Retrieve Services To Stop

This operation retrieves the premises with stoppable service that were previously determined and persisted on the self-service start/stop/transfer task. A list of SAs is returned for each premise. Each entry has two attributes:

- Service Type
- Badge Number of the meters currently installed on the SPs associated with the SA

Pagination is applied to the returned premise list using the page offset and page limit input parameters.

Validate Stop Service Agreement Selection

This operation uses the Stop Level, Require SAs At Same SP To Behave Together, and Validate Services To Stop Algorithm controls to validate the selected SP-based services to stop. It is used when stopping service or transferring service. The SP-based services to stop for the account should be determined before this operation can be used.

Process Services To Stop

This operation marks which of the premises and SP-based SAs previously determined by the Determine Services To Stop operation will be stopped based on the input premises and SAs when stopping service or transferring service. If Stop Level control is 'Account' all premises and SAs are marked. If Stop Level control is 'Premise', all SAs for the selected premises are marked. If Stop Level control is 'SA', only the selected SAs are marked.

This operation also process response to stop service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for stop or add non SP-based SAs to the services being stopped.

All services being stopped are validated using the Validate Services To Stop Algorithms control.

Stop Service Finalization

This is the final operation called when stopping or transferring service. It is used to update the self-service start/stop/transfer task with any additional contact information for the main customer and to transition it out of the pending status.

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.

Copyright © 2026, Oracle and/or its affiliates.

- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages.

Transfer Service Finalization

This is the final operation called when transferring service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Configuring Rate Compare Usage Adjustment Profiles

This section describes the steps involved in setting up usage adjustment profiles for use with the Rate Compare feature in Oracle Utilities Customer Self- Service.

1. Create a characteristic type and values for each type of usage adjustment to be made available for rate comparison purposes. For example, if you wanted to allow adjustments for installation of solar panels, use of an energy-efficient appliance, or use of an electric vehicle, you would create three characteristic types (one for each type of adjustment), and values for each option within each type (each type of appliance or electric vehicle supported).
2. Create profile (stand-alone) measuring components that correspond to each characteristic type value.
3. Create profile data for each measuring component. This is interval data that represents the impact of the usage adjustment on a customer's consumption.
4. Create a profile factor for each usage adjustment type.
5. Create factor values for each factor. These values correspond to the characteristic type value, and link characteristic type values to profile measuring components.
6. Create one (or more) Profile Accumulation usage calculation rules that will apply the usage adjustment profile to the customer's interval consumption when calculating usage for the rate comparison request.

Copyright © 2026, Oracle and/or its affiliates.

7. Create entries in the Customer Rate Schedule extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to a rate schedule.
8. Create entries in the Usage Adjustment Types extendable lookup for each usage adjustment type.
9. Set up the Rate Compare Configuration section of the MDM Self-Service Master Configuration to link usage adjustment factors and usage adjustment types to rate schedules Oracle Utilities Customer Care and Billing (defined in the Customer Rate Schedule extendable lookup).

Characteristic Types

Create a characteristic type and values for each type of usage adjustment you wish to make available to customer self-service users. For example, to create a usage adjustment profile for use of an electric vehicle, you would create an "electric vehicle" characteristic type and define values for each type of electric vehicle users can select.

Example Characteristic Type:

- Characteristic Type: ELEC_VEH
- Description: Electric Vehicles
- Type of Char Value: Predefined Value
- Characteristic Values:

Characteristic Value	Description
LEAF	Nissan Leaf
TESLA	Tesla Model S
VOLT	Chevrolet Volt

Profile Measuring Components

Create profile measuring components for each characteristic type value. These measuring components will be used to store profile data for each type of usage adjustment.

Note: The base package does not include stand-alone measuring component/measuring component type business objects, but the demonstration database contains "Standalone Interval" and "Standalone Interval Measuring Component Type" business objects that can be used to create profile measuring components and types.

Example Profile Measuring Component Type:

- Measuring Component Type: KWH-PROFILE
- Description: KWH Profile
- Measuring Component Business Object: Standalone Interval (demo)
- Measurement Business Object: Measurement
- Service Type: Electric
- Allow Negative Consumption: Allowed
- Consumptive / Subtractive: Consumptive
- Seconds Per Interval: 01:00:00
- Value Identifiers:

Copyright © 2026, Oracle and/or its affiliates.

- Value Identifier Type: Measurement
- Short-Hand Description: kWh
- UOM: Kilowatt-Hours

Example "Nissan Leaf" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Nissan Leaf

Example "Tesla Model S" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Tesla Model S

Example "Chevrolet Volt" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Chevrolet Volt

Profile Data

Create profile data for each profile measuring component. This data represents the impact of the usage adjustment on a customer's consumption.

Note that this profile data can (and often will) include negative interval values to represent the difference in consumption applicable for the usage adjustment type. For example, if an energy-efficient electric clothes dryer uses an average of 30 kilowatt hours less per month than an average electric clothes dryer, profile data for that appliance might be a "straight line" hourly profile (a profile in which all intervals are of the same value) in which each value equals "0.042" (30 kWh per month divided by an average of 720 hours per month).

Copyright © 2026, Oracle and/or its affiliates.

Factors / Factor Values

Create a profile factor for each usage adjustment type. This factor should use the "Factor Characteristic Source N/A Algorithm" to derive the appropriate characteristic type value based on the factor value, and should reference the characteristic type created earlier.

Example Electric Vehicle Factor:

- **Factor**: ELECTRIC_VEHICLE
- **Description**: Electric Vehicle
- **Factor Class**: Profile
- **Characteristic Source Algorithm**: Factor Characteristic Source N/A Algorithm
- **Factor Characteristic Type**: Electric Vehicle

Example "Nissan Leaf" Factor Value

- **Factor: Electric Vehicle**
- **Factor Characteristic Type: Electric Vehicle**
- **Factor Characteristic Value: LEAF**
- **Effective Date/Time: 01-01-2014 12:00:00AM**
- **Profile: Nissan Leaf, KWH Profile**

Example "Tesla Model S" Factor Value

- **Factor: Electric Vehicle**
- **Factor Characteristic Type: Electric Vehicle**
- **Factor Characteristic Value: LEAF**
- **Effective Date/Time: 01-01-2014 12:00:00AM**
- **Profile: Tesla Model S, KWH - 60 Minutes**

Example "Chevrolet Volt" Factor Value

- **Factor: Electric Vehicle**
- **Factor Characteristic Type: Electric Vehicle**
- **Factor Characteristic Value: LEAF**
- **Effective Date/Time: 01-01-2014 12:00:00AM**
- **Profile: Chevrolet Volt / KWH - 60 Minutes**

Profile Accumulation Usage Calculation Group and Rule

Create a usage calculation group that contains a "Profile Accumulation" usage calculation rule. This rule will calculate usage by accumulating historical usage with profile data. based on a selected profile factor value.

Note: Profile Accumulation rules should use eligibility criteria to ensure they are only executed when the "Calculation Mode" on the usage transaction is set to "Hypothetical Calculation" (D2HC).

Example: Profile Accumulation Usage Calculation Rule

- **Usage Calculation Group: Electric Residential Interval KWH**

Copyright © 2026, Oracle and/or its affiliates.

- **Usage Calculation Rule: KWH_PROFILE_ACCUMULATION**
- **Sequence: 10**
- **Description: KWH Profile Accumulation**
- **Category: Usage Calculation**
- **Vector Source Configuration:**
- **Vector Type**: Channels Linked to Usage Subscription
- **Unit of Measure**: Kilowatt-Hours
- **Time of Use**:
- **Service Quantity Identifier**:
- **Target SPI**: 01:00:00
- **Result Processing Configuration**:
- **Apply TOU Map to Derived Vector: Yes**
- **TOU Map: Summer / Winter, 15 minute interval**
- **Result Storage Configuration**:
- **Insert Primary SQ Entry:** Yes
- **Save Derived Vector:** No
- **Service Quantity Identifier:**
- **Extract Interval Data:** No

Customer Rate Schedule Extendable Lookup

Create an entry in the "Customer Rate Schedule" extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to an applicable rate schedule in Oracle Utilities Customer Care and Billing.

Example Customer Rate Schedule extendable lookup:

- **Rate**: E-INT-RES
- **Description**: Electric Residential Interval Rate
- **Default Usage Calculation Group**: Electric Residential Interval KWH (E-INT-RES)

Usage Adjustment Types Extendable Lookup

Create an entry in the "Usage Adjustment Type" extendable lookup for each type of usage adjustment that will be available to customer self-service users. These entries are used in the Rate Compare Configuration section of the Self-Service Master Configuration (see below).

Example Electric Vehicle entry:

- **Usage Adjustment Type: ELEC_VEHICLE**
- **Description: Purchase of Electric Vehicle**
- **Override Description: Purchase of Electric Vehicle**
- **External Reference ID: Purchase of Electric Vehicle**

Copyright © 2026, Oracle and/or its affiliates.

MDM Self-Service Master Configuration - Rate Compare Configuration

Configure the "Rate Compare Configuration" section of the MDM Self-Service Master Configuration to associate usage adjustment factors and usage adjustment types with an applicable rate schedule in Oracle Utilities Customer Care and Billing (defined in the Customer Rate Schedule extendable lookup).

Example MDM Self-Service Master Configuration:

- **Factor Characteristic Type Indicating No Value Variation: N/A**
- **External Reference Factor Value Characteristic Type: External Reference ID**
- **Minimum Days of Usage Adjustment Data: 2**
- **Rate / Usage Adjustments:**
- **Rate**: Electric Residential - Interval KWH
- **Usage Adjustments**:
- Usage Adjustment Factor: Electric Vehicle
- Usage Adjustment Type: Purchase of Electric Vehicle

Defining DataConnect Options

Oracle Utilities DataConnect facilitates data extraction from Oracle Utilities applications such as Oracle Utilities Customer to Meter and Oracle Utilities Customer Care and Billing for use in external applications; such as, analytics applications and energy management systems.

This section describes how Oracle Utilities DataConnect works and how to implement and configure the system to support data extract processing.

> **Note**
>
> There are two versions of DataConnect. The initial version is referred to as “Legacy DataConnect”. The current and recommended version is simply referred to as “DataConnect” or “Current DataConnect”. Implementations are recommended to use the current version. “Legacy DataConnect” remains available for implementations that used the initial version, but is not recommended for new implementations.

- DataConnect Data Extracts
- Customer and Premise Data Extracts
- Characteristic Data Extracts
- Billing Data Extracts
- Consumption Data Extracts
- Extract Flat File Formats
- File Naming Formats

DataConnect Data Extracts

Oracle Utilities DataConnect can be used to extract the following types of data:

Copyright © 2026, Oracle and/or its affiliates.

- **Customer Data**

  (see Customer and Premise Data Extracts for more information)

  - Account information (including service agreement, account, and person related information)
  - Service agreement's service point information
  - Mailing address information
- **Premise Data**

  (see Customer and Premise Data Extracts for more information)

  - Premise information
  - Service point information
  - Device installation information
  - Device information
  - Measuring component information
- **Billing Data**

  (see Billing Data Extracts for more information)

  - Bill
  - Bill segment
  - Bill segment calculation lines
  - Bill segment service quantities
- **Measurement Data**

  (see Consumption Data Extracts for more information)

The data extracted can be correlated in external systems using the service agreement and/or service point data that is included in each type of extract. All data extracts contain a combination of the following data elements that can be used for this correlation:

- **CCB Service Point ID**: The service point ID in Oracle Utilities Customer to Meter and/or
- **MDM Service Point ID**: The service point ID in Oracle Utilities Meter Data Management and/or
- **Service Agreement ID:** The service agreement ID in Oracle Utilities Customer to Meter

External systems receiving data extracted from the Oracle Utilities DataConnect facilities can use these IDs to associate billing data and measurement data to extracted master data.

> **Note**
>
> There is a version 1 and version 1+ for the DataConnect extracts. In the following pages where a system object such as a batch control or data area is noted the objects are listed as (v1/v1+). When only a single object is noted it applies to both v1 and v1+.

Customer and Premise Data Extracts

Customer and premises data extracts are performed through the use of data synchronization, audit algorithms, business objects, and related batch processes.

Copyright © 2026, Oracle and/or its affiliates.

Batch processes are used to create initial load extracts for service agreement / account / person, service point, device configuration, device, and install event related master data. The initial load includes the historical data in the system (either all or a subset, depending on how the batch process is configured). Following the initial load, data synchronization requests are created when master data is added or changed.

- Customer and Premise Data Extracts: Maintenance Object Audit Algorithms
- Customer and Premise Data Extracts: Business Objects and Algorithms
- Customer and Premise Data Extracts: Batch Controls
- Setting Up and Executing Customer and Premise Data Extracts

Customer and Premise Data Extracts: Maintenance Object Audit Algorithms

Detecting changes in customer and premise data can be identified by audit algorithms on the following maintenance objects:

- Service Agreement
- Account
- Person
- Service Point (MDM Service Point)
- Install Event
- Device

The Generic Change Data Capture algorithm type (F1-GCHG-CDCP), which is provided in the base package, can be used to create audit algorithms for following maintenance objects:

- Service Agreement
- Service Point (MDM Service Point)
- Install Event

In addition, the following audit algorithm types can be used to create audit algorithms for customer and premise data:

- Account Change Data Capture (Customer Data Extract) (C1-ACCECDCCU)
- Person Change Data Capture (Customer Data Extract) (C1-PERECDCCU)
- Account Mailing Address Change Data Capture (C1ACCMACDC)
- Device Change Data Capture (SP/Meter-Based) (D1-SPDV-CDCP)
- Install Event Change Data Capture (SP/Meter-Based) (D1-SPIE-CDCP)
- Device Change Data Capture (SP/Meter-Based) (D1-SPDC-CDCP)

The following algorithm types are used with v1 ONLY.

- An **Account Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Account maintenance object to determine if a service agreement sync request record is to be created for each of the account's non-closed, non-canceled service agreement(s). A change in a related account's details will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-ACCECDCSA) that is based on this algorithm type.

Copyright © 2026, Oracle and/or its affiliates.

- A **Person Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Person maintenance object to determine if a service agreement sync request record is to be created for each of the person's non-closed, non-canceled service agreement(s). A change in the main person details linked to the service agreement's account will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-PERECDCSA) that is based on this algorithm type.

Customer and Premise Data Extracts: Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests in the following manner:

- If the Generic Change Data Capture (F1-GCHG-CDCP) algorithm type (provided in the base package) is used, the synchronization requests are based on the Sync Request BO maintenance object options.
- Alternatively, if the base package supplied Maintenance Object – Audit algorithm types, which are outlined in the Customer and Premise Data Extracts: Maintenance Object Audit Algorithms section are used, the synchronization requests are based on the Sync Request BO defined in the algorithm parameters.

Customer Data

Extraction of customer data, including account, service agreement, and person information, is supported by the following data synchronization business objects.

- Current DataConnect
  - **Customer Data Extract for DataConnect** (C1-ExternalRepoPlusCusDataSync): used to extract service agreement / account / person related information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object.
  - **SA/SP Data Extract for DataConnect** (C1-ExternalRepoPlusSASPSync): used to extract service agreement service point information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object.
  - **Mailing Address Data for DataConnect** (C1-ExternalRepoPlusMailAddSync): used to extract mailing address information. This business object should be defined as a value for the "Sync Request BO" options on the Person maintenance object.
  - **SP/Meter Sync for DataConnect** (D1-ExternalRepositorySPMtrSync): used to extract service point and meter information. This business object should be defined as a value for the "Sync Request BO" options on the Service Point, Device Configuration, and Device maintenance objects.
- Legacy DataConnect
  - **SA/Account/Person Sync for Legacy DataConnect** (C1-ExternalRepoSASync): used to extract service agreement / account / person related information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object. (Used with v1)
  - **SP Sync for Legacy DataConnect** (D1-ExternalRepositorySPSync): used to extract service point information. This business object should be defined as a value for the "Sync Request BO" options on the Service Point maintenance object. (Used with v1)

Copyright © 2026, Oracle and/or its affiliates.

- **Install Event Sync for Legacy DataConnect** (D1-ExternalRepositoryIESync): used to extract install event information. This business object should be defined as a value for the "Sync Request BO" options on the Install Event maintenance object. (Used with v1)

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Current DataConnect
  - Capture Customer Data's Initial Snapshot for DataConnect(C1-CEXTRCSAD)
  - Capture SA/SP Data's Initial Snapshot (C1CAPSASPI)
  - Capture Mailing Address Data Initial Snapshot (C1CAPMLADDI)
- Legacy DataConnect
  - Capture SP/Meter Initial Snapshot for Legacy DataConnect (D1-SPMINISNP)
  - Capture SP Initial Snapshot for Legacy DataConnect (D1-SPEINISNP)
  - Capture SA-Based Initial Snapshot for Legacy DataConnect (C1-CEXTRCSAI)
  - Capture Install Event Initial Snapshot for Legacy DataConnect (D1-IEEINISNP)

These algorithms specify the batch control used for the extract process (see below).

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Current DataConnect
  - Capture SA-Based Final Snapshot for DataConnect(C1-CEXTRPSAF)
  - Capture SA/SP Data's Final Snapshot (C1CAPSASPF)
  - Capture Mailing Address Data’s Final Snapshot (C1CAPMLADDF)
  - Capture SP and Meter Data's Final Snapshot for DataConnect (C1-CEXTRSPMF)
  - Capture SP/Meter Final Snapshot for DataConnect (D1-SPMFINSNP)
- Legacy DataConnect
  - Capture SA-Based Final Snapshot for Legacy DataConnect (C1-CEXTRCSAF)

The Prepare Delimited Extract Data (Ignore Custom Sync Records) Enter algorithm (C1-PRPEXDNCU/C1-PRTBDEXDT) or the Prepare Delimited Extract Data Enter algorithm (D1-PRPEXTDTA) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Premise Data

Extraction of premise data, including premise, service point, device installation, device, and measuring component informatiob, is supported by the following data synchronization business objects.

- **SP/Meter Sync for DataConnect** (D1-ExternalRepositorySPMtrSync): used to extract service point and device related information. This business object should be defined as a

Copyright © 2026, Oracle and/or its affiliates.

value for the Sync Request BO option on the Service Point, Device Configuration, and Device maintenance objects.

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture SP/Meter Initial Snapshot for Legacy DataConnect (D1-SPMINISNP)

These algorithms specify the batch control used for the extract process (see below).

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture SP/Meter Final Snapshot for DataConnect (D1-SPMFINSNP)

The Prepare Delimited Extract Data (Ignore Custom Sync Records) Enter algorithm (C1-PRPEXDNCU/C1-PRTBDEXDT) or the Prepare Delimited Extract Data Enter algorithm (D1-PRPEXTDTA) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Customer and Premise Data Extracts: Batch Controls

Customer Data

The customer data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
  - **Customer Data Initial Load for DataConnect (C1-CDTIL):** This batch control creates initial synchronization requests for account data (service agreements/accounts/persons) and SA's SP data (SA/SP). The appropriate sync business objects for the two extracts should be plugged in as parameters to the batch job.
  - **Mail Address Initial Load DataConnect (C1-MADIL):** This batch control creates initial synchronization requests for accounts.
- Legacy DataConnect
  - **SA-Based Initial Load for Legacy DataConnect (C1-SAEIL):** This batch control creates initial synchronization requests for service agreements / accounts / persons.
  - **SP Initial Load for Legacy DataConnect (D1-SPEIL):** This batch control creates initial synchronization requests for service points.

The following batch processes are used to create extract files from synchronization requests.

> **Note**
>
> These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

Copyright © 2026, Oracle and/or its affiliates.

- Current DataConnect
  - **Customer Data Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
  - **SA/SP Data Extract for DataConnect (C1-SSDTX)**
  - **Mailing Address Extract DataConnect (C1-MADTX):** This batch control creates extract file(s) that contain mailing address information.
  - **SA-Based Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
- Legacy DataConnect
  - **SP Extract for Legacy DataConnect (D1-SPESR):** This batch control creates extract file(s) that contain service point information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Premise Data

The premise data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
  - **SP/Meter Initial Load for DataConnect (D1-SPMIL)**: This batch control creates initial synchronization requests for service points, device configurations, and devices.
- Legacy DataConnect
  - **Install Event Initial Load for Legacy DataConnect (D1-IEEIL):** This batch control creates initial synchronization requests for install events.

The following batch processes are used to create extract files from synchronization requests.

> **Note**
>
> These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- Current DataConnect
  - **SP/Meter Extract for DataConnect (D1-SPMSR)**: This batch control creates extract file(s) that contain service point, device configuration, and device information.
- Legacy DataConnect
  - **Install Event Extract for Legacy DataConnect (D1-IEESR):** This batch control creates extract file(s) that contain install event information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Copyright © 2026, Oracle and/or its affiliates.

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Customer and Premise Data Extracts

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Service Agreement, Account, Person, MDM Service Point, Install Event, and Device maintenance objects.
    a. Add the Generic Change Data Capture algorithm as an audit algorithm on the Service Agreement, MDM Service Point, and Install Event maintenance objects.
    b. Add the Account Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Account maintenance object.
    c. Add the Person Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Person maintenance object.
    d. Add the Device Change Data Capture (Install Event-Based) algorithm as an audit algorithm on the Device maintenance object.
2. Add the DataConnect synchronization request business objects as Sync Request BO options on the Service Agreement, Service Point and Install Event maintenance objects.
3. Execute initial load batch processes related to service agreements, service points and install events.
4. Once the initial load synchronization has been executed, changes to service agreements, accounts, persons, service points, install events or related devices will trigger the creation of new synchronization requests and resulting extraction files.
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to service agreements, service points and install events.

Characteristic Data Extracts

Characteristic data extracts are performed through the use of audit algorithms, data synchronization business objects, and related batch processes.

Batch processes are used to create initial load extracts for Account, Person, Premise, Service Agreement, and Service Point characteristic data. The initial load includes the historical data in the system (either all or a subset, depending on how the batch process is configured). Following the initial load, data synchronization requests are created when characteristic data is added or changed.

Maintenance Object Audit Algorithms

Detecting changes in characteristic data can be identified by the Characteristic Change Data Capture (C1MOCHARCDC) audit algorithm on the following maintenance objects:

- Account
- Person
- Premise
- Service Agreement

Copyright © 2026, Oracle and/or its affiliates.

- Service Point - CCB
- Service Point- MDM

Detecting changes in characteristic type data can be identified by the Characteristic Type Change Data Capture (C1CHARTYPCDC) audit algorithm on the Characteristic Type (CHAR TYPE) maintenance object.

Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests based on the Sync Request BO defined in the audit algorithm parameters:

Audit Algorithm	Data Synchronization Request Business Object
Characteristic Change Data Capture (C1MOCHARCDC)	Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync)
Characteristic Type Change Data Capture (C1CHARTYPCDC)	Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync)

Extraction of characteristic data, including account, person, premise, service agreement, and service point information, is supported by the following data synchronization business objects.

- **Characteristic Data Sync for DataConnect** (C1-ExternalRepoPlusCharDatSync): used to extract characteristics data for accounts, persons, premises, service agreements, and service points. The specific maintenance objects for which characteristics data is extracted is defined in the Characteristic Entities Included in DataConnect Extract (C1-DataConnectIncludedCharEnty) extendable lookup. This lookup maps characteristic entities and maintenance objects to mappings business objects that define the characteristic data to be extracted.
- **Characteristic Type Sync for DataConnect** (C1-ExternalRepoPlusCharTypSync): used to extract data for characteristic types.

The Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync) business object uses the following Enter algorithm on the Pending state to take initial data snapshots:

- Capture Characteristic Data's Initial Snapshot (C1CAPMOCHARI)

The Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business object uses the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture Characteristic Type Data's Initial Snapshot (C1CAPCHTYI)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture Characteristic Data's Final Snapshot (C1CAPMOCHARF)
- Capture Characteristic Type Data's Final Snapshot (C1CAPCHTYF)

The Prepare Tab-delimited Extract Data (C1-PRTBDEXDT) algorithm on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Copyright © 2026, Oracle and/or its affiliates.

Batch Controls

The characteristic data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Account Characteristic Data Initial Load for DataConnect (C1-CHACI): This batch process creates initial sync request records for Account Characteristics.
- Person Characteristic Data Initial Load for DataConnect (C1-CHPEI): This batch process creates initial sync request records for Person Characteristics.
- Premise Characteristic Data Initial Load for DataConnect (C1-CHPRI): This batch process creates initial sync request records for Premise Characteristics.
- SA Characteristic Data Initial Load for DataConnect (C1-CHSAI): This batch process creates initial sync request records for Service Agreement Characteristics.
- SP - CCB Characteristic Data Initial Load for DataConnect (C1-CHSPI): This batch process creates initial sync request records for SP - CCB Characteristics.
- SP - MDM Characteristic Data Initial Load for DataConnect (X1-CHSPI): This batch process creates initial sync request records for SP - MDM Characteristics.
- Characteristic Type Data Initial Load for DataConnect (C1-CHTIL): This batch process creates initial Characteristic Type Data sync request records for the specified CHAR TYPE maintenance object

The following batch processes are used to create extract files from synchronization requests:

- Account Characteristic Data Extract for DataConnect (C1-ACCHX): This batch process creates Account flat file(s).
- Person Characteristic Data Extract for DataConnect (C1-PECHX): This batch process creates Person flat file(s).
- Premise Characteristic Data Extract for DataConnect (C1-PRCHX): This batch process creates Premise flat file(s).
- SA Characteristic Data Extract for DataConnect (C1-SACHX): This batch process creates service agreement flat file(s).
- SP - CCB Characteristic Data Extract for DataConnect (C1-SPCHX): This batch process creates CCB service point flat file(s).
- SP - MDM Characteristic Data Extract for DataConnect (X1-SPCHX): This batch process creates MDM service point flat file(s).
- Characteristic Type Data Extract for DataConnect (C1-CHTYX): This batch process creates characteristic type flat file(s). This batch control is defined as values for the Batch Process for Extract algorithm parameter on the Pre-Processing algorithm on the Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Characteristic Data Extracts

Setting up master data extracts involves the following steps:

Copyright © 2026, Oracle and/or its affiliates.

1. Add audit algorithms on the Account, Characteristic Type, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    a. Add the Characteristic Change Data Capture (C1MOCHARCDC) algorithm as an audit algorithm on the Account, Characteristic Type, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    b. Add the Characteristic Type Change Data Capture (C1CHARTYPCDC) algorithm as an audit algorithm on the Characteristic Type maintenance object.
2. Add Sync Request BO options on the Account, Person, Characteristic Type, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects
    a. Add the Characteristic Data Sync for DataConnect (C1-ExternalRepoPlusCharDatSync) business object as Sync Request BO options on the Account, Person, Premise, Service Agreement, Service Point - CCB, and Service Point - MDM maintenance objects.
    b. Add the Characteristic Type Sync for DataConnect (C1-ExternalRepoPlusCharTypSync) business object as a Sync Request BO option on the Characteristic Type maintenance object.
3. Execute initial load batch processes related to accounts, persons, premises, service agreements, and service points.
4. Once the initial load synchronization has been executed, changes to accounts, characteristic types, persons, premises, service agreements, and service points will trigger the creation of new synchronization requests and resulting extraction files.
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to accounts, characteristic types, persons, premises, service agreements, and service points.

Billing Data Extracts

When sending billing related data to an external system, both historical and current data needs to be extracted.

Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data includes data history for all bill segments for a specified historical period that are:

- Linked to completed bills.
- Not linked to bills but are linked to frozen FTs that are linked to completed bills.

Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any billing corrections should be extracted as well.

Extraction of billing data is performed through use of data synchronization, post bill completion algorithms, business objects and related batch processes.

- Billing Data Extracts: Business Objects and Algorithms
- Billing Data Extracts: Batch Controls
- Setting Up and Executing Billing Data Extracts
- Billing Data DataConnect Master Configurations

Billing Data Extracts: Business Objects and Algorithms

Copyright © 2026, Oracle and/or its affiliates.

Billing generates synchronization requests when bills complete through a Customer Class – Post Bill Completion algorithm. The Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type provided in the base package can be used to create a Customer Class – Post Bill Completion algorithm that creates a billing synchronization request record for each of the bill's bill segments if one does not exist in the initial state.

Billing related information extracts are supported by the following data synchronization business objects.

- Current DataConnect
  - Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)
  - Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)
- **Legacy DataConnect**
  - Billing Sync for Legacy DataConnect (Tab-delimted) (C1-ExternalRepoPlusBillingSync)
  - Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)

These business objects should be defined as an algorithm parameter on the algorithm based on the Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type. These business object use the following Pre-Processing algorithms to take an initial data snapshot, and define the batch control used to extract data and export to a flat file. However, since billing data are always synched when it gets completed, no actual initial snapshot is taken. Instead, the parameters used for building the snapshots are taken and stored on the sync request record for later use when building the final snapshot.

Current DataConnect

Business Object	Pre-Processing Algorithm
Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)	Capture Bill Data Initial Snapshot (C1EXTCBILLI)
Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)	Capture Bill Segment Data Initial Snapshot (C1EXTRCBSI)

Legacy DataConnect

Business Object	Pre-Processing Algorithm
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Capture Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP)
Billing Sync for Legacy DataConnect (Tab-delimited) (C1-ExternalRepoPlusBillingSync)	Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states extract a final snapshot of the data if the billing related data is to be extracted and exported. These include:

- Algorithms that check if there is a need to export the billing data. It will discard the synchronization request if one of the following is true:
  - The synchronization request is for a cancelled bill segment whose original usage has not been previously sent out.

Copyright © 2026, Oracle and/or its affiliates.

– The synchronization request has been marked for non-synchronization (such as, the bill segments related SA Type is not configured to be extracted on the Billing Data Configuration for DataConnect master configuration record).

Business Object	Algorithm
Billing Sync for Legacy DataConnect (Tab—delimted) (C1-ExternalRepoPlusBillingSync)	Determine if the Billing Sync is Needed (C1-DSCANUSNS)
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Determine if the Billing Sync is Needed (C1-DSCANUSNS)

- Algorithms that capture the billing data information and stores it on the synchronization request.

  Current DataConnect

Business Object	Algorithm
Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)	Capture Bill Data Final Snapshot (C1EXTCBILLF)
Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)	Capture Bill Segment Data Final Snapshot (C1EXTRCBSF)

  Legacy DataConnect

Business Object	Algorithm
Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)	Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN)
Billing Sync for Legacy DataConnect (Tab-delimted) (C1-ExternalRepoPlusBillingSync)	Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN)

When using Legacy DataConnect, if a single extract file that combines both the billing and master data (customer and premise) information is preferred, the following algorithms can be used to capture the master data information of the bill. These algorithms should be plugged in on the Determine if Sync Needed state after the Capture Billing Data Final Snapshot for DataConnect algorithm.

- Capture Billing's SA Final Snapshot for DataConnect (C1-CEXTRCSA) - This is the algorithm that captures the service agreement, account and person information associated with the bill.
- Capture Billing's SP Final Snapshot for DataConnect (C1-CEXTRCSP) - This is the algorithm that captures the service point and premise information associated with the bill.
- Capture Billing's Installation Event Final Snapshot for DataConnect (X1-CEXTRCIE). This is the algorithm that captures install event information associated with the bill.

When using DataConnect v1, the Prepare Delimited Extract Data (Process All) Enter algorithm (C1-PRPEXDCUS/C1-PRPTDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the extract batch control defined by the pre-processing algorithm).

Copyright © 2026, Oracle and/or its affiliates.

Billing Data Extracts: Batch Controls

The billing data extraction process uses a set of batch processes to create data synchronization requests and extract files.

Creating Initial Synchronization Requests

The following batch processes are used to create initial synchronization requests for bills:

- Current DataConnect
  - Bill Data Initial Load for DataConnect (C1-BLDIL)
  - Bill Segment Data Initial Load for DataConnect (C1-BSDIL)
- **Legacy DataConnect**
  - Billing Data Initial Load for Legacy DataConnect (C1-BLEIL)

These batch processes should be run to create initial load data synchronization requests based on the sync business objects described above.

Creating Extract Files

The following batch process is used to create extract files from synchronization requests for billing related information.

- Current DataConnect
  - Bill Data Extract for DataConnect (C1-BLDTX)
  - Bill Segment Data Extract for DataConnect (C1-BSDTX)
- **Legacy DataConnect**
  - Billing Data Extract for Legacy DataConnect (C1-BSYEX)

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the sync business objects described above.

The following batch controls are used to extract bill segment lines and service quantities:

- Bill Seg Lines Extract - DataConnect (C1-BSLDX)
- Bill Segment SQ Extract - DataConnect (C1-BSSQX)

These should be run after bill segment extract has been run.

Use the **Batch Control** portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file) for a delimited flat file containing extracted data.

Setting Up and Executing Billing Data Extracts

Setting up billing data extracts involves the following steps:

1. Configure the Billing Data Configuration for the DataConnect master configuration record. This is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.
2. Add the Capture Bill and Bill Segment Extract for DataConnect v1+ (C1CAPBILBSEG) related post bill completion algorithm to the applicable customer classes.

Copyright © 2026, Oracle and/or its affiliates.

If using DataConnect v1, use the Capture Billing Data for DataConnect (Comma-delimited) (C1-CAPBILLEX) algorithm.

3. Execute initial load batch processes related to billing data.
4. Once the initial load synchronization has been executed, current data should be extracted on a regular ongoing (or incremental) basis. In addition to sending current data, any billing corrections will be extracted as well (data related to bill segments not linked to bills but are linked to frozen FTs that are linked to completed bills).
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to billing.

Billing Data DataConnect Master Configurations

The master configuration business objects for billing data Configuration for DataConnect define general configuration details for the DataConnect functionality.

Billing Data Configuration for Legacy DataConnect

The Billing Data Configuration for Legacy DataConnect master configuration is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.

Billing Extract Master Configuration for DataConnect

The Billing Extract Master Configuration for DataConnect master configuration is used to define the configuration used to extract billing data. This includes the extraction types, including bill and bill segment sync request business objects, as well as CIS Divisions and SA Types for each, the number of historical periods for initial load, and the calculation line's category based on the rating engine used (billing extract assumes that only one rating engine is used by the system).

Navigate using**Admin**, then **General**, then **Master Configuration.** In the Master Configuration list, scroll to the appropriate master configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Consumption Data Extracts

When sending interval measurement usage data to an external system, both historical and current data needs to be extracted. Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data should include data history for all active service points for a specified historical period. Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any historical corrections received by the system should be extracted as well.

Extract Requests

There are several types of consumption extract requests:

- **Initial Load**: Initial load extract requests are created and submitted manually via the Consumption Extract Request portal. Consumption extract requests are based on a

Copyright © 2026, Oracle and/or its affiliates.

specified Consumption Extract Type (see below) and extraction date range. An initial load request must be created and submitted for each consumption extract type defined in the system.

- **Incremental / Ongoing (Current Data)**: Incremental / ongoing extract requests can be manually created, but more often will be created via a batch process. The "Create Daily Consumption Extract Requests" batch control scans active consumption extract types and creates a request for each one that has Frequency of "Automated Daily." Ad-hoc incremental requests can be created and submitted manually if needed.
- **Historical Correction**: Historical correction extracts are created via batch process. Algorithms on the Finalized state of the initial measurement and measurement business objects determine if a finalized initial measurement or rederived values are historical corrections. These algorithms create records which are evaluated by a batch process which extracts the measurements for the related initial measurements.

Consumption Extract Type

Consumption Extract Types define the specific parameters used when processing a consumption extract request. Consumption Extract Types control the service point type, type of measurement, and how the measurements are grouped into TOU periods if applicable. Consumption extract types also define the algorithm and batch processes to use when extracting data for different types of requests (initial load, incremental, and historical).

There are two consumption extract type business objects provided with the base package:

- **Energy Management Extract (D2-ConsumptionExtractType):** This business object retrieves interval data and converts it to a specified Target UOM and Interval Size. This business object does not support TOU mapping.
- **Energy Management Extract with TOU Mapping (D2-ConsumptionExtractTypeTOU):** This business object retrieves interval data, converts it to a specified Target UOM and Interval Size, and maps it to a specific TOU map prior to extraction.

Historical Versus Current Data

The "Extract Through Date/Time" field on the Consumption Extract Type is used to differentiate between current data (the most recently extracted data) and historical corrections, and is set to the last date on which data was extracted for that extract type. For example, if data is extracted on June 1, 2015, the "Extract Through Date/Time" would be set to "June 1, 2015 12:00AM." If/ when data is extracted the next day, "Extract Through Date/Time" would be updated to "June 2, 2015 12:00AM."

When evaluating data for extract:

- Interval data is considered current if its measurement date time is after the "Extract Through Date/Time".
- Interval data is considered a historical correction if its measurement date time is on or before the "Extract Through Date/ Time".

Historical data changes to an initial measurement can be detected when it enters the Finalized state. If the initial measurement is determined to be for a historical period by comparing its end date/time against the "Extracted Through Date/Time" on the Consumption Extract Type, a general process record will be written for the initial measurement so that measurements for it can be extracted. In addition, re-derived values on final measurements can also trigger the creation of a general process record for related initial measurements.

The following algorithms are used in this process:

- The "Create General Process Record if IMD is Historical Correction" algorithm is used to determine if a finalized initial measurement data is a historical correction. If it is, the

Copyright © 2026, Oracle and/or its affiliates.

algorithm creates a general process record for the initial measurement. This algorithm is provided in the base package, but not specified on initial measurement business objects by default. This algorithm should be defined as an Enter algorithm on the Finalized state of the initial measurement business objects.

- The "Create General Process Record for Re-derived Values" algorithm creates general process records for initial measurements associated with re-derived values. Processing will proceed as if a historical correction came in through an initial measurement. This algorithm is provided in the base package, but not specified on measurement business object by default. This algorithm should be defined as an Enter algorithm on the Re-derive state of the final measurement business object.

- Consumption Extract Requests
- Consumption Extract Requests - Batch Controls
- Consumption Extract Requests - Setup Steps

Consumption Extract Requests

Initial load and ongoing consumption extracts are created via Consumption Extract Requests. While extracts of these types can be created via adhoc submission of a batch job, requests are the preferred method for these types of consumption extracts.

The consumption extract request business object lifecycle includes logic that maintains and updates the "Extraction Through Date/Time" field on Consumption Extract Types, which is used to determine if daily requests should be created by the "Create Daily Consumption Extract Requests" batch control, and detect historical corrections.

A single business object is provided in the base package for consumption extract requests:

- **Consumption Request (D2-IntervalDataExtRepository):** This business object contains the information and lifecycle responsible for submitting the extract job, monitoring the run until it's finished, and then updating the Consumption Extract Type's "Extract Through Date/Time" on the Consumption Extract Type. This business object is based on the Request (F1-REQ) maintenance object.

The consumption extract process uses a set of base package algorithms to extract and format the interval data for export. These algorithms are specified in the "'Algorithms" section on the Consumption Extract Type as appropriate. These algorithms can be configured to allow for extraction of data for frequently-read scalar measuring components as well as interval measuring components. Frequently-read scalar measuring components are defined as scalar measuring components whose Read Method is set to "Automatic Read." When extracting measurements for frequently-read scalar measuring components, scalar measurements are converted to interval measurements as part of the extraction process. This conversion uses the profile associated with the measuring component type. If no profile can be found, the interval data uses a flat line profile.

Initial Load / Incremental / Ongoing Requests: the following algorithms are used to extract and format interval data for initial load and incremental / ongoing requests:

- **Extract Initial Load/Ongoing Consumption for DataConnect (D2-IDEXTPRD):** This algorithm retrieves a service point's consumption for a given period and writes the results to a flat file.
- **Extract Tab-Delimited Initial Load/Ongoing Consumption (with UTC Offset)** (D2-IDEXTPRDU): This algorithm retrieves a service point's consumption for a given period and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.

Copyright © 2026, Oracle and/or its affiliates.

- **Extract Initial/Ongoing Consumption and Apply TOU Map for DataConnect (D2-IDEXTPTOU):** This algorithm retrieves a service point's consumption for a given period, applies a TOU Map to the consumption, and writes the results to a flat file
- **Extract Tab-Delimited Initial/Ongoing Consumption and Apply TOU Map (with UTC Offset)** (D2-IDEXTPTUU): This algorithm retrieves a service point's consumption for a given period, applies a TOU Map to the consumption, and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.

Historical Corrections: the following algorithms are used to extract and format interval data for historical correction requests.

- **Extract Historical Correction Consumption for DataConnect (D2-IDEXTIMD):** This algorithm retrieves historical correction consumption for a service point and writes the results to a flat file.
- **Extract Tab-Delimited Historical Correction Consumption (with UTC Offset)** (D2-IDEXTIMDU): This algorithm retrieves historical correction consumption for a service point and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.
- **Extract Historical Corrections and Apply TOU Map for DataConnect (D2-IDEXTITOU):** This algorithm retrieves historical correction consumption for a service point, applies a TOU map to the consumption, and writes the results to a flat file.
- **Extract Tab-Delimited Historical Corrections and Apply TOU Map (with UTC Offset)** (D2-IDEXTITUU): This algorithm retrieves historical correction consumption for a service point, applies a TOU map to the consumption, and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.

Consumption Extract Requests - Batch Controls

The consumption extraction process uses a set of base package batch controls to extract and format the interval data for export.

- **Create Daily Consumption Extract Requests (D2-CRERQ):** This batch process scans for active Consumption Extract Types, and for each one that has Frequency of Automated Daily creates a pending request. This process should be scheduled to run daily (or at another regular interval).

The following sample batch controls are provided to extract and format interval data. Unique batch controls of each of these is required for each consumption extract type. You should create custom versions of the above batch controls for each consumption extract type in your implementation. Extract type-specific versions of these batch controls should be specified in the "Batch Control" section on the Consumption Extract Type as appropriate.

- **Initial Load/Ongoing Consumption Extract (D2-IDEPD):** This batch process extracts interval data for a specified period. This batch control uses the "Initial Load/Ongoing Extract Algorithm" defined on the Consumption Extract Type.
- **Historical Corrections Consumption Extract (D2-IDEHC):** This batch process extracts interval data for historical corrections. This batch control uses the "Historical Corrections Extract Algorithm" defined on the Consumption Extract Type.

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Consumption Extract Requests - Setup Steps

Example Setup Steps

Setting up consumption extracts involves the following steps:

1. Create Consumption Request Types: you should create a consumption request type for each unique type of request required by your implementation.
2. Create Consumption Extract Types: you should create a consumption extract type for each unique combination of output details (target UOM, target interval size, TOU map/template) and measurement selection criteria.
3. Add the "Create General Process Record if IMD is Historical Correction" historical correction algorithm as an Enter algorithm on the Finalized state of the initial measurement business objects.
4. Add the "Create General Process Record for Re-derived Values" historical correction algorithm as an Enter algorithm on the Finalized state on the measurement business object.
5. Create and submit initial load consumption extract requests for each consumption extract type you created earlier.
6. Set up batch processes for daily extract requests and historical corrections. Batch processing for consumption extracts should include the following:
    a. The **Create Daily Consumption Extract Requests** (D2-CRERQ) batch control should be configured to run on a regular (i.e. daily) schedule to create ongoing consumption extract requests.
    b. The **Request Monitor (Deferred)** (F1-SUBRQ) batch control should be used to monitor for pending requests and transition them to the "Submit Job" state.
    c. **Historical corrections consumption extract batch controls** (based on D2-IDEHC, one for each consumption extract type), should be configured to run on a regular basis to check for and create historical correction extracts.

Extract Flat File Formats

This section outlines the format of output flat files created by master data, billing data, and consumption data extracts.

Data Areas:

- C1-AcctMailingAddrDataSnapshot
- C1-BillDataSnapshot
- C1-BillSegmentDataSnapshot
- C1-CustomerDataSnapshot
- C1-ExternalRepoSABasedSnapshot
- D1-ExternalRepositorySPSnapsht
- D1-ExternalRepositorySPMtrSnap
- D1-ExternalRepositoryIESnapsht
- C1-ExternalRepoBillingSnapshot

Copyright © 2026, Oracle and/or its affiliates.

- D2-IntervalDataExtRepoSnapshot (used for interval consumption extract for Legacy DataConnect)
- D2-IntervalDataExtRepoTOUSnap (used for interval consumption extract mapped to TOU periods for Legacy DataConnect)
- D2-IntervalDataExtRepoSnpstUTC (used for interval consumption extract)
- D2-IntervalDataExtRepoTOUSnUTC (used for interval consumption extract mapped to TOU periods)

Specifics for how the flat files are created are defined on batch controls and algorithms used by the extract process.

- **File Name and Path:** Parameters on batch controls define the file name, path, and other details about the output file.
- **File Size and Contents:** Batch controls for initial load/ongoing consumption requests include a parameter to specify the number of service points to be included in each file.

C1-AcctMailingAddrDataSnapshot

C1-AcctMailingAddrDataSnapshot is used for mailing address data extracts, and includes the following information:

Field Name	Schema Element	Metadata Field
Account ID	accountId	ACCOUNT_ID

```

File Naming Formats

This topic provides details concerning how DataConnect extract files are named.

Master Data and Billing Data Extracts

Extract files for master data and billing data extracts (except extracts for Bill Segment Lines and Service Quantities, see below) use the following naming format:

Copyright © 2026, Oracle and/or its affiliates.

<provided_file_name><data_source_indicator><batch_number><batch_thread_number><sysdate date/time>.dat

where:

- <provided_file_name> is the file name as specified for the Flat File Name parameter on the batch control.
- <data_source_indicator>is the Data Source Indicator value, which comes from the Environment ID field on the Installation Options table (CI_INSTALLATION.ENV_ID). This field is 6 digits, with left padded zeros as appropriate.
- <batch_number> is the batch number of the batch process that created the file. This field is 10 digits, with left padded zeros as appropriate.
- <batch_thread_number> is the thread number of the process that created the file. This field is 3 digits, with left padded zeros as appropriate.
- <sysdate date/time> is the date and time at which the file was created, if the Include Run Date/Time on Flat File Name parameter on the batch control was set to "Y", displayed as YYYYMMDDHHMMSS.

Example: If run with the following parameters and values:

- D_ACCT_EXT is the value in the Flat File Name parameter
- 000004 is the Data Source Indicator value
- 0000000003 is the batch number
- 001 is the thread number
- 20141001123020 is the system date/time (2014-10-01.12.30.20)

the extract file name would be as follows:

```
D_ACCT_EXT000004000000000300120141001123020.DAT
```

This file naming format is used for extracts created using the following batch controls:

- Account Characteristic Data Extract for DataConnect (C1-ACCHX)
- Bill Data Extract for DataConnect (C1-BLDTX)
- Bill Segment Data Extract for DataConnect (C1-BSDTX)
- Characteristic Type Data Extract for DataConnect (C1-CHTYX)
- Customer Data Extract for DataConnect (C1-CUDTX)
- Mailing Address Extract for DataConnect (C1-MADTX)
- Person Characteristic Data Extract for DataConnect (C1-PECHX)
- Premise Characteristic Data Extract for DataConnect (C1-PRCHX)
- SA/SP Data Extract for DataConnect (C1-SSDTX)
- SA Characteristic Data Extract for DataConnect (C1-SACHX)
- SP and Meter Data Extract for DataConnect (C1-SPMSY)
- SP - CCB Characteristic Data Extract for DataConnect (C1-SPCHX)
- SP - MDM Characteristic Data Extract for DataConnect (X1-SPCHX)
- Billing Data Extract for Legacy DataConnect (C1-BSYEX)
- Meter History Extract for Legacy DataConnect (C1-SMSYX)

Copyright © 2026, Oracle and/or its affiliates.

- SA-Based Extract for Legacy DataConnect (C1-SASYX)
- SP-Based Extract for Legacy DataConnect (C1-SPSYX)

Bill Segment Line and Service Quantity Extracts

Extract files for for bill segment lines and service quantities use a naming format as specified on the File Name parameter. This can include the following system variables

- {BC} or {batchCode}: the batch code for the batch control.
- {BN} or {batchNumber}: the batch number of the batch process that created the file. This field is 4 digits, with left padded zeros as appropriate.
- {RN} or {rerunNumber}: the rerun number of the batch process that created the file if rerun. This field is 2 digits, with left padded zeros as appropriate.
- {TN} or {threadNumber}: the thread number of the process that created the file. This field is3 digits, with left padded zeros as appropriate. For multi-threaded runs, {threadNumber} will be inserted if not supplied.
- {RDT} or {runDateTime}: the date and time at which the file was created, displayed as yyyyMMddHHmmss.
- {RD} or {runDate}: the date on which the file was created, displayed as yyyyMMdd.
- {RT} or {runTime}: the time at which the file was created, displayed as HHmmss.

Example: Specifting 'EXTRACT_FILE_{BN}_{RN}_{TN}.zip' as the File Name will create the following files for batch number 10, rerun number 0, with 3 threads:

```
EXTRACT_FILE_0010_00_001.zip

EXTRACT_FILE_0010_00_002.zip

EXTRACT_FILE_0010_00_003.zip
```

This file naming format is used for extracts created using the following batch controls:

- Bill Segment Lines Extract for DataConnect (C1-BSLDX)
- Bill Segment SQ Extract for DataConnect Extract (C1-BSSQX)

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems. See Business Flags for more information.

This section provides further information about business flags and their use in the system.

- Understanding Business Flags
- Business Flag Available Actions
- Business Flag Can Prevent Bills from Freezing
- Field Activities Can Determine Business Flag Confidence

Copyright © 2026, Oracle and/or its affiliates.

- Configuring Business Flag Integration
- Meter Operations Insights Business Flags
- A Field Activity Can Determine Business Flag Confidence
- Business Flags Can Create Alerts

Understanding Business Flags

Refer to About Business Flags in the *Oracle Utilities Framework Administration User Guide* for detailed information about the components of business flags.

Customer to Meter allows for business flags that typically represent situations, exist at a customer's service point, and are shared across external applications; such as, Oracle DataRaker, Oracle Utilities Mobile Workforce Management / Oracle Field Service Cloud. and Oracle Utilities Operational Device Management. The situations that a business flag can represent range from critical knowledge that requires manual analysis for resolution to purely informational notifications.

Sharing information allows users of each system to quickly understand the status of a service point (or device, or network location in some cases) as it relates to situations or insights that would benefit users of the system. For example, the advanced analytics system (Oracle DataRaker) may identify potential theft situations that should be investigated prior to releasing the next bills from CCB with usage transactions from MDM for the related service point's consumption.

The subsequent sections describe business flag functionality that is specific to the service point business flag, as implemented by this product.

When creating a new MDM device type there are the following options:

Name	Details	Business Object
Service Point Business Flag Type	Provides configuration for business flags associated to a service point. This type offers an ability to hold a business flag for manual analysis.	D1-SPBusinessFlagType
Service Point Monitor Business Flag Type	Provides configuration for business flags that should initiate service issue monitors and convey results of a field activity to the intended subscribers.	D1-SPMonitorBusinessFlagType

Important Business Flag Business Object Options

Below are a list of business object options that are defined on the business flag business object associated to a given business flag type:

- **Valid Action**: identifies a BPA script that can be used to guide the user though an action that can be taken on a business flag. Note: this option should be paired with a business object lifecycle option of "Execution of Valid Actions Permitted" with a value of "true" for any lifecycle status that should support the execution of valid actions.

Copyright © 2026, Oracle and/or its affiliates.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Business Flag Available Actions

Allowed actions are implemented as BPA scripts that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity:** This will initiate a field activity associated to the business flag's service point. The type of field activity will be selected by the user.
- **Create Case:** This will initiate a case associated to the business flag's service point. The type of case will be selected by the user.
- **Create Notification:** This will initiate communication with the customer for the business flag's service point. The type of communication will be determined by the notification type selected by the user.
- **Create Service Issue Monitor:** This will initiate a Service Issue Monitor (SIM) process associated to the business flag's service point. The SIM type is identified on the Business Flag Type configuration. If there are already existing SIM records of this type for the service point, the most recent SIM process will be linked to the business flag.
- Business Flag Adding Available Actions
- Making Allowed Actions Available

Business Flag Adding Available Actions

To extend the actions that are available to the user for investigating a business flag the following steps can be taken:

1. A new BPA script should be developed that provides the functionality for your particular business use case.
2. That BPA script will be added to the transactional business object for the business flag using the option type "Valid Action".
3. Edit the business flag type to include the newly created action in the "Allowed Actions" section of the business flag type.

Making Allowed Actions Available

Allowed actions are only accessible on those business object statuses that have been configured to support them. To permit access to the available actions on a given status one must add a business object status option for the type "Execution of Valid Actions Permitted" with a value of "Y".

Business Flag Can Prevent Bills from Freezing

Some business flags, particularly those that require investigation, should place a hold on the billing process to prevent potentially incorrect bills from being issued to the customer. When certain types of business flags are present on a service point it indicates that there may be a problem with the reported usage that is underlying the bill and as such it may not be desirable to allow the billing process to complete until the investigation into that usage has been completed. For example, if the business flag indicated potential theft or abnormally high usage

Copyright © 2026, Oracle and/or its affiliates.

it may be preferable to delay issuing the bill until an investigation can be performed and the issue rejected or resolved.

This functionality can be enabled through configuration of the Prevent Bill Segment Freeze Due to Business Flag algorithm.

See algorithm type Prevent Bill Segment Freeze Due to Business Flag (C1-PRVBSFBF) for more detail.

In MDM, Usage Transactions can also be prevented by configuring the *Valid Business Processes for Hold* with *Usage Processing* on the Service Point Business Flag Type.

Field Activities Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will determine the confidence of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark - activation plug-in spot.

Refer to the **Assign Business Flag Final Confidence** (D1-ABFFC) algorithm type for additional details.

Configuring Business Flags

For information on configuring business flags, see Setting Up Business Flag Configuration in the Oracle Utilities Application Framework *Administrative User Guide*.

Business Flags Can Require Analysis

For more serious situations a business flag can require manual analysis from a user. These types of business flags will generate a To Do when they are received from the external application. To resolve the To Do a user will investigate the service point based on the type of business flag present. Generally this investigation will result in the business flag being either confirmed or rejected. To reach the conclusion of whether the business flag should be confirmed or denied the user can be provided with a set of available actions that can be performed on the business flag.

See C1-BFANL for more information.

Configuring Business Flag Integration

Oracle Utilities Meter Solution products include the following components used business flag integrations:

Copyright © 2026, Oracle and/or its affiliates.

Master Configuration

The following master configurations are used to configure the data synchronization process between MDM and external analytics applications:

Master Configuration	Description
Oracle Utilities DataRaker Integration Master Configuration	This master configuration is used to enable deep linking into Oracle Utilities Analytics Insights. Multiple URL patterns are supported with an ability to provide substitution variables to satisfy the URL parameters (e.g. "&searchTech="). This also provides a mapping between Oracle Utilities Meter Data Management service types and point types defined in external analytics applications.

Oracle Utilities Data Intelligence

Receiving business flag insights from external analytics applications such as Oracle Utilities Data Intelligence requires set up of the following:

- Standard Measurement Identifier (D1-StdMsrmtIdentifierLookup) extendable lookup
- Measurement Identification - Electric Configuration (D1-MsrmtIdentifyElectricConfig) master configuration
- Measurement Identification - Gas Configuration (D1-MsrmtIdentifyGasConfig) master configuration
- Measurement Identification - Water Configuration (D1-MsrmtIdentifyWaterConfig) master configuration

See Defining Standard Measurement Identifiers for more information.

Service Provider Processing Methods

The following processing methods should be associated to the service provider configured for external analytics applications:

Processing Role	Description
Business Flag Confidence Change	This role will identify the appropriate message to send when a business flag confidence has been changed (e.g. from Suspected to Confirmed). When not configured no message will be sent.
Business Flag Discarded Notification	This role will identify the appropriate message to send when a business flag has been discarded. When not configured no message will be sent.
Business Flag Field Work Details	This role will identify the appropriate message to send when a business flag has completed that initiated field work. When not configured no message will be sent.

Copyright © 2026, Oracle and/or its affiliates.

Processing Role	Description
Business Flag Added Notification	This role will identify the appropriate message to send when a business flag has been created from within Oracle Utilities Meter Data Management. When not configured no message will be sent.

Extendable Lookups

The following extendable lookups should be configured when setting up business flag integrations:

Extendable Lookup	Description
Business Flag Standard Name	If external analytics applications will be communicating business flags using a non-standard name provide an entry in the Valid External Name with the non-standard name for each standard name communicated by external analytics applications.

Meter Operations Insights Business Flags

Meter Operations Insights are analytics produced by Oracle Utilities Data Intelligence (OUDI) that evaluate meter and service-point data to identify potential operational issues. OUDI publishes the resulting insights to Meter Solution Cloud Service, Customer Cloud Service, or Meter Data Management as Business Flags with supporting context, so users can prioritize and review potential issues in their existing MDM workflow.

Meter Operations Insights sends the following insights as business flags:

- Meter Bypass
- Frequent Power Outage
- Power Factor Monitoring

The Business Flag identifies the service point and includes context that supports review of the insight.

For general information about business flags, see Business Flags in the *Application Framework Administrative User Guide*. For general integration configuration, see Business Flag Integration and Configuring Business Flag Integration.

Meter Operations Insight Context

The following optional context values can be included with Meter Operations business flags:

Insight	Context Value	Description
Meter Bypass	Usage Before	Daily average kWh observed before the suspected bypass.
Meter Bypass	Usage After	Daily average kWh observed after the suspected bypass.
Frequent Power Outage	Power Outage Count	Number of power outages associated with the insight.
Power Factor Monitoring	Power Factor	Calculated power factor.

Copyright © 2026, Oracle and/or its affiliates.

Insight	Context Value	Description
Power Factor Monitoring	Usage Loss	Aggregated kWh loss for the duration of the business flag.

Context information is displayed on the business flag when it is available. A business flag can be created with or without context values.

Configuring Meter Operations Insight Business Flags

Configure a separate Service Point Business Flag Type for each Meter Operations insight you wish to enable. Use the Service Point Business Flag (D1-SPBusinessFlag) business object unless your implementation requires monitor-driven follow-up or field work.

The following table lists the business flag types to configure. Use the standard names and any delivered type codes supplied with your release.

Insight	Business Object	Description
Meter Bypass	Service Point Business Flag (D1-SPBusinessFlag)	Review the business flag using the standard Business Flag portal.
Frequent Power Outage	Service Point Business Flag (D1-SPBusinessFlag)	Review the business flag using the standard Business Flag portal.
Power Factor Monitoring	Service Point Business Flag (D1-SPBusinessFlag)	Review the business flag using the standard Business Flag portal.

The Service Point Business Flag (D1-SPBusinessFlag) business object does not create a service issue monitor, field activity, or investigation task. If your implementation requires monitor-driven follow-up or field work, configure the applicable business flag type using the Initiate SP Monitoring Business Flag (D1-SPMonitorBusinessFlag) business object. See Service Issue Monitors and Service Order Management for configuration details.

If the external system uses a name that differs from the configured standard name, add the external name to the **Business Flag Standard Name** extendable lookup. See Configuring Business Flag Integration for more information.

Configuring Measurement Identification

Meter Operations Insights uses the measurement identification configuration in Meter Solution Cloud Service and Meter Data Management to identify the customer-specific measurement channels used by the insights. Configure the mappings for the measurements required by the insights you enable. See Defining Standard Measurement Identifiers for more information.

For Power Factor Monitoring, configure the mappings for power factor and the supporting measurements used by the implementation, including kVA when applicable. If the required power factor data is not available in the system, configure pass-through measuring processing before enabling Power Factor Monitoring. See Measuring Component Filtering for more information.

Reviewing Meter Operations Insight Business Flags (Section)

Use the **Business Flag** portal to search for and review Meter Operations insight business flags. You can search by business flag type to review insight records across service points. Review the business flag context together with the service point information and follow the investigation process defined by your implementation.

Copyright © 2026, Oracle and/or its affiliates.

A Field Activity Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will drive the resolution of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark – activation plug-in spot.

Pease refer to algorithm type Business Flag Confidence Update (C1-BSFLGCFUP) for more detail.

Business Flags Can Create Alerts

Some business flags have a high enough importance that they should be highlighted to any user that is viewing data for the service point the business flag is related to. Whether a business flag should create an alert is controlled on the business flag type. Furthermore, the appropriate algorithm must be configured in the “Installation Options – Framework” “Algorithms” page for the “Control Central Alert” system event.

The product delivers the algorithm type “Highlight Open Business Flags”

Pease refer to algorithm type *Business Flag Confidence Update (C1-BSFLGCFUP)* for more detail.

Customer Engagement

Customer engagement integration allows information about communications sent from an external system such as Opower to be stored in the system as customer contacts. This information includes who the communication was for, what it was about, a reference to the communication content (content path), and a unique identifier from the external system (external reference ID). The account and person defines who the communication was for, while the communication product and event type defines what the communication was about. The content path allows the user to view the content of the communication. A single customer contact is created for each external reference ID.

Receiving Communication

For a customer contact to be created, a one-to-one mapping between the communication product/event type combination and a notification event type lookup value must be defined in the Communication Product Event Type Mapping (C1-CustEngageValueMapping) extendable lookup. The system is delivered with mappings for the Opower communication products and event types. Additionally, the following must also be defined for the notification event type lookup value:

- Notification Event Type
- Notification Type
- Customer Contact Type with Contact Action set to 'Record Customer Engagement'.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> An error is raised if a Notification Event Type or Notification Type is not defined. If a Customer Contact Type is not defined, the communication is skipped.

The system receives communications in two ways:

- Customer Engagement (C1-CustomerEngagement) inbound web service
- On-demand retrieval of communications for an account

The inbound web service is the primary mechanism through which communication are received. It is expected to be invoked periodically to receive communications for one or more accounts.

To enable on-demand retrieval of communications for an account, set the **Enable On Demand Communication Query** parameter in the Customer Engagement Integration Configuration (C1-CustEngageIntegration) extendable lookup. When enabled, recent communications for an account are retrieved from the external system in real time when the Customer Activity History zone is loaded. The on-demand retrieval is limited to communications sent after the contact date/time of the most recent customer engagement customer contact, if one exists. Otherwise, all communications for the account are retrieved. The **On Demand Communication Query Interval (Minutes)** parameter in the same extendable lookup determines how soon after that contact date/time the on-demand retrieval can be performed again. Set this parameter to zero to perform the on-demand retrieval each time the zone loads. The external system and outbound message type used in this process are defined in the same extendable lookup.

Error Handling

If an error occurs while processing a communication, a Customer Engagement Error (C1-CustomerEngagementError) business object instance, or error record, is created to store the communication information for later remediation and reprocessing. Only one non-final error record can exist for each communication external ID. Error records can be viewed and maintained in the Inbound Sync Request portal. An error record is created in the Error state and remains there until it is reprocessed or discarded. Communication information in the error record is reprocessed the same way as information received through the inbound web service or on-demand account communication retrieval.

Viewing Communication Content

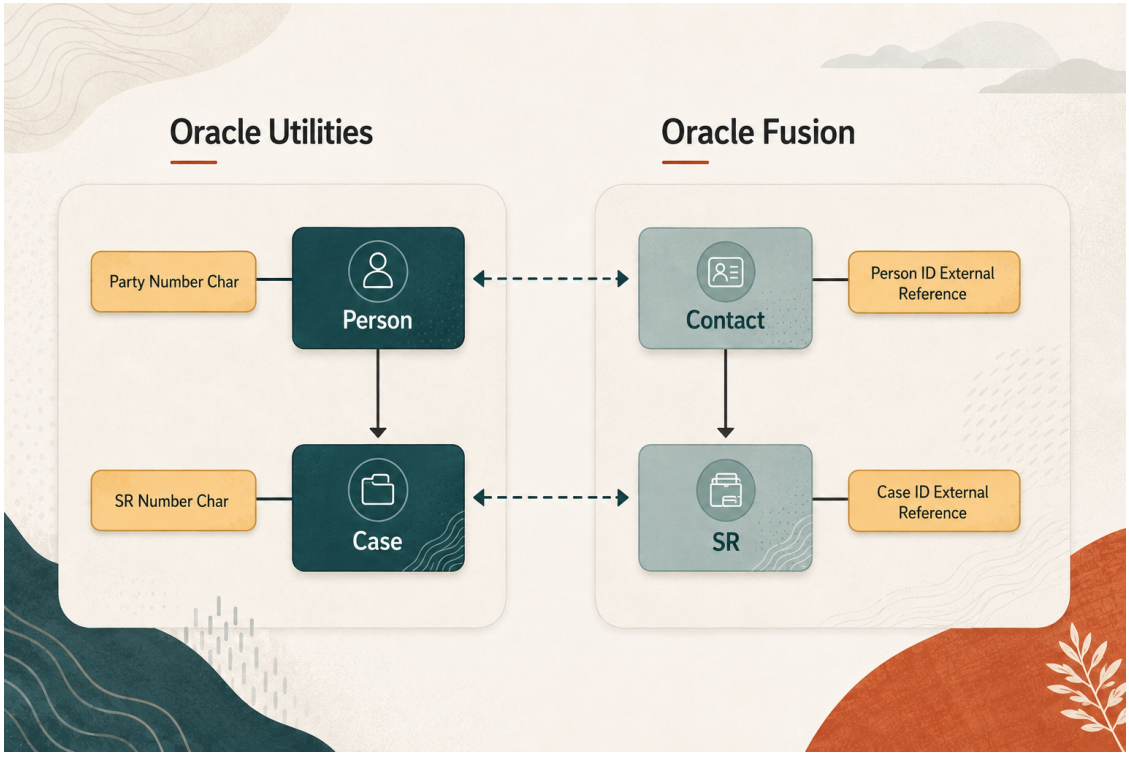
Communication content can be viewed using the **View Communication** action button in the **Customer Contact** portal. On click of the button, a real-time outbound message is sent to the external system to retrieve a pre-authenticated resource (PAR) link for the content path stored in the customer contact. The PAR link then opens in a new window to display the communication content. The validity of the PAR link is determined by the external system. The external system and outbound message type used in this process are defined in the Customer Engagement Integration Configuration (C1-CustEngageIntegration) extendable lookup.

Oracle Fusion Customer Experience Cloud Service Integrations

This section provides information about the integrations that are available with Oracle Fusion Customer Experience Cloud Services.

- Service Request to Case Integration

Copyright © 2026, Oracle and/or its affiliates.



Service Request to Case Integration

Use this integration to synchronize selected Oracle Utilities cases with Oracle Fusion service requests (SRs). The integration is optional and supports these scenarios:

- Create or update a Fusion SR from a case.
- Create or update a case from a Fusion SR.
- Maintain cross-references between the case and Fusion SR.

The integration allows you to synchronize only the case types that your organization selects. The integration does not synchronize case or SR configurations, such as workflows, topics, or field setup. You can configure those items independently in each application.

This image illustrates the data flow of the integration:

Before continuing with the integration setup, be aware of the following:

- Case synchronization is optional and can be enabled only for selected case types.
- The integration uses cross-references rather than full configuration synchronization.
- Oracle Utilities-to-Fusion processing is asynchronous. Cloud deployments process messages near-real-time, while on-premises deployments use the configured monitor batch.
- This integration does not support an initial load of existing cases or SRs. It applies to new and updated records after you enable it.

Prerequisites

Confirm the following prerequisites:

Copyright © 2026, Oracle and/or its affiliates.

- Person synchronization between Oracle Utilities and Oracle Fusion is enabled and operational.
- Oracle Integration Cloud (OIC) is configured to route messages between Oracle Utilities and Oracle Fusion.
- The required case synchronization components are available in your release.
- Configuring the Service Request to Case Integration

Configuring the Service Request to Case Integration

The following sections provide details about the tasks you need to complete in your Oracle Utilities system.

Verify the SR Number Characteristic Type

Verify that the `C1-SRNO` characteristic type is valid for the Case entity.

> **Note**
>
> You need a valid case characteristic type for each case type you want to synchronize with Oracle Fusion.

Oracle Utilities uses this characteristic to store the Oracle Fusion SR number after a case is synchronized. The Oracle Fusion SR stores the case ID as its external reference.

Specify Eligible Case Types

Configure the `Case Synchronization` master configuration business object to list the case types that can be synchronized with Fusion, and specify the Oracle Fusion Service Request page URL. For example, `https://<FUSION_HOST>/fscmUI/redwood/service/ec/container/sr/details?srNumber=`

Only cases that use the specified case types are eligible for synchronization. Additionally, configure eligible case types to require a person.

Activate Data Synchronization Control

The Case entry is available in the **Data Synchronization Control** extendable lookup. Keep the entry inactive until all integration configuration and testing are complete. Activate it when you are ready to begin synchronization.

This table as an example of the values in the extendable lookup:

Setting	Value
Synchronization Name	Case
Status	Inactive
Maintenance Object	Case
External System	C1FUSION
Sequence	10
Synchronization Script	Case Data Synchronization
Near Real-Time	Enabled

Copyright © 2026, Oracle and/or its affiliates.

Configure the OIC Endpoint

Configure the message sender to use the Oracle Integration Cloud (OIC) endpoint for the Service Request to Case integration.

Confirm the endpoint-management approach for your deployment. In particular, determine whether the endpoint is supplied through a framework URL variable or through a customer-specific message-sender configuration.

For on-premises deployments, configure and schedule the required monitor batch for case synchronization requests.

Customer Profile Insights

The following section describes how customer insights from external sources can be stored in Accounts' Customer Profiles.

Refer to Understanding Customer Profiles for more information on the Customer Profile maintenance object.

- Uploading Customer Insights

Uploading Customer Insights

There are certain types of customer insights that can be uploaded from an external system. For example, the system could receive flat files containing affordability information, indicating specific Accounts that may be in the low-to-moderate (LMI) income segment. This customer insight can be loaded into the Account's Customer Profile, using the Customer Profile Business Flag Upload (`C1-CPRUP`) batch process.

Refer to Understanding Business Flags for general information on how Business Flags are processed.

How the Customer Profile Upload Works

The Customer Profile Upload is a plugin-driven upload process that reads a flat file (e.g. a CSV file) and invokes the 'File Upload' algorithm that is plugged in on the Batch Control.

The base product provides a 'File Upload' algorithm for the purposes of the LMI/affordability use case: Add LMI Customer Profile Business Flag (`C1-CPRBUSFLG`). This algorithm maps the LMI indicator's external name - i.e., `lmi_selection_flag` (referenced in the input file) - to the Standard Name that is configured in the External Insight Standard Name (F1-BusinessFlagStandardName) lookup value, `C1-LMI`. This Standard Name value maps`lmi_selection_flg` as a Valid External Name.

The Standard Name determines the Business Flag Type, which in turn, determines the Business Flag object to create.

The 'Additional Processing' algorithm plugged in on the Business Flag Type is then invoked, to add or update the Account's Customer Profile. The base product provides the algorithm, Add/Update Customer Profile Attributes (`C1CPAUCPA`), which is meant to be plugged in for a specific Customer Profile Type (defined in the algorithm parameter). The base algorithm performs the following:

- Checks if the Account already has an active Customer Profile of the configured type.
- Creates the Customer Profile when one does not exist.

Copyright © 2026, Oracle and/or its affiliates.

- Adds new attributes to (or updates existing attributes in) the Customer Profile, based on the Customer Profile Attribute Type definition. Existing attributes are updated based on the Occurrence setting:
  - If set to `Single`, the existing value is updated.
  - If set to `Single - Per Related Object`, the attribute that references the same related object (e.g., Service Agreement) is updated.
  - If set to `Multiple`, the new values are compared with the existing values. to determine what to add or delete.

Customer Profile creation and attribute changes are captured on the Customer Profile log, for audit purposes.

Customer Profile Upload Validation and Error Handling

The Customer Profile Upload performs initial validation of the file record, including confirmation that the account ID is provided and valid. Detailed validation of Customer Profile and attribute information occurs during Customer Profile Business Flag BO and Customer Profile BO processing. If an error is encountered, the Business Flag is moved to the Validation Error state and an exception log entry is created. Users can review, make corrections and retry processing. The upload record skips the record in error and proceeds to process the next records in the file.

Refer to the `C1-CustomerProfBusinessFlag` and `C1-CustomerProfile` business objects in the application, for more information on the Business Flag and Customer Profile schemas and lifecyle processing.

Setting Up the System for Customer Profile Uploads

The following are the steps to enable Customer Profile Batch Upload processing:

- Set up a Customer Profile Attribute Type for each unique attribute to capture in the Customer Profile. For example, with the LMI use case, there could be two attribute types - one for the LMI indicator (true/false switch) and another for the LMI Selection Reason (extendable lookup). Refer to Setting Up Customer Profile Attribute Types for more information.
- Set up the Customer Profile Type and link the new Customer Profile Attribute Types to it. Refer to Setting Up Customer Profile Types for more information.
- Add an Algorithm for the Add/Update Customer Profile Attributes (`C1CPAUCPA`) Algorithm Type and set its algorithm parameter to the new Customer Profile Type.
- Update the External Insight Standard Name (`F1-BusinessFlagStandardName`) Extendable Lookup, with the applicable Standard Name (lookup value) and its associated Valid External Name(s). For the LMI use case, the base product provides the `C1-LMI` lookup value. It just needs to be updated with any additional implementation-specific Valid External Name(s) that differ the `lmi_selection_flg` name that is already included.
- Set up a Customer Profile Business Flag Type using the Customer Profile Business Flag Type (`C1-CustomerProfBusFlagType`) business object:
  - Set the Standard Name. For example, in the LMI use case, set the Standard Name to the `C1-LMI` extendable lookup value or an implementation-specific Valid External Name, if any.
  - Configure attribute relationships, if any. This applies to cases where multiple attribute types are received and some attribute types provide more information related to the key attribute type. For example, with the LMI use case, the LMI indicator is defined

Copyright © 2026, Oracle and/or its affiliates.

with LMI Selection Reason as a related attribute. The LMI Selection Reason's external name (in the input file) is mapped to a corresponding Customer Profile Attribute Type.

  - Configure the 'Additional Processing' Algorithm with the new algorithm instance of Add/Update Customer Profile Attributes (`C1CPAUCPA`) algorithm type, created above.

- Set up other implementation-specific configuration. For example, for LMI Selection Reasons, add the valid values for the LMI Selection Reason extendable lookup, `C1-LMISelectionReasonLookup`.
- Set up Object Storage access. Refer to External File Storage for more information.

Customer Relationship Management Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with customer relationship management applications such as Oracle Social Relationship Management (SRM).

The following sections describe this functionality.

- About Customer Relationship Requests
- Setting Up Customer Relationship Request Configuration
- Maintaining Customer Relationship Requests

About Customer Relationship Requests

A customer relationship request is used to process requests that are initiated from an external customer relationship management system.

The following sections highlight customer relationship request functionality.

- Social Relationship Management Requests
- Creating Customer Relationship Requests

Social Relationship Management Requests

Oracle Social Relationship Management (SRM) is an example of an external system that can initiate customer relationship requests.

Social network posts cover a vast range of topics, a number of which could be related to the users' concerns with their utility service. For example:

- A Facebook user could post on a community page about a power outage in a specific area.
- A Twitter user might post about specific problems with their utility service (*e.g.*, high bill complaints).

Social conversations of this nature can be monitored and managed via Oracle SRM. Oracle SRM’s Engage module allows its users to see all social conversations, identify customer-specific issues and route the messages to the appropriate systems/channels.

Requests from social relationship management systems typically include:

- Information about the original posting on the social network/community (*e.g.*, author’s identifier, link to the post, etc.).
- Information about the posting within the social relationship management system (*e.g.*, the user that sent the request to the utility, link to the post, etc.).

Copyright © 2026, Oracle and/or its affiliates.

- Additional details that will help with processing/resolution (*e.g.*, customer/account numbers, address, bill IDs, etc.).

Creating Customer Relationship Requests

Most customer relationship requests will be initiated from an external system.

The base product provides an Add Customer Relationship Request (C1–AddCustRR) inbound web service that can be used in a customer relationship management integration to create customer relationship request records. This inbound web service invokes a processing script that is configured in Customer Relationship Integration master configuration. The base product supplies an example of this processing script. It maps the inbound service's input data into the customer relationship request record. Refer to the C1-CreCustRR service script system data for processing details.

Setting Up Customer Relationship Request Configuration

The following topics highlight the general configuration steps required to use customer relationship request functionality and to integrate with a customer relationship management application such as Oracle Social Relationship Management (SRM).

- Customer Relationship Management Integration Configuration
- Defining Customer Relationship Request Types

Customer Relationship Management Integration Configuration

The integration with a customer relationship management application such as Oracle Social Relationship Management (SRM) requires the setup of master configuration data that controls the processing of your customer relationship requests.

To set up customer relationship integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Customer Relationship Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Defining Customer Relationship Request Types

A customer relationship request type defines properties that control how a customer relationship request is processed.

Refer to About Customer Relationship Requests for an overview of customer relationship request functionality.

To maintain customer relationship request types, open **Admin**, and then **Integration**, and then **Customer Relationship Request Type**, and then **Search**.

This is a standard All-In-One Portal.

The information captured on the customer relationship request type depends on the business objects supported by your implementation. Refer to the embedded help text for more information.

Maintaining Customer Relationship Requests

This section describes the functionality supported for viewing and maintaining customer relationship requests.

Copyright © 2026, Oracle and/or its affiliates.

Refer to About Customer Relationship Requests for an overview of customer relationship request functionality.

Navigate using **Menu**, and then **Integration**, and then **Customer Relationship Request**, and then **Search**. You are brought to a query portal with options for searching for customer relationship requests.

Once a customer relationship request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Customer Relationship Request** zone provides basic information about a customer relationship request. Refer to the embedded help for more information.

The **Notes** zone allows users to capture additional notes to the customer relationship request.

RightNow Knowledge Integration

Oracle Utilities Customer Care and Billing provides an integration with Oracle RightNow Knowledge that allows users to view frequently asked questions about business processes/ functions that relate to the portal or page that they are currently viewing and/or working on.

The following sections describe this functionality.

- Displaying Frequently Asked Questions
- RightNow Knowledge Integration Configuration

Displaying Frequently Asked Questions

The Oracle RightNow Knowledge application can be used to develop content for frequently asked questions about business processes. It also functions within the Oracle Customer Care and Billing application. The RightNow KnowledgeSyndication widget defines the interface for the retrieval of this content.

The Oracle Customer Care and Billing application provides a **Frequently Asked Questions** sidebar zone that uses the RightNow KnowledgeSyndication widget to retrieve content from a RightNow Knowledge base instance. This zone is context-sensitive.

Configuration data controls how information is displayed in the **Frequently Asked Questions** sidebar zone. Refer to RightNow Knowledge Integration Configuration for more details.

RightNow Knowledge Integration Configuration

The integration with Oracle RightNow Knowledge requires the setup of master configuration data that controls how content from the RightNow Knowledge base is retrieved and presented on the **Frequently Asked Questions** sidebar zone. This configuration includes the following settings:

- The URL of the RightNow Knowledge base instance.
- The list of portals and pages for which the **Frequently Asked Questions** sidebar zone will display.
- Settings for each portal / page:
  - Search terms to pass to the RightNow KnowledgeSyndication widget. The base product supplies a number of common search term types. Implementation-specific search term types can be added.

Copyright © 2026, Oracle and/or its affiliates.

- Number of results/answers to display in the **Frequently Asked Questions** sidebar zone.

To set up the RightNow Knowledge Integration master configuration, navigate using **Admin**, and then **General**, and then **Master Configuration.** You are brought to an all-in-one portal with options to add/edit the RightNow Knowledge Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

External Applications

- Understanding External Applications
- Configuring External Applications
- Initiating Smart Meter Commands from an External Application

Understanding External Applications

External applications are applications and systems that are external to the Oracle Utilities meter data products, and can include customer information systems, outage management systems, or other types of applications.

External system service providers utilize processing methods to specify how the system sends and creates data used by the two applications. .

Refer to Understanding Process Methods for more information about processing methods.

External Applications Impact Data Import and Export

External Applications are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each external application can be associated to an external system which is used to define the messages that can be sent to that service provider and how each message is sent.

Configuring External Applications

This portal is used to display and maintain External Applications.

Refer to Understanding External Applications for more information.

You can access the portal from the **Admin**, then **Integration**, then **External Application**.

The following zones may appear as part of the portal's **Main** tab page:

- **External Applications List:** This zone lists all External Application records. Broadcast a record to display the details of the selected record.
- **External Application:** This zone provides information about the selected External Application.

Copyright © 2026, Oracle and/or its affiliates.

- **Processing Method List:** This zone provides the list of processing methods defined for the External Application.
- **Translation Method List:** This zone provides the list of translation methods defined for the External Application.
- **Inbound BOs Send By Service Provider:** This zone lists inbound Business Objects that are sent by this External Application. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current External Application.

Initiating Smart Meter Commands from an External Application

Though often initiated as part of an orchestration activity (such as Enable Service or Exchange Meter) or from the Oracle Utilities Meter Data Management application, smart meter commands can also be initiated from external applications such as a customer information system such as Oracle Utilities Customer Care and Billing, a self-service application such as Oracle Utilities Digital Self-Service Transactions, or an outage management system such as Oracle Utilities Network Management System.

External applications initiate commands through the use of inbound web services, and outbound messages are used to send the results back to the initiating application. This section describes how smart meter commands can be initiated from external applications.

Command Processing Overview

This section provides a high level overview of how the system processes commands initiated from external applications.

For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used. Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process. This example uses an "On-Demand Read - Interval" command.

Step	Process	Sample Object
1	External application initiates a command request via inbound web service	Inbound Web Service: D1-OnDemandReadInterval
2	Command activity is created in the Pending state.	Activity Business Object: D1-OnDemandReadInterval
3	The command activity goes through it's lifecycle, creating outbound communications as defined by the head end system, receiving the response.	
4	When the command enters the Completed state, an Enter algorithm sends the result to the initiating application.	Algorithm: Send On Demand Read to Edge Application (D1-SNDRDTEA)

Copyright © 2026, Oracle and/or its affiliates.

Step	Process	Sample Object
5	The algorithm uses a "Response - Success" processing method (based on the the Response - Success (D1SR) processing role) defined for the external application to create an outbound message (based on the outbound message type defined for the processing method).	Processing Method Business Object: How to Send Activity Related O\B Messages (D1-HowToSendActivityResponse) Outbound Message Business Object: Outbound Message for Communication BOs (D1-OutboundMessage)
6	The external system and message sender sends the outbound message to the external application.	

Inbound Web Services

This section provides information about the inbound web services available for initiating smart meter commands from an external application. The table below lists the smart meter commands available, and the specific inbound web services provided for each.

Command	Inbound Web Service
Device Status Check	Device Status Check (D1-DeviceStatusCheck)
On-Demand Read (Interval)	On Demand Read Interval (D1-OnDemandReadInterval)
On-Demand Read (Scalar)	On Demand Read Scalar (D1-OnDemandReadScalar)
Remote Connect	Remote Connect (D1-RemoteConnect)
Remote Disconnect	Remote Disconnect (D1-RemoteDisconnect)

See **Inbound Web Services** for more information about using inbound web services.

Required Data Elements

The inbound web service calls used to initiate commands must include some specific data elements in order to be successfully processed.

The table below lists the specific data elements required when initiating commands via inbound web service calls. Use the **WSDL** link to view the full web service description language definition for each command.

Data Element	Description	Used by
`requester`	The system or person submitting the command request. This should be the name of the external application.	Device Status Check On-Demand Read (Interval) On-Demand Read (Scalar) Remote Connect Remote Disconnect

Copyright © 2026, Oracle and/or its affiliates.

Data Element	Description	Used by
`utilityDeviceIdentifierNumber`	The ID of the device in the external system. This should be based on the **Utility Device ID Type** defined for the external application. For example, if the external application uses Serial Numbers for their device IDs, this would be the device's serial number.	Device Status Check On-Demand Read (Interval) On-Demand Read (Scalar) Remote Connect Remote Disconnect
`measurementDestination`	The destination for measurements returned by On-Demand read commands, from the Measurement Destination (MSRMT_DEST_FLG) lookup. Valid values include: • Calling Edge Application (D1EA) • Calling & Subscribing Edge Application (D1ES) • Measurement Subscribing Edge Application (D1SE)	On-Demand Read (Interval) On-Demand Read (Scalar)

Send to Edge Application Algorithms

As noted above, when the command enters the Completed state, an Enter algorithm sends the result to the initiating application. The table below lists the specific algorithms used with each command.

Activity Business Object	Send to Edge Application Algorithm
Device Status Check (D1-DeviceStatusCheck)	Send Device Status Check Notification to Edge Application (D1-SNDDVSTCK)
On Demand Read Interval (D1-OnDemandReadInterval)	Send On Demand Read to Edge Application (D1-SNDRDTEA)
On Demand Read Scalar (D1-OnDemandReadScalar)	Send On Demand Read to Edge Application (D1-SNDRDTEA)
Remote Connect (D1-RemoteConnect)	Send Remote Connect Notification to Edge Application (D1-SRCNTEA)
Remote Disconnect (D1-RemoteDisconnect)	Send Remote Disconnect Notification to Edge Application (D1-SRDNTEA)

Sending Messages Back to the External Application

Sending outbound communications to am external application involves configuring a number of entities. This section provides an overview of the objects required to send outbound communications to external applications.

Outbound Message Types

Outbound message types define the details of outbound messages sent to the external application. You should create an outbound message type for each different type of message to be sent to the external application.

Copyright © 2026, Oracle and/or its affiliates.

See **Outbound Messages** and **Defining Outbound Message Types** for more information about creating outbound message types.

Message Senders

Message senders define details for sending messages to external applications. You must create a message sender for each type of message to be sent to the external application.

Note: The Message Class MUST be set to **SOAPSNDR** (Sender for real-time HTTP / SOAP messages).

See **Message Senders** for more information about creating message senders.

External Systems

You must create an external system that represents the external application and defines the outbound message types that can be sent to the external application. The external system will be referenced on the external application.

You must configure an outbound message type on the external system for each type of message you will send to the external application. An external system's outbound message types are defined by the following:

- **Outbound Message Type**: The outbound message type (see above) created for the message
- **Processing Method**: The method by which the message will be sent. This should be set to "Real-time".
- **Message Sender**: The message sender (see above) created for the message.
- **Message XSL / Response XSL**: XSL files used to transform your message and the response to the message into the appropriate format used by the external application (Message XSL) and Smart Grid Gateway (Response XSL).

See **External Systems** for more information about creating external systems.

External Applications

The external applications that can initiate smart meter commands must be defined as External Applications. Examples can include:

- A customer information system (such as Oracle Utilities Customer Care and Billing)
- A self-service application (such as Oracle Utilities Digital Self-Service Transactions)

Information defined for external applications include:

- **External System**: The external system (see above) the defines the types of outbound messages to be sent to the external application.
- **Our Name/ID in Their System**: The value that the external application uses to identify our system.
- **Utility Device ID Type**: The Device ID Type that will be used when communicating with the external application and it will be the assumed Device ID Type for any device identifiers sent from the external application.
- **Utility Service Point ID Type**: The Service Point ID Type that will be used when communicating with the external application and it will be the assumed Service Point ID Type for any service point identifiers sent from the external application.

Copyright © 2026, Oracle and/or its affiliates.

- **Processing Methods**: The external application's processing methods define how data relevant to the application is sent and/or created. At least one processing method should reference the outbound message type used to send responses to the external application. External applications that initiate smart meter commands should use the following processing roles:
  - Response- Success: Used to send an acknowledgement that the command was successfully executed and the results of the command, if applicable.

Refer to **Understanding External Applications** and **Configuring External Applications** for more information about external applications.

Configuring Master Data Synchronization

Refer to Customer To Meter Master Data Synchronization for more information.

Oracle Utilities Operational Device Management

- Overview
- Configuring Master Data Synchronization

Overview

This section provides an overview of how Oracle Utilities Meter Data Management supports integrations with Oracle Utilities Operational Device Management. In an integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management:

- Oracle Utilities Meter Data Management is typically considered the "system of record" for service points (asset locations), contacts, and device installation information (install events)
- Oracle Utilities Operational Device Management is typically considered the "system of record" for assets (devices) and asset specification configuration (device configurations)

Given this breakdown of data between the two systems, any integration between them must account for the passage of data between the two to ensure that each system can accurately perform its business functions. The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management is based on data synchronization between the two systems.

Configuring Master Data Synchronization

The specific data synchronization flows supported between Oracle Utilities Meter Data Management (MDM) and Oracle Utilities Operational Device Management (ODM) include the following:

- **Asset-Device Synchronization**: As new assets and asset specification configurations are created or changed in ODM, corresponding devices and device configurations must be created or changed in MDM
- **Service Point/Contact - Asset Location/Contact**: As Service Points and/or Contacts are created or changed in MDM, corresponding Asset Locations and Contacts must be created or changed in ODM

Copyright © 2026, Oracle and/or its affiliates.

- **Install Events- Asset Location/Disposition**: As devices are installed/removed in MDM, corresponding changes to an asset's Disposition (location and status) must be made in ODM

This synchronization process is supported through a set of business objects, master configurations, batch controls, and pre-configured Inbound Web Services. Refer to the *Oracle Utilities Integration for Device Operations Implementation Guide* for more information about this integration and the data synchronization processes used by this integration.

Master Configuration

The following master configurations are used to configure the sync process between MDM and ODM:

Master Configuration	Name / Description
Master Data Synchronization Configuration	Lists all foreign key references that need resolution. Each one should reference the view that contains the external key / production key cross-reference. For entities that undergo both the initial and the ongoing sync, two views are specified. For entities that undergo the ongoing sync, an external system / ID type mapping is specified to cater for entities that might be synchronizing from more than one external system.
Seeder Sync Request Master Configuration	Lists the maintenance objects (device, device configuration, etc.) that require synchronization. Each references the synchronization business object that needs to be instantiated when processing a synchronization request for that maintenance object. For maintenance objects that undergo both initial and the ongoing synchronization, two business objects are specified.
ODM Integration Master Configuration	Specifies the external system used to represent Oracle Utilities Operational Management, and the URL for the Oracle Utilities Operational Management application. Also specifies the outbound message types used to send synchronization requests to Oracle Utilities Operational Management.

Inbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following inbound (to Oracle Utilities Mater Data Management) synchronization business objects:

Object Name	Business Object	Description
Device Ongoing Sync Request	D1-OngoingSyncRequestDevice	Used to synchronize devices and device configurations in Oracle Utilities Mater Data Management based on assets and asset specification configurations created/updates in Oracle Utilities Operational Device Management.

Copyright © 2026, Oracle and/or its affiliates.

Outbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following outbound (from Oracle Utilities Mater Data Management) synchronization business objects (based on the F1-SYNC REQ maintenance object)

Object Name	Business Object	Description
ODM Sync Request	D1-ODMContactSyncRequest	Used to synchronize contacts in Oracle Utilities Operational Device Management based on contacts created/updated in Oracle Utilities Meter Data Management
ODM Install Event Sync Request	D1-ODMInstallEventSyncRequest	Used to synchronize asset location/disposition in Oracle Utilities Operational Device Management based on install events created/ updated in Oracle Utilities Meter Data Management
ODM SP Sync Request	D1-ODMSPSyncRequest	Used to synchronize asset locations in Oracle Utilities Operational Device Management based on service points created/updated in Oracle Utilities Meter Data Management. This includes updating asset locations when equipment is attached to or remove from a service point.

Analytics Integrations

This section describes integrations with external analytics applications such as Oracle Utilities Data Intelligence.

- Business Flag Integration
- Meter Insights and Investigations
- Usage and Event Integration

Business Flag Integration

With the business flag integration with external analytics applications:

- Either Oracle Utilities Meter Solution Cloud Service/Meter Data Management or an external analytics application can initiate a business flag
- Oracle Utilities Meter Solution Cloud Service/Meter Data Management can notify external analytics applications of a change in status of a business flag:
  - if a business flag in error has been discarded
  - if a business flag's confidence has been updated

Copyright © 2026, Oracle and/or its affiliates.

  - with the results of field work initiated by a business flag
- Oracle Utilities Data Intelligence can also publish Meter Operations insights as service point business flags. See **Meter Operations Insights Business Flags** for insight-specific configuration and context information.

For additional details see About Business Flags in the Oracle Utilities Application Framework *Administrative User Guide*.

Meter Insights and Investigations

The Meter Insights and Investigations functionality leverages external analytics application business flag integrations to support receipt of revenue protection events (referred to as "insights") from external analytics applications for research and investigation using Oracle Utilities Meter Data Management (or Oracle Utilities Meter Solution Cloud Service). Revenue protection insights sent from external analytics applications for investigation are events that suggest potential theft or loss of revenue such as unexpected consumption from an inactive meter, evidence of meter tampering, discovery of an improperly installed meter (such as a meter installed upside down or in reverse), and so on. Insights received from external analytics applications create business flags, which in turn create related Meter Insight Investigation service tasks (referred to as “investigations”), which can then be researched and investigated using a dedicated **Meter Insights Investigations Viewer** portal.

See **Business Flags** in the *Administrative User Guide* for general information about the business flag functionality provided by the Oracle Utilities Application Framework.

See **Business Flag Integration** in the *Administrative User Guide* for more information about the Business Flag integration with external analytics applications.

See **Service Issue Monitors** in the *Business User Guide* and **Service Task Types** in the *Administrative User Guide* for general information about service issue monitors.

See **Using the Meter Insights Investigations Viewer Portal** in the *Business User Guide* for more information about viewing meter insight service issue monitors.

Meter Insights and Investigation Business Objects

Business flags and service issue monitors used by Meter Insights and Investigations functionality are based on specific business objects:

Type of Object	Business Object
Business Flag	Revenue Protection Insight (D1-RevenueProtectionInsight)
Service Issue Monitor (Service Task)	Meter Insight Investigation (D1-MeterInsightInvestigation)
Investigation Type (Service Task Type)	Meter Insight Investigation Type (D1-MtrInsightInvestigationType)

Meter Insights and Investigation Processing

The table below provides a brief description of the process by which insights are received and processed, and lists example objects used by the Oracle Utilities Meter Data Management (and Oracle Utilities Meter Solution Cloud Service). Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Copyright © 2026, Oracle and/or its affiliates.

Step	Process	Example Data
1.	Oracle Utilities Analytics Insights sends events ("insights") to Meter Data Management, via the Business Flag integration, creating business flags based on the business flag type configuration.	Business Flag Business Object: Revenue Protection Insight (D1-RevenueProtectionInsight)
2.	An Enter algorithm on the "Create Service Issue Monitor" state creates a Service Issue Monitor based on the Service Task type defined on the business flag's type. The investigation is created in "Pending" status.	Enter Algorithm: Business Flag - Create Service Issue Monitor (D1-CREATESIM) Note: This algorithm is on the parent business object (D1-SPMonitorBusinessFlag). Service Issue Monitor (Service Task) Business Object: Meter Insight Investigation (D1-MeterInsightInvestigation)
3.	The investigation evaluates the service point (based on configuration of the service task type). • If there are no issues, the investigation moves into the Discarded (No Investigation Needed) state. • Otherwise, the investigation continues to the Open state.	Evaluate Algorithm: Meter Insight Investigation - Analyze Service Point For Service Issues (D1-MII-ANZ)
4.	An Enter algorithm on the Open state creates a To Do entry.	Open Enter Algorithm: Meter Insight Investigation - Create To Do Entry (D1-MIICRTODO)
5.	Once the investigation is in the Open state, a business user can use the **Meter Insights Investigation Viewer** portal to examine the issue. See "Using the Meter Insights Investigation Portal" in the *Business User Guide* for more information about using this portal. The user can add comments and update the investigation to one of the following states: • Waiting for Field Work • Issue Resolved • No Issue • Discarded When the investigation moves into the Issue Resolved, No Issue, or Discarded states, it transitions the business flag the Completed state with a Final Confidence based on the investigation's state (see below).	

Copyright © 2026, Oracle and/or its affiliates.

Step	Process	Example Data
6.	If the service issue monitors enters the Waiting for Field Work state, a Monitor algorithm evaluates the Completion Criteria on the Service Task Type and transitions the investigation to one of the following states: • Fieldwork Error • Open • Issue Resolved • No Issue • Inconclusive When the investigation moves into the Issue Resolved, No Issue, or Inconclusive states, it transitions the business flag the Completed state with a Final Confidence based on the investigation's state (see below).	Waiting For Field Work Monitor Algorithm: Evaluate Completion Criteria (D1-MIIEVCMCR)
7.	If the service issue monitors enters the Issue Resolved state: • An Enter algorithm completes the To Do entry • An Enter algorithm transitions the Business Flag to the Completed state (Final Confidence: Confirmed)	Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPLE) Enter Algorithm: Transition Business Flags - Completed (D1-TRBUSFLGC)
8.	If the service issue monitors enters the No Issue state, • An Enter algorithm completes the To Do entry • Transitions the Business Flag to Completed (Final Confidence: Rejected)	Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPLE) Enter Algorithm: Transition Business Flags - Rejected (D1-TRBUSFLGR)
9.	If the service issue monitors enters the Inconclusive state, • An Enter algorithm completes the To Do entry • Transitions the Business Flag to Completed (Final Confidence: Suspected)	Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPLE) Enter Algorithm: Transition Business Flags - Suspected (D1-TRBUSFLGI)
10.	If the service issue monitors enters the Discarded state • An Enter algorithm completes the To Do entry • Transitions the Business Flag to Completed (Final Confidence: Rejected)	Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPLE) Enter Algorithm: Transition Business Flags - Rejected (D1-TRBUSFLGR)

- Configuring Meter Insights and Investigations

Copyright © 2026, Oracle and/or its affiliates.

Configuring Meter Insights and Investigations

Configuring the Meter Insights and Investigations functionality involves creation and configuration of the following:

- Business Flag Types
- Extendable Lookup Values
- To Do Types
- Service Tasks Types
- Master Configuration

Business Flag Types

Create a business flag type for each type of revenue protection insight that will be received from external analytics applications, including the following:

- **Business Object**: Service Point Monitor Business Flag Type (D1-SPMonitorBusinessFlagType)
- **Related Transaction BO**: Revenue Protection Insight (D1-RevenueProtectionInsight)
- **Service Issue Monitor Type**: The service task type for investigations created from business flags of this type.

> **Note**
>
> Because the **Service Issue Monitor Type** field is required, when initially creating business flag types, select a placeholder Service Issue Monitor Type to enable you to save the business flag type. After you have created the appropriate service task types, return to each business flag type and select the correct Service Issue Monitor Type.

Define other fields based on your business requirements.

Extendable Lookups

The **Meter Insights Investigation Viewer** portal uses the following profile extendable lookups when displaying consumption and insights (events):

- **360 View Event Bar Profile**: Defines events to highlight that are pertinent to investigations, including your new business flag types
- **Final Values Overlay Profile**: Defines values to graph that are pertinent to investigations

Use the **Extendable Lookup** portal to create new extendable lookup values:

1. Create a new 360 View Event Bar Profile extendable lookup value that includes your business flag types as well as other events pertinent to your investigations.
2. Create a new Final Values Overlay Profile extendable lookup value that includes the values to graph that are pertinent to your investigations.

These extendable lookup values will be referenced by your service task types.

Copyright © 2026, Oracle and/or its affiliates.

To Do Types

Use the **To Do Type** portal to create a To Do Type (or update an existing To Do Type) with the Set Investigation Priority (D1-STINVSGPR) algorithm defined for the **Calculate Priority** system event.

These To Do Types will be referenced by your service task types.

Service Task Types

Create a service task type for each type of revenue protection insight (each type of investigation) that will be received from Oracle Utilities Analytics Insights, including the following:

- **Business Object**: Meter Insight Investigation Type (D1-MtrInsightInvestigationType)
- **Related Transaction BO**: Meter Insight Investigation (D1-MeterInsightInvestigation)
- **Evaluation Criteria**: The criteria used to evaluate the service point, including the existence of business flags of specified types (the business flag types you created earlier). See the embedded help for more details.
- **Service Investigation Order**: The field activity type and Field Task Type for field activities created by the investigation.
- **Completion Criteria**: The criteria used to determine if the service investigation order (field activity) should be completed and the result to be returned to the investigation. See the embedded help for more details.
- **Consumption Data Source**: Details that specify the types of consumption data will be displayed and how it is displayed in the **Meter Insights Investigation Viewer** portal, including the 360 Event Bar Profile and Final Values Overlay Profile extendable lookup values created earlier.
- **To Do Information**: The To Do Type and To Do Role used for To Do Entries created by the investigation. This should reference the To Do Type configured earlier.

Note: After you have created the appropriate service task types, return to the corresponding business flag type and select the correct service task type from the **Service Issue Monitor Type** drop-down list.

Master Configuration

Create a Meter Insights Configuration master configuration to capture key details used by Oracle Utilities Analytics Insights when creating insights including:

- Tolerances details related to specific types of insights (Flipped Meter, Unauthorized Consumption, and Leak Detection)
- Core sources of consumption for electric, gas, and water service types (including service point types, and unit of measure/time of use/service quantity identified combinations for each)

The master configuration is synchronized with Oracle Utilities Analytics Insights, and is used by Oracle Utilities Analytics Insights when generating insights for potential investigation.

Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters can be configured to publish initial measurement and device event data for use in external analytics applications or other external systems.

Copyright © 2026, Oracle and/or its affiliates.

Published data is posted to a user-defined directory that Oracle Utilities Analytics Insights can monitor for import.

Initial measurement and device event data is published in the “native” data format (the format of the initial measurement and device event seeder business objects). This format includes normalized unit of measure, condition, and device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

> **Note**
>
> Initial measurement data published via this feature is published prior to VEE processing. In addition, filtering can NOT be applied to initial measurement or device event data published via this feature.

- Configuring Analytics Usage and Event Integration

Configuring Analytics Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters use OSB and BPEL components when publishing initial measurement and device event data for integration with external analytics applications.

OSB Projects

The following “CM” Oracle Service Bus projects are used to configure the integration between SGG and external analytics applications:

Adapter	OSB Projects
Landis+Gyr	SGG-D3-USAGE-CM (used to publish usage) SGG-D3-EVENT-CM (used to publish device events)
NES	SGG-D4-USAGE-CM (used to publish usage) SGG-D4-EVENT-CM (used to publish device events)
MV90	SGG-D5-USAGE-CM (used to publish usage)
Sensus	SGG-D6-USAGE-CM (used to publish usage) SGG-D6-EVENT-CM (used to publish device events)
Silver Spring Networks	SGG-D7-SSNXML-CM (used to publish usage) SGG-D7-CSV-CM (used to publish device events)
Itron OpenWay	SGG-D8-ITRONXML-CM (used to publish usage) SGG-D8-EXCEPTION-CM (used to publish device events)
Adapter Development Kit	SGG-DG-SEEDER-CM (used to publish usage and device events)

The following components provided with these projects are used in publishing measurement data and device events to Oracle Utilities Analytics Insights:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This business service is specified in the EnvironmentSettings.xq file (see below).

Copyright © 2026, Oracle and/or its affiliates.

- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Enabling Data Publishing

Publishing initial measurement and device event data is enabled by referencing a publisher business service (DataRakerBusinessService) in the publishServices/service element in the EnvironmentSettings.xq files provided with the OSB projects listed above as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

BPEL Composites

The SGGDRIntegration BPEL composite handles publishing the data to external analytics applications or other systems.

Configuring Publishing Output

The following parameters can be used to configure details of how the data is provided to external analytics applications, including the directory where files are posted for external analytics applications to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the **DataRakerBusinessService** business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging

Copyright © 2026, Oracle and/or its affiliates.

Parameter	Description	Default Value
SOA_DR_INTEGRATION_DIR	Mount point/directory from which external analytics applications will consume the converted XML files.	/spl/sploutput/int

- Consumption Analytics Aggregations Overview

Timeliness and Quality Aggregations Overview

Oracle Utilities Meter Solution Cloud Service and Oracle Utilities Customer Cloud Service can be integrated with Oracle Utilities Analytics Visualization (OUAV) to allow users to view analytics data based on the quality and timeliness of measurement data.

This section describes integration of Oracle Utilities Meter Solution Cloud Service and Oracle Utilities Customer Cloud Service with Oracle Utilities Analytics Visualization (OUAV).

See Operational Analytics in the *Administrative User Guide* for general information about integrating with Oracle Utilities Analytics Visualization.

- Base Package Timeliness and Quality Aggregation Measuring Components and Measurement Business Objects
- Configuring Timeliness and Quality Aggregation for Use with Oracle Utilities Analytics Visualization
- Timeliness and Quality Aggregation Processing for Use with Oracle Utilities Analytics Visualization

Base Package Timeliness and Quality Aggregation Measuring Components and Measurement Business Objects

Oracle Utilities Meter Data Management and Oracle Utilities Customer To Meter include a number of standard timeliness and quality aggregation processes delivered as part of the base product that can be used with Oracle Utilities Analytics Visualization (OUAV). These aggregate measurement data (including quantities and counts) for constituent measuring components based on the following dimensions: Postal, City, Head-End, Device Type, Usage Calculation Group, Market and Service Provider, and Service Type.

The table below lists the names (and business object codes) for these aggregators, along with the corresponding Oracle Utilities Analytics Visualization subject area.

Copyright © 2026, Oracle and/or its affiliates.

Aggregator	Description
Measurement Timeliness Quantity Aggregator Business Object: D2-MsrmtTimelinessQuantityAggr OUAV Subject Area: Meter - Aggregated Timeliness Quantity	Aggregates measurement quantities that arrived on time or are late.
Measurement Timeliness Count Aggregator Business Object: D2-MsrmtTimelinessCountAggr OUAV Subject Area: Meter - Aggregated Timeliness Count	Aggregates measurement counts that arrived on time or are late.
Measurement Quality Count Aggregator Business Object: D2-MsrmtQualityCountAggregator OUAV Subject Area: Meter - Aggregated Measurement Count	Aggregates measurement counts and distributes the constituents' counts across Value Identifiers based on condition codes.
Measurement Measured Quantity Aggregator Business Object: D2-MeasuredQuantityAggregator OUAV Subject Area: Meter - Aggregated Measurement Quantity	Aggregates measurement quantities and distributes the constituents' measurements across Value Identifiers based on condition codes.

Refer to the Oracle Utilities Analytics Visualization User Guide for more information about Oracle Utilities Analytics Visualization subject areas.

In addition, the base package also includes measurement business objects used to store aggregated measurement data. These include:

- Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- Quality Count Measurement (D2-QualityCountMsrmt)
- Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)

Configuring Timeliness and Quality Aggregation for Use with Oracle Utilities Analytics Visualization

This topic outlines the configuration needed for timeliness and quality aggregations used with Oracle Utilities Analytics Visualization.

Master Configuration

Create a Timeliness Master Configuration, defining the following:

- **Heating Degree Days Factor**: A number-based factor that contains heating degree days. These are aggregated and stored on the Measurement Measured Quantity Aggregator.
- **Cooling Degree Days Factor**: A number-based factor that contains cooling degree days. These are aggregated and stored on the Measurement Measured Quantity Aggregator.
- **Number of Hours to Consider IMD as Late**: The number of hours after which an initial measurement is considered late.

Copyright © 2026, Oracle and/or its affiliates.

- **Buckets**: Value Identifiers that specify the late buckets used by the Measurement Timeliness Count and Measurement Timeliness Quantity aggregators.

Extendable Lookup: BI Aggregation — Usage Group Mapping

If your implementation makes use of dynamic usage calculation group determination on usage subscriptions (via the **Calculation Group Determination Override Algorithm** on the usage subscription type, the **Rate History** collection on the usage subscription, and the Customer Rate Schedule extendable lookup (D2-CCBRateScheduleLookup)), you will need to configure the BI Aggregation Usage Group Mapping extendable lookup (D2-UsageCalculationGroupLookup) with the usage calculation groups you wish to aggregate. If in the future you add new usage calculation groups, you will also need to add those usage calculation groups to this extendable lookup if you want them to be aggregated.

Note that an aggregation measuring component will be created for all dimension combinations and each usage calculation group in the extendable lookup (this is done to alleviate the need to execute the usage group determination algorithm for all usage subscriptions during the dimension scanning process).

> **Note**
>
> Configuring this extendable lookup is required ONLY if using dynamic usage calculation group determination.

Measuring Component Types

Create a master aggregator measuring component type and sub aggregator measuring component types for the four types of aggregators outlined above. Details for each aggregator measuring component type are listed below.

> **Note**
>
> When creating the master aggregator measuring component type, we recommend setting the **Aggregation Horizon** at 7 days or less. See Aggregation Recommendations for more information.

Measurement Measured Quantity Aggregator

- **Measuring Component Type Business Object**: Master Measurement Aggregator Type (D2-MasterMsrmtAggregatorType)
- **Measuring Component Business Object**: Measurement Measured Quantity Aggregator (D2-MeasuredQuantityAggregator)
- **Measurement Business Object**: Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	Regular kWh	Kilowatt-Hours
Value 02	Estimated kWh	Kilowatt-Hours

Copyright © 2026, Oracle and/or its affiliates.

Value Identifier Type	Description	Unit of Measure
Value 03	User-Edited kWh	Kilowatt-Hours
Value 06	Count	Count
Value 07	Heating Degree	Fahrenheit
Value 08	Cooling Degree	Fahrenheit
Value 09	Ave kWh	Kilowatt-Hours

- **Sub Aggregator MC Types** (see below):
  - Measurement Quality Count Aggregator Type
  - Measurement Timeliness Count Aggregator Type
  - Measurement Timeliness Quantity Aggregator Type

Measurement Quality Count Aggregator

- **Measuring Component Type Business Object**: Sub Measurement Aggregator Type (D2-SubMeasurementAggType)
- **Measuring Component Business Object**: Measurement Quality Count Aggregator (D2-MsrmtQualityCountAggregator)
- **Measurement Business Object**: Quality Count Measurement (D2-QualityCountMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	Regular Count	Count
Value 02	Estimated Count	Count
Value 03	User-Edited Count	Count
Value 04	N Meas/No IMD Count	Count
Value 05	No Meas/IMD Exists Count	Count
Value 06	Read Outage Count	Count
Value 07	Read Other Count	Count
Value 08	Missing Count	Count

Measurement Timeliness Count Aggregator

- **Measuring Component Type Business Object**: Sub Measurement Aggregator Type (D2-SubMeasurementAggType)
- **Measuring Component Business Object**: Measurement Timeliness Count Aggregator (D2-MsrmtTimelinessCountAggr)
- **Measurement Business Object**: Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours

Copyright © 2026, Oracle and/or its affiliates.

Value Identifier Type	Description	Unit of Measure
Value 01	On Time Count	Count
Value 02	Late Count	Count
Value 03	Very Late Count	Count
Value 04	Very, Very Late Count	Count
Value 05	Missing Count	Count

Measurement Timeliness Quantity Aggregator

- **Measuring Component Type Business Object**: Sub Measurement Aggregator Type(D2-SubMeasurementAggType)
- **Measuring Component Business Object**: Measurement Timeliness Quantity Aggregator (D2-MsrmtTimelinessQuantityAggr)
- **Measurement Business Object**: Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	On Time kWh	Kilowatt-Hours
Value 02	Late kWh	Kilowatt-Hours
Value 03	Very Late kWh	Kilowatt-Hours
Value 04	Very, Very Late kWh	Kilowatt-Hours

Activity Type

Create a Measurement Quantity Scanner activity type, based on the following business objects:

- **Business Object**: Measurement Quantity Scanner Type
- **Related Transaction Business Object**: Measurement Quantity Scanner

Timeliness and Quality Aggregation Processing for Use with Oracle Utilities Analytics Visualization

This topic describes the processes involved in running timeliness and quality aggregation processing for use with Oracle Utilities Analytics Visualization.

Execute Measurement Quantity Scan

Create an activity of the Measurement Quantity Scanner activity type, and process the activity (by clicking **Scan** in the **Record Action** section in the **Activity** zone).

This process uses the Measurement Quality and Timeliness Dimension Scanner batch control (D1-MQTDS) which creates measuring component aggregators that will also serve as the measuring component dimensions. This process will create a measuring component aggregator for each unique combination of Postal Code, City, Device Type, Head-End System,

Copyright © 2026, Oracle and/or its affiliates.

Usage Group, Market, Service Type, Geographic Code, Manufacturer/Model, Service Provider (where Market Relationship Type is specified on the dimension scanner activity).

> **Note**
>
> The Measurement Quality and Timeliness Dimension Scanner batch control (D1-MQTDS) supports multi-threading.

This step will create aggregator measuring components for all **Valid MC Types to Aggregate** defined on the master aggregator type (Measurement Measured Quantity Aggregator).

The created aggregator measuring component's characteristics will contain the Postal Code, City, Device Type, Head-End System, Usage Group, Market, Service Type, Geographic Code, Manufacturer/Model, Service Provider information.

Execute Aggregation

Once the measuring component aggregators have been created, run the Aggregation Monitor (D2-AGG) batch process. This will process ALL active master aggregators (together with the linked sub aggregators) that satisfy the batch filter parameters. Aggregated measurements will be created for the span of the aggregator horizon which is the current date less the horizon days in intervals defined on the master aggregation measuring component type (Measurement Measured Quantity Aggregator).

Condition Top Range and Condition Bottom Range parameters on the Aggregate Measurement Counts and Quantity (D2-AGG-MCQ) algorithm (an Enter algorithm on the Aggregate state of the Measurement Measured Quantity Aggregator (D2-MeasuredQuantityAggregator) business object) define condition ranges for quantity and count aggregation buckets.

This batch process should be run on a scheduled reoccurring basis.

Aggregated Data

Aggregated measurements are created in the Measurement (D1_MSRMT) and Aggregation Measurement (D1_AGG_MSRMT) tables, using the following base package measurement business objects:

- Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- Quality Count Measurement (D2-QualityCountMsrmt)
- Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)

Oracle Utilities Analytics Visualization Fact views access the Aggregation Measurement table.

Oracle Utilities Analytics Visualization Dimension views access the Measuring Component and Measuring Component Characteristics tables.

Consumption Analytics Aggregations Overview

This section outlines the configuration needed to support integration with Oracle Utilities Analytics Visualization for the following consumption-based analytics:

- Usage by Network Location
- Usage by Region

Copyright © 2026, Oracle and/or its affiliates.

- Usage by Customer Classification
- Unaccounted for Losses

These analytics are accessed in Oracle Utilities Analytics Visualization (OUAV) via the following subject areas:

Analytics	OUAV Subject Areas
Usage by Network Location Usage by Region	Meter - Distribution Nodes
Usage by Customer Classification	Meter - Customer Classification
Unaccounted for Losses	Meter - Downstream Usage Meter - Downstream Service Points Meter - Facility Usage Meter - Facilities

- Configuring Dynamic Aggregation for Consumption Analytics
- Dynamic Aggregation Processing for Consumption Analytics

Configuring Dynamic Aggregation for Consumption Analytics

This section outlines the configuration needed for consumption analytics aggregations used with Oracle Utilities Analytics Visualization.

Consumption analytics leverage data generated through dynamic aggregation, and requires configuration of the following objects:

- Data Sources
- Aggregator Measuring Component Types
- Aggregation Groups
- Measuring Component Sets

Refer to **Dynamic Aggregation** for more information about configuring dynamic aggregation.

Note: The configuration outlined below is based on data in the demonstration database. This sample configuration uses Electric service for Usage by Network Location, Region, and Customer Classification, and Gas service for Unaccounted for Losses.

Data Sources

Create the following data sources, based on the Measurements from US Service Points (D1-DataSourceMeasurements) business object:

For Usage by Network Location, Usage by Region, and Usage by Customer Classification (Electric)

Field / Section	Value
Data Source	CM-E-KWH-60-TRANS
Description	Electric kWh 60min Transformer Interval Measurements
Status	Active
Data Source Class	Measurements from US Service Points
Interval / Scalar	Interval

Copyright © 2026, Oracle and/or its affiliates.

Field / Section	Value
Sourced Measuring Component Type	

Measuring Component Type	Value Identifier Type
Measuring Component Types for measuring components to be aggregated	Measurement

For Unaccounted for Losses (Gas)

Field / Section	Value
Data Source	CM-G-CCF-60-FACIL
Description	Gas CCF 60min Facility Interval Measurements
Status	Active
Data Source Class	Measurements from US Service Points
Interval / Scalar	Interval
Sourced Measuring Component Type	

Measuring Component Type	Value Identifier Type
Measuring Component Types for measuring components to be aggregated	Measurement

Aggregator Measuring Component Types

Create the following aggregator measuring component types, based on the Dynamic Aggregator - Type (D1-AggregationIntervalType) business object:

For Usage by Network Location, Usage by Region, and Usage by Customer Classification (Electric)

Field / Section	Value
Measuring Component Type	CM-E-I-AGG-KWH-60-TRANS
Description	Electric - Interval - Aggregation - kWh 60min Transformer Load
Measuring Component Business Object	Dynamic Aggregator - Interval (D1-AggregatorInterval)
Measurement Business Object	Aggregation Measurement (D1-AggregationMeasurement)
Measuring Component Class	Aggregator
Service Type	Electric
Allow Negative Consumption	Allowed
Consumptive/Subtractive	Consumptive
Interval Size	01:00:00
Data Source	Electric kWh 60min Transformer Interval Measurements

Copyright © 2026, Oracle and/or its affiliates.

Field / Section	Value
Value Identifiers	

Value Identifier Type	Short Hand Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours

For Unaccounted for Losses (Gas)

Field / Section	Value
Measuring Component Type	CM-G-I-AGG-CCF-60-FACIL
Description	Gas - Interval - Aggregation - CCF 60min Downstream
Measuring Component Business Object	Dynamic Aggregator - Interval (D1-AggregatorInterval)
Measurement Business Object	Aggregation Measurement (D1-AggregationMeasurement)
Measuring Component Class	Aggregator
Service Type	Gas
Allow Negative Consumption	Allowed
Consumptive/Subtractive	Consumptive
Interval Size	01:00:00
Data Source	Gas CCF 60min Facility Interval Measurements
Value Identifiers	

Value Identifier Type	Short Hand Description	Unit of Measure	SQI	Value Calculation Method
Measurement	CCF	100 Cubic Feet (Gas)		Sum
Value 01	Count	Count		Count
Value 02	Average	100 Cubic Feet (Gas)	Average	Average
Value 03	Min	100 Cubic Feet (Gas)	Minimum	Min
Value 04	Max	100 Cubic Feet (Gas)	Maximum	Max

Aggregation Groups

Create the following aggregation groups based on the Aggregation Group (D1-AggregationGroup) business object:

For Usage by Network Location and Usage by Region (Electric)

Field / Section	Value
Aggregation Group	CM-E-CONS-TRANS
Description	Electric Dynamic Consumption

Copyright © 2026, Oracle and/or its affiliates.

Field / Section	Value
Status	Finalized
Aggregation Category	Analytics
Time Zone	US Pacific Time
Aggregation Schedule	• **Aggregation Schedule Type**: Defined Lag • **Aggregation Cut-Off Time**: 0:00:00 • **Aggregation Horizon**: 24:00:00 • **Aggregation Lag**: 48:00:00
Aggregation Measuring Component Sets	

Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class
10	Electric - Consumption - Transformer - Interval	Manual	Aggregation Foundation

For Usage by Customer Classification (Electric)

Field / Section	Value
Aggregation Group	CM-E-CONS-PROF
Description	Consumption - Profile Class
Status	Finalized
Aggregation Category	Analytics
Time Zone	
Aggregation Schedule	• **Aggregation Schedule Type**: Defined Lag • **Aggregation Cut-Off Time**: 0:00:00 • **Aggregation Horizon**: 24:00:00 • **Aggregation Lag**: 48:00:00
Aggregation Measuring Component Sets	

Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class
10	Consumption - Profile Class - Interval	Manual	Aggregation Foundation

For Unaccounted for Losses (Gas)

Field / Section	Value
Aggregation Group	CM-G-LOSS
Description	Gas Dynamic Consumption
Status	Finalized
Aggregation Category	Analytics
Time Zone	US Pacific Time

Copyright © 2026, Oracle and/or its affiliates.

Field / Section	Value
Aggregation Schedule	• **Aggregation Schedule Type**: Defined Lag • **Aggregation Cut-Off Time**: 0:00:00 • **Aggregation Horizon**: 24:00:00 • **Aggregation Lag**: 48:00:00
Aggregation Measuring Component Sets	

Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class
10	Gas - Consumption - Downstream - Interval	Automatic	Aggregation Foundation

Measuring Component Sets

Create the following measuring component sets based on the Aggregation Foundation Set (D1-AggregationFoundationSet) business object:

For Usage by Network Location and Usage by Region (Electric)

Field / Section	Value
Measuring Component Set	CM-E-CONS-TRANS
Status	Active
Description	Electric - Consumption - Transformer - Interval
Measuring Component Type	Electric - Interval - Aggregation - kWh 60min Transformer Load
Aggregation Group	Electric Dynamic Consumption
Measuring Component Set Class	Aggregation Foundation
Allow Partial Constituent Aggregation	Yes
Extract	Do Not Extract
General Processing	
Criteria Processing	• **Non-Individually Managed Formula**: TFORM
Dimensions	

Source Type	Source Entity	Column/Type	Represent Missing Data

Dynamic Aggregation Processing for Consumption Analytics

Processing of dynamic aggregation for consumption analytics uses the standard approach to dynamic aggregation execution. Refer to **Dynamic Aggregation** in the *Business User Guide* for more information about dynamic aggregation execution and processing.

Oracle Utilities Network Management System

- Outage Care Integration
- The Big Picture of Outage Care Integration
- Customer Information Integration
- Interfacing Outage Calls
- Outage Inquiry
- Setting Up The System To Enable Outage Integration

Copyright © 2026, Oracle and/or its affiliates.

Outage Care Integration

The following section describes functionality provided for the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

The Big Picture of Outage Care Integration

Oracle Utilities Customer Care and Billing is the central repository for customer information; for example, name, address, phone number, etc. Oracle Utilities Network Management System is the central repository for outage information; for example, outage calls, affected supply nodes, expected restoration time, etc.

In an integrated environment, each system provides information to the other system so that they can operate together seamlessly.

- The outage system uses the set of current customers to determine and manage outages to minimize their impact.
- The outage system is informed of outages captured in Oracle Utilities Customer Care and Billing.
- Oracle Utilities Customer Care and Billing uses the current status of an outage at a given premise for customer service.

Customer Information Integration

The outage system needs information about current customers to determine and manage outages to minimize their impact. The current customer information must be made available in Oracle Utilities Network Management System. This can be done via data synchronization.

Depending on the specific edge application and version you are using, there are components of the integration that use Sync Request for the change data capture step. The following points highlight how to get more information:

- Refer to your products integration to Oracle Utilities Network Management System Implementation Guide to configure the Sync Request and change data capture functionality.
- Review the Sync Request Business Objects provided by your product for NMS integration.
- Refer to Data Synchronization for a high level understanding of the process.

NOT_SUPPORTED

Refer to The Big Picture of Sync Requests for more information about synchronizing data.

Interfacing Outage Calls

The following points describe the integration:

Copyright © 2026, Oracle and/or its affiliates.

- Oracle Utilities Customer Care and Billing is able to record trouble calls for a particular service point that exists in the system, as well as for an unknown service point, i.e. a fuzzy call. For a fuzzy call, the caller must provide either a street intersection, or a street segment.
- When an outage call is created and sent to the external system, an algorithm on the outage call business object is responsible for creating an outbound message that's sent to the external system. This is a real-time synchronous interface between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.
- Oracle Utilities Network Management System processes the Calls table and creates Incidents.

NOT_SUPPORTED

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage call integration.

Outage Inquiry

Oracle Utilities Customer Care and Billing provides query transactions that can be used to make real-time synchronous calls to NMS and inquire on one of the following:

- Job History for a particular customer, service point, location or call identifier
- Call History for a particular customer, service point, location or call identifier
- Planned Outage Jobs for a particular service point

NOT_SUPPORTED

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage query integration.

The product also supports the option of storing key Outage Event information in snapshot database tables for the purpose of reporting on active, planned and recently resolved outages. This information is made available by Oracle Utilities Network Management System as part of the integration flow that notifies impacted customers of outage event updates. The outage notification integration flow can be enabled to also share records for the latest updates of an outage event. Having outage data readily available within the application allows for more robust inquiries and insight analysis that does not overload the outage management system with real-time calls.

NOT_SUPPORTED

Refer to the *Oracle Utilities Notifications Hub Configuration Guide* for information about enabling outage data snapshot integration. When enabled, outage data is interfaced in using the **Outage Event Notifications** (C1-OutageEventNotifications) web service.

Copyright © 2026, Oracle and/or its affiliates.

You may review outage snapshot data in the following portals:

- Outage Event.
- Customer Outage Information.

Setting Up The System To Enable Outage Integration

The following section provides an overview of how to enable the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

- External System Setup
- Define Characteristic Types
- Schema Constants - Feature Configuration
- NMS Outage Integration - Master Configuration
- Outage Notification Preferences

External System Setup

An external system must be setup in order integrate Oracle Utilities Network Management System. Define message senders for the following Outbound Message Types and associate them to the external system:

- NMS Outage Call (C1-NMSOUTCAL)
- NMS Job History Query (C1-NMSJOBHST)
- NMS Call History Query (C1-NMSCALHST)
- NMS Planned Outages Query (C1-NMSPLNOUT)

For synchronizing outage related notification preferences to NMS, define a message sender for the Outbound Message to Notify Edge Applications (C1-NTFOUTMSG) Outbound Message Type and associate it to the external system.

Once the external system is defined, configure the so the system knows which external system to use for outage queries.

Define Characteristic Types

The following characteristic types must be defined to facilitate Outage integration:

NOT_SUPPORTED

Refer to Defining Characteristic Types for information on how to set up characteristic types.

Outage Group Code Characteristic Type

These characteristics are used to describe the outage problem.

Copyright © 2026, Oracle and/or its affiliates.

- Create at least one pre-defined characteristic type
- For each characteristic type, define its list of valid values
- Include Service Task Type in the characteristic entity collection

> **Note**
>
> **Integration with Outage Management**. The outage codes must be defined in both Oracle Utilities Customer Care and Billing and the outage management system. Refer to your Oracle Utilities Network Management System documentation for information about defining the outage codes there.

Critical Customer Characteristic Type

These characteristics are used to associate a service point with one or more critical customer identifiers (e.g., medical, key account, government, etc.).

- Create a pre-defined characteristic type
- Define one or more critical customer predefined values
- Include Service Point in the characteristic entity collection
- Associate the characteristic and pre-defined values to the Critical Customer Types Characteristic Mapping section of the NMS Sync Integration Mater Configuration.

> **Note**
>
> **Integration with Outage Management**. The outage codes must be defined in both Oracle Utilities Customer Care and Billing and the outage management system. Refer to your Oracle Utilities Network Management System documentation for information about defining the outage codes there.

Contact Name Characteristic Type

This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Contact Name Characteristic Type feature option

Contact Number Characteristic Type

This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Contact Number Characteristic Type feature option

Call Identifier Characteristic Type

Copyright © 2026, Oracle and/or its affiliates.

This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Identifier Characteristic Type feature option

Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Street Name Characteristic Type feature option

Cross Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Cross Street Name Characteristic Type feature option

Block Number Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call Block Number Characteristic Type feature option

City Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on theSchema Constants Feature Configuration using the Outage Call City Characteristic Type feature option

State Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection

Copyright © 2026, Oracle and/or its affiliates.

- Specify this characteristic type on the Schema Constants Feature Configuration using the Outage Call State Characteristic Type feature option

Schema Constants - Feature Configuration

Create a feature configuration with the type Schema Constants. Populate entries for all the options listed below.

> **Note**
>
> **Only one**. The system expects only one Schema Constants feature configuration to be defined.

Configure the options for your interaction with the outage system.

> **Note**
>
> Your implementation may define additional options types. You do this by adding new lookup values to the lookup field F1CN_OPT_TYP_FLG.

Option	Description
Outage Call Contact Name Characteristic Type	This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call Contact Number Characteristic Type	This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call Identifier Characteristic Type	This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call Street Name Characteristic Type	This is used to link the street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.

Copyright © 2026, Oracle and/or its affiliates.

Outage Call Cross Street Name Characteristic Type	This is used to link the cross street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call Block Number Characteristic Type	This is used to link the block number supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call City Characteristic Type	This is used to link the city supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.
Outage Call State Characteristic Type	This is used to link the state supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to Defining Service Order Options for more information. Only one value is allowed for this option.

NMS Outage Integration - Master Configuration

The integration with Oracle Utilities Network Management System (NMS) requires the setup of master configuration data that controls the processing of master data synchronization and outage management operations.

Navigate to **Admin**, and then **General**, and then **Master Configuration**

Set up the following master configurations:

- **NMS Outage Integration Master Config**: This master configuration relates to the outage call and outage query integration with NMS.
- **NMS Sync Integration Master Config**: This master configuration relates to the service point based master data synchronization to NMS.

Refer to the embedded help for more details on how each section is configured.

Outage Notification Preferences

The system supports the ability to synchronize notification preferences that are owned by other edge applications. For example, during an outage event, Oracle Utilities Network Management System (NMS) is the system responsible for sending notifications to impacted customers that are subscribed or opted-in to receive notifications for these events. To support this functionality, notification preference statuses for outage related notification types that are updated under a customers account must be synchronized to NMS.

To configure your system to synchronize outage related notification preferences to NMS, perform the following steps:

Copyright © 2026, Oracle and/or its affiliates.

- Configure the outage notification types that are owned by NMS (e.g. Planned Outage, Unplanned Outage, Outage Started, Estimated Restoration Type, Outage Restored). Notification types can be configured as template based subscription, or template based parent/individual push. Refer to Setting Up Notification Preference Options for more information.
- Configure the **Notification Preferences** master configuration. Under the master configuration's Edge Application Notification section, add the notification types along with the edge application (Network Management System) and External System/Outbound Message Type for each entry. Refer to the embedded help for more details.

Once configured, the **Notification Preference Sync Initial Load (C1–NCPIL)** batch process is used to create initial synchronization requests. This batch control creates initial synchronization requests for Notification Contact Preference data (Maintenance Object C1–NT-PREF). The maintenance object and sync business object (C1-NtfContactPreferenceSync) are plugged in as parameters to the batch job.

For ongoing synchronization requests, the **Sync Request Monitor batch control (F1-SYNRQ)** is responsible for monitoring synchronization requests in the Pending state and transitions them to the Determine if Sync Needed state. Use the following parameters when running the F1-SYNRQ batch job:

- Maintenance Object: F1-SYNC REQ
-
- Restrict By Business Object: C1-NtfContactPreferenceSync
- Restrict By Status Code: PENDING

> **NOT_SUPPORTED**
>
> Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage notification integration.

Oracle Utilities Customer Program Cloud Service

The Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Customer Program Cloud Service provides the following functionality:

- Initial and incremental extract of customer data including persons, service points, and service agreements from Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing).
- Initial and incremental import of customer data into Oracle Utilities Customer Program Management Cloud Service.

This section describes the customer data extract functionality within Oracle Utilities Customer Care and Billing (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) used with this integration.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> This integration is only used if Oracle Utilities Customer Cloud Service and Oracle Utilities Customer Program Management Cloud Service are deployed in separate environments.

- Customer Data Extract

Customer Data Extract

Customer information including persons, service points and service agreements in Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) can be extracted and sent to Oracle Utilities Customer Program Management Cloud Service (or Oracle Utilities Customer Program Management) for use in enrolling customers in demand response programs.

- An initial extract is used to duplicate customer information data as of a given date in Oracle Utilities Customer Cloud Service in Oracle Utilities Customer Program Management Cloud Service. This is typically done during initial set up of the Digital Asset Cloud Service implementation.
- Following the initial extract, audit algorithms track new data and changes to existing data and create data synchronization requests, which can be used to create incremental extract files via batch processing.

Extracted data is sent to Customer Program Management in a delimited file, which is uploaded into the system via batch processing and data synchronization. See **Importing Customer-Related Data from a Customer Information System** in the *Oracle Utilities Customer Program Management Cloud Service User Guides* for more information about the import process.

Extract Process Overview

This section provide an overview of the extract process and outlines the various system objects used for each type of data (contacts, service points, and service agreements). The overall process is as follows:

1. An initial "extract" batch process is used to extract customer data into files that can be imported into Digital Asset Cloud Service.
2. Audit algorithms on the Contact, Service Point, and Service Agreement maintenance objects create synchronization requests.
3. Sync requests are processed using the specific batch processes (a separate batch control is provided for contacts, service points, and service agreements) to create incremental extracts.

Initial Load vs. Incremental Downloads

Customer data can be extracted in one of two modes: Initial or Incremental.

Initial extracts are used when setting up the system to export contact, service point, and service agreement data from Oracle Utilities Customer Cloud Service.

Incremental extracts are used to update customer data in Customer Program Management Cloud Service as customer data changes in Oracle Utilities Customer Cloud Service.

Copyright © 2026, Oracle and/or its affiliates.

Initial Extract Batch Processes

Extract files are created using object-specific "extract" batch processes. See Extract Process Object Summary below for the specific "extract" batch process used for each type of customer data. These are used only for the initial extract.

These processes use the following parameters:

- **File Name**: The name of the extract file. File names can use wildcards (Required)
- **Flat Path**: The file location where the extract file is created. This can be a file location on a local server or a location in Object Storage. See Referencing URIs in the *Framework Administrative User Guide* for more information. (Required)
- **File Format**: The file format used for extract file. This should be FIXD. Each extract type has its own format.
- **Low SP Id Override Value**: A service point ID used to define the low value in a a range of IDs to limit the data extracted.
- **High SP Id Override Value**: A service point ID used to define the high value in a a range of IDs to limit the data extracted.

Use the **Batch Control** portal to learn more about these and other parameters used by these batch processes.

Audit Algorithms and Sync Request Business Objects

Sync requests are created by audit algorithms, and are based on data specific sync request business objects. See Extract Process Object Summary below for the specific audit algorithms and "Sync Request" business objects used for each type of customer data.

The table below outlines the stages of the sync request lifecycle. Use the **Business Object** portal to learn more about these business objects and the details of each lifecycle state.

State	Notes
Pending	Sync requests begin in this state. An Enter algorithms creates the initial snapshot of the Customer Program Management Cloud Service (CPMCS) data (contact, service point, or service agreement). The Sync Request Monitor (F1-SYNRQ) batch process is used to transition sync requests in this state to the Determine if Sync Needed state.
Determine if Sync Needed	An Enter algorithms creates the final snapshot of the CPMCS data. An Enter algorithms compares the initial and final snapshots. If there is no difference, the sync request moves to the Discarded state. Otherwise, the request moves to the Send Request state,
Discarded	Sync requests for which there is no different between the initial snapshot and final snapshot are sent to this state.
Send Request	An Enter algorithm creates a General Process record for the sync request. The request then moves to the Awaiting Acknowledgement state.

Copyright © 2026, Oracle and/or its affiliates.

State	Notes
Awaiting Acknowledgement	Requests remain in this state until the system receives an acknowledgement that CPMCS has received the data contained in the request.
Synchronized	Sync requests enter this state following the Awaiting Acknowledgement state when the system receives an acknowledgement that CPMCS has received the data contained in the request. If an error occurs, the request moves to the Synchronized with Error state.
Error	Sync requests enter this state if an error occurs while in the Awaiting Acknowledgement state. An Enter algorithm creates a To Do entry.
Canceled	Sync requests enter this state if canceled in either the Error or Synchronized with Error states.
Synchronized with Error	Sync requests enter this state if an error occurs while in the Synchronized state . An Enter algorithm creates a To Do entry.

Incremental Extract Batch Processes

Incremental extract files are created from General Process records using "Incremental Extract" batch processes. See below for the specific "Incremental Extract" batch processes used for each type of customer data. These should be run as needed for incremental updates.

Use the **Batch Control** portal to view the parameters used by these batch processes.

Extract Process Object Summary

The table below lists the batch controls, algorithms, and business objects used by each type of customer data.

Object Type	Initial Extract Batch Process	Audit Algorithms	Sync Request Business Object	Incremental Extract Batch Process
Person	Migrate Person to DACS Contact (C1-DCTIL)	Sync Person as DACS Contact (C1_DAPERSYNC)	Sync CCB Person to DACS Contact (C1-DACSContactSyncRequest)	Contact Incremental Sync Batch Control (C1-DCTEX)
Service Point	Migrate CCB SP to DACS MSP (C1-DSPIL)	Sync Service Point as DACS Metered Service Point (C1_DASPSYNC)	Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest)	SP Incremental Sync Batch Control (C1-DSPEX)
Service Agreement	Migrates SA to DACS Metered Service (C1-DMSIL)	Sync Service Agreement as DACS Metered Service (C1_DASASYNC)	Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest)	MS Incremental Sync Batch Control (C1-DMSEX)

Copyright © 2026, Oracle and/or its affiliates.

Acknowledgement Messages

When Customer Program Management Cloud Service processes incremental updates, it can send an acknowledgement back to Customer Cloud Service.

Refer to the Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Customer Program Cloud Service documentation for more information about configuring Customer Program Management Cloud Service to send acknowledgements.

- Extracting Persons
- Extracting Service Points
- Extracting Service Agreements

Extracting Persons

This topic provides additional details related to extracting Persons from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

> **Note**
>
> Persons are converted to Contacts in Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for persons are created using the Migrate Person to DACS Contact (C1-DCTIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Person as DACS Contact (C1_DAPERSYNC) audit algorithm tracks new person data and changes to existing person data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Person sync requests are based on the Sync CCB Person to DACS Contact (C1-DACSContactSyncRequest) business object.

Incremental Extract Batch Process

Incremental person extract files are created from sync requests and General Process records using the Contact Incremental Sync Batch Control (C1-DCTEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Person (Contact) Extract File Format

Person (Contact) extract files use the following tab-separated values format:

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
External Reference Id	Optional	The contact's reference ID in the CIS application
Change Date Time	Optional	The date and time on which the contact was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same contact.
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**
External Id	Required	The contact's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID.
Contact Type	Required	The type of contact. When importing data from Customer to Meter or Customer Cloud Service this will be either Person or Business. If the provided contact type has not been defined as a Program Subscription Contact Type in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Contact Type used in Digital Asset Management / Digital Asset Cloud Service.
Name	Required	The contact's name. For format for this is <FIRST_NAME> <LAST_NAME> (note the space between them.
Home Phone	Optional	A home phone number associated with person-type contacts.
Mobile Phone	Optional	A mobile phone number associated with person-type contacts.
Phone	Optional	A phone number associated with business-type contacts.
Email	Optional	An email address for the contact.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Life Support Sensitive Load	Required	A flag that indicates if the contact requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Digital Asset Management / Digital Asset Cloud Service
Life Support Sensitive Load Description	Optional	An optional description for Life Support Sensitive Load.
Is Erased	Optional	A flag that indicates if the contact has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default) **Applicable only to Incremental Uploads** This should be set to "N" if Object Erasure is not supported in the CIS application.

Sample Record

Below is a sample file:

```
EXTREFCON11    2023-06-21T13:15:00-08:00    F1IC    EXTCONTACT1    P    John
Smith    (510)777-8888    (510)777-9090    (510)556-4556
johnsmith@gmail.com    false    None    N
```

Extracting Service Points

This topic provides additional details related to extracting service points from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for service points are created using the Migrate CCB SP to DACS MSP (C1-DSPIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Point as DACS Metered Service Point (C1_DASPSYNC) audit algorithm tracks new service point data and changes to existing service point data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Service point sync requests are based on the Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest) business object.

Copyright © 2026, Oracle and/or its affiliates.

Incremental Extract Batch Process

Incremental service point extract files are created from sync requests and General Process records using the SP Incremental Sync Batch Control (C1-DSPEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Point Extract File Format

Service point extract files use the following tab-separated values format:

Field Name	Optional/Required	Notes
External Reference Id	Optional	The metered service point's reference ID in the CIS application.
Change Date Time	Optional	The date and time on which the metered service point was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same metered service point.
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**
External Id	Required	The metered service point's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Point External ID.
Metered SP Type	Required	The type of metered service point. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Point Type. If the provided metered service point type has not been defined as a Metered Service Point Type in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Metered Service Point Type used in Customer Program Management / Customer Program Management Cloud Service.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
SP Source Status	Required	The metered service point's source status. Valid values are values for the Source Status (SP_SRC_STAT_FLG) lookup, and include: • **D1CN (Connected)** • **D1DC (Disconnected)**
Division	Optional	The metered service point's division. If the provided division has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Division used in Customer Program Management / Customer Program Management Cloud Service.
External Premise Id	Optional	The ID of the premise associated with the metered service point in the CIS application.
Time Zone	Required	The time zone in which the metered service point is located.
Country	Optional	The country in which the metered service point is located.
Postal	Optional	The metered service point's postal code.
Address 1	Optional	The metered service point's address.
Address 2	Optional	Additional details regarding the metered service point's address (if applicable).
Address 3	Optional	Additional details regarding the metered service point's address (if applicable).
Address 4	Optional	Additional details regarding the metered service point's address (if applicable).
City	Optional	The city in which the metered service point is located.
County	Optional	The county in which the metered service point is located.
State	Optional	The state in which the metered service point is located.
Longitude	Optional	The metered service point's longitude.
Latitude	Optional	The metered service point's latitude.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Life Support Sensitive Load Flag	Required	A flag that indicates if the metered service point requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Customer Program Management / Customer Program Management Cloud Service
Life Support Sensitive Load Description	Optional	An optional description for Life Support Sensitive Load.
Status	Required	The current state of the metered service point. Valid values are "ACTIVE" and "INACTIVE".
Is OK to Enter?	Optional	
SP Warning	Optional	
SP Instructions	Optional	
SP Instructions Details	Optional	
Is Key	Optional	
Key Id	Optional	
Device Location	Optional	
Device Location Details	Optional	

Sample Record

Below is a sample file:

```
EXTREFMSP11    2023-06-21T14:01:00-08:00    F1IC    EXTMSP1    ZZ-EXTMSPTYPE

41.501120    false        ACTIVE
```

Extracting Service Agreements

This topic provides additional details related to extracting service agreements from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Customer Program Management Cloud Service.

Initial Extract Batch Process

Initial extract files for service agreements are created using the Migrates SA to DACS Metered Service (C1-DMSIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Agreement as DACS Metered Service (C1_DASASYNC) audit algorithm tracks new service agreement data and changes to existing service agreement data and creates data synchronization requests, which are used to create incremental extract files.

Copyright © 2026, Oracle and/or its affiliates.

Sync Request Business Object

Service agreement sync requests are based on the Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest) business object.

Incremental Extract Batch Process

Incremental service agreements extract files are created from sync requests and General Process records using the MS Incremental Sync Batch Control (C1-DMSEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Agreement Extract File Format

Service agreement extract files use the following tab-separated values format:

Field Name	Optional/Required	Notes
External Reference Id	Optional	The metered service's reference ID in the CIS application.
Change Date Time	Optional	The date and time on which the metered service was changed. **Applicable only for Incremental Uploads** Will be used to sequence processing in case there are multiple changes to the same metered service point.
Initial Load Sync Flag	Required	**A value that indicates the type of upload. Valid values are:** • **F1IL - Initial Load** • **F1IC - Incremental**
External Id	Required	The metered service's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Agreement External ID.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Metered Service Type	Required	The type of metered service. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Agreement Type. If the provided metered service point type has not been defined as a Metered Service Type in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Metered Service Type used in Customer Program Management / Customer Program Management Cloud Service.
External Contact ID	Optional	The ID of the contact associated with the metered service in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID.
External Account ID	Optional	An ID used to identify the account associated with the metered service record in the CIS application.
Start Date Time	Required	The date and time on which the metered service record started.
End Date Time	Optional	The date and time on which the metered service record ended or will end (if applicable).
Division	Optional	The metered service's division. If the provided division has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to the Division used in Customer Program Management / Customer Program Management Cloud Service.

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
SA Status	Optional	The metered service's status. If the provided status has not been defined as a Division in Customer Program Management / Customer Program Management Cloud Service an extendable lookup is used to map this value to a Status defined in Customer Program Management / Customer Program Management Cloud Service.
Rate Schedule List	Optional	A concatenated list of rate schedules and effective dates associated with the metered service. **Each row in this list is composed of the following:** • **Rate Schedule** • **Effective Date** Each element in the row will be delimited by comma (,). Each row in the list will be delimited by semi-colon (;). **For example:** **ERES-1,2022-01-01ERES-2,2021-01-01**
Metered SP List	Optional	A concatenated list of metered service points associated with the metered service. **Each row in this list is composed of the following:** • **External Metered SP Id (Required)** • **Start Date Time (Required)** • **End Date Time (Optional)** Each element in the row will be delimited by comma (,). Each row in the list will be delimited by semi-colon (;). **Example:** **6800401571,2022-12-13T14:30:00-05:00,1703304223,2022-12-13T14:30:00-05:00,**

Copyright © 2026, Oracle and/or its affiliates.

Field Name	Optional/Required	Notes
Is Erased	Optional	A flag that indicates if the customer has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default) **Applicable only to Incremental Uploads** This should be set to "N" if Object Erasure is not supported in the CIS application.

Sample Record

Below is a sample file:

```

Asset Management System Integration

The following section describes functionality provided for the integration with an asset management system, such as Oracle Utilities Work and Asset Management (OUWAM).

- Interfacing Service Calls
- Setting Up The System To Enable Asset Management System Integration

Interfacing Service Calls

Oracle Utilities Customer Care and Billing is able to record service calls for a particular service point in the system, as well as for an unknown service point, i.e. a fuzzy call. Service call information is sent to the asset management system that will process any work that may be required due to the service call.

When recording a service call, the system creates a service call process flow and assigns it a service call communication type. The process flow type and service call communication type are determined from the action method with Action Method Role of **Service Call**. See Action Method for more information about setting up action methods. Service call communication type defines the rules and controls for creating service call communication. It also defines the service call communication business object.

The system is delivered with the following objects that are used to record a service call:

- Process Flow Type **C1-SERVICECALL**
- Service Call Communication Type business object **C1-ServiceCallCommTaskType**
- Service Call Communication business object **C1-ServiceCallCommunication**

Refer to Service Calls for more details.

Setting Up The System To Enable Asset Management System Integration

The following section describes how to enable the integration between Oracle Utilities Customer Care and Billing and your asset management system.

- External System Setup
- WAM Integration Master Configuration

External System Setup

An external system must be setup to integrate with Oracle Utilities Work and Asset Management (WAM).

For sending service call information to WAM, define message senders for the following outbound message types:

- **New Service Call Communication Request Outbound Message (C1-SVCCALNEW)**. This is used to send new service call information.
- **Update Service Call Communication Request Outbound Message (C1-SVCCALUPD)**. This is used to send service call comments and service call cancel request.

For retrieving service call information from WAM, define message senders for the following outbound message types:

- **Service Call Search (C1-SVCCLSRCH)**. This is used by the service call search panel to retrieve service calls from the external system.
- **Service Call Details (C1-SVCCALDTL)**. This is used in the service call details pop up window to retrieve details of a service call from external system.
- **Retrieve Work Documents (C1-RETWRKDOC)**. This is used in the service call details pop up window to retrieve work documents related to a service call.

Once the external system is defined, configure the WAM Integration Master Configuration so the system knows which external system and outbound message types to use.

WAM Integration Master Configuration

The integration with Oracle Utilities Work and Asset Management (WAM) requires the setup of master configuration data that controls the processing of service call information.

To maintain master configuration, open **Admin**, and then **General**, and then **Master Configuration**

Set up the **CC&B WAM Integration** master configuration, which defines the external system and outbound message types to send and receive service call information. It also defines the URL of the WAM environment. This is used by the service call details pop-up window to render the service call hyperlink. The hyperlink is available if the user has access to the **Go To WAM (C1-GOTOWAM)** application service. Note that the login user to WAM should have access to the service call transaction. This authorization needs to be done in WAM.

Oracle Customer Experience for Utilities

This section provides configuration and implementation information used when Customer Cloud Service is used with Customer Experience for Utilities (CX4U). This includes:

Copyright © 2026, Oracle and/or its affiliates.

- Person Export: Batch controls and master configuration used to support export of person data for use with Customer Experience for Utilities.
- Person Export for Customer Experience for Utilities

Person Export for Customer Experience for Utilities

When integrating with Customer Experience for Utilities, all person records for individuals and business must be exported from Customer Cloud Service so they can be imported into, and synchronized between, all related Oracle Fusion systems. This involves defining mapping person and business values to corresponding values in the Oracle Fusion systems via a master configuration, and a pair of batch processes to export and synchronize the data.

Master Configuration

The CX4U Person Sync Mapping master configuration maps Customer Cloud Service person and business related values to their corresponding Fusion values for the purpose of an initial data export via a batch process. This includes the following:

- Phone Country Code
- Communication Types
- Person Characteristics
- Business Characteristics

On this master configuration, "internal" values are those used in Customer Cloud Service, and "external" values are those used in related Oracle Fusion systems.

Batch Processes

Two batch processes are used to export and synchronize person data.

- The **CX4U Export Person Information** (C1-PEREX) batch process exports person records into multiple files that can be used to perform an initial import of person information into Oracle Fusion to support Oracle Customer Experience for Utilities.
- After the initial import of records into Oracle Fusion, the **CX4U Update Person External ID** (C1-PERSY) batch process updates the External ID characteristics for Person records that exist in Oracle Fusion to reference their Oracle Fusion party number.
  Note: The **CX4U Update Person External ID** (C1-PERSY) batch process uses the CX4U Data Synchronization (CX4U) External System and the FA Person Synchronization (C1FsnPerSync) Message Sender to communicate with the Fusion systems to retrieve the Fusion party number. Refer to the External Systems and Message Sender sections for more information about these components.

Refer to the **Detailed Descriptions** of the CX4U Export Person Information (C1-PEREX) and CX4U Update Person External ID (C1-PERSY) batch controls for more information about parameters used with these batch processes.

Oracle Utilities Data Intelligence

- Defining Standard Measurement Identifiers

Defining Standard Measurement Identifiers

Copyright © 2026, Oracle and/or its affiliates.

Oracle Utilities Data Intelligence (OUDI) can perform data aggregation and enrichment on Advanced Metering Infrastructure (AMI) data extracted from Oracle Utilities Meter Solution Cloud Service and Oracle Utilities Customer Cloud Service. Data is extracted using Measurement Data Extract.

Enabling the extract process requires defining the data to extract which involves defining the "standard measurement identifiers" used by Data Intelligence in Meter Solution Cloud Service and Customer Cloud Service, and mapping those identifiers to specific combinations of Units of Measure (UOM), Time of Use (TOU), and Service Quantity Identifiers (SQI) for specific service types.

Extendable Lookups

The Standard Measurement Identifier (D1-StdMsrmtIdentifierLookup) extendable lookup is used to define standard measurement identifiers. Values for this extendable lookup include the following:

- **Standard Measurement Identifier**: A code for the identifier
- **Standard Service Type**: The basic or standard service type for the identifier, from the Standard Service Type (STD_SVC_TYPE_FLG) lookup.
- **Status**: The current status of the identifier
- **Description**: The label used for the identifier in the Meter Solution Cloud Service and Customer Cloud Service user interface.

As an example, the standard measurement identifier for consumed electric kilowatt hours is defined as follows:

- **Standard Measurement Identifier**: E-KWH-CONS
- **Standard Service Type**: Electric
- **Status**: Active
- **Description**: Electric kWh - Consumed

Master Configurations

A set of "Measurement Identification Configuration" master configurations are used to map relationships between "standard measurement identifiers" defined in the Standard Measurement Identifier (D1-StdMsrmtIdentifierLookup) extendable lookup and specific UOM/TOU/SQIs combinations per service type. There are three of these master configurations, one for each of the Standard Service Types used in the extendable lookup. These are:

- Measurement Identification - Electric Configuration (D1-MsrmtIdentifyElectricConfig)
- Measurement Identification - Gas Configuration (D1-MsrmtIdentifyGasConfig)
- Measurement Identification - Water Configuration (D1-MsrmtIdentifyWaterConfig)

Mappings in these master configurations are defined by the following:

- **Service Type**: The service type associated with a channel (see Service Types for more information)
- **Channel Identification**: Details regarding how to identify data for a channel, including
  - **Standard Measurement Identifier**: One or more standard measurement identifiers (from the Standard Measurement Identifier (D1-StdMsrmtIdentifierLookup) extendable lookup) for the channel

Copyright © 2026, Oracle and/or its affiliates.

- **Color Option**: The color used to display measurement data for this channel (from the Color Option (F1-Color) extendable lookup)
- **Measurement Value Identification**: One more UOM/TOU/SQI combinations that defines what the channel measures
  - **Unit of Measure**: The unit of measure for the combination, such as kWh, kW, and so on
  - **Time of Use**: The time of use period for the combination, such as On-Peak, Off-Peak, and so on
  - **Service Quantity Identifier**: The service quantity identifier for the combination, such as "Generated", "Consumed", and so on

For example, the following configuration could be used to map three standard measurement identifiers (Electric kWh - Consumed, Electric kWh - Generated, and Electric kW) to the "Electric Services" service type and define the UOM/TOU/SQI combinations for each.

- **Service Type**: Electric Service
- **Channel Identification**:
  - **Standard Measurement Identifier**: Electric kWh - Consumed
  - **Color Option**: Green 010
  - **Measurement Value Identification**:
    - **Unit of Measure**: Kilowatt Hour
    - **Service Quantity Identifier**: Consumed
  - **Measurement Value Identification**:
    - **Unit of Measure**: Kilowatt Hour
- **Standard Measurement Identifier**: Electric kWh - Generated
  - **Color Option**: Blue 010
  - **Measurement Value Identification**:
    - **Unit of Measure**: Kilowatt Hour
    - **Service Quantity Identifier**: Generated
- **Standard Measurement Identifier**: Electric Kilowatt
  - **Color Option**: Orange 010
  - **Measurement Value Identification**:
    - **Unit of Measure**: Kilowatt

Message Formats

Oracle Utilities Meter Data Management supports three core transactional data imports: Initial Measurement Data, Device Event Data, and Usage Transactions. To see the appropriate format for each of these imports please see the following:

- **Initial Measurement Data**: Please see the IMD Seeder (D1-IMDSeeder) business object for the appropriate format
- **Device Events**: Please see the Device Event Seeder (D1-DeviceEventSeeder) business object for the appropriate format

Copyright © 2026, Oracle and/or its affiliates.

- **Usage Transactions**: Please see the Usage Transaction Seeder (D2-UsgTranSeeder) business object for the appropriate format*

Data Import - Message Driven Bean Configuration

- Overview
- JMS Configuration
- Message Driven Bean Configuration
- Notification Queue Configuration

Overview

This section describes the steps for configuring the Message Driven Bean (MDB) feature of Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway to listen to inbound JMS messages. This feature is used when importing IMDs and device events from head-end systems or when receiving Usage Transactions from CIS.

JMS Configuration

JMS configuration involves setting up JMS queues which will received inbound usage readings and device events. The JMS queues need to be created first on the application server where the OSB component is deployed. This server is referred to as remote server in the sections below. In the following section the JMS queue on the remote server is assumed to be created with the name **DestinationQueueWatch-CM**.

Note: The JMS changes described in the following sections are not persistent during patches or upgrades. They will need to be re-created after applying any patches or upgrades to Oracle Utilities Smart Grid Gateway. It is recommended to keep a backup of the `$SPLEBASE/splapp/config.xml` file.

Create a new JMS Module

Log in to the Oracle Utilities Smart Grid Gateway Weblogic console and create a JMS Module with an appropriate name. Specify the following values for this JMS module:

- **Name**: the name of JMS module. For example, JMSModule-CM
- **Target**: the name of the target server where the Oracle Utilities Smart Grid Gateway application is running. This should be specified as myserver.

Create a Foreign JMS Server

Create a Foreign JMS server under the JMS module created in the above step. Specify the following values for this foreign JMS server:

- **Name**: Name of the foreign server. For example, JMSFAServer-CM
- **Target**: This should be specified as myserver
- **JNDI Initial Context Factory**: This should be specified as weblogic.jndi.WLInitialContextFactory
- **JNDI Connection URL**: The URL of the server where OSB is deployed. For example: t3://osbserver:7001

Copyright © 2026, Oracle and/or its affiliates.

- **JNDI Properties Credential**: Password for the OSB server user
- **JNDI Properties**: The java.naming.security.principal additional property should be specified and set to the OSB server user. For example, java.naming.security.principal=weblogic

Create a Foreign Destination

Create a Foreign destination for each remote queue. Specify the following values for this foreign destination:

- **Name**: Name of foreign destination. For instance, DestinationQueue-CM
- **Local JNDI Name**: Local JNDI name for the foreign JMS queue. For example, ForeignDestinationQueue-CM
- **Remote JNDI Name**: JNDI name of the queue on the remote server. For example, DestinationQueueWatch-CM

Create a Remote Connection Factory

Create a remote connection factory for the foreign JMS server. Specify the following values for this remote connection factory:

- **Name**: Name of remote connection factory. For example, DestinationQueueConnectionFactory-CM
- **Local JNDI Name**: Local JNDI name for the Remote Connection Factory. For example, ForegnDestinationQueueConnectionFactory-CM
- **Remote JNDI Name**: JNDI name of the JMS Connection Factory on the remote server. For example, weblogic.jms.XAConnectionFactory

Message Driven Bean Configuration

Configuration of message driven beans (MDB) involved modifying the **ejb-jar.xml** and **weblogic-ejb-jar.xml** configuration files delivered with Oracle Utilities Smart Grid Gateway. It is recommended that instead of modifying these files directly you create "Customer Modification" (CM) versions of these files to make changes to these configuration files. This ensures that your modifications are not overwritten by future application patches.

The following section describes the changes required in the CM files for configuring the MDBs to read from the foreign JMS queues set up in the steps above. This requires creating the following files under $SPLEBASE/templates:

- cm_ejb-jar.xml.wls.jms_1.include
- cm_ejb-jar.xml.wls.jms_2.include
- cm_weblogic-ejb-jar.xml.jms.include.

Note: After making these changes the initialSetup script needs to be run and Oracle Utilities Smart Grid Gateway application needs to be redeployed. However the initialSetup script will overwrite the JMS configuration changes made in the steps above. So it is recommended to keep a backup of the $SPLEBASE/splapp/config.xml file before running this script.

Copyright © 2026, Oracle and/or its affiliates.

Changes to cm_ejb-jar.xml.wls.jms_1.include

The following is an an example of the `cm_ejb-jar.xml.wls.jms_1.include` file:

```
<message-driven>
   <description>MDB for DestinationQueue-CM</description>
   <display-name>DestinationQueueWatcher-CM</display-name>

      <ejb-name>DestinationQueueWatch-CM</ejb-name>

   <ejb-class>com.splwg.ejb.mdb.MessageProcessor</ejb-class>
   <messaging-type>javax.jms.MessageListener</messaging-type>
   <transaction-type>Bean</transaction-type>
   <message-destination-type>javax.jms.Queue</message-destination-type>
</message-driven>
```

The values specified in the above file include the following:

- **ejb-name**: This is the name of the MDB.

Changes to cm_ejb-jar.xml.wls.jms_2.include

The following is an example of the `cm_ejb-jar.xml.wls.jms_2.include` file:

```
   <assembly-descriptor>
   <security-role>
   <role-name>cisusers</role-name>
   </security-role>
   <container-transaction>
   <method>

      <ejb-name>DestinationQueueWatch-CM</ejb-name>

   <method-name>onMessage</method-name>
   </method>
   <trans-attribute>NotSupported</trans-attribute>
   </container-transaction>
   </assembly-descriptor>
```

The values specified in the above file include the following:

- **ejb-name**: This is the name of the MDB

Changes to cm_ejb-jar.xml.wls.jms_2.include

The following is an example of the `cm_weblogic-ejb-jar.xml.jms.include` file:

```
   <weblogic-enterprise-bean>

    <ejb-name>DestinationQueueWatch-CM</ejb-name>

   <message-driven-descriptor>
```

Copyright © 2026, Oracle and/or its affiliates.

```
<pool>
<max-beans-in-free-pool>5</max-beans-in-free-pool>
<initial-beans-in-free-pool>1</initial-beans-in-free-pool>
</pool>

 <destination-jndi-name>ForeignDestinationQueue-CM</destination-jndi-name>

 <connection-factory-jndi-name>ForeignConnectionFactory-CM</connection-
factory-jndi-name>

</message-driven-descriptor>
</weblogic-enterprise-bean>
```

The values specified in the above file include the following:

- **ejb-name**: This should be the name of the MDB as specified in ejb-jar.xml
- **destination-jndi-name**: This should be the JNDI name of the foreign destination as provided in JMS module ' Foreign server ' Foreign destination ' Local JNDI name.
- **connection-factory-jndi-name**: This should be the JNDI name of the connection factory as provided in JMS module ' Foreign server ' Remote Connection Factory ' Local JNDI name.

Notification Queue Configuration

Payload statistics and payload summary records must be submitted sequentially in order for them to be processed correctly. To prevent them from being processed at the same time, you should set the number of notification queue polling threads to 1. Follow these steps to configure the number of notification queue threads:

1. Log in to the WebLogic Server Administration Console.
2. Under Helpful Tools, click **Configure Applications.**
3. Click on **Webservices**.
4. Click on the NotificationQueue link. for the EJB that you want to configure.
5. Go to the Configuration tab.
6. In the Change Center, click **Lock & Edit.**
7. Specify the new value of polling threads in **Max Beans in Free Pool.**
8. Click **Save.**
9. Click **Release Configuration.**
10. Restart the OUAF WebLogic instance.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts that direct the user to the appropriate target portal or page for a specific entity such as an account or service point. Refer to Creating Application Links in External

Copyright © 2026, Oracle and/or its affiliates.

Applications in the *Application Framework Administrative User Guide* for more information about creating links.

Note: When creating application links, the use of the following parameters will help speed up launching the target page

- **initNav=false**: skips launching the default home page for the user
- **minSidebar=true** minimizes the sidebar for the user

Go to Portal Script

The Framework provides a generic script (F1-GoToPrtl) that can be used to navigate to the maintenance portal for a specified maintenance object and entity. Refer to Navigating to a Given Record's Maintenance Portal in the *Application Framework Administrative User Guide* for more information about using this script.

Go To CCB Script

Oracle Utilities Customer Care and Billing includes the Go To CCB script (C1-GoToCCB) that can be used to navigate directly to a specific page on Control Central. This script uses the following syntax:

```
script=C1-GoToCCB&FLAG=<FLAG_VALUE>&PKVALUE1=<ID>
```

Where:

- **<FLAG_VALUE>**: A value from the C1_TARGET_PORTAL_FLG lookup that specifies which Control Central page to open.
- **<ID>**: The primary key value for the entity (such as a Account, Person, or Premise) you wish to view.

Examples:

Script	Flag Value	ID	Example
C1-GoToCCB	FLAG=C1CC (Control Central Account)	Account ID	script=C1-GoToCCB&FLAG=C1CC&PKVALUE1={your Account ID}
C1-GoToCCB	FLAG=C1CP (Control Central Person)	Person ID	script=C1-GoToCCB&FLAG=C1CP&PKVALUE1={your Person ID}
C1-GoToCCB	FLAG=C1CR (Control Central Premise)	Premise ID	script=C1-GoToCCB&FLAG=C1CR&PKVALUE1={your Premise ID}

Full URL Example:

```
https://<ENV_BASE_URL>/ouaf/cis.jsp/?minSidebar=true&initNav=false&script=C1-GoToCCB&FLAG=C1CC&PKVALUE1={your Account ID}
```

Copyright © 2026, Oracle and/or its affiliates.

Go To MDM Script

Oracle Utilities Meter Data Management includes the Go To MDM script (D1-GoToMDM) that can be used to navigate directly to a specific 360 Degree View tab. This script uses the following syntax:

```
script=D1-GoToMDM&FLAG=<FLAG_VALUE>&PKVALUE1=<ID>
```

where:

- **<FLAG_VALUE>**: A value from the DRILL_ENTITY_FLG lookup that specifies which 360 Degree View page to open.
- **<ID>**: The primary key value for the entity (such as a Device, Measuring Component, or Service Point) you wish to view.

Examples:

Script	Flag Value	ID	Example
D1-GotoMDM	FLAG=D1DV (360 View for Device)	Device ID	script=D1-GotoMDM&FLAG=D1DV&PKVALUE1={your Device ID}
D1-GotoMDM	FLAG=D1MC (360 View for Measuring Component)	Measuring Component ID	script=D1-GotoMDM&FLAG=D1MC&PKVALUE1={your Measuring Component ID}
D1-GotoMDM	FLAG=D1SP (360 View for Service Point)	Service Point ID	script=D1-GotoMDM&FLAG=D1SP&PKVALUE1={your Service Point ID}

Full URL Example:

```
https://<ENV_BASE_URL>/ouaf/cis.jsp/?minSidebar=true&initNav=false&script=D1-GotoMDM&FLAG=D1DV&PKVALUE1={your Device ID}
```

Defining Communications Options

- Device Event Types
- Activity Types
- Communication Types
- Service Task Types

Device Event Types

- Understanding Device Event Types

Copyright © 2026, Oracle and/or its affiliates.

- Configuring Device Event Types

Understanding Device Event Types

Device event types define properties common to specific types of events.

Device event types represent different types of events that can take place relative to a device. Examples of device events include power outages, power restoration, tampering alerts, and other events.

Device event types can be defined by the following attributes:

- **Standard Event Name:** the "standard" name of the event type. Device vendors may have their own specific names for device events. Only a single active device event type may be mapped to a given standard name at any time.
- **Device Event Category:** a category (defined as an Extendable Lookup) used to group device event types.
- **Reporting Category:** a category used to group device event types for reporting purposes.
- **Activity Type:** the activity type for activities created for device events of this type.

Device Event Mapping

The first step to device event type configuration is defining the list of standard event names that will be processed by the system. This is done by populating the Standard Event Name extendable lookup (D1-StdEventNameLookup). More information about this extendable lookup can be found in About Device Events.

With the fully defined list of Standard Event Names each head-end specific event name (which is also called an external event name) that the system will receive from a given head-end should be mapped to a standard event name. This mapping is configured using a device event mapping extendable lookup. Each head-end system should have its own extendable lookup to define event name mapping in order to prevent possible conflicts between mappings. Each of these business objects should be defined as a child of the parent business object Device Event Mapping (D1-DeviceEventMappingLookup).

For example, head-end systems A and B might both use the same event name, such as the code "1", but this event might need to be mapped to "outage" for head-end system A but "tamper" for head-end system B.

The device event mapping extendable lookup business object is configurable. Each Oracle Utilities Smart Grid Gateway adapter includes a device event mapping lookup business object for the supported head-end system.

Lastly, each device event type is associated to a standard name. This means that as each device event that is received will go through the following mapping steps:

1. The head end specific event name is mapped to a standard event name using the head end specific device event mapping extendable lookup
2. The standard event name is mapped to a device event type
3. The device event type is used to select the appropriate device event business object

Device Event - Additional Processing

Certain device event business objects can be used to update master data as a result of device events received into the system. For example, when a utility's field worker arms a meter, the

Copyright © 2026, Oracle and/or its affiliates.

resulting device event can trigger an update to the device's arming status in the Oracle Utilities application. This processing is initiated by the Execute - Additional Processing system event

algorithm during the Additional Processing status of the business object's lifecycle.

The following base package business objects are configured to execute additional processing:

If a standard device event requires additional processing, the algorithms that execute the processing should be specified in the Additional Processing Algorithms list on the Standard Event Name extendable lookup for the event. The base package includes the additional processing algorithm Arm Meter (D1-ARM-METER).

Only a subset of base package device event business objects are configured to execute additional processing

Description	Business Object Name
Device Event Communication Response	D1-DeviceEventComResp
Standard Device Event	D1-StandardDeviceEvent

If additional processing is required for any business objects not listed above it can easily be added by configuring the algorithm Executer - Additional Processing System Event (D1-EXTADDPRC) in the Additional Processing status.

Reader Remarks

Reader remark types define properties common to specific types of reader remarks.

Reader remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a meter reader is manually reading scalar meters. Reader remark types represent the different types of remarks that meter readers can record. Examples of reader remark types include evidence of tampering, broken seals, damaged meter, dog on premises, and other notices.

When creating a new device type there are the following options:

Name	Details	Business Object
Reader Remark Type	Provides the configuration for a reader remark type	D1-ReaderRemarkType

Field Activity Remarks

Field activity remark types define properties common to specific types of field activity remarks.

Field activity remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a field worker is performing field work at a service point. Field activity remarks represent can represent situations that are found as well as actions that were taken in the field.

When creating a new device type there are the following options:

Name	Details	Business Object
Device Field Remark Type	Provides the configuration for a field activity remark type	D1-DeviceFieldRemarkType

Copyright © 2026, Oracle and/or its affiliates.

Configuring Device Event Types

This portal is used to display and maintain a Device Event Type.

Refer to Understanding Device Event Types for more information.

You can access the portal by selecting **Admin**, then **Communication**, then **Device Event Type**.

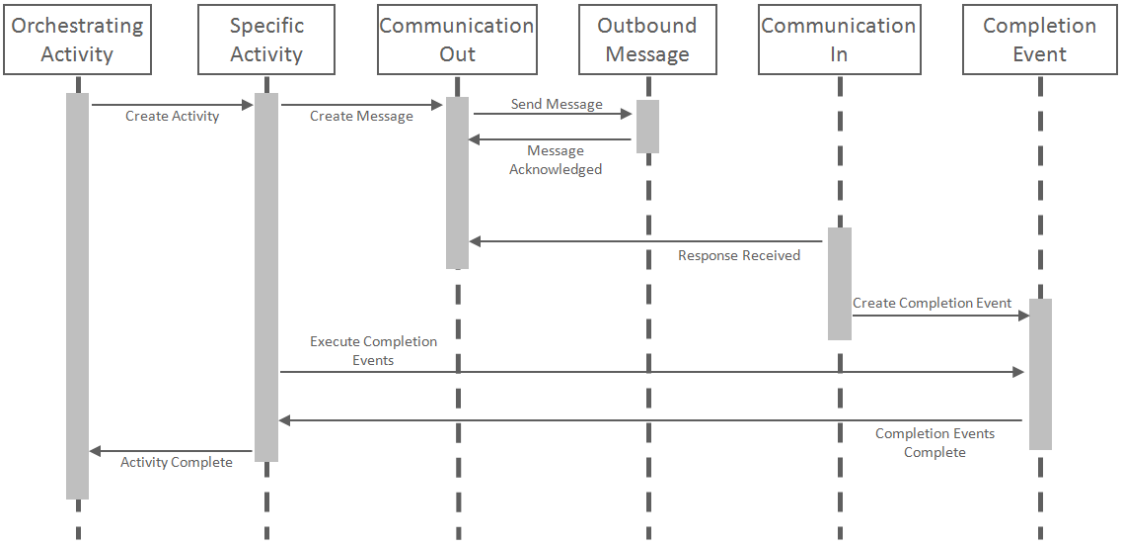
The following zones may appear as part of the portal's **Main** tab page:

- **Device Event Type List:** This zone lists all Device Event Type records. Broadcast a record to display the details of the selected record.
- **Device Event Type:** This zone provides information about the selected Device Event Type.

Activity Types

- Understanding Activity Types
- Configuring Activity Types
- Configuring Service Order Management Activity Types

Understanding Activity Types



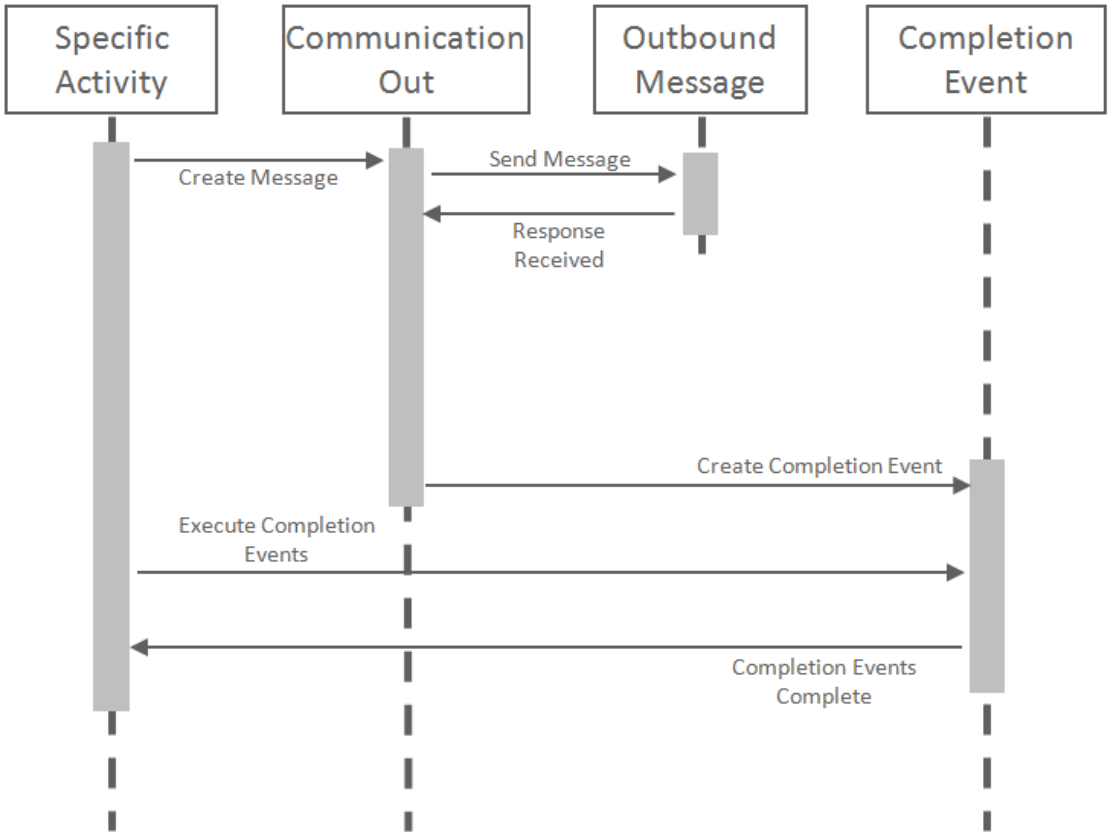
Activities are records of a communication or event related to a device, measuring component, service point or other entity in the system. Examples of activities include smart meter command request, field activities, meter read downloads (for manually read meters) or the combined event of a "last gasp" and "power up" message sent by devices when they detects they experience an outage.

Each type of activity is assigned to an activity type category, please refer to About Activities for more information about the activity type categories supported by base product.

Activities Orchestrate Communication

Certain types of activities such as request orchestrators, field activities, and command requests coordinate a large number of child transactions that represent the communication to and from an external application. The following diagram depicts a two-way communication with an external system:

Copyright © 2026, Oracle and/or its affiliates.



Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- Orchestrating Activity: controls the overall intent of the communication. For example it may "Start Service" which would include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- Specific Activity: can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- Communication Out: orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- Outbound Message: represents the message payload sent to the external system and the synchronous response.
- Communication In: orchestrates the handling of an asynchronous or unsolicited response from an external system.
- Completion Event: carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The following diagram involves many of the same objects but instead represents a one-way communication with an external system. All objects maintain the same duties described above with the addition of the communication out handling the synchronous response which contains the result of the message.

Copyright © 2026, Oracle and/or its affiliates.

Important Activity Type System Events

The activity type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Customer-Device Compatibility**: receives information about the activity being analyzed and returns an indication of whether the customer and device are compatible. This system event is primarily used in service order management. See algorithm type Ensure Device-Usage Calculation Group Compatibility (D2-ENSDVCCMP) as an example.
- **Override Device / Task**: receives information about the activity such as whether the device is installed at a service point, whether the service point is connected, where it is disconnected (if applicable), and the installation event status override. Based on those inputs it should determine the output device configuration type as well as the field activity business object and field task type. This system event is primarily used in service order management. See algorithm type Evaluate Smart Meter Opt-Out for Device Installation (D2-EVSMOPDV) as an example.

Service Order Activity and Service Order Field Activity Types and Divisions

Service order activity types and service order field activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the**Miscellaneous** tab of the **User** portal.

Copyright © 2026, Oracle and/or its affiliates.

> **Note**
>
> In Oracle Utilities Customer to Meter, the **Control By CIS Division** setting on the **Main** tab on the **Installation Options** portal is used to restrict data access based on divisions.

See Understanding Divisions for more information about divisions.

Activity Type Maintenance Category

Activity types can be assigned an Activity Type Maintenance Category to specify that they should be maintained using the SOM Activity Type portal rather than the standard Activity Type portal. This option is used with the following categories of activity types:

- Field Activity Types
- Non-Dispatchable Activity Types
- Orchestration Maintenance Types
- Request Orchestration Types

Assigning activity types to the "Service Order Management Activity Type" Activity Type Maintenance Category is done via the Activity Type Maintenance Category business object option on the appropriate activity type business objects.

Configuring Activity Types

You use the **Activity Type** portal is to view and maintain activity types.

Refer to Understanding Activity Types for more information.

You can access the portal by selecting **Admin**, **Communication**, **Activity Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured activity types as well activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List**: This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type**: This zone provides information about the selected Activity Type
- **Field Task By Device Condition**: This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Update Device (D1-UPDDVC) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the

Copyright © 2026, Oracle and/or its affiliates.

algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition**: This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Create Specific Activity (D1-CRSPACT) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Configuring Service Order Management Activity Types

You use the **SOM Activity Type** portal to view and maintain activity types whose business object has the Activity Type Maintenance Category business object option set to D1SO (Service Order Management Activity Type).

Refer to Understanding Activity Types for more information.

You can access the portal by selecting **Admin**, **Communication**, **SOM Activity Type**.

> **Note**
>
> If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order management activity types as well activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List**: This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type**: This zone provides information about the selected Activity Type

Copyright © 2026, Oracle and/or its affiliates.

- **Field Task By Device Condition**: This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Update Device (D1-UPDDVC) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

  > **Note**
  >
  > If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition**: This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the Create Specific Activity (D1-CRSPACT) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

  > **Note**
  >
  > If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Communication Types

- Understanding Communication Types
- Configuring Communication Types

Understanding Communication Types

Communication types define properties common to a specific type of communication. This single admin object covers both communication in and communication out types.

Communication types include types of communications between an application and an external system such as a head-end system or the work management system. These are outbound communications such as smart meter command requests or field activities as well as inbound communications such as a message response that indicates the results of a request.

Communication types typically provide configuration around exception handling:

- **To Do Type and Role**: identifies the To Do to be created when an error is encountered
- **Retry Frequency**: defines how often the communication should be retried. As many errors can be due to connectivity the ability to retry provides automatic resolution.

Copyright © 2026, Oracle and/or its affiliates.

- **Maximum Retries**: provides an upper limit to the number of times a communication can be re-attempted
- Each communication type can have its own unique set of fields, please refer to the embedded help for that communication type for more details on those fields.

Configuring Communication Types

This portal is used to display and maintain a Communication Type.

Refer to Understanding Communication Types for more information.

You can access the portal by selecting **Admin**, then **Communication**, then **Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List:** This zone works differently than the typical zone that list types in that it displays both those communication types that have been configured as well as those communication types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Communication Type:** This zone provides information about the selected Communication Type

Service Task Types

- Understanding Service Task Types
- Configuring Service Task Types

Understanding Service Task Types

Service tasks types define properties common to specific types of service tasks.

Service task types represent types of tasks that can be performed by users of other Oracle Utilities applications, such Oracle Utilities Customer Self Service or Oracle Utilities Network Management System. Examples of service tasks include self service meter reads, in which users enter their own meter reads via the Customer Self Service application, and service issue monitor types used when determining if service investigation is needed for a service point.

When creating a new record, the following options are available:

Name	Details	Business Object
Service Issue Monitor Type	The service issue monitor type defines the parameters for when a service investigative order should be created. It can also optionally define the completion parameters for that indicate the investigative order was successful in its purpose.	D1-ServiceIssueMonitorType
Self-Service Rate Compare Scenario Request Type	A simple description of a rate compare scenario request type.	D2-RateCompareScenarioRqstType

Copyright © 2026, Oracle and/or its affiliates.

Self-Service Meter Read Task Type	Provides the default settings for meter reads created through self service.	D2-SSMeterReadTaskType

Configuring Service Task Types

This portal is used to display and maintain a Service Task Type.

Refer to Understanding Service Task Types for more information.

You can access the portal by selecting **Admin**, then **Customer**, then **Service Task Type**

The following zones may appear as part of the portal's **Main** tab page:

- **Service Task Type List:** This zone lists all Service Task Type records. Broadcast a record to display the details of the selected record.
- **Service Task Type:** This zone provides information about the selected Service Task Type.

Data Extracts

This section describes functionality that support extract and export of data for use in external applications and systems.

- Configurable Consumption Extracts
- Maintenance Object Data Export
- Service Point Consumption Extracts
- Consumption Extract Type
- Analytics Configuration
- Migrating Data Extract Processing from Legacy Measurement Processing to Direct Measurement Processing

Configurable Consumption Extracts

Configurable Consumption Extracts are measurement data extracts for a set of usage subscriptions optionally related to a specific market participant.

Configuration options for these extracts include:

- Type of Market Participant, based on Service Point Market Participant or Usage Subscription Market Participant tables and market relationship
- Usage Subscriptions Types associated with the market participant (typically a customer information system receiving bill determinants)
- Unique combinations of unit of measure (UOM), time of use (TOU), and service quantity identifier (SQI) associated with the usage subscriptions
- Specific identifiers used to identify the usage subscriptions, service points, and devices associated with extracted measurement data
- Date and time parameters and frequency of extract

Copyright © 2026, Oracle and/or its affiliates.

- Extract file naming and compression options

Consumption extracts are exported to a file in a specified file location, either on an application server (in an on-premises implementation) or an Oracle Cloud Infrastructure Object Storage location.

Consumption extracts are created via Consumption Extract Requests. See Consumption Extract Requests in the *Business User Guide*.

This section describes the configuration needed for these types of consumption extracts.

Master Configuration

When using Direct Measurement Processing, the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration must be set to "Yes" in order to run historical extracts. When this is set to "Yes", change data capture information is recorded in the Measurement Extract Request table instead of the General Process table.

Consumption Extract Types

Configuration for consumption extracts are defined via a Consumption Extract Type. See Consumption Extract Type in the *Administrative User Guide* for more information about creating these records.

Configurable consumption extract types should be created using the Extract US Consumption to File (D1-ExtractUSConsumptionToFile) business object. Refer to the embedded help on this business object for more details about the parameters defined for consumption extract types.

Extract US Consumption to File consumption extract types define the following parameters:

- The market participants for which measurement data will be extracted. You define market participants based on their type (Service Point Market Participant or Usage Subscription Market Participant) and market relationship type (retailer, distributor, supplier, and so on), and a specific market participant. Note: If Market Participant Specific is set to "No", the market participant used is based on the Usage Recipient on the Usage Subscription or its Usage Subscription Type.
- The consumption type (interval or scalar)
- One or more Usage Subscription Types and a related unique UOM/TOU/SQI combination
- The specific ID types to include in the extract file for the Usage Subscription, Service Point, child Service Point (if applicable), and Device
- Execution parameters, including:
  - The date and time through which data has been extracted for this consumption extract type
  - A Request Type. Request types used with consumption requests should be created using the Consumption Extract Request Type (D2-IntervalDataExtRepoType) business object, and should reference the Consumption Extract (D2-IntervalDataExtRepository) business object in the **Request Business Object** field. (see The Big Picture of Requests in the *Application Framework Administrative User Guide*)
  - The frequency of extracts for this type (adhoc or daily)
  - Batch controls used for the extract process (see **Batch Controls** below)
- File parameters, including:
  - The file location where extract files will be saved (see External File Storage in the *Application Framework Administrative User Guide*)

Copyright © 2026, Oracle and/or its affiliates.

- An optional child folder in the file location
- File naming options (including an optional prefix and date/time stamp)
- Whether or not to compress the extract file (file compression is performed using gzip)

Batch Controls

The data extract process and creation of export files is performed by the following batch controls:

- **Extract Current US Intervals to File** (D1-ECUSI): Used for daily extracts of interval consumption. This process requires that Interval Snapshot Mapping data be generated for any of the interval sizes being extracted. This aides in the efficiency of transposing the interval data into daily interval columns. (see Interval Snapshot Mapping for more information).
- **Extract Replacement US Intervals to File** (D1-ERUSI): Used for extracts of replacement historical interval consumption. This process runs against Change Data Capture records in the General Process or Measurement Extract Request table (see **Initial Measurement Subsequent Correction Change Data Capture** below).
- **Extract Current US Scalar Reads to File** (D1-ECUSS): Used for daily extracts of scalar consumption.
- **Extract Replacement US Scalar Reads to File** (D1-ERUSI): Used for extracts of replacement scalar interval consumption. This process runs against Change Data Capture records in the General Process or Measurement Extract Request table (see **Initial Measurement Subsequent Correction Change Data Capture** below).

These batch controls are run for a specific Consumption Extract Type and date range. Batch processing is threaded by on Usage Subscription ID.

Refer to Consumption Extract Requests - Batch Controls in the **Defining DataConnect Options** section of the **Integrations** chapter for general information about consumption extract batch processing,

Initial Measurement Subsequent Correction Change Data Capture

The following algorithms maintain measuring component date/times based on the latest measurement date time for the measuring component. These algorithms also check for a Consumption Extract Type that applies to the current initial measurement's measuring component and identifies whether the initial measurement is for a date/time that has already been extracted.

Algorithm	Description	Consumption Type
D1-UPD-DTMC	Update Latest Measurement Date/Time on MC with Consumption Sync	Interval
D1-UDTSCMCRE	Update Latest Measurement Date/Time on Scalar MC with Consumption Sync	Scalar
D1-UPD-DTMCF	Update Latest Date/Time on MC from a Future Measurement	Interval
D1-UPDDTSCMC	Update Latest Date/Time on Scalar Measuring Component	Scalar

If an initial measurement is for a date/time that has already been extracted, these algorithms create Change Data Capture records in the General Process table that capture the batch code, batch run number, and the initial measurement's ID. The "Replacement" batch processes run off of these records.

Copyright © 2026, Oracle and/or its affiliates.

Note that the following parameter must be set to “true” on the above algorithms to enable historical change data capture:

- Capture CET Historical Measurement Changes: true
- Capture Historical Measurement Changes: true (when using Direct Measurement Processing)

Data Extract File Format - Interval

The interval extract process produces JavaScript Object Notation (JSON) files with the extract data described in the following table.

Note that interval extract files can store up to a maximum of 300 intervals. This means that export files can store approximately:

- 12.5 days worth of hourly data
- 3 days worth of 15 minute data
- 1 day worth of 5 minute data

Field	Sample Value	Comments
usId	995647003500	Usage Subscription ID defined by the Consumption Extract Type
usType	E-RES	Usage Subscription type
pSpId	458081	Parent Service Point ID, Null when there is no parent service point.
spId	458081_001	Child Service Point ID This is the Service Point ID defined by the Consumption Extract Type
dvcId	SN823287793219	Device ID defined by the Consumption Extract Type
uomTouSqi	KWH//	UOM / TOU / SQI, separated by forward slashes ("/")
tz	US/Eastern	Time zone of the service point. This is the time zone name from the CI_TIME_ZONE table not the time zone code.
intPerDay	288	Number of Intervals for the day, will be 1 hour less or 1 hour more of intervals for DST transitions
intSize	300	Length of each interval in seconds
mktPart	DIRECT_ENERGY	Market Participant ID of the market participant (if applicable)
stDttm	2020-01-01T00:00:00-05:00	Start of the day, similar to initial measurement, this represents the start of the first interval.
q1	1.325	Measurement Value for the first interval, the measurement date/time for this interval would be the stDttm plus the intSize
c1	301000	Measurement Condition for the first interval. Null when "Regular" (501000)

Copyright © 2026, Oracle and/or its affiliates.

Field	Sample Value	Comments
q2	1.230	
c2	301000	
...	q/c 3 through 299 here	
q300	.9134	
c300	30100	

Example:

```
{"usId":"995647003500", "usType":"E-RES", "pSpId":"458081",
"spId":"458081_001", "dvcId":"SN823287793219", "uomTouSqi":"KWH//",
 "tz":"US/Eastern", "intPerDay":"288", "intSize":"300",
"mktPart":"DIRECT_ENERGY",
 "stDttm":"2020-01-01T00:00:00-05:00", "q1":"1.325", "c1":"301000",
"q2":"1.325",
 "c2":"301000" "q3":"1.325", "c3":"301000",
<intervening intervals>, "q300":"1.325", "c300":"301000"}
```

Data Extract File Format - Scalar

The scalar extract process produces JavaScript Object Notation (JSON) files with the extract data described in the following table.

Name	Sample Value	Comments
c	301000	Measurement Condition for the scalar reading Null when "Regular" (501000)
dvcId	SN823287793219	Device ID defined by the Consumption Extract Type
enDttm	2020-01-02T00:00:00-05:00	End date/time of the reading
mktPart	DIRECT_ENERGY	Market Participant ID of the market participant (if applicable)
pSpId	458081	
q	1.325	Measurement Value for scalar reading
r	678645	Dial reading of the meter
spId	458081_001	Service Point ID defined by the Consumption Extract Type
stDttm	2020-01-01T00:00:00-05:00	Start date/time of the reading (the End Date/Time of the previous reading)
tz	US/Eastern	Time zone of the service point. This is the time zone name from the CI_TIME_ZONE table not the time zone code.
uomTouSqi	KWH//	UOM / TOU / SQI, separated by forward slashes ("/")
usId	995647003500	Usage Subscription ID defined by the Consumption Extract Type

Copyright © 2026, Oracle and/or its affiliates.

Name	Sample Value	Comments
usType	E-RES	Usage subscription type

Example (3 records):

```
{"usId":"995647003500", "usType":"E-RES", "pSpId":"458081",

```

Extending the Extract Processing

Some implementations may wish to extend and/or customize the extract process based on specific requirements.

Extending List of IDs To Use

Consumption Extract Types define specific types of IDs to use for Usage Subscriptions, Service Points, child Service Points (if applicable), and Devices. If an implementation wishes to extend the types of IDs available, they need to add appropriate values to the lookup flags used by each of ID type. The table below lists the lookup codes used by the "IDs to Use" fields.

ID Type	Lookup Flag
Usage Subscription ID	Usage Subscription Identifier Type (US_ID_TYPE_FLG)
Service Point ID (used for both parent and child service points)	Service Point Identifier Type (SP_ID_TYPE_FLG)
Device ID	Device Identifier Type (DVC_ID_TYPE_FLG)

Processing Records and Creating Output Files

The extract process leverages the generic Plug-in Driven Background Processes functionality but works in a slightly different manner. Instead of using the Select Records algorithm to retrieve the IDs of the individual records to be processed, that algorithm returns a range of

Copyright © 2026, Oracle and/or its affiliates.

Usage Subscription IDs to be extracted and the Process Records algorithm performs the detailed query to extract the range of Usage Subscription IDs.

This provides two benefits:

1. There is no limitation on the length of the query in the Process Records algorithm.
2. Retrieving data for many Usage Subscriptions at a single time is significantly more efficient.

This means that any required customization can be achieved by creating a new custom (CM) batch control and duplicating the Process Records Groovy script. Changes can be made within the custom Groovy script to the extraction SQL to retrieve additional information or provide additional selection criteria. If any changes are needed to the file format that can be done within the record processing logic that populates the file.

> **Note**
>
> The Process Records scripts include a number of steps each containing specific processing logic and SQL based on the configuration of the Market Participants on the Consumption Extract Type as well as whether or not the specified UOMs measure peak quantities or not. Be sure to edit each of these steps as appropriate when creating customized versions of these scripts.

Maintenance Object Data Export

This section describes the process by which data can be exported from maintenance objects used with Oracle Utilities Customer Cloud Service and Oracle Utilities Meter Solution Cloud Service for use in external applications and systems.

This section provides details regarding how the data export process is used with specific maintenance objects. See Data Export in the *Application Framework Administrative User Guide* for a general description of the data export process.

- Enabling Maintenance Objects for Generalized Data Export
- Measurement Data Export
- Initial Measurement Data Header Export
- Aggregated Measurement Data Export

Enabling Maintenance Objects for Generalized Data Export

Export of data from most maintenance objects is supported via "Generalized" export. See Generalized Data Export in the *Application Framework Administrative User Guide* for more information about generalized data export.

Data Export Control Records for Maintenance Objects

Data export from a maintenance object requires a Data Export Control record configured for that maintenance object. See **Enabling Data Export** in Generalized Data Export in the *Application Framework Administrative User Guide* for more information.

Copyright © 2026, Oracle and/or its affiliates.

Change Data Capture for Measuring Components and Usage Subscriptions

For most maintenance objects, changes are tracked via the Capture Change for Ongoing Export audit algorithm (F1-MO-REGCHN).

Measuring Components and Usage Subscriptions use a "Most Recent" date field to track related transactions (Initial Measurements and Measurements in the case of Measuring Components and Usage Transactions in the case of Usage Subscriptions). These "Most Recent" fields are updated with each new initial measurement or usage transaction created by the system.

In order to prevent the Change Data Capture process from capturing changes based on these frequent transactions (daily for measurements and monthly for usage transactions), the Capture Change for Ongoing Export audit algorithm has been disabled on the Measuring Component and Usage Subscription maintenance objects.

Enabling change data capture and generalized data export for these maintenance objects requires adding the “Generalized Data Export BO Change Data Capture” (D1-BO-REGCHN) Audit algorithm to the appropriate Measuring Component and Usage Subscription business objects. This algorithm creates records in the Data Export Update table used by the generalized export process.

Measurement Data Export

Export of data from the Measurement maintenance object is supported via "Specialized" export. See **Specialized Data Export** in the *Application Framework Administrative User Guide* for more information about specialized data export.

The Measurement maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	F1SE (Specialized)
Export Batch Control	D1-SMDEC (Specialized Measurement Data Extract Current)

Master Configuration

When using Direct Measurement Processing, the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration must be set to "Yes" in order to run historical extracts. When this is set to "Yes", change data capture information is recorded in the Measurement Extract Request table instead of the General Process table.

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Measurement maintenance object:

- **Initial Extracts** gather an initial extract of measurement data, controlled by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the measurement data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the **Measurement Date/Time** and **Last Update Timestamp** fields on the Measurement table, as well as the **Export Through Date/Time** field on the Data Export Control record (see below) to include only changes since the last extract.

Copyright © 2026, Oracle and/or its affiliates.

- **Daily Historical Extracts** gather measurement data for measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Measurement table, this extract is based on Change Data Capture. During initial measurement data processing if an initial measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process or Measurement Extract Request table.
  Enabling historical change data capture requires configuration of the following algorithm parameters:
  - Capture Historical Measurement Changes: true
  - Historical Measurement Data Extract Batch Control: D1-SMDEH (Specialized Measurement Data Extract Historical)
  - Capture Historical Measurement Changes: true (when using Direct Measurement Processing)

  These parameters should be configured as described on the following algorithms:
  - Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
  - Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
  - Update Latest Date/Time on MC from a Future Measurement (D1-UPD-DTMCF)
  - Update Latest Date/Time on Scalar Measuring Component (D1-UPDDTSCMC)
  - Re-derive other values (D1-REDEROVAL)

> **Note**
>
> This use of Change Data Capture is an exception to the general rule described in the **Specialized Data Export** section of the *Application Framework Administrative User Guide*.

Data Export Control Records

Data export from the Measurement maintenance object requires a Data Export Control record. This record designates that the Measurement maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See **Defining Data Export Control** in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized Measurement Initial Extract** (D1-SMDIE): Used for initial extract of measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the measurement data prior to using the current extract (D1-SMDEC) and the historical extract (D1-SMDEH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all measurements with a measurement date/time that is greater than the input start date/time and less than or equal to the input end date/time.

Copyright © 2026, Oracle and/or its affiliates.

- **Specialized Measurement Data Extract Current** (D1-SMDEC): Used for daily extracts of current (new) measurement data. This process extracts data that has changed since the last extract process has run (based on the **Export Through Date/Time** field on the Data Export Control record. This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized Measurement Data Extract Historical** (D1-SMDEH): Used for daily extracts of historical measurement data. This process runs against Change Data Capture records in the General Process or Measurement Extract Request table.

Batch processing is threaded by on Measuring Component ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files).
2. The **File Size Limit** parameter can be used to specify set the number of measurement rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve measurement data for a set of Measuring Component IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- MSRMT_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<thread file indicator>_<process date time>.csv.gz

where:

- <file prefix batch parameter> is an optional file prefix defined using the **File Name Prefix** batch control parameter
- <batch number> is the batch number for the process
- <batch thread number> is the thread number that created the file
- <total thread count> is the total number of threads
- <thread file indicator>: is an identified for the first and last files created by a thread, S for first file E for last file
- <process date time>is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_S_20191104173233.csv.gz
- All files before the last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_20191104173233.csv.gz
- Last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_E_20191104173233.csv.gz

Copyright © 2026, Oracle and/or its affiliates.

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to “Y”.

> **Note**
>
> All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

				Applicability		
Field	**Data Type**	**Sample Content**	**Description**	**Interval**	**Scalar**	**Subtractive Interval**
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of Channel from Meter (aka Device)	X	X	X
MSRMT_DTTM	DATE	2019-01-01T00:00:00Z	End of the time period the measurement covers. For example, if this were an hourly interval it would cover 2018-12-31T23:00:00Z to 2019-01-01T00:00:00Z.	X	X	X
PREV_MSRMT_DTTM	DATE	2018-12-31T00:00:00Z	For scalar measurements this identifies the start of the period being measured. Note: there should be another measurement for the same MC with this date as the MSRMT_DTTM.		X

Initial Measurement Data Header Export

Copyright © 2026, Oracle and/or its affiliates.

Export of header data from the Initial Measurement Data maintenance object is supported via "Specialized" export. See **Specialized Data Export** in the *Application Framework Administrative User Guide* for more information about specialized data export.

The Initial Measurement Data maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	F1SE (Specialized)
Export Batch Control	D1-SIMDC (Specialized IMD Header Extract Current)

> **Note**
>
> When Initial Measurement Data Header Export is used with Direct Measurement Processing, exports contain only IMD header information for exceptions, including Informational Exception Headers created due to "Informational" exceptions.

Master Configuration

When using Direct Measurement Processing, the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration must be set to "Yes" in order to run historical extracts. When this is set to "Yes", change data capture information is recorded in the Measurement Extract Request table instead of the General Process table.

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Initial Measurement Data maintenance object:

- **Initial Extracts** gather an initial extract of initial measurement data headers, controlled by providing a start and end date time of the initial measurement data headers that should be extracted. This process should be used to perform the initial extract of the data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the **Last Update Timestamp** field on the Initial Measurement Data table, as well as the **Export Through Date/Time** field on the Data Export Control record (see below) to include only changes since the last extract.
- **Daily Historical Extracts** gather data for initial measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Initial Measurement Data table, this extract is based on Change Data Capture. During initial measurement data processing if an initial measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process or Measurement Extract Request table.
  Enabling historical change data capture requires configuration of the following algorithm parameters:
  - Capture Historical Measurement Changes: true
  - Historical IMD Extract Batch Control: D1-SMDEH (Specialized IMD Header Extract - Historical)
  - Capture Historical Measurement Changes: true (when using Direct Measurement Processing)

  These parameters should be configured as described on the following algorithms:

Copyright © 2026, Oracle and/or its affiliates.

- Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
- Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
- Update Latest Date/Time on MC from a Future Measurement (D1-UPD-DTMCF)
- Update Latest Date/Time on Scalar Measuring Component (D1-UPDDTSCMC)

> **Note**
>
> This use of Change Data Capture is an exception to the general rule described in the **Specialized Data Export** section of the *Application Framework Administrative User Guide*.

Data Export Control Records for Maintenance Objects

Data export from the Initial Measurement Data maintenance object requires a Data Export Control record. This record designates that the Initial Measurement Data maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See **Defining Data Export Control** in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized IMD Header Initial Extract** (D1-SIMDI): Used for initial extract of initial measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the IMD headers that should be extracted. This process should be used to perform the initial extract of the IMD header data prior to using the current extract (D1-SIMDC) and the historical extract (D1-SIMDH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all IMD headers with a IMD to date/time that is greater than the input start date/time and less than or equal to the input end date/time.
- **Specialized IMD Header Data Extract - Current** (D1-SIMDC): Used for daily extracts of current (new) initial measurement data. This process extracts data that has changed since the last extract process has run (based on **the Export Through Date/Time** field on the Data Export Control record). This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized IMD Header Extract - Historical** (D1-SIMDH): Used for daily extracts of historical initial measurement data. This process runs against Change Data Capture records in the General Process or Measurement Extract Request table.

Batch processing is threaded by on Initial Measurement Data ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files)

Copyright © 2026, Oracle and/or its affiliates.

2. The **File Size Limit** parameter can be used to specify set the number of initial measurement data rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve initial measurement data for a set of Initial Measurement Data IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- IMD_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<file number>_<last file indicator>_<process date>.csv.gz

where:

- <file prefix batch parameter> is an optional file prefix defined using the **File Name Prefix** batch control parameter
- <batch number> is the batch number for the process
- <batch thread number> is the thread number that created the file
- <total thread count> is the total number of threads
- <file number> is the number of the file
- <last file indicator>: identifies the last files created by a thread (E)
- <process date time>is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads:
  IMD_EXPORT_SOME_PREFIX_135_3_10_1_20191104173233.csv.gz
- All files before the last file of 3rd out of 10 threads:
  IMD_EXPORT_SOME_PREFIX_135_3_10_2_20191104173233.csv.gz
- Last file of 3rd out of 10 threads:
  IMD_EXPORT_SOME_PREFIX_135_3_10_E_20191104173233.csv.gz

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to “Y”.

> **Note**
>
> All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

Copyright © 2026, Oracle and/or its affiliates.

				Applicability		
Field	**Data Type**	**Sample Content**	**Description**	**Interval**	**Scalar**	**Subtractive Interval**
INIT_MSRMT_DATA_ID	CHAR(12)	5248224511660 4	Primary Key of the initial measurement	X	X	X
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of the measuring component for the initial measurement	X	X	X
IMD_EXT_ID	CHAR(12)	external_file	External ID for the initial measurement. Usually the name of the file that the initial measurement data was received in.	X	X	X
BUS_OBJ_CD	CHAR(12)	D1-ManualIMDInterval	The business object that governs the initial measurement	X	X	X
BO_STATUS_CD	VARCHAR(30)	COMPLETED	The status of the initial measurement	X	X	X
BO_STATUS_REASON_CD	VARCHAR(30)	FORCE COMPLETE	A reason code for the status. Generally populated when there was a VEE exception that was overridden and the initial measurement was completed without fixing the error.	X	X	X

Copyright © 2026, Oracle and/or its affiliates.

				Applicability		
Field	**Data Type**	**Sample Content**	**Description**	**Interval**	**Scalar**	**Subtractive Interval**
D1_FROM_DTTM	DATE/TIME	2019-01-01T00:00:00Z	Start of the time period the initial measurement covers. For subtractive scalar data this represents the prior measurement that will be used as the start reading when calculating consumption. For interval data this represents the start of the first interval for the initial measurement. Note: no measurements will be created for this date/time as MDM represents intervals as the end of the interval. So the first interval of the initial measurement will be this date/time plus the interval size (e.g. if the interval size is 15 minutes then the first interval would be 15 minutes after this date/time).	X	X	X

Copyright © 2026, Oracle and/or its affiliates.

				Applicability		
Field	**Data Type**	**Sample Content**	**Description**	**Interval**	**Scalar**	**Subtractive Interval**
D1_TO_DTTM	DATE/TIME	2019-01-02T00:00:00Z	End of the time period the initial measurement covers. For scalar data this date/time will match the measurement. For interval data this will match the date/time of the last interval measurement.	X	X	X
CRE_DTTM	DATE/TIME	2019-01-03T00:00:00Z	Date and time when the initial measurement was initially created	X	X	X
STATUS_UPD_DTTM	DATE/TIME	2019-01-03T00:00:00Z	Date and time when the initial measurement's status was last updated	X	X	X
LAST_UPDATE_DTTM	DATE/TIME	2019-01-03T00:00:00Z	Date and time when the initial measurement was last updated. Note: updates can happen outside of a status change so this can be more recent than the STATUS_UPD_DTTM.	X	X	X

Sample Export File

The following is a sample export file containing initial measurement header records. Note that this does not include labels or column headers, but the data is in the same order as the column descriptions above in the **File Format** section above.

Aggregated Measurement Data Export

Export of data from the Aggregated Measurement maintenance object (D1-AGGMSRMT) is supported via "Specialized" export. See **Specialized Data Export** in the *Application Framework Administrative User Guide* for more information about specialized data export. The Aggregated Measurement maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	F1SE (Specialized)
Export Batch Control	D1-SAMDC (Specialized Agg. Measurement Extract Cur.)

Master Configuration

When using Direct Measurement Processing, the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration must be set to "Yes" in order to run historical extracts. When this is set to "Yes", change data capture information is recorded in the Measurement Extract Request table instead of the General Process table.

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Aggregated Measurement maintenance object:

- **Initial Extracts** gather an initial extract of aggregated measurement data, controlled by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the aggregated measurement data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather aggregated measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the Measurement Date/Time and Last Update Timestamp fields on the Aggregated Measurement table, as well as the Export Through Date/Time field on the Data Export Control record (see below) to include only changes since the last extract.
- **Daily Historical Extracts** gather aggregated measurement data for measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Aggregated Measurement table, this extract is based on Change Data Capture. During initial measurement data processing if an aggregated measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process or Measurement Extract Request table.

Enabling historical change data capture for aggregated measurement data requires configuration of the following algorithm parameters:

- Capture Historical Aggregation Changes: true
- Aggregation Historical Batch Control: D1-SAMDH (Specialized Aggregated Measurement Data Extract Historical)

Copyright © 2026, Oracle and/or its affiliates.

- Capture Historical Measurement Changes: true (when using Direct Measurement Processing)

These parameters should be configured as described on the following algorithms:

- Create General Process Record for Historical Dynamic Aggregation (D1CGPHISAGG)
- Create General Process Record for Historical Static Aggregation (D1CGPHISA)

> **Note**
>
> This use of Change Data Capture is an exception to the general rule described in the **Specialized Data Export** section of the *Application Framework Administrative User Guide*.

Data Export Control Records

Data export from the Aggregated Measurement maintenance object requires a Data Export Control record. This record designates that the Aggregated Measurement maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See **Defining Data Export Control** in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized Aggregate Msrmt. Initial** (D1-SAMDI): Used for initial extract of aggregated measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of aggregated measurement data prior to using the current extract (D1-SAMDC) and the historical extract (D1-SAMDH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all aggregated measurements with a measurement date/time that is greater than the input start date/time and less than or equal to the input end date/time.
- **Specialized Agg. Measurement Extract Cur.** (D1-SAMDC): Used for daily extracts of current (new) aggregated measurement data. This process extracts data that has changed since the last extract process has run (based on the **Export Through Date/Time** field on the Data Export Control record. This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized Aggregated Measurement Data Extract Historical** (D1-SAMDH): Used for daily extracts of historical aggregated measurement data. This process runs against Change Data Capture records in the General Process or Measurement Extract Request table

Batch processing is threaded by on Measuring Component ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files).

Copyright © 2026, Oracle and/or its affiliates.

2. The **File Size Limit** parameter can be used to specify set the number of aggregated measurement rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve aggregated measurement data for a set of Measuring Component IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- MSRMT_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<thread file indicator>_<process date time>.csv.gz

where:

- <file prefix batch parameter> is an optional file prefix defined using the **File Name Prefix** batch control parameter
- <batch number> is the batch number for the process
- <batch thread number> is the thread number that created the file
- <total thread count> is the total number of threads
- <thread file indicator>: is an identified for the first and last files created by a thread, S for first file E for last file
- <process date time>is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_S_20191104173233.csv.gz
- All files before the last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_20191104173233.csv.gz
- Last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_E_20191104173233.csv.gz

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to “Y”.

> **Note**
>
> All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

Field	Data Type	Sample Content	Description
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of Channel from Meter (aka Device)

Copyright © 2026, Oracle and/or its affiliates.

Field	Data Type	Sample Content	Description
MSRMT_DTTM	DATE	2019-01-01T00:00:00Z	End of the time period the measurement covers. For example, if this were an hourly interval it would cover 2018-12-31T23:00:00Z to 2019-01-01T00:00:00Z.
PREV_MSRMT_DTTM	DATE	2018-12-31T00:00:00Z	For scalar measurements this identifies the start of the period being measured. Note: there should be another measurement for the same MC with this date as the MSRMT_DTTM.
MSRMT_COND_FLG	CHAR(6)	501000	Defines the quality of the measurement (e.g. estimated, regular, super). Valid values defined on F1_EXTENDABLE_LOOKUP_VAL for the BUS_OBJ_CD D1-MeasurementConditionLookup.
MSRMT_USE_FLG	CHAR(4)	D101	Indicates whether the measurement is usable. Valid values defined on CI_LOOKUP.
USER_EDITED_FLG	CHAR(4)	D1UE	Indicates whether the user has edited the measurement. Valid values defined on CI_LOOKUP.
READING_VAL			Values for this field are not included in the aggregated measurement export.
READING_COND_FLG			Values for this field are not included in the aggregated measurement export.
COMBINED_MULTIPLIER			Values for this field are not included in the aggregated measurement export.
MSRMT_VAL	NUMBER(16,6)	1.23	This is the consumption reported from the meter after going through VEE (aka billing ready).

Copyright © 2026, Oracle and/or its affiliates.

Field	Data Type	Sample Content	Description
MSRMT_VAL1	NUMBER(16,6)		This and the subsequent measurement values (MSRMT_VAL 1 through 10) are derived values that are computed from the core MSMRT_VAL. Examples of this are UOM conversion (CCF to THERM) or loss adjustment.
MSRMT_VAL2	NUMBER(16,6)		
MSRMT_VAL3	NUMBER(16,6)		
MSRMT_VAL4	NUMBER(16,6)		
MSRMT_VAL5	NUMBER(16,6)		
MSRMT_VAL6	NUMBER(16,6)		
MSRMT_VAL7	NUMBER(16,6)		
MSRMT_VAL8	NUMBER(16,6)		
MSRMT_VAL9	NUMBER(16,6)		
MSRMT_VAL10	NUMBER(16,6)		
CRE_DTTM	DATE	2019-10-31T11:09:31Z	When the record was created.
LAST_UPDATE_DTTM	DATE	2019-11-09T16:35:02Z	When the record was last updated.

Sample File

The following is a sample export file for interval data spanning a six hour window. Note that this does not include labels or column headers, but the data is in the same order as the column descriptions above in the **File Format** section above.

```

Service Point Consumption Extracts

Service Point Consumption extracts are measurement data extracts for a set of service points assigned to an entity group.

Configuration options for these extracts include:

- Type of measurement data to extract (interval or scalar)
- Unique combinations of unit of measure (UOM), time of use (TOU), and service quantity identifier (SQI) associated with the usage subscriptions
- Date and time parameters and frequency of extract
- Extract file naming and location

Service Point Consumption extracts are created via Requests. Service Point Consumption extracts are exported to a file in a specified file location, either on an application server (in an on-premises implementation) or an Oracle Cloud Infrastructure Object Storage location. External URL attachments linking to extract files are created on the Request for each extract.

This section describes the configuration needed for these types of extracts.

> **Note**
>
> Service Point Consumption Extracts are only available in cloud (SaaS) implementations.

Service Point Consumption Extract Entity Groups

Entity groups used with Service Point Consumption Extracts must be created using the Service Point Measurement Extract Group (D1-SPMeasurementExtractGroup) business object. These entity groups will have a Group Category of "SP Measurement Extract".

Refer to Understanding Entity Groups for more information.

Copyright © 2026, Oracle and/or its affiliates.

Service Point Consumption Extract Request Types and Requests

Configuration for service point consumption extracts are defined via Requests. See Understanding Requests in the *Application Framework Administrative User Guide* for more information about creating these records.

Service point consumption extract request types should be created using the SP Measurement Extract Request Type (D1-SPMsrmtExtractRequestType) business object, and define the following parameters:

- The Device Identifier Type (such as Asset Number, Badge Number, and so on) to include in the extract file
- File parameters, including:
  - **File Name**: String used as the prefix for extract file names
  - **File Location**: The location where extract files will be saved (see External File Storage in the *Application Framework Administrative User Guide*)
  - **Child Folder**: An optional child folder in the file location
  - **Record Limit**: A limit on the number of records to include in extract files

Service point consumption extract requests should be created using the SP Measurement Extract Request (D1-SPMsrmtExtractRequest) business object, and define the following parameters:

- **Start/End Date/Time**: The date and time range for the extract
- **Entity Group**: The entity to which the service points for which consumption is extracted are assigned
- **UOM/TOU/SQI**: The type of measurement data extracted, filtered based on the Service Type for the selected Entity Group
- **Device Identifier Type**: The device ID type to include in the extract file (such as Asset Number, Badge Number, and so on)
- **Consumption Type**: The type of consumption (Interval or Scalar) for extract
- **Target Interval Size**: The interval size for the extract, applicable only if Consumption Type is Interval. Note that the interval size must be larger than the SPI of the measurement data
- **Batch Number**: The batch number for the batch process used to perform the extract. This is populated by the batch process that performs the extract.

Extract files for Service Point Consumption Requests are created as external URL attachments on the Request that processed the extract.

Interval Snapshot Mapping

Service point consumption extracts require interval snapshot mapping data be defined for the interval size and date range of the extract. See About Interval Snapshot Mapping and Maintaining Interval Snapshot Mapping for more information.

Request Processing

Creating a request starts batch job to extract the usage to Oracle Object Storage or a file directory in a CSV format. This CSV format can easily be imported into Excel or other software.

When a request is created, it starts in the Pending state, and an Enter algorithm creates a deferred request and the SP Measurement Extract Request Monitor (D1-SPMRQ) batch

Copyright © 2026, Oracle and/or its affiliates.

process moves the request into the Extract state, where the Perform SP Measurement Extract (D1PMSPMSRMEX) algorithm performs the extract process.

The extract process creates an "External URL" attachment in which the attachment contains a URL to the extract file in the location specified in the Request Type. Attachments created for a request can be accessed via the **Request Attachments** zone in the **Request** portal.

File Naming and Formats (SECTION)

Extract file names use the following format:

```
<file location><file name>-<request id>-<start dttm>-<end dttm>_<file number>
```

where:

- **<file location>** is the **File Location** specified in the Request Type
- **<file name>** is the **File Name** specified in the Request Type
- **<request id>** is the ID of the Request
- **<start dttm>** is the start date and time for the request, displayed as YYYYMMDDHH24MISS
- **<end dttm>** is the end date and time for the request, displayed as YYYYMMDDHH24MISS
- **<file number>** is the file number for the extract file. This is a 4-digit number with padded leading zeros. Multiple files are created if a **Record Limit** is specified on the Request Type and the records extracted exceeds the limit.

For example if the **File Location** was set to "file-storage://CM-CloudStorage/sp-measurement-extracts/" and the **File Name** was set to "sp-kWh-extract" with an extract date/time of 2026-01-01 00:00:00 to 2026-02-01 00:00:00 then the first file would be named:

Scalar Record Format

```
file-storage://CM-CloudStorage/sp-measurement-extracts/sp-kWh-
extract-10392739850273-20260101000000-20260102000000_0001.csv.gz
```

Scalar records will only have one measurement per row. The **Start Date/Time** isn't the start of the day but rather the start of the measurement. Measurements are extracted based on when they end, so the first measurement chronologically for each measuring component may cover a period that falls before the extract time period. Extract data comes from the following tables and columns:

Header Field	Table	Column	Notes
Start Date/Time	D1_MSRMT	PREV_MSRMT_DTTM	Converted from the time zone defined in Installation Options to the service point time zone
Customer Name	D1_CONTACT_NAME	NAME_VALUE	This is for the "Main" usage subscription Contact and for the Primary name
Address	D1_SP	ADDRESS1 + ADDRESS2 + ADDRESS3 + ADDRESS4	ADDRESS2 through 4 will be trimmed

Copyright © 2026, Oracle and/or its affiliates.

Header Field	Table	Column	Notes
Service Point	D1_SP	D1_SP_ID	
Local Time Zone	CI_TIME_ZONE	F1_TIMEZONE_NAME	The time zone from the service point
Measuring Component	D1_MEASR_COMP	MEASR_COMP_ID	
Meter Number	D1_DVC_IDENTIFIER	ID_VALUE	Based on the device identifier type to use (such as badge number, serial number, and so on) from the Request Type
How to Use Flag	D1_MEASR_COMP	MEASR_COMP_USAGE_FLG	
UOM	D1_MC_TYPE_VALUE	D1_UOM_CD	Unit of Measure (Description)
TOU	D1_MC_TYPE_VALUE	D1_TOU_CD	Time of Use (Description)
SQI	D1_MC_TYPE_VALUE	D1_SQI_CD	Service Quantity Identifier (Description)
Date/Time	D1_MSRMT	MSRMT_DTTM	Converted from the time zone defined in Installation Options to the service point time zone
Measurement	D1_MSRMT	MSRMT_VAL	The appropriate Measurement Value field based on the Measuring Component Type's Value Identifier that was selected using the UOM/TOU/SQI. This is the main measurement Measurement Value the majority of the time but for Gas or Water, derived values from the other measurement value fields may be requested.
Condition	D1_MSRMT	MSRMT_COND_FLG	

Interval Record Format

Interval records will have multiple measurements per row. Extract data comes from the following tables and columns:

Header Field	Table	Column	Notes
Start Date/Time	D1_INT_SNAP_MAP	D1_LOCAL_DT	Converted from the time zone defined in Installation Options to the service point time zone

Copyright © 2026, Oracle and/or its affiliates.

Header Field	Table	Column	Notes
Customer Name	D1_CONTACT_NAME	NAME_VALUE	This is for the "Main" usage subscription Contact and for the Primary name
Address	D1_SP	ADDRESS1 + ADDRESS2 + ADDRESS3 + ADDRESS4	ADDRESS2 through 4 will be trimmed
Service Point	D1_SP	D1_SP_ID	
Local Time Zone	CI_TIME_ZONE	F1_TIMEZONE_NAME	The time zone from the service point
Measuring Component	D1_MEASR_COMP	MEASR_COMP_ID	
Meter Number	D1_DVC_IDENTIFIER	ID_VALUE	Based on the device identifier type to use (such as badge number, serial number, and so on) from the Request Type
How to Use Flag	D1_MEASR_COMP	MEASR_COMP_USAGE_FLG	
UOM	D1_MC_TYPE_VALUE	D1_UOM_CD	Unit of Measure (Description)
TOU	D1_MC_TYPE_VALUE	D1_TOU_CD	Time of Use (Description)
SQI	D1_MC_TYPE_VALUE	D1_SQI_CD	Service Quantity Identifier (Description)
Total	D1_MSRMT	MSRMT_VAL<N>	The sum of the measurements for the Start Date/Time for the Measuring Component. The appropriate Measurement field will be used based on the Measuring Component Type's Value Identifier that was selected using the UOM/TOU/SQI.
Time<N>	D1_MSRMT	MSRMT_DTTM	This is date and time of each interval, calculated as follows: Start Date/Time (D1_LOCAL_DT) + (interval number * SPI). SPI is based on the **Target Interval Size** if it was provided in the Request or the **Interval Size** of the Measuring Component Type if not.

Copyright © 2026, Oracle and/or its affiliates.

Header Field	Table	Column	Notes
Measurement<N>	D1_MSRMT	MSRMT_VAL<N>	The appropriate Measurement Value field based on the Measuring Component Type's Value Identifier that was selected using the UOM/TOU/SQI. This is the main measurement Measurement Value the majority of the time but for Gas or Water, derived values from the other measurement value fields may be requested.
Condition<N>	D1_MSRMT	MSRMT_COND_FLG	This will either be the the Minimum (MIN) or Maximum (MAX) Measurement Condition Flag based on the configuration of the Perform SP Measurement Extract (D1PMSPMSRMEX) algorithm. The default is to use the MIN. Note: MIN or MAX is only important for Measuring Components that have a lower SPI than the **Target Interval Size**. If no **Target Interval Size** is provided then data is extracted based on the **Interval Size** of the of the Measuring Component Type.

Interval data is values are returned as a single string of comma-separated values that are sub delimited by tildas (~). For example:

```
3.732~1~501000,5.804~2~501000,6.432~3~501000,5.572~4~501000,7.384~5~501000,7.3
58~6~501000,4.67772~7~501000,7.8132~8~501000,7.83564~9~501000,6.14856~10~50100
0,8.0988~11~501000,8.16816~12~501000,4.63186~13~501000,7.7366~14~501000,7.7588
2~15~501000,6.08828~16~501000,8.0194~17~501000,8.08808~18~501000,3.808~19~5010
00,4.448~20~501000,7.69~21~501000,6.94~22~501000,7.964~23~501000,7.316~24~5010
00
```

Customizing Extract Output

The Perform SP Measurement Extract (D1PMSPMSRMEX) algorithm uses the Extract Measurements for SP Entity Group Library (D1EMSPEGLib) script to return queries, format headers, and format records. This script implements three high level types of methods:

Copyright © 2026, Oracle and/or its affiliates.

1. Method to return the query that will extract the measurement data and master data details
    a. This takes in the same fields as are available in the plug-in driven script process data plug-in spot
    b. This returns a prepared statement
    c. There is one script for Interval and one script for Scalar since the queries are very different
2. Method to populate a header row for the CSV file
    a. For scalar this is always the same fields since we only ever extract one row at a time
    b. For interval this creates the measurement fields according to the maximum SPI or the target SPI and whether or not the extract period covers a DST transition
3. Method to process the returned data into the formatted row
    a. This takes in the results from executing the queries
    b. This formats the data into what will be streamed into the file and return that as a string

Use the **Script** portal to view this script in more detail.

To customize the data extracted via this process (for example to add an additional column), a custom (CM) version of the Groovy Library script can created. This involves the following steps:

1. Duplicate the Extract Measurements for SP Entity Group Library (D1EMSPEGLib) script.
2. Adjust the generate query method(s) to retrieve the additional information.
3. Adjust the generate header method(s) to return the new field for the header.
4. Adjust the result formatting method(s) to place the new data into the result string according to their requirements.
5. Add this new CM script as the value for the **Override Extract Groovy Library** parameter on the the Perform SP Measurement Extract (D1PMSPMSRMEX) algorithm.

Consumption Extract Type

- Understanding Consumption Extract Type
- Configuring Consumption Extract Type

Understanding Consumption Extract Type

The Consumption Extract Type controls which service point's measurements are extracted for Oracle Utilities DataConnect, what type of measurement is extracted, and how the measurements are grouped into TOU periods (if preferred).

The Consumption Extract Type also controls the request type used for creating Consumption Extract Requests of this type, how frequent automated requests are created for incremental extract, the batch jobs that are triggered for extracting data and the algorithms that extract, format, and write the data that is extracted.

Refer to the Defining DataConnect Options section for more details on how this object is specifically put into use.

Copyright © 2026, Oracle and/or its affiliates.

Configuring Consumption Extract Type

This portal is used to display and maintain a Consumption Extract Type.

Refer to Understanding Consumption Extract Types for more information.

You can access the portal by selecting **Admin**, then **Integration**, then **Consumption Extract Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Consumption Extract Type List**: displays all of the Consumption Extract Types so you can choose the one you want to display in more detail
- **Consumption Extract Type**: shows the specific configuration for the selected Consumption Extract Type

Analytics Configuration

This portal provides a bird's eye view of the configuration information for Oracle Utilities Analytics. It provides links and guidelines for the areas that need configuration to successfully run the extract transfer and load processes from Oracle Utilities Analytics.

Refer to the *Oracle Utilities Analytics Administration Guide* for more information.

You can access the portal from the **Admin**, and then **Analytics Configuration**, and then **Customer Analytics Configuration**

The following zones may appear as part of the portal's **Main** tab page

- **Bucket Configuration List.** This zone lists bucket configurations to set up.
- **BI-Related Business Objects Information.** This zone lists additional control entities to set up.

The following zones may appear as part of the portal's **OWB-Based ETL** tab page

- **Outbound Sync BOs and Algorithm List.** This zone lists business objects and algorithms involved in the extract process.
- **BI-Oriented Extendable Lookup.** This zone lists extendable lookups to set.
- **External Data Source Indicators List.** This zone lists the external identifiers of the various sources for your analytics data.

Note: Service Point business objects can make use of the following System Events:

- **Service Point Snapshot**: This system event defines the algorithm used to create a snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Snapshot."
- **Usage Snapshot**: This system event defines the algorithm used to create a usage snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Usage Snapshot."
- **Unreported Usage Analysis Snapshot**: This system event defines the algorithm used to create a snapshot of the Service Point's consumption since the last usage transaction for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Unreported Usage Analysis Snapshot."

Copyright © 2026, Oracle and/or its affiliates.

- **SP VEE Exception Snapshot**: This system event defines the algorithm used to create a snapshot of VEE exceptions for the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - VEE Exception Snapshot."

Migrating Data Extract Processing from Legacy Measurement Processing to Direct Measurement Processing

When processing data extracts using Direct Measurement Processing, change data capture information is recorded in the Measurement Extract Request table instead of the General Process table. This requires that the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration be set to "Yes". This applies to all types of data extracts, including:

- Configurable Consumption Extracts
- Measurement Data Extracts
- Initial Measurement Data Header Extracts
- Aggregated Measurement Data Extracts
- DataConnect Consumption Extracts (see Oracle Utilities Dataconnect / Opower for more information about DataConnect extracts)

For customers who had been using Legacy Measurement Processing and processing data extracts (in which change data capture information is recorded in the Genera Process table), migrating to using Direct Measurement Processing will involve transitioning out of Legacy-based extract processing and into Direct Measurement Processing extract processing.

There are two approaches to this transition, one involves continuing to use the current batch controls, the other involves creating new batch controls.

Using Existing Batch Controls

To use existing batch controls, do the following:

1. Pause all Initial Measurement Data Processing.
2. Run each of the Historical extract processes to process all remaining records in the General Process table.
3. Enable use of the Measurement Extract Request table by setting the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration be set to "Yes".
4. Flush the batch server.
5. Resume Initial Measurement Data processing.

Creating New Batch Controls

To create new batch controls, do the following:

1. Duplicate all of the Historical extract batch controls
2. Update the Initial Measurement Data algorithms and Consumption Extract Types to reference the new batch controls.
3. Flush the batch server.
4. Process one final run using the original Historical extract batch controls.

Copyright © 2026, Oracle and/or its affiliates.

5. Enable use of the Measurement Extract Request table by setting the **Use Measurement Extract Request for Historical Extracts** parameter on the MDM Master Configuration be set to "Yes".
6. Start using the new batch controls for all extract processing.

Aggregation

- Standard Aggregation
- Dynamic Aggregation

Standard Aggregation

- Configuring an Out-of-the-box Aggregation
- Understanding an Example Out-of-the-box Aggregation
- Creating a New Custom Aggregation

Configuring an Out-of-the-box Aggregation

Aggregation calculations should be run on an as needed basis. This can include running the following batch processes:

- Scanning for new aggregation dimension (D1-ADS): This process is applicable if the system is configured to use aggregation dimension scanners to detect new aggregation dimensions (such as a service point referencing a new transformer for which an aggregator measuring component doesn't currently exist)
- Performing aggregation calculations (D2-AGG): this batch handles the summarization of measurement values in order to create aggregated measurements.

Note that aggregation calculations should precede usage transaction processing if aggregated values serves as input to the calculation of bill determinants.

Refer to the About Aggregations section of the *Oracle Utilities Meter Solution Business User Guide* for more information on this functionality. Refer to Understanding Measuring Component Types for information on Measuring Component Types provided for aggregation.

Understanding an Example Out-of-the-box Aggregation

The Oracle Utilities Meter Data Management base package includes an aggregation that aggregates measurement quantities for constituent measuring components based on postal code and service type dimensions. The table below outlines the types of objects used in this aggregation, based on the steps outlined above), and the specific objects for each type.

Dependency Order	Object Type	Base Package Example
1	Aggregator Measuring Component Business Object	D2-Aggregator (Aggregator - Postal and Service Type)

Copyright © 2026, Oracle and/or its affiliates.

2	Aggregator Measuring Component UI Maps	Display: D2-AggMCDisp (Service Type and Postal Aggregator-Display) Maintenance: D2-AggMCMaint (Service Type and Postal Aggregator-Maintenance)
3	Aggregator Business Object Info Algorithm	D2-AMC-INFO (Service Type and Postal Aggregator - Information)
4	Find Constituent Measuring Components Algorithm	D2-DET-CMC (Find Constituent Measuring Components Based on Service Type and Postal)
5	Measuring Component Type	D2-AggregatorType (Aggregator Type)
6	Query Zone for Consumption Statistics Portal	D2-AGGMCQRY (Aggregator Search)
7	Dimension Scanner Activity Business Object	D2-ActivityAggDimScanner (Aggregator Creator - Postal / Service Type)
8	Dimension Scanner Activity UI Maps	Display: D2-AggDimScannerActDisp (Aggregator DS Activity-Display) Maintenance: D2-AggDimScannerActMaint (Aggregator DS Activity-Maintenance)
9	Dimension Scanner Activity Business Object Info Algorithm	D2-ADS-INFO (Aggregator Dimension Scanner Information)
10	Enter Algorithm for Scan State	D2-CRE-AGGMC (Aggregator MC Creation for Post Code and Service Type)
11	Activity Type	D2-ActivityTypeAggDimScanner (Aggregator Dimension Scanner Activity Type)

Refer to the About Aggregations section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Creating a New Custom Aggregation

This section describes the overall process for creating a new custom Aggregation.

Refer to the About Aggregations section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Execute the following steps:

1. Create a business object for the aggregator measuring component. This will flatten the dimensional value(s) into searchable characteristics. Whether this business object is a

Copyright © 2026, Oracle and/or its affiliates.

parent or a child of another aggregator business object depends on when periodic aggregation should occur:

a. If you want the periodic aggregation to occur when another aggregation occurs, it can be a child business object (meaning that it inherits the lifecycle (and therefore the deferred monitor) of the parent)

b. If you want to schedule its periodic aggregation independently from other aggregation business objects, this must NOT be a child business object as it will require its own deferred monitor (and deferred monitors can only be defined on parent business objects)

2. Create UI maps for the aggregator business object as follows:

   a. One to display the aggregator measuring component (Display)

   b. One to allow user to change / add a new one (Maintenance)

> **Note**
>
> A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in for the aggregator business object that concatenates together its dimension types and values.

4. Create a "Find Constituent Measuring Components" algorithm and plug it on the aggregator business object. This will be passed the aggregator measuring component and the from and to date/times. It will insert the constituent measuring component IDs and the respective from / to date-time of each onto a temporary table.

5. Create a measuring component type instance and reference the new aggregator measuring component business object (as well as the types of constituent measuring component types that should be aggregated).

6. Create a query zone for Consumption Statistics search to allow users to find the aggregator measuring component.

Optional steps:

1. Create a business object for the dimension scanner activity. This should be a child business object of the base package dimension scanner business object.

2. Create UI maps for the activity business object, as follows:

   a. One to display the dimension scanner activity (Display).

   b. One to allow users to change/add a new one (Maintenance).

> **Note**
>
> A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in that will describe what it scans.

4. Create an Enter algorithm on the Scan state that finds distinct combinations of the dimensional values and creates new aggregator measuring components when new ones are detected.

- Aggregation Groups
- Measuring Component Sets
- Configuring Dynamic Aggregation Step-by-Step
- Extending Dynamic Aggregation

Dynamic Aggregation Configuration Overview

Standard aggregation processing uses specific algorithms configured to work with a specified set of dimensions. For example, the base package Service Type and Postal aggregation uses specific algorithms for dimension scanning and finding constituent measuring components.

In contrast, dynamic aggregation uses dynamic queries for the dimension scanning, find constituents, and aggregation processes. These dynamic queries are based on configuration of administrative data, including:

- **Data Sources** define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or other sources of data.
- **Aggregation Measuring Component Types** define the most important properties of aggregation measuring components used to store aggregated data.
- **Aggregation Groups** define the ordering of a series of related aggregations and the schedule of aggregation.
- **Measuring Component Sets** define the dimensions and criteria by which aggregation will be performed.

Aggregation Master Configuration

The Aggregation Master Configuration defines common parameters used with aggregation processing, including:

- Batch Controls used by the dimension scan and aggregation process, for both scheduled and adhoc execution.
- Details for how the system compares interval and billing data for the same set of customers in order to use only one source or other.

Data Sources

- Understanding Data Sources
- Configuring Data Sources
- Configuring Data Source Template SQL

Understanding Data Sources

Data Sources define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or measuring component sets. Data sources also define configurations used when generating dynamic queries used by aggregation processing.

Data Source Classes

Data sources are defined by classes, each of which is based on a specific business object, and determines the type of configuration used by aggregation processing. More specifically, the data types configured on the data source are used when generating dynamic queries used by aggregation processing.

The table below lists the data source classes and the business object and configuration options for each. Consult the embedded help for more information about the specific configuration options used by each data source class.

Data Source Class	Usage	Business Object	Configuration Options
Measurements from US Service Points	Used when aggregating data from measuring components linked to service points via a usage subscription.	D1-DataSourceMeasurements	Measuring Component Types
Badged Items	Used when aggregating data from badged items.	D1-BadgedItemsDataSource	Item Types
Billed Service Quantities	Used when aggregating data based on billed services quantities.	D1-DataSourceBilledSerQuantity	Usage Subscription Types
Measuring Component Sets	Used when aggregating data from measuring component sets. Data sources of this class are used with composite aggregation.	D1-DataSourceMCSet	Usage Subscription Types
Unbadged Items	Used when aggregating data from unbadged items.	D1-DataSourceUnbadgedItems	Item Types

Data Source Class	Usage	Business Object	Configuration Options
Measurements from US Direct Links	Used when aggregating data from measuring components directly linked to a usage subscription.	D1-DataSourceMeasurementDirect	Measuring Component Types
Service Point Quantities	Used when aggregating data based on service point quantities.	D1-DataSourceSPQuantities	Service Point Quantity Types

Data Source Template SQL

Data sources also provide template structured query language (SQL) used when generating dynamic queries used by aggregation processing. This template SQL is used as the basis for dynamic queries, and is extended by additional SQL generated from the data source configuration as well as configuration defined for measuring component sets, measuring components, and measuring component types that reference the data source. Template SQL is provided via the Data Source SQL (D1-DataSourceSQLLookup) extendable lookup. Values for this extendable lookup are used as the **Option Value** for the following business object options on the data source business object.
