This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software" or "commercial computer software documentation" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Abstract

This manual provides security guidelines for the Oracle Linux 6 operating system.

Document generated on: 2021-03-31 (revision: 11688)

Table of Contents

Preface	
1 Oracle Linux Security Overview	1
1.1 Basic Security Considerations	1
1.1.1 Keep Software up to Date	
1.1.2 Restrict Network Access to Critical Services	
1.1.3 Follow the Principle of Least Privilege	1
1.1.4 Monitor System Activity	2
1.1.5 Keep up to Date on the Latest Security Information	2
1.2 The Oracle Linux Security Model	2
1.3 Overview of Oracle Linux Security	2
1.4 Understanding the Oracle Linux Environment	3
1.5 Recommended Deployment Configurations	3
1.6 Component Security	
1.7 References	4
2 Secure Installation and Configuration	7
2.1 Pre-Installation Tasks	
2.2 Installing Oracle Linux	
2.2.1 Shadow Passwords and Hashing Algorithms	8
2.2.2 Strong Passwords	
2.2.3 Separate Disk Partitions	
2.2.4 Encrypted Disk Partitions	
2.2.5 Software Selection	
2.2.6 Network Time Service	
2.3 Post-Installation Tasks	
3 Implementing Oracle Linux Security	
3.1 Configuring and Using Data Encryption	
3.2 Configuring a GRUB Password	12
3.3 Configuring and Using Certificate Management	
3.3.1 About the openssl Command	
3.3.2 About the keytool Command	
3.4 Configuring and Using Authentication	
3.4.1 About Local Oracle Linux Authentication	
3.4.2 About IPA	
3.4.3 About LDAP Authentication	
3.4.4 About NIS Authentication	20
3.4.5 About Winbind Authentication	
3.4.6 About Kerberos Authentication	
3.5 Configuring and Using Pluggable Authentication Modules	
3.6 Configuring and Using Access Control Lists	
3.7 Configuring and Using SELinux	
3.7.1 About SELinux Administration	
3.7.2 About SELinux Modes	
3.7.3 Setting SELinux Modes	
3.7.4 About SELinux Policies	
3.7.5 About SELinux Context	
3.7.6 About SELinux Users	
3.8 Configuring and Using Auditing	
3.9 Configuring and Using System Logging	
3.10 Configuring and Using Process Accounting	
3.11 Configuring and Using Software Management	

Oracle® Linux 6

3.11.1 Configuring Update and Patch Management 40 3.11.2 Installing and Using the Yum Security Plugin 41 3.12.1 Configuring and Using TCP Wrappers 43 3.12.1 Configuring and Using TCP Wrappers 47 3.13.2 Configuring and Using TCP Wrappers 47 3.13.2 Configuring and Using TCP Wrappers 49 3.13.1 Running DNS and FTP Services in a Chroot Jail 49 3.13.2 Creating a Chroot Jail 49 3.13.3 Using a Chroot Jail 49 3.14.3 Configuring and Using Linux Containers 50 3.15.1 Address Space Layout Randomization 50 3.15.1 Address Space Layout Randomization 51 3.15.3 Position Independent Executables 51 4.1 Design Principles for Network Programs 53 4.3 General Guidelines for Secure Coding 58 5.4 General Guidelines for Network Programs 58 5.5 Secure Deployment Checklist 57 5.6 Configuring System Logging 58 5.7 Source Deployment Checklist 53 5.8 Secure Deployment Checklist 53 5.9 Count Deployment Checklist 53 5.9 Count Deployment Checklist 53 5.9 Con		
3.12 Configuring Access to Network Services 43 3.12.1 Configuring and Using Packet-filtering Firewalls 44 3.12.2 Configuring and Using TCP Wrappers 47 3.13 Configuring and Using TCP Wrappers 48 3.13.1 Running DNS and FTP Services in a Chroot Jail 49 3.13.1 Running DNS and FTP Services in a Chroot Jail 49 3.13.1 Configuring and Using Linux Containers 50 3.15 Configuring and Using Kernel Security Mechanisms 50 3.15.1 Address Space Layout Randomization 50 3.15.2 Data Execution Prevention 51 3.15.3 Position Independent Executables 51 4.1 Design Principles for Secure Coding 54 4.3 General Guidelines for Network Programs 55 5 Secure Deployment Checklist 57 5.1 Minimizing the Software Footprint 57 5.2 Configuring a Packet-filtering Firewall 63 5.3 Disabiling Core Dumps 59 5.4 Configuring a Packet-filtering Firewall 63 5.5 Cocking Down Network Services 62 5.6 Configuring a Packet-filtering Firewall 63 5.7 Configuring TCP Wrappers 63 5.8 Configuring Verne Network Services	3.11.1 Configuring Update and Patch Management	. 40

Preface

Oracle® *Linux 6: Security Guide* provides security guidelines for the Oracle Linux 6 operating system. The guide presents steps that you can take to harden an Oracle Linux system and the features that you can use to protect your data and applications. You can tailor the recommendations in the guide to suit your site security policy.

Audience

This document is intended for administrators who analyze security requirements, implement site security policy, install and configure the Oracle Linux operating system, and maintain system and network security. It is assumed that readers have a general knowledge of Linux administration, a good foundation in software security, and knowledge of your organization's site security policy.

Document Organization

The document is organized as follows:

- Chapter 1, Oracle Linux Security Overview provides an overview of Oracle Linux security.
- Chapter 2, Secure Installation and Configuration outlines the planning process for a secure installation and describes how the choices that you make during installation affect system security.
- Chapter 3, *Implementing Oracle Linux Security* describes the various ways in which you can configure the security of an Oracle Linux system.
- Chapter 4, Security Considerations for Developers provides information for developers about how to create secure applications for Oracle Linux, and how to extend Oracle Linux to access external systems without compromising security.
- Chapter 5, Secure Deployment Checklist provides guidelines that help secure your Oracle Linux system.
- Chapter 6, *Using OpenSCAP to Scan for Vulnerabilities* describes how to use OpenSCAP to scan your Oracle Linux system for security vulnerabilities.
- Chapter 7, FIPS 140-2 Compliance in Oracle Linux describes the FIPS 140 Level 1 certifications for cryptographic components that have been completed by Oracle and reside within Oracle Linux 6.9.

Oracle® Linux Documentation

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.

Convention	Meaning
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at

https://www.oracle.com/corporate/accessibility/.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit

https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers' existing technologies and the need to ensure continuity of service as Oracle's offerings and industry standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.

Chapter 1 Oracle Linux Security Overview

Table of Contents

1.1 Basic Security Considerations	1
1.1.1 Keep Software up to Date	1
1.1.2 Restrict Network Access to Critical Services	1
1.1.3 Follow the Principle of Least Privilege	1
1.1.4 Monitor System Activity	2
1.1.5 Keep up to Date on the Latest Security Information	2
1.2 The Oracle Linux Security Model	
1.3 Overview of Oracle Linux Security	2
1.4 Understanding the Oracle Linux Environment	3
1.5 Recommended Deployment Configurations	3
1.6 Component Security	4
1.7 References	4

This chapter provides an overview of Oracle Linux security.

1.1 Basic Security Considerations

The following sections list the fundamental principles for using Oracle Linux securely.

1.1.1 Keep Software up to Date

One of the principles of good security practice is to keep all software versions and patches up to date. Throughout this document, we assume a maintenance level of Oracle Linux Release 6 or later.

For more information, see Section 3.11, "Configuring and Using Software Management"

1.1.2 Restrict Network Access to Critical Services

Keep both middle-tier applications and databases behind a firewall. In addition, place a firewall between middle-tier applications and databases if these are hosted on separate servers. The firewalls provide assurance that access to these systems is restricted to a known network route, which can be monitored and restricted, if necessary. As an alternative, a firewall router substitutes for multiple, independent firewalls.

If firewalls cannot be used, restrict access based upon IP address. Restricting database access by IP address often causes application client/server programs to fail for DHCP clients. To resolve this, consider using static IP addresses, a software/hardware VPN or Windows Terminal Services or its equivalent.

For more information, see Section 3.12, "Configuring Access to Network Services".

1.1.3 Follow the Principle of Least Privilege

The principle of least privilege states that users should be given the least amount of privilege to perform their jobs. Over ambitious granting of responsibilities, roles, grants, and so on, especially early on in an organization's life cycle when people are few and work needs to be done quickly, often leaves a system wide open for abuse. User privileges should be reviewed periodically to determine relevance to current job responsibilities.

For more information, see Section 5.11, "Checking User Accounts and Privileges".

1.1.4 Monitor System Activity

System security stands on three legs: good security protocols, proper system configuration, and system monitoring. Auditing and reviewing audit records address the third requirement. Each component within a system has some degree of monitoring capability. Follow audit advice in this document and regularly monitor audit records.

For more information, see Section 3.8, "Configuring and Using Auditing".

1.1.5 Keep up to Date on the Latest Security Information

Oracle continually improves its software and documentation. Check regularly on the Oracle Technology Network at https://www.oracle.com/technetwork/server-storage/linux for revisions. For information about common vulnerabilities and exposures (CVE) and errata that are available on the Unbreakable Linux Network, see https://linux.oracle.com/cve and https://linux.oracle.com/errata.

1.2 The Oracle Linux Security Model

Oracle Linux provides a complete security stack, from network firewall control to access control security policies, and is designed to be secure by default.

Traditional Linux security is based on a Discretionary Access Control (DAC) policy, which provides minimal protection from broken software or from malware that is running as a normal user or as **root**. The SELinux enhancement to the Linux kernel implements the Mandatory Access Control (MAC) policy, which allows you to define a security policy that provides granular permissions for all users, programs, processes, files, and devices. The kernel's access control decisions are based on all the security relevant information available, and not solely on the authenticated user identity. By default, SELinux is enabled when you install an Oracle Linux system.

For more information, see Section 3.7, "Configuring and Using SELinux".

1.3 Overview of Oracle Linux Security

Oracle Linux has evolved into a secure enterprise-class operating system that can provide the performance, data integrity, and application uptime necessary for business-critical production environments.

Thousands of production systems at Oracle run Oracle Linux and numerous internal developers use it as their development platform. Oracle Linux is also at the heart of several Oracle engineered systems, including the Oracle Exadata Database Machine, Oracle Exalytics In-Memory Machine, Oracle Exalogic Elastic Cloud, and Oracle Database Appliance.

Oracle On Demand services, which deliver software as a service (SaaS) at a customer's site, via an Oracle data center, or at a partner site, use Oracle Linux at the foundation of their solution architectures. Backed by Oracle support, these mission-critical systems and deployments depend fundamentally on the built-in security and reliability features of the Oracle Linux operating system.

Released under an open-source license, Oracle Linux includes the Unbreakable Enterprise Kernel that provides the latest Linux innovations while offering tested performance and stability. Oracle has been a key participant in the Linux community, contributing code enhancements such as Oracle Cluster File System and the Btrfs file system. From a security perspective, having roots in open source is a significant

advantage. The Linux community, which includes many experienced developers and security experts, reviews posted Linux code extensively prior to its testing and release. The open-source Linux community has supplied many security improvements over time, including access control lists (ACLs), cryptographic libraries, and trusted utilities.

1.4 Understanding the Oracle Linux Environment

To better understand your security needs, ask yourself the following questions:

Which resources am I protecting?	Many resources in the production environment can be protected, including information in databases accessed by WebLogic Server and the availability, performance, applications, and the integrity of the Web site. Consider the resources you want to protect when deciding the level of security you must provide.
From whom am I protecting the resources?	For most Web sites, resources must be protected from everyone on the Internet. But should the Web site be protected from the employees on the intranet in your enterprise? Should your employees have access to all resources within the WebLogic Server environment? Should the system administrators have access to all WebLogic resources? Should the system administrators be able to access all data? You might consider giving access to highly confidential data or strategic resources to only a few well trusted system administrators. Perhaps it would be best to allow no system administrators access to the data or resources.
What will happen if the protections on strategic resources fail?	In some cases, a fault in your security scheme is easily detected and considered nothing more than an inconvenience. In other cases, a fault might cause great damage to companies or individual clients that use the Web site. Understanding the security ramifications of each resource will help you protect it properly.

1.5 Recommended Deployment Configurations

This section describes recommended architectures for deploying Oracle products with secure Internet access.

Figure 1.1, "Simple Firewall Deployment Configuration" shows a simple deployment architecture.

Figure 1.1 Simple Firewall Deployment Configuration

This single-computer deployment may be cost effective for small organizations. However, it cannot provide high availability because all components are stored on the same computer.

Figure 1.2, "DMZ Deployment Configuration" shows the recommended configuration, which uses the well-known and generally accepted Internet-Firewall-DMZ-Firewall-Intranet architecture.

Figure 1.2 DMZ Deployment Configuration

A *demilitarized zone* (DMZ) refers to a server that is isolated by firewalls from both the Internet and the intranet, and which acts a buffer between them. The firewalls that separate DMZ zones provide two essential functions:

- · Block any traffic types that are not permitted.
- Provide intrusion containment in the event that successful intrusions take over processes or processors.

1.6 Component Security

Each application software component usually has its own security considerations that you should take into account independently of those that apply to the operating system. Refer to the security guidelines for each component to determine how best to configure it for the requirements of security at your site.

Note

The most up-to-date advice that is available from some of the sources applies to Oracle Linux 5. However, most of the advice is also applicable to Oracle Linux 6.

Chapter 2 Secure Installation and Configuration

Table of Contents

2.1	Pre-Installation Tasks	7
2.2	Installing Oracle Linux	7
	2.2.1 Shadow Passwords and Hashing Algorithms	. 8
	2.2.2 Strong Passwords	
	2.2.3 Separate Disk Partitions	. 8
	2.2.4 Encrypted Disk Partitions	8
	2.2.5 Software Selection	9
	2.2.6 Network Time Service	. 9
2.3	Post-Installation Tasks	9

This chapter outlines the planning process for a secure installation and describes how the choices that you make during installation affect system security.

2.1 Pre-Installation Tasks

An important consideration is the security of the physical system on which you will install Oracle Linux. If possible, keep server systems in a locked data center and limit access to authorized personnel. Such personnel should also receive appropriate administrative training as human error is often the cause of a security breach. For more information about the available Oracle Linux coursework and certification options, see https://education.oracle.com.

Aside from the risks of theft and data compromise, physical security is critical because it prevents an unauthorized user from possibly modifying the system BIOS, altering the boot device, and booting from an alternate medium. If a system is not kept in a locked data center, consider password-protecting the BIOS. Consult the system manufacturer's documentation for information on setting a BIOS password. Edit the BIOS settings to disable booting from the CD-ROM drive, floppy disk drive, USB ports, and other external devices. In addition, you can configure disk encryption during installation, or password-protect the GRUB boot loader after installation.

Note

Setting a BIOS, encrypted disk, or boot-loader password requires you to enter the password whenever you reboot the system. Only disk encryption can prevent access to the data on disk when an attacker uses techniques such as resetting the BIOS, accessing the disk by booting an operating system from a memory stick, or simply removing the hard drive to read its contents on another system.

2.2 Installing Oracle Linux

When you install Oracle Linux, you can reduce the attack surface by installing only the software packages that are required for operation. Software packages are a potential source of setuid programs, network services, and libraries that an attacker can potentially use to gain access illegitimately and compromise a system.

You can use a pretested kickstart profile to provide consistent and precise control over what is installed. Automated installation using a kickstart profile reduces both security risk and administrative effort.

Alternatively, you can use Oracle Enterprise Manager Ops Center, which supports the import of OS images and explicit provisioning profiles. For more information, refer to the Oracle Enterprise Manager Ops Center documentation.

2.2.1 Shadow Passwords and Hashing Algorithms

By default, an Oracle Linux system is configured to use password hashes that are stored in the /etc/ shadow file rather than in the world-readable /etc/passwd file. If shadow passwords were not used, an attacker is much more likely to be able to discover a password by applying cracking software to the hashes. Similarly, using a password-hashing algorithm that is weaker than SHA-512 would make it much easier to find likely candidates that match a hash value.

2.2.2 Strong Passwords

During installation, you are prompted to enter passwords for **root** and one additional user, if you choose the user to be authenticated locally rather than over the network. The passwords that you enter should be strong in that they should be extremely difficult to deduce by guesswork or by other means, such as automated FTP or SSH logins. By default, the installation process rejects null passwords and warns about weak passwords, but it does not enforce strong passwords. It is your responsibility to ensure that passwords are sufficiently strong.

Some general guidelines for creating a strong password are:

- · Make the password at least eight characters long.
- Use a mixture of lower and upper case letters, numbers, and other characters.
- Do not include whole words from English, LEET speak, or any other language or technology, even if you spell the words in reverse order.
- Do not include personal information such as names, dates, addresses, email addresses, or telephone numbers.
- Do not use well-known acronyms, abbreviations, or character sequences such as QWERTY.
- Do not use a password that is the same as or very similar to a password that you used previously on the system.
- Use a password for root that is different from the password for any other user.

2.2.3 Separate Disk Partitions

The National Security Agency (NSA) recommendations state that you should set up user-writable file systems such as /home, /tmp, and /var/tmp on partitions that are separate from /. In addition, /boot must be a dedicated file system if you encrypt the root file system.

For more information, see https://www.nsa.gov/ia/_files/factsheets/rhel5-pamphlet-i731.pdf.

2.2.4 Encrypted Disk Partitions

When choosing a disk layout, you have the option of encrypting disk partitions with the Linux Unified Key Setup (LUKS) format. As for any other password, ensure that you enter a strong passphrase if you choose to encrypt any partitions.

Note

The /boot file system cannot be encrypted.

2.2.5 Software Selection

If you choose to customize the software to be installed on a system, you can select or deselect packages from the default set. For example, the basic server configuration does not install the Gnome and KDE desktop software and the X Windows System packages from the **Desktops** section. Additional packages that you might want to install on a server system are available under the **Servers**, **Web Services**, **Databases**, and other section headings.

2.2.6 Network Time Service

If you select to synchronize the data and time over the network, the system is configured as an NTP client that uses the [012].rhel.pool.ntp.org public servers by default. If your systems rely on Kerberos authentication, which requires close synchronization of the clocks on each participating system, you might prefer to configure your systems to use a local NTP server instead.

2.3 Post-Installation Tasks

For information about the way that you can configure the security of an Oracle Linux system, see Chapter 3, *Implementing Oracle Linux Security*.

For guidelines about hardening an Oracle Linux system, see Chapter 5, Secure Deployment Checklist.

Chapter 3 Implementing Oracle Linux Security

Table of Contents

3.1 Configuring and Using Data Encryption	11
3.2 Configuring a GRUB Password	. 12
3.3 Configuring and Using Certificate Management	. 13
3.3.1 About the openssl Command	14
3.3.2 About the keytool Command	16
3.4 Configuring and Using Authentication	. 17
3.4.1 About Local Oracle Linux Authentication	. 18
3.4.2 About IPA	. 18

3.12 Configuring Access to Network Services	. 43
3.12.1 Configuring and Using Packet-filtering Firewalls	
3.12.2 Configuring and Using TCP Wrappers	
3.13 Configuring and Using Chroot Jails	
3.13.1 Running DNS and FTP Services in a Chroot Jail	
3.13.2 Creating a Chroot Jail	
3.13.3 Using a Chroot Jail	
3.14 Configuring and Using Linux Containers	50
3.15 Configuring and Using Kernel Security Mechanisms	. 50
3.15.1 Address Space Layout Randomization	
3.15.2 Data Execution Prevention	
3.15.3 Position Independent Executables	51

This chapter describes the various ways in which you can configure the security of an Oracle Linux system.

3.1 Configuring and Using Data Encryption

You can use data encryption to protect data that is stored or that is being transmitted. Data on storage devices and media can be at risk of theft or device loss. Data being transmitted over local area networks

and the Internet can be intercepted or altered. In addition, data encryption to protect privacy and personal data is increasingly being made a mandatory requirement of corporate security policy and by governmental regulations (for example, HIPAA, GLBA, SOX, and PCI DSS).

Oracle Linux systems provide several strategies for protecting data:

- When installing systems and application software, only accept RPM packages that have been digitally signed. To ensure that downloaded software packages are signed, set gpgcheck=1 in the repository configuration file and import the GPG key provided by the software supplier. You can also install RPMs using the Secure Sockets Layer (SSL) protocol, which uses encryption to protect the communications channel.
- To protect against data theft, consider using full-disk encryption, especially on laptops, external hard drives, or removable devices such as USB memory sticks. Oracle Linux supports block device encryption using dm-crypt and the Linux Unified Key Setup (LUKS) format. The cryptsetup administration command is available in the cryptsetup-luks package. These technologies encrypt device partitions so that the data is inaccessible when a system is turned off. When the system boots and you supply the appropriate passphrase, the device is decrypted and its data is accessible. For more infomation, see the cryptsetup(8) manual page.
- An alternative approach for protecting data on a device is to use the eCryptfs utilities to encrypt a file system. The eCryptfs utilities are available in the ecryptfs-utils package. Unlike dm-crypt, which encrypts block devices, eCryptfs encrypts data at the file-system level, and you can also use it to protect individual files and directories. For more information, see the ecryptfs(7), ecryptfs-setup-private(1), ecryptfs-mount-private(1), and ecryptfs-umount-private(1) manual pages.
- Oracle Linux uses encryption to support Virtual Private Networks (VPN), Secure Shell (ssh), and password protection. By default, Oracle Linux uses a strong password hashing algorithm (SHA-512) and stores hashed passwords in the /etc/shadow file.
- Oracle Linux takes advantage of hardware-accelerated encryption on Intel CPUs that support the Advanced Encryption Standard New Instructions (AES-NI) instruction set, which speeds up the execution of AES algorithms as well as SHA-1 and RC4 algorithms on x86 and x86_64 architectures.

3.2 Configuring a GRUB Password

If a system is not kept in a locked data center, and as an alternative to using any password protection mechanism built into the BIOS, you can add a degree of protection to the system by requiring a valid password be provided to the GRUB boot loader.

Note

Password protecting GRUB access prevents unauthorized users from entering single user mode and changing settings at boot time. It does not prevent someone from accessing data on the hard drive by booting into an operating system from a memory stick, or physically removing the drive to read its contents on another system.

To configure a GRUB password:

1. Use the following command to generate the MD5 hash of your password:

/sbin/grub-md5-crypt

```
Password: clydenw
Retype password: clydenw
$1$qhqh.1$7MQxS6GHg4IlOFMdnDx9S.
```

2. Edit /boot/grub/grub.conf, and add a password entry below the timeout entry near the top of the file, for example:

```
timeout=5
password --md5 pwhash
```

where *pwhash* is the hash value that grub-md5-crypt returned.

3. If GRUB has been configured to boot multiple operating systems on the same machine, add a lock entry to after the title entry for each operating system, for example:

```
title Windows
lock
```

When you reboot the machine, you must press P and enter the password before you can access the GRUB command interface.

For more information, use the info grub command to access the GRUB manual.

3.3 Configuring and Using Certificate Management

Public-key cryptography allows secure communication on an insecure public network and verification of the identity of the entity at the other end of a network connection. Public-key cryptography is based on establishing pairs of secret and public keys. Either key can be used to encrypt some data, and the other key can then be used to decrypt that data. You cannot use just one of the keys to perform both operations on the same data. Because of the asymmetric nature of the key operations, you can distribute the public key without fear of compromising security. Possession of the private key is required to be able to read messages that are encrypted with the public key.

However, if you receive a public key, this in itself does not establish the identity of the sender. A publickey infrastructure implements digital certificates that allow public keys to be distributed in a hierarchy of trusted relationships. A Certification Authority (CA) acts as a trusted third party that can issue signed certificates on behalf of another entity on a network. The CA uses its own private key to encrypt the certificate, which contains the entity's public key together with other information about the entity (*subject*), the CA (*issuer*), the period of validity of the certificate, and the cryptographic algorithms used. Assuming that you trust the CA, you can also trust the entity's public key stored in the certificate. Decrypting the certificate with the CA's public key yields the entity's public key, and this key can be used to establish a secure communications channel.

For the Internet, there are many public top-level (*root*) CAs and there are also many intermediate CAs that are trusted by a root CA to issue certificates on behalf of entities. An intermediate CA usually returns a certificate chain, where each certificate in the chain authenticates the public key of the signer of the previous certificate in the chain up to and including a root CA. The secure communication channels that are required for website security usually use the Transport Layer Security (TLS) or Secure Sockets Layer (SSL) cryptographic protocols. Because most financial transactions on the Internet rely on TLS and SSL, a more limited number of CAs are permitted to issue TLS/SSL certificates that web browsers trust, and these CAs are regularly audited for security.

OpenSSL is an open-source implementation of the TLS and SSL protocols. If a hierarchy of trust is confined to your organization's intranet, you can use OpenSSL to generate a root certificate and set up a CA for that domain. However, unless you install this self-signed root certificate on each system in your

organization, browsers, LDAP or IPA authentication, and other software that use certificates will prompt the user about the potentially untrusted relationship. If you use certificates for your domain that are validated by a root or intermediate-level CA, you do not need to distribute a root certificate as the appropriate certificate should already be present on each system.

Typically, TLS/SSL certificates expire after one year. Other certificates, including root certificates that are distributed with web browsers, and which are issued by root and intermediate CAs usually expire after a period from five to 10 years. To avoid applications displaying warnings about out-of-date certificates, you should plan to replace TLS/SSL certificates before they expire. For root certificates, this is not usually a problem as you would typically update the software before the certificate would expire.

If you request a signed certificate from a CA for which a root certificate or certificate chain that authenticates the CA's public key does not already exist on your system, obtain a trusted root certificate from the CA. To avoid a potential man-in-the-middle attack, verify the authenticity of the root certificate before importing it. Check that the certificate's fingerprint matches the fingerprint that the CA publishes.

The openssl command allows you to generate self-signed certificates that web browsers can use. You can also use the keytool command to generate self-signed certificates, but this command's primary purpose is to install and manage JSSE (Java Secure Socket Extension) digital certificates for use with Java applications.

Note

For production environments, you should obtain external CA-signed certificates, which can be revoked if the private key is compromised. Self-signed certificates cannot be revoked, and should only be used when developing, testing, or demonstrating software.

For more information about using TLS/SSL and certificates with the Apache HTTP server, see the Apache documentation at http://httpd.apache.org/docs.

3.3.1 About the openssl Command

The openssl command, which is included in the openssl package, allows you to perform various cryptography functions from the OpenSSL library including:

- Creating and managing pairs of private and public keys.
- Performing public key cryptographic operations.
- Creating self-signed certificates.
- Creating certificate signing requests (CSRs).
- Creating certificate revocation lists (CRLs).
- Converting certificate files between various formats.
- Calculating message digests.
- Encrypting and decrypting files.
- Testing both client-side and server-side TLS/SSL with HTTP and SMTP servers.
- Verifying, encrypting and signing S/MIME email.

· Generating and testing prime numbers, and generating pseudo-random data.

The following are some sample opensel commands.

Create a self-signed X.509 certificate that is valid for 365 days, writing the unencrypted private key to prikey.pem and the certificate to cert.pem.

openssl req -x509 -nodes -days 365 -subj '/C=US/ST=Ca/L=Sunnydale/CN=www.unserdom.com' \
 -newkey rsa:1024 -keyout prikey.pem -out cert.pem

Test a self-signed certificate by launching a server that listens on port 443.

openssl s_server -accept 443 -cert cert.pem -key prikey.pem -www

Test the client side of a connection. This command returns information about the connection including the certificate, and allows you to directly input HTTP commands.

openssl s_client -connect server:443 -CAfile cert.pem

Convert a root certificate to a form that can be published on a web site for downloading by a browser.

openssl x509 -in cert.pem -out rootcert.crt

Extract a certificate from a server.

echo | openssl s_client -connect server:443 2>/dev/null | \
 sed -ne '/BEGIN CERT/,/END CERT/p' > svrcert.pem

Display the information contained in an X.509 certificate.

openssl x509 -text -noout -in svrcert.pem

Display the SHA1 fingerprint of a certificate.

openssl x509 -sha1 -noout -fingerprint -in cert.pem

Generate a CSR, writing the unencrypted private key to prikey.pem and the request to csr.pem for submission to a CA. The CA signs and returns a certificate or a certificate chain that authenticates your public key.

```
# openssl req -new -nodes '/CN=www.unserdom.com/O=Unser Dom, Corp./C=US/ST=Ca/L=Sunnydale' \
    -newkey rsa:1024 -keyout prikey.pem -out csr.pem
```

Display the information contained in a CSR.

openssl req -in csr.pem -noout -text

Verify a certificate including the signing authority, signing chain, and period of validity.

openssl verify cert.pem

Display the directory that holds information about the CAs trusted by your system. By default, this directory is /etc/pki/tls. The /etc/pki/tls/certs subdirectory contains trusted certificates.

openssl version -d

Create an SHA1 digest of a file.

openssl dgst -sha1 file

Sign the SHA1 digest of a file using the private key stored in the file prikey.pem.

openssl dgst -shal -sign prikey.pem -out file.shal file

Verify the signed digest for a file using the public key stored in the file pubkey.pem.

openssl dgst -shal -verify pubkey.pem -signature file.shal file

List all available ciphers.

openssl list-cipher-commands

Encrypt a file using Blowfish.

openssl enc -blowfish -salt -in file -out file.enc

Decrypt a Blowfish-encrypted file.

openssl enc -d -blowfish -in file.enc -out file.dec

Convert a base 64 encoded certificate (also referred to as PEM or RFC 1421) to binary DER format.

openssl x509 -in cert.pem -outform der -out certificate.der

Convert the base 64 encoded certificates for an entity and its CA to a single PKCS7 format certificate.

openssl crl2pkcs7 -nocrl -certfile entCert.cer -certfile CACert.cer -out certificate.p7b

For more information, see the openssl(1), ciphers(1), dgst(1), enc(1), req(1), s_client(1), s_server(1), verify(1), and x509(1) manual pages.

3.3.2 About the keytool Command

Most Java applications use the *keystore* that is supplied with the JDK to store cryptographic keys, X.509 certificate chain information, and trusted certificates. The default JDK keystore on Oracle Linux is the file / etc/pki/java/cacerts. You can use the keytool command to generate self-signed certificates and to install and manage certificates in the keystore. Note that the keytool command syntax changed in Java SE 6. The examples given here are for that version of keytool.

The following are some sample keytool commands.

List the contents of the keystore /etc/pki/java/cacerts. The default keystore password is changeit. If specified, the verbose option -v displays detailed information.

keytool -list [-v] -keystore /etc/pki/java/cacerts

Change the password for a keystore (for example, /etc/pki/java/cacerts).

keytool -storepasswd -keystore /etc/pki/java/cacerts

Create a new keystore keystore.jks for managing your public/private key pairs and certificates from entities that you trust, generate a public/private key pair using the RSA algorithm and a key length of 1024 bits, and create a self-signed certificate that includes the public key and the specified distinguished name information. *pkpassword* is the private key password and *storepassword* is the keystore password.

The certificate is valid for 100 days and is associated with the private key in a keystore entry that has the alias engineering.

keytool -genkeypair -alias mycert -keyalg RSA -keysize 1024 \
-dname "CN=www.unserdom.com, OU=Eng, O=Unser Dom Corp, C=US, ST=Ca, L=Sunnydale" \
-alias engineering -keypass pkpassword -keystore keystore.jks \
-storepass storepassword -validity 100

Print the contents of a certificate file in a human-readable form. If specified, the verbose option –v displays detailed information.

keytool -printcert [-v] -file cert.cer

Generate a CSR in the file carequest.csr for submission to a CA. The CA signs and returns a certificate or a certificate chain that authenticates your public key.

keytool -certreq -file carequest.csr

Import the root certificate or certificate chain for the CA from the file ACME.cer into the keystore keystore.jks and give it the alias acmeca. If specified, the -trustcacerts option instructs keytool to add the certificate only if it can validate the chain of trust against the existing root CA certificates in the cacerts keystore. Alternatively, use the keytool -printcert command to check that the certificate's fingerprint matches the fingerprint that the CA publishes.

keytool -importcert -alias acmeca [-trustcacerts] -file ACME.cer \
 -keystore keystore.jks -storepass storepassword

Import the signed certificate for your organization after you have received it from the CA. In this example, the file containing the certificate is <u>ACMEdom.cer</u>. The <u>-alias</u> option specifies the entry for the first entity in the CA's root certificate chain. The signed certificate is added to the front of the chain and becomes the entity that is addressed by the alias name.

```
# keytool -importcert -v -trustcacerts -alias acmeca -file ACMEdom.cer \
    -keystore keystore.jks -storepass storepassword
```

Delete the certificate with the alias *aliasname* from the keystore keystore.jks.

keytool -delete -alias aliasname -keystore keystore.jks -storepass storepassword

Export the certificate with the alias *aliasname* as a binary PKCS7 format file, which includes the supporting certificate chain as well as the issued certificate.

keytool -exportcert -noprompt -alias aliasname -file output.p7b \
 -keystore keystore.jks -storepass storepassword

Export the certificate with the alias *aliasname* as a base 64 encoded text file (also referred to as PEM or RFC 1421). For a certificate chain, the file includes only the first certificate in the chain, which authenticates the public key of the aliased entity.

keytool -exportcert -noprompt -rfc -alias aliasname -file output.pem \
 -keystore keystore.jks -storepass storepassword

For more information, see the keytool(1) manual page.

3.4 Configuring and Using Authentication

Authentication is the verification of the identity of a user. A user logs in by providing a user name and a password, and the operating system authenticates the user's identity by comparing this information

to data stored on the system. If the login credentials match and the user account is active, the user is authenticated and can successfully access the system.

The information that verifies a user's identity can either be located on the local system in the /etc/ passwd and /etc/shadow files, or on remote systems using Identity Policy Audit (IPA), the Lightweight Directory Access Protocol (LDAP), the Network Information Service (NIS), or Winbind. In addition, IPSv2, LDAP, and NIS data files can use the Kerberos authentication protocol, which allows nodes communicating over a non-secure network to prove their identity to one another in a secure manner.

You can use the Authentication Configuration GUI (system-config-authentication) to select the authentication mechanism and to configure any associated authentication options. Alternatively, you can use the authconfig command. Both the Authentication Configuration GUI and authconfig adjust settings in the PAM configuration files that are located in the /etc/pam.d directory.

3.4.1 About Local Oracle Linux Authentication

You can use the User Manager GUI (system-config-users) to add or delete users and groups and to modify settings such as passwords, home directories, login shells, and group membership. Alternatively, you can use commands such as useradd and groupadd.

Unless you select a different authentication mechanism during installation or by using the Authentication Configuration GUI or the authconfig command, Oracle Linux verifies a user's identity by using the information that is stored in the /etc/passwd and /etc/shadow files.

The /etc/passwd file stores account information for each user such as his or her unique user ID (or *UID*, which is an integer), user name, home directory, and login shell. A user logs in using his or her user name, but the operating system uses the associated UID. When the user logs in, he or she is placed in his or her home directory and his or her login shell runs.

The /etc/group file stores information about groups of users. A user also belongs to one or more groups, and each group can contain one or more users. If you can grant access privileges to a group, all members of the group receive the same access privileges. Each group account has a unique group ID (*GID*, again an integer) and an associated group name.

Oracle Linux implements the *user private group* (*UPG*) scheme where adding a user account also creates a corresponding UPG with the same name as the user, and of which the user is the only member.

Only the root user can add, modify, or delete user and group accounts. By default, both users and groups use shadow passwords, which are cryptographically hashed and stored in /etc/shadow and /etc/gshadow respectively. These shadow password files are readable only by the root user. root can set a group password that a user must enter to become a member of the group by using the newgrp command. If a group does not have a password, a user can only join the group by root adding him or her as a member.

The /etc/login.defs file defines parameters for password aging and related security policies.

For more information about the content of these files, see the group(5), gshadow(5), login.defs(5), passwd(5), and shadow(5) manual pages.

3.4.2 About IPA

IPA allows you to set up a domain controller for DNS, Kerberos, and authorization policies as an alternative to Active Directory Services. You can enrol client machines with an IPA domain so that they can access

information for single sign-on authentication. IPA combines the capabilities of existing well-known technologies such as certificate services, DNS, LDAP, Kerberos, LDAP, and NTP.

To be able to configure IPA authentication, use yum to install the ipa-client and ipa-admintools packages.

If you use the Authentication Configuration GUI and select IPA v2 as the user account database, you are prompted to enter the names of the IPA domain, realm, and server. You can also select to configure NTP so that the system time is consistent with the IPA server. If you have initialized Kerberos, you can click **Join Domain** to create a machine account on the IPA server and grant permission to join the domain.

For more information about configuring IPA, see http://freeipa.org/page/Documentation.

3.4.3 About LDAP Authentication

LDAP allows systems to access centrally stored information over a network. LDAP servers store the information in directory-based database that is optimized for searching. Directory entries are arranged in a hierarchical tree-like structure that can store a variety of information such as names, addresses, phone numbers, authentication data, network services, printers, and many other types of data. LDAP can also be used to authenticate users, allowing users to access their account from any machine on the LDAP network.

An entry is the basic unit of information within an LDAP directory. Each entry has one or more attributes. Each attribute has a name, a type or description, and one or more values. Examples of types are cn for common name and mail for an email address. In addition, the objectClass attribute allows you to control which attributes are required and which are optional. The values of objectClass determine the schema rules that an entry must obey.

Each entry in an LDAP directory is uniquely identified and referenced by its Distinguished Name (DN). The DN is constructed by taking the name of the entry itself (called the Relative Distinguished Name or RDN) and concatenating the names of its ancestor entries, known as the LDAP Search Base DN. For example, the DN for a user with an RDN of uid=gab451 might be similar to uid=gab451, ou=People,dc=mydomain,dc=com, where ou=People,dc=mydomain,dc=com is the LDAP Search base DN, ou stands for Organizational Unit and dc stands for Domain Component.

To be able to configure LDAP authentication, use yum to install the openIdap-clients package.

If you use the Authentication Configuration GUI and select LDAP as the user account database, you are prompted to enter the LDAP Search Base DN and the URL of the LDAP server including the port number (for example, ldap://ldap-svr.mydomain.com; 389).

You can configure LDAP to use either LDAP authentication or Kerberos authentication. LDAP authentication requires that you use either LDAP over SSL (Idaps) or Transport Layer Security (TLS) to secure the connection to the LDAP server. If you use TLS, you must enter the URL from which to download the CA certificate that provides the basis for authentication within the domain.

You can also enable and configure LDAP by using the authconfig command.

To use LDAP as the authentication source, specify the <u>--enableldapauth</u> option together with the full LDAP server URL (including the port number) and the LDAP Search Base DN, as shown in the following example:.

[#] authconfig --enableldap --enableldapauth \
 --ldapserver=ldap://ldap-svr.mydomain.com:389 \
 --ldapbasedn="ou=people,dc=mydomain,dc=com" \

--update

If you want to use TLS, additionally specify the --enableldaptls option and the download URL of the CA certificate:

```
# authconfig --enableldap --enableldapauth \
    --ldapserver=ldap://ldap-svr.mydomain.com:389 \
    --ldapbasedn="ou=people,dc=mydomain,dc=com" \
    --enableldaptls \
    --ldaploadcacert=https://ca-server.mydomain.com/caCert.crt \
    --update
```

For information about using Kerberos authentication with LDAP, see Section 3.4.6, "About Kerberos Authentication".

For more information, see the authconfig(8) manual page.

For more information about LDAP, see the ldap(3) manual page.

3.4.4 About NIS Authentication

NIS stores administrative information such as user names, passwords, and host names on a centralized server. Client systems on the network can access this common data. This configuration allows to move from machine to machine without having to remember different passwords and copy data from one machine to another. Storing administrative information centrally, and providing a means of accessing it from networked systems, also ensures the consistency of that data. NIS also reduces the overhead of maintaining administration files such as /etc/passwd on each system.

A network of NIS systems is a *NIS domain*. Each system within the domain has the same NIS domain name, which is different from a DNS domain name. The DNS domain is used throughout the Internet to refer to a group of systems. A NIS domain is used to identify systems that use files on a NIS server. A NIS domain must have exactly one primary (master) server but can have multiple secondary (slave) servers.

To be able to configure NIS authentication, use yum to install the yp-tools and ypbind packages.

If you use the Authentication Configuration GUI and select NIS as the user account database, you are prompted to enter the names of the NIS Domain and the NIS primary server.

You can configure NIS to use either NIS authentication or Kerberos authentication.

Warning

NIS authentication is deprecated as it has security issues, including a lack of protection of authentication data.

For information about using Kerberos authentication with NIS, see Section 3.4.6, "About Kerberos Authentication".

3.4.5 About Winbind Authentication

Winbind is a client-side service that resolves user and group information on a Windows server, and allows Oracle Linux to understand Windows users and groups. To be able to configure Winbind authentication, use yum to install the samba-winbind package. This package includes the winbindd daemon that implements the winbind service.

If you use the Authentication Configuration GUI and select Winbind as the user account database, you are prompted for the information that is required to connect to a Microsoft workgroup, Active Directory, or Windows NT domain controller. Enter the name of the Winbind domain and select the security model for the Samba server:

ads

In the Activity Directory Server (ADS) security model, Samba acts as a domain member in an ADS realm, and clients use Kerberos tickets for Active Directory authentication. You must configure Kerberos and join the server to the domain, which creates a machine account for your server on the domain controller.

In the domain security model, the local Samba server has a machine domain account (a domain security trust account) and Samba authenticates user names and passwords with a domain controller in a domain that implements Windows NT4 security.

Warning

If the local machine acts as a Primary or Backup Domain Controller, do not use the domain security model. Use the user security model instead.

server

user

In the server security model, the local Samba server authenticates user names and passwords with another server, such as a Windows NT server.

Warning

The server security model is deprecated as it has numerous security issues.

In the user security model, a client must log in with a valid user name and password. This model supports encrypted passwords. If the server successfully validates the client's user name and password, the client can mount multiple shares without being required to specify a password.

Depending on the security model that you choose, you might also need to specify the following information:

- The name of the ADS realm that the Samba server is to join (ADS security model only).
- The names of the domain controllers. If there are several domain controllers, separate the names with spaces.
- The login template shell to use for the Windows NT user account (ADS and domain security models only).
- Whether to allow user authentication using information that has been cached by the System Security Services Daemon (SSSD) if the domain controllers are offline.

Your selection updates the security directive in the [global] section of the /etc/samba/smb.conf configuration file.

If you have initialized Kerberos, you can click Join Domain to create a machine account on the Active Directory server and grant permission for the Samba domain member server to join the domain.

You can also use the authconfig command to configure Winbind authentication. To use the userlevel security models, specify the name of the domain or workgroup and the host names of the domain controllers. for example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity user \
 [--enablewinbindoffline] --smbservers="adl.mydomain.com ad2.mydomain.com" \
    --smbworkgroup=MYDOMAIN --update
```

To allow user authentication using information that has been cached by the System Security Services Daemon (SSSD) if the domain controllers are offline, specify the --enablewinbindoffline option.

For the domain security model, additionally specify the template shell, for example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity domain \
 [--enablewinbindoffline] --smbservers="adl.mydomain.com ad2.mydomain.com" \
    --smbworkgroup=MYDOMAIN --update --winbindtemplateshell=/bin/bash --update
```

For the ADS security model, additionally specify the ADS realm and template shell, for example:

```
# authconfig --enablewinbind --enablewinbindauth --smbsecurity ads \
 [--enablewinbindoffline] --smbservers="adl.mydomain.com ad2.mydomain.com" \
    --smbworkgroup=MYDOMAIN --update --smbrealm MYDOMAIN.COM \
    --winbindtemplateshell=/bin/bash --update
```

For more information, see the authconfig(8) manual page.

3.4.6 About Kerberos Authentication

Both LDAP and NIS authentication optionally support Kerberos authentication. (In the case of IPA, Kerberos is fully integrated.) Kerberos provides a secure connection over standard ports, and it also allows offline logins by using credential caching with SSSD.

To be able to use Kerberos authentication, use yum to install the krb5-libs and krb5-workstation packages.

If you use the Authentication Configuration GUI and select LDAP or NIS as the user account database, select Kerberos password as the authentication method. You are prompted for the following information that is required to connect to the Kerberos realm:

- The name of the Kerberos realm.
- A comma-separated list of Key Distribution Center (KDC) servers that can issue Kerberos tickets.
- A comma-separated list of Kerberos Administration Servers.

You can also select whether Kerberos should use DNS to resolve the host names of Kerberos servers and to search for KDCs within the realm. DNS domains are typically coterminous with Kerberos realms.

You can use the following options with the authconfig command to configure Kerberos authentication with LDAP or NIS:

enablekrb5	Use Kerberos authentication. (Specify instead ofenableldapauth for LDAP.)
enablekrb5kdcdns	Use DNS to resolve the host names of Kerberos servers.

enablekrb5realmdns	Use DNS to search for KDCs within a Kerberos realm.
krb5adminserver=server	Specify a Kerberos Administration Server.
krb5kdc= <i>server</i>	Specify a KDC server.
krb5realm= <i>realm</i>	Specify the name of the Kerberos realm.

For more information, see the authconfig(8) manual page.

3.5 Configuring and Using Pluggable Authentication Modules

The Pluggable Authentication Modules (PAM) feature is an authentication mechanism that allows you to configure how applications use authentication to verify the identity of a user. The PAM configuration files, which are located in the /etc/pam.d directory, describe the authentication procedure for an application. The name of each configuration file is the same as, or is similar to, the name of the application for which the module provides authentication. For example, the configuration files for passwd and sudo are named passwd and sudo.

Each configuration file contains a list (*stack*) of calls to authentication modules. For example, the following is the content of the login configuration file:

#%PAM-1.0		
	unknown=igno:	re success=ok ignore=ignore default=bad] pam_securetty.so
auth :	include	system-auth
account :	required	pam_nologin.so
account :	include	system-auth
password :	include	system-auth
# pam_selin	ux.so close	should be the first session rule
session :	required	pam_selinux.so close
session :	required	pam_loginuid.so
session (optional	pam_console.so
<pre># pam_selin</pre>	ux.so open s	hould only be followed by sessions to be executed in the user context
session :	required	pam_selinux.so open
session :	required	pam_namespace.so
session o	optional	pam_keyinit.so force revoke
session :	include	system-auth
-session (optional	pam_ck_connector.so

Comments in the file start with a # character. The remaining lines each define an operation type, a control flag, the name of a module such as pam_rootok.so or the name of an included configuration file such as system-auth, and any arguments to the module. PAM provides authentication modules as 32 and 64-bit shared libraries in /lib/security and /lib64/security respectively.

For a particular operation type, PAM reads the stack from top to bottom and calls the modules listed in the configuration file. Each module generates a success or failure result when called.

The following operation types are defined for use:

auth	The module tests whether a user is authenticated or authorized to use a service or application. For example, the module might request and verify a password. Such modules can also set credentials, such as a group membership or a Kerberos ticket.
account	The module tests whether an authenticated user is allowed access to a service or application. For example, the module might check if a user

	account has expired or if a user is allowed to use a service at a given time.
password	The module handles updates to an authentication token.
session	The module configures and manages user sessions, performing tasks such as mounting or unmounting a user's home directory.

If the operation type is preceded with a dash (-), PAM does not add an create a system log entry if the module is missing.

With the exception of include, the control flags tell PAM what to do with the result of running a module. The following control flags are defined for use:

optional	The module is required for authentication if it is the only module listed for a service.
required	The module must succeed for access to be granted. PAM continues to execute the remaining modules in the stack whether the module succeeds or fails. PAM does not immediately inform the user of the failure.
requisite	The module must succeed for access to be granted. If the module succeeds, PAM continues to execute the remaining modules in the stack. However, if the module fails, PAM notifies the user immediately and does not continue to execute the remaining modules in the stack.
sufficient	If the module succeeds, PAM does not process any remaining modules of the same operation type. If the module fails, PAM processes the remaining modules of the same operation type to determine overall success or failure.

The control flag field can also define one or more rules that specify the action that PAM should take depending on the value that a module returns. Each rule takes the form *value=action*, and the rules are enclosed in square brackets, for example:

[user_unknown=ignore success=ok ignore=ignore default=bad]

If the result returned by a module matches a value, PAM uses the corresponding action, or, if there is no match, it uses the default action.

The include flag specifies that PAM must also consult the PAM configuration file specified as the argument.

Most authentication modules and PAM configuration files have their own manual pages. In addition, the /usr/share/doc/pam-version directory contains the PAM System Administrator's Guide (html/Linux-PAM_SAG.html or Linux-PAM_SAG.txt) and a copy of the PAM standard (rfc86.0.txt).

For more information, see the pam(8) manual page. In addition, each PAM module has its own manual page, for example pam_unix(8).

3.6 Configuring and Using Access Control Lists

POSIX Access Control Lists (ACLs) provide a richer access control model than traditional UNIX Discretionary Access Control (DAC) that sets read, write, and execute permissions for the owner, group,

and all other system users. You can configure ACLs that define access rights for more than just a single user or group, and specify rights for programs, processes, files, and directories. If you set a default ACL on a directory, its descendents inherit the same rights automatically. The kernel provides ACL support for ext3, ext4, and NFS-exported file systems.

The following are examples of setting and displaying ACLs for directories and files.

Grant read access to a file or directory by a user.

setfacl -m u:user:r file

Display the name, owner, group, and ACL for a file or directory.

getfacl file

Remove write access to a file for all groups and users by modifying the effective rights mask rather than the ACL.

setfacl -m m::rx file

Remove the entry for a group from the ACL of a file.

setfacl -x g:group file

Copy the ACL of file f_1 to file f_2 .

getfacl f1 | setfacl --set-file=- f2

Promote the ACL settings of a directory to default ACL settings that can be inherited.

getfacl --access dir | setfacl -d -M- dir

For more information on how to manage ACLs, see the setfacl(1) and getfacl(1) manual pages.

3.7 Configuring and Using SELinux

Traditional Linux security is based on a Discretionary Access Control (DAC) policy, which provides minimal protection from broken software or from malware that is running as a normal user or as **root**. Access to files and devices is based solely on user identity and ownership. Malware or broken software can do anything with files and resources that the user that started the process can do. If the user is **root** or the application is **setuid** or **setgid** to **root**, the process can have **root**-access control over the entire file system.

The National Security Agency created Security Enhanced Linux (SELinux) to provide a finer-grained level of control over files, processes, users and applications in the Linux operating system. The SELinux enhancement to the Linux kernel implements the Mandatory Access Control (MAC) policy, which allows you to define a security policy that provides granular permissions for all users, programs, processes, files, and devices. The kernel's access control decisions are based on all the security relevant information available, and not solely on the authenticated user identity.

When security-relevant access occurs, such as when a process attempts to open a file, SELinux intercepts the operation in the kernel. If a MAC policy rule allows the operation, it continues; otherwise, SELinux blocks the operation and returns an error to the process. The kernel checks and enforces DAC policy rules before MAC rules, so it does not check SELinux policy rules if DAC rules have already denied access to a resource.

Package	Description
policycoreutils	Provides utilities such as load_policy, restorecon, secon, setfiles, semodule, sestatus, and setsebool for operating and managing SELinux.
libselinux	Provides the API that SELinux applications use to get and set process and file security contexts, and to obtain security policy decisions.
selinux-policy	Provides the SELinux Reference Policy, which is used as the basis for other policies, such as the SELinux targeted policy.
selinux-policy- targeted	Provides support for the SELinux targeted policy, where objects outside the targeted domains run under DAC.
libselinux-python	Contains Python bindings for developing SELinux applications.
libselinux-utils	Provides the avcstat, getenforce, getsebool, matchpathcon, selinuxconlist, selinuxdefcon, selinuxenabled, setenforce, and togglesebool utilities.

The following table describes the SELinux packages that are installed by default with Oracle Linux:

The following table describes a selection of useful SELinux packages that are not installed by default:

Package	Description
mcstrans	Translates SELinux levels, such as s0-s0:c0.c1023, to an easier-to-read form, such as SystemLow-SystemHigh.
policycoreutils-gui	Provides a GUI (system-config-selinux) that you can use to manage SELinux. For example, you can use the GUI to set the system default enforcing mode and policy type.
policycoreutils- python	Provides additional Python utilities for operating SELinux, such as audit2allow, audit2why, chcat, and semanage.
selinux-policy-mls	Provides support for the strict Multilevel Security (MLS) policy as an alternative to the SELinux targeted policy.
setroubleshoot	Provides the GUI that allows you to view setroubleshoot-server messages using the sealert command.
setroubleshoot- server	Translates access-denial messages from SELinux into detailed descriptions that you can view on the command line using the sealert command.
setools-console	Provides the Tresys Technology SETools distribution of tools and libraries, which you can use to analyze and query policies, monitor and report audit logs, and manage file context.

Use yum or another suitable package manager to install the SELinux packages that you require on your system.

For more information about SELinux, refer to the SELinux Project Wiki, the selinux(8) manual page, and the manual pages for the SELinux commands.

3.7.1 About SELinux Administration

The following table describes the utilities that you can use to administer SELinux, and the packages that contain each utility.

Utility	Package	Description
audit2allow	policycoreutils- python	Generates SELinux policy allow_audit rules from logs of denied operations.
audit2why	policycoreutils- python	Generates SELinux policy don't_audit rules from logs of denied operations.
avcstat	libselinux-utils	Displays statistics for the SELinux Access Vector Cache (AVC).
chcat	policycoreutils- python	Changes or removes the security category for a file or user.
findcon	setools-console	Searches for file context.
fixfiles	policycoreutils	Fixes the security context for file systems.
getenforce	libselinux-utils	Reports the current SELinux mode.
getsebool	libselinux-utils	Reports SELinux boolean values.
indexcon	setools-console	Indexes file context.
load_policy	policycoreutils	Loads a new SELinux policy into the kernel.
matchpathcon	libselinux-utils	Queries the system policy and displays the default security context that is associated with the file path.
replcon	setools-console	Replaces file context.
restorecon	policycoreutils	Resets the security context on one or more files.
restorecond	policycoreutils	Daemon that watches for file creation and sets the default file context.
sandbox	policycoreutils- python	Runs a command in an SELinux sandbox.
sealert	setroubleshoot- server, setroubleshoot	Acts as the user interface to the setroubleshoot system, which diagnoses and explains SELinux AVC denials and provides recommendations on how to prevent such denials.
seaudit-report	setools-console	Reports from the SELinux audit log.
sechecker	setools-console	Checks SELinux policies.
secon	policycoreutils	Displays the SELinux context from a file, program, or user input.
sediff	setools-console	Compares SELinux polices.
seinfo	setools-console	Queries SELinux policies.
selinuxconlist	libselinux-utils	Displays all SELinux contexts that are reachable by a user.
selinuxdefcon	libselinux-utils	Displays the default SELinux context for a user.
selinuxenabled	libselinux-utils	Indicates whether SELinux is enabled.
semanage	policycoreutils- python	Manages SELinux policies.
semodule	policycoreutils	Manages SELinux policy modules.
semodule_deps	policycoreutils	Displays the dependencies between SELinux policy packages.

Utility	Package	Description
semodule_expand	policycoreutils	Expands a SELinux policy module package.
semodule_link	policycoreutils	Links SELinux policy module packages together.
semodule_package	policycoreutils	Creates a SELinux policy module package.
sesearch	setools-console	Queries SELinux policies.
sestatus	policycoreutils	Displays the SELinux mode and the SELinux policy that are in use.
setenforce	libselinux-utils	Modifies the SELinux mode.
setsebool	policycoreutils	Sets SELinux boolean values.
setfiles	policycoreutils	Sets the security context for one or more files.
system-config- selinux	policycoreutils-gui	Provides a GUI that you can use to manage SELinux.
togglesebool	libselinux-utils	Flips the current value of an SELinux boolean.

3.7.2 About SELinux Modes

SELinux runs in one of three modes.

Disabled	The kernel uses only DAC rules for access control. SELinux does not enforce any security policy because no policy is loaded into the kernel.
Enforcing	The kernel denies access to users and programs unless permitted by SELinux security policy rules. All denial messages are logged as AVC (Access Vector Cache) denials. This is the default mode that enforces SELinux security policy.
Permissive	The kernel does not enforce security policy rules but SELinux sends denial messages to a log file. This allows you to see what actions would have been denied if SELinux were running in enforcing mode. This mode is intended to used for diagnosing the behavior of SELinux.

3.7.3 Setting SELinux Modes

You can set the default and current SELinux mode in the Status view of the SELinux Administration GUI.

Alternatively, to display the current mode, use the getenforce command:

# getenforce Enforcing	
To set the current mode to Enforcing, enter:	
# setenforce Enforcing	

To set the current mode to Permissive, enter:

setenforce Permissive

The current value that you set for a mode using setenforce does not persist across reboots. To configure the default SELinux mode, edit the configuration file for SELinux, /etc/selinux/config, and set the value of the SELINUX directive to disabled, enabled, or permissive.

3.7.4 About SELinux Policies

An SELinux policy describes the access permissions for all users, programs, processes, and files, and for the devices upon which they act. You can configure SELinux to implement either Targeted Policy or Multilevel Security (MLS) Policy.

3.7.4.1 Targeted Policy

Applies access controls to a limited number of processes that are believed to be most likely to be the targets of an attack on the system. Targeted processes run in their own SELinux domain, known as a *confined domain*, which restricts access to files that an attacker could exploit. If SELinux detects that a targeted process is trying to access resources outside the confined domain, it denies access to those resources and logs the denial. Only specific services run in confined domains. Examples are services that listen on a network for client requests, such as httpd, named, and sshd, and processes that run as root to perform tasks on behalf of users, such as passwd. Other processes, including most user processes, run in an unconfined domain where only DAC rules apply. If an attack compromises an unconfined process, SELinux does not prevent access to system resources and data.

The following table lists examples of SELinux domains.

Domain	Description
initrc_t	init and processes executed by init
kernel_t	Kernel processes
unconfined_t	Processes executed by Oracle Linux users run in the unconfined domain

3.7.4.2 Multilevel Security (MLS) Policy

Applies access controls to multiple levels of processes with each level having different rules for user access. Users cannot obtain access to information if they do not have the correct authorization to run a process at a specific level. In SELinux, MLS implements the Bell–LaPadula (BLP) model for system security, which applies labels to files, processes and other system objects to control the flow of information between security levels. In a typical implementation, the labels for security levels might range from the most secure, top secret, through secret, and classified, to the least secure, unclassified. For example, under MLS, you might configure a program labelled secret to be able to write to a file that is labelled top secret, but not to be able to read from it. Similarly, you would permit the same program to read from and write to a file labelled secret, but only to read classified or unclassified files. As a result, information that passes through the program can flow upwards through the hierarchy of security levels, but not downwards.

Note

You must install the selinux-policy-mls package if you want to be able to apply the MLS policy.

3.7.4.3 Setting SELinux Policies

Note

You cannot change the policy type of a running system.

You can set the default policy type in the Status view of the SELinux Administration GUI.

Alternatively, to configure the default policy type, edit /etc/selinux/config and set the value of the SELINUXTYPE directive to targeted or mls.

3.7.4.4 Customizing SELinux Policies

You can customize an SELinux policy by enabling or disabling the members of a set of boolean values. Any changes that you make take effect immediately and do not require a reboot.

You can set the boolean values in the Boolean view of the SELinux Administration GUI.

Alternatively, to display all boolean values together with a short description, use the following command:

```
# semanage boolean -1
SELinux boolean State Default Description
ftp_home_dir (off , off) Allow ftp to read and write files in the user home ...
smartmon_3ware (off , off) Enable additional permissions needed to support dev...
xdm_sysadm_login (off , off) Allow xdm logins as sysadm
.
.
```

You can use the getsebool and setsebool commands to display and set the value of a specific boolean.

```
# getsebool boolean
# setsebool boolean on off
```

For example, to display and set the value of the ftp_home_dir boolean:

```
# getsebool ftp_home_dir
ftp_home_dir --> off
# setsebool ftp_home_dir on
# getsebool ftp_home_dir
ftp_home_dir --> on
```

To toggle the value of a boolean, use the togglesebool command as shown in this example:

```
# togglesebool ftp_home_dir
ftp_home_dir: inactive
```

To make the value of a boolean persist across reboots, specify the -P option to setsebool, for example:

```
# setsebool -P ftp_home_dir on
# getsebool ftp_home_dir
ftp_home_dir --> on
```

3.7.5 About SELinux Context

Under SELinux, all file systems, files, directories, devices, and processes have an associated security context. For files, SELinux stores a context label in the extended attributes of the file system. The context contains additional information about a system object: the SELinux user, their role, their type, and the security level. SELinux uses this context information to control access by processes, Linux users, and files.

You can specify the -z option to certain commands (1s, ps, and id) to display the SELinux context with the following syntax:

SELinux user:Role:Type:Level

where the fields are as follows:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. About SELinux Context

SELinux user	An SELinux user account compliments a regular Linux user account. SELinux maps every Linux user to an SELinux user identity that is used in the SELinux context for the processes in a user session.
Role	In the Role-Based Access Control (RBAC) security model, a role acts as an intermediary abstraction layer between SELinux process domains or file types and an SELinux user. Processes run in specific SELinux domains, and file system objects are assigned SELinux file types. SELinux users are authorized to perform specified roles, and roles are authorized for specified SELinux domains and file types. A user's role determines which process domains and file types he or she can access, and hence, which processes and files, he or she can access.
Туре	A type defines an SELinux file type or an SELinux process domain. Processes are separated from each other by running in their own domains. This separation prevents processes from accessing files that other processes use, and prevents processes from accessing other processes. The SELinux policy rules define the access that process domains have to file types and to other process domains.
Level	A level is an attribute of Multilevel Security (MLS) and Multicategory Security (MCS). An MLS range is a pair of sensitivity levels, written as $low_level_high_level$. The range can be abbreviated as low_level if the levels are identical. For example, s0 is the same as s0-s0. Each level has an optional set of security categories to which it applies. If the set is contiguous, it can be abbreviated. For example, s0:c0.c3 is the same as $s0:c0,c1,c2,c3$.

3.7.5.1 Displaying SELinux User Mapping

To display the mapping between SELinux and Linux user accounts, select the User Mapping view in the the SELinux Administration GUI.

Alternatively, enter the following command to display the user mapping:

# semanage login -1		
Login Name	SELinux User	MLS/MCS Range
default root system_u	unconfined_u unconfined_u system_u	s0-s0:c0.c1023 s0-s0:c0.c1023 s0-s0:c0.c1023

3.7.5.2 Displaying SELinux Context Information

To display the context information that is associated with files, use the ls -z command:

```
# ls -Z
-rw-----. root root system_u:object_r:admin_home_t:s0 anaconda-ks.cfg
drwx-----. root root unconfined_u:object_r:admin_home_t:s0 Desktop
-rw-r--r-. root root system_u:object_r:admin_home_t:s0 install.log
-rw-r--r-. root root system_u:object_r:admin_home_t:s0 install.log.syslog
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. About SELinux Context

To display the context information that is associated with a specified file or directory:

ls -Z /etc/selinux/config
-rw-r--r-. root root system_u:object_r:selinux_config_t:s0 /etc/selinux/config

To display the context information that is associated with processes, use the ps -z command:

```
# ps -Z
LABEL PID TTY TIME CMD
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 3038 pts/0 00:00:00 su
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 3044 pts/0 00:00:00 bash
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 3322 pts/0 00:00:00 ps
```

To display the context information that is associated with the current user, use the id -z command:

```
# id -z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

3.7.5.3 Changing the Default File Type

Under some circumstances, you might need to change the default file type for a file system hierarchy. For example, you might want to use a DocumentRoot directory other than /var/www/html with httpd.

To change the default file type of the directory hierarchy /var/webcontent as httpd_sys_content_t:

1. Use the semanage command to define the file type httpd_sys_content_t for the directory hierarchy:

/usr/sbin/semanage fcontext -a -t httpd_sys_content_t "/var/webcontent(/.*)?"

This command adds the following entry to the file /etc/selinux/targeted/contexts/files/ file_contexts.local:

/var/webcontent(/.*)? system_u:object_r:httpd_sys_content_t:s0

2. Use the restorecon command to apply the new file type to the entire directory hierarchy.

/sbin/restorecon -R -v /var/webcontent

3.7.5.4 Restoring the Default File Type

To restore the default file type of the directory hierarchy /var/webcontent after previously changing it to httpd_sys_content_t:

1. Use the semanage command to delete the file type definition for the directory hierarchy from the file / etc/selinux/targeted/contexts/files/file_contexts.local:

/usr/sbin/semanage fcontext -d "/var/webcontent(/.*)?"

2. Use the restorecon command to apply the default file type to the entire directory hierarchy.

/sbin/restorecon -R -v /var/webcontent

3.7.5.5 Relabelling a File System

If you see an error message that contains the string file_t, the problem usually lies with a file system having an incorrect context label.

To relabel a file system, use one of the following methods:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. About SELinux Users

- In the Status view of the SELinux Administration GUI, select the Relabel on next reboot option.
- Create the file /.autorelabel and reboot the system.
- Run the fixfiles onboot command and reboot the system.

3.7.6 About SELinux Users

As described in Section 3.7.5, "About SELinux Context", each SELinux user account compliments a regular Oracle Linux user account. SELinux maps every Oracle Linux user to an SELinux user identity that is used in the SELinux context for the processes in a user session.

SELinux users form part of a SELinux policy that is authorized for a specific set of roles and for a specific MLS (Multi-Level Security) range, and each Oracle Linux user is mapped to an SELinux user as part of the policy. As a result, Linux users inherit the restrictions and security rules and mechanisms placed on SELinux users. To define the roles and levels of users, the mapped SELinux user identity is used in the SELinux context for processes in a session. You can display user mapping in the **User Mapping** view of the SELinux Administration GUI. You can also view the mapping between SELinux and Oracle Linux user accounts from the command line:

# semanage	login -1	
Login Name	SELinux User	MLS/MCS Range
default	unconfined_u	s0-s0:c0.c1023
root	unconfined_u	s0-s0:c0.c1023
system_u	system_u	s0-s0:c0.c1023

The MLS/MCS Range column displays the level used by MLS and MCS.

By default, Oracle Linux users are mapped to the SELinux user unconfined_u.

You can configure SELinux to confine Oracle Linux users by mapping them to SELinux users in confined domains, which have predefined security rules and mechanisms as listed in the following table.

SELinux User	SELinux Domain	Permit Running su?	Permit Network Access?	Permit Logging in Using X Window System?	Permit Executing Applications in \$HOME and /tmp?
guest_u	guest_t	No	No	No	No
staff_u	staff_t	Yes	Yes	Yes	Yes
user_u	user_t	No	Yes	Yes	Yes
xguest_x	xguest_t	No	Firefox only	Yes	No

3.7.6.1 Mapping Oracle Linux Users to SELinux Users

To map an Oracle Linux user *oluser* to an SELinux user such as user_u, use the semanage command:

semanage login -a -s user_u oluser

3.7.6.2 Configuring the Behavior of Application Execution for Users

To help prevent flawed or malicious applications from modifying a user's files, you can use booleans to specify whether users are permitted to run applications in directories to which they have write access, such as in their home directory hierarchy and /tmp.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Auditing

To allow Oracle Linux users in the guest_t and xguest_t domains to execute applications in directories to which they have write access:

```
# setsebool -P allow_guest_exec_content on
# setsebool -P allow_xguest_exec_content on
```

To prevent Linux users in the staff_t and user_t domains from executing applications in directories to which they have write access:

```
# setsebool -P allow_staff_exec_content off
# setsebool -P allow_user_exec_content off
```

3.8 Configuring and Using Auditing

Auditing collects data at the kernel level that you can analyze to identify unauthorized activity. Auditing collects more data in greater detail than system logging, but most audited events are uninteresting and insignificant. The process of examining audit trails to locate events of interest can be a significant challenge that you will probably need to automate.

The audit configuration file, /etc/audit/auditd.conf, defines the data retention policy, the maximum size of the audit volume, the action to take if the capacity of the audit volume is exceeded, and the locations of local and remote audit trail volumes. The default audit trail volume is /var/log/audit/ audit.log. For more information, see the auditd.conf(5) manual page.

By default, auditing captures specific events such as system logins, modifications to accounts, and sudo actions. You can also configure auditing to capture detailed system call activity or modifications to certain files. The kernel audit daemon (auditd) records the events that you configure, including the event type, a time stamp, the associated user ID, and success or failure of the system call.

The entries in the audit rules file, /etc/audit/audit.rules, determine which events are audited. Each rule is a command-line option that is passed to the auditctl command. You should typically configure this file to match your site's security policy.

The following are examples of rules that you might set in the /etc/audit/audit.rules file.

Record all unsuccessful exits from open and truncate system calls for files in the /etc directory hierarchy.

-a exit, always -S open -S truncate -F /etc -F success=0

Record all files opened by a user with UID 10.

-a exit, always -S open -F uid=10

Record all files that have been written to or that have their attributes changed by any user who originally logged in with a UID of 500 or greater.

-a exit, always -S open -F auid>=500 -F perm=wa

Record requests for write or file attribute change access to /etc/sudoers, and tag such record with the string sudoers-change.

-w /etc/sudoers -p wa -k sudoers-change

Record requests for write and file attribute change access to the /etc directory hierarchy.

-w /etc/ -p wa

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using System Logging

Require a reboot after changing the audit configuration. If specified, this rule should appear at the end of the /etc/audit/audit.rules file.

-e 2

You can find more examples of audit rules in /usr/share/doc/audit-version/stig.rules, and in the auditctl(8) and audit.rules(7) manual pages.

Stringent auditing requirements can impose a significant performance overhead and generate large amounts of audit data. Some site security policies stipulate that a system must shut down if events cannot be recorded because the audit volumes have exceeded their capacity. As a general rule, you should direct audit data to separate file systems in rotation to prevent overspill and to facilitate backups.

You can use the -k option to tag audit records so that you can locate them more easily in an audit volume with the <u>ausearch</u> command. For example, to examine records tagged with the string <u>sudoers-change</u>, you would enter:

ausearch -k sudoers-change

The aureport command generates summaries of audit data. You can set up cron jobs that run aureport periodically to generate reports of interest. For example, the following command generates a reports that shows every login event from 1 second after midnight on the previous day until the current time:

aureport -1 -i -ts yesterday -te now

For more information, see the ausearch(8) and aureport(8) manual pages.

3.9 Configuring and Using System Logging

The log files contain messages about the system, kernel, services, and applications. For those files that are controlled by the system logging daemon rsyslogd, the main configuration file is /etc/rsyslog.conf, which contains global directives, module directives, and rules.

Global directives specify configuration options that apply to the rsyslogd daemon. All configuration directives must start with a dollar sign (\$) and only one directive can be specified on each line. The following example specifies the maximum size of the rsyslog message queue:

\$MainMsgQueueSize 50000

The available configuration directives are described in the file /usr/share/doc/rsyslog-versionnumber/rsyslog_conf_global.html.

The design of rsyslog allows its functionality to be dynamically loaded from modules, which provide configuration directives. To load a module, specify the following directive:

\$ModLoad MODULE_name

Modules have the following main categories:

- Input modules gather messages from various sources. Input module names always start with the imprefix (examples include imfile and imrelp).
- Filter modules allow rsyslogd to filter messages according to specified rules. The name of a filter module always starts with the fm prefix.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using System Logging

- Library modules provide functionality for other loadable modules. rsyslogd loads library modules automatically when required. You cannot configure the loading of library modules.
- Output modules provide the facility to store messages in a database or on other servers in a network, or to encrypt them. Output module names always starts with the om prefix (examples include omsnmp and omrelp).
- Message modification modules change the content of an rsyslog message.
- Parser modules allow rsyslogd to parse the message content of messages that it receives. The name of a parser module always starts with the pm prefix.
- String generator modules generate strings based on the content of messages in cooperation with rsyslog's template feature. The name of a string generator module always starts with the sm prefix.

Input modules receive messages, which pass them to one or more parser modules. A parser module creates a representation of a message in memory, possibly modifying the message, and passes the internal representation to output modules, which can also modify the content before outputting the message.

A description of the available modules can be found at https://www.rsyslog.com/doc/ rsyslog_conf_modules.html.

An rsyslog rule consists of a filter part, which selects a subset of messages, and an action part, which specifies what to do with the selected messages. To define a rule in the /etc/rsyslog.conf configuration file, specify a filter and an action on a single line, separated by one or more tabs or spaces.

You can configure rsyslog to filter messages according to various properties. The most commonly used filters are:

- Expression-based filters, written in the rsyslog scripting language, select messages according to arithmetic, boolean, or string values.
- Facility/priority-based filters filter messages based on facility and priority values that take the form *facility.priority*.
- Property-based filters filter messages by properties such as timegenerated or syslogtag.

Facility Keyword Description auth, authpriv Security, authentication, or authorization messages. crond messages. cron daemon Messages from system daemons other than crond and rsyslogd. kern Kernel messages. Line printer subsystem. lpr mail Mail system. Network news subsystem. news Messages generated internally by rsyslogd. syslog User-level messages. user UUCP subsystem. UUCP

The following table lists the available facility keywords for facility/priority-based filters:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using System Logging

Facility Keyword	Description
local0 - local7	Local use.

The following table lists the available priority keywords for facility/priority-based filters, in ascending order of importance:

Priority Keyword	Description
debug	Debug-level messages.
info	Informational messages.
notice	Normal but significant condition.
warning	Warning conditions.
err	Error conditions.
crit	Critical conditions.
alert	Immediate action required.
emerg	System is unstable.

All messages of the specified priority and higher are logged according to the specified action. An asterisk (*) wildcard specifies all facilities or priorities. Separate the names of multiple facilities and priorities on a line with commas (,). Separate multiple filters on one line with semicolons (;). Precede a priority with an exclamation mark (!) to select all messages except those with that priority.

The following are examples of facility/priority-based filters.

Select all kernel messages with any priority.

kern.*

Select all mail messages with crit or higher priority.

mail.crit

Select all daemon and kern messages with warning or err priority.

daemon,kern.warning,err

Select all cron messages except those with info or debug priority.

cron.!info,!debug

By default, /etc/rsyslog.conf includes the following rules:

```
# Log all kernel messages to the console.
# Logging much else clutters up the screen.
#kern.* /dev/console
# Log anything (except mail) of level info or higher.
# Don't log private authentication messages!
*.info;mail.none;authpriv.none;cron.none /var/log/messages
# The authpriv file has restricted access.
authpriv.* /var/log/secure
# Log all the mail messages in one place.
mail.* -/var/log/maillog
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Process Accounting

# Log cron stuff	
cron.*	/var/log/cron
	, vai, 109, cion
# Everybody gets emergency messages	
*.emerg	*
# Come name and the local suit and bighter in a succial	641 a
# Save news errors of level crit and higher in a special	. Ille.
uucp,news.crit	/var/log/spooler
# Save boot messages also to boot.log	
	/
local7.*	/var/log/boot.log

You can send the logs to a central log server over TCP by adding the following entry to the forwarding rules section of /etc/rsyslog.conf on each log client:

. @@logsvr:port

where *logsvr* is the domain name or IP address of the log server and port is the port number (usually, 514).

On the log server, add the following entry to the MODULES section of /etc/rsyslog.conf:

\$ModLoad imtcp
\$InputTCPServerRun port

where *port* corresponds to the port number that you set on the log clients.

To manage the rotation and archival of the correct logs, edit /etc/logrotate.d/syslog so that it references each of the log files that are defined in the RULES section of /etc/rsyslog.conf. You can configure how often the logs are rotated and how many past copies of the logs are archived by editing / etc/logrotate.conf.

It is recommended that you configure Logwatch on your log server to monitor the logs for suspicious messages, and disable Logwatch on log clients. However, if you do use Logwatch, disable high precision timestamps by adding the following entry to the GLOBAL DIRECTIVES section of /etc/rsyslog.conf on each system:

\$ActionFileDefaultTemplate RSYSLOG_TraditionalFileFormat

For more information, see the logrotate(8), logwatch(8), rsyslogd(8) and rsyslog.conf(5) manual pages, the HTML documentation in the /usr/share/doc/rsyslog-5.8.10 directory, and the documentation at https://www.rsyslog.com/doc/manual.html.

3.10 Configuring and Using Process Accounting

The psacct package implements the process accounting service in addition to the following utilities that you can use to monitor process activities:

ac	Displays connection times in hours for a user as recorded in the wtmp file (by default, /var/log/wtmp).
accton	Turns on process accounting to the specified file. If you do not specify a file name argument, process accounting is stopped. The default system accounting file is /var/account/pacct.
lastcomm	Displays information about previously executed commands as recorded in the system accounting file.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Software Management

sa

Summarizes information about previously executed commands as recorded in the system accounting file.

Note

As for any logging activity, ensure that the file system has enough space to store the system accounting and wtmp files. Monitor the size of the files and, if necessary, truncate them.

For more information, see the ac(1), accton(8), lastcomm(1), and sa(8) manual pages.

3.11 Configuring and Using Software Management

Oracle Linux provides the yum utility which you can use to install or upgrade RPM packages. The main benefit of using yum is that it also installs or upgrades any package dependencies. yum downloads packages from repositories such as those that are available on the Oracle Linux yum server and the Unbreakable Linux Network (ULN), but you can also set up your own repositories on systems that do not have Internet access.

The Oracle Linux yum server is a convenient way to install Oracle Linux packages rather than installing them from installation media. You can also subscribe to the Oracle Linux errata mailing list, and obtain bug fixes, security fixes and enhancements. You can access the server at https://yum.oracle.com/.

If you have registered your system with ULN, you can use yum with the ULN channels to maintain the software on your system

You can use the RPM package manager to verify the integrity of installed system files. The rpm -v package and rpm -vf filename commands verify packages and files respectively by comparing them with package metadata in the RPM database. The verify operation compares file size, MD5 sum, permissions, type, owner, and group and displays any discrepancies. To see more verbose information, specify the -v option. You can use the rpm -qa command to verify the integrity of all the packages that are installed on a system, for example:

```
# for i in `rpm -qa`
> do
> rpm -V $i > .tmp || echo -e "\nDiscepancies for package $i" && cat .tmp
> rm -f .tmp
> done
Discepancies for package gdm-2.30.4-33.0.1.el6_2.x86_64
.M....G.. /var/log/gdm
            /var/run/gdm
.M....
          /var/run/gdm/greeter
missing
Discepancies for package libgcj-4.4.6-4.el6.x86_64
......T. c /usr/lib64/security/classpath.security
Discepancies for package sudo-1.7.4p5-12.el6_3.x86_64
S.5....T. c /etc/sudoers
Discepancies for package libcgroup-0.37-4.el6.x86_64
S.5....T. c /etc/cgconfig.conf
Discepancies for package yum-3.2.29-30.0.1.el6.noarch
.....T. c /etc/yum.conf
Discepancies for package kernel-2.6.32-279.el6.x86_64
....T.
           /etc/ld.so.conf.d/kernel-2.6.32-279.el6.x86_64.conf
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring Update and Patch Management

. . .

A string of character codes indicates the discrepancies between an installed file and the metadata for that file. The following table lists the meanings of the character codes in the output from rpm -V:

Code	Description of Difference					
5	MD5 sum.					
D	Device major or minor number.					
G	Group ownership.					
L	Symbolic link path.					
М	Mode including permissions or file type.					
Р	Capabilities.					
S	File size.					
Т	Modification time.					
U	User ownership.					
	None (test passed).					
?	Unknown (test could not be performed).					

If displayed, a single character code preceding the affected file denotes the file type, and can take the values shown in the following table:

Code	Description
С	Configuration file.
d	Documentation file.
g	Ghost file, whose file contents are not included in the package payload.
1	License file.
r	Readme file.

Most discrepancies are caused by editing the configuration files of subsystems. To see which files change over time, create a baseline file of discrepancies immediately after installation, and diff this file against the results found by rpm - v at a later date.

You can also use a file integrity checker to test whether a system has been compromised. There are several available open source and commercial file integrity checking tools, including AIDE (Advanced Intrusion Detection Environment) and Tripwire. AIDE and Tripwire are intrusion detection systems that scan file systems and record cryptographic hashes of each file in a database. After creating the database, you should then move it to a read-only medium to avoid tampering. On subsequent file system checks, the tool alerts you if the stored checksums do not match those for the current files. For more information, see the AIDE or Tripwire websites.

For more information about using yum, see the yum(8) manual page and the Oracle Linux Administrator's Solutions Guide.

3.11.1 Configuring Update and Patch Management

Effective security practice relies on keeping system software up to date. It is therefore essential to apply system security updates as soon as they are published. It is strongly recommended that you register every IT system with an update management infrastructure. For Oracle Linux systems, the Unbreakable Linux

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Installing and Using the Yum Security Plugin

Network (ULN) tracks system software release levels, and advises you as soon as critical updates become available. Updates and errata are also available at no charge from the Oracle Linux yum server.

Updating the kernel or core system libraries typically requires a system reboot. In mission-critical enterprise and cloud environments, crucial updates might not get installed until you reboot the systems during a scheduled maintenance window. As a result, systems that support critical business applications could be running while they are not protected from known vulnerabilities. To tackle this problem, Oracle Linux Premier Support includes access to Ksplice Uptrack, which is an innovative technology that allows administrators to apply security updates, patches, and critical bug fixes to the running kernel without requiring a reboot. Ksplice Uptrack improves the security, reliability, and availability of Oracle Linux systems by enabling zero downtime updates, helping to keep systems up to date without downtime or service disruption.

For more information about Ksplice, see https://oss.oracle.com/ksplice/docs/ksplice-quickstart.pdf.

3.11.2 Installing and Using the Yum Security Plugin

The yum-plugin-security package allows you to use yum to obtain a list of all of the errata that are available for your system, including security updates. You can also use Oracle Enterprise Manager 12c Cloud Control or management tools such as Katello, Pulp, Red Hat Satellite, Spacewalk, and SUSE Manager to extract and display information about errata.

To install the yum-plugin-security package, enter the following command:

yum install yum-plugin-security

To list the errata that are available for your system, enter:

```
# yum updateinfo list
Loaded plugins: refresh-packagekit, rhnplugin, security
ELBA-2012-1518 bugfix
                             NetworkManager-1:0.8.1-34.el6_3.x86_64
ELBA-2012-1518 bugfix
                              NetworkManager-glib-1:0.8.1-34.el6_3.x86_64
ELBA-2012-1518 bugfix
                             NetworkManager-gnome-1:0.8.1-34.el6_3.x86_64
ELBA-2012-1457 bugfix
                              ORBit2-2.14.17-3.2.el6_3.x86_64
                              ORBit2-devel-2.14.17-3.2.el6_3.x86_64
ELBA-2012-1457 bugfix
ELSA-2013-0215 Important/Sec. abrt-2.0.8-6.0.1.el6_3.2.x86_64

ELSA-2013-0215 Important/Sec. abrt-desktop-2.0.8-6.0.1.el6_3.2.x86_64
. . .
```

The output from the command sorts the available errata in order of their IDs, and it also specifies whether each erratum is a security patch (*severity*/Sec.), a bug fix (bugfix), or a feature enhancement (enhancement). Security patches are listed by their severity: Important, Moderate, Or Low.

You can use the --sec-severity option to filter the security errata by severity, for example:

```
# yum updateinfo list --sec-severity=Moderate
Loaded plugins: refresh-packagekit, rhnplugin, security
ELSA-2013-0269 Moderate/Sec. axis-1.2.1-7.3.el6_3.noarch
ELSA-2013-0668 Moderate/Sec. boost-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-date-time-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-devel-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-filesystem-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-graph-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-graph-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-iostreams-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-program-options-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-python-1.41.0-15.el6_4.x86_64
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Installing and Using the Yum Security Plugin

• • •

To list the security errata by their Common Vulnerabilities and Exposures (CVE) IDs instead of their errata IDs, specify the keyword cves as an argument:

```
# yum updateinfo list cves
Loaded plugins: refresh-packagekit, rhnplugin, security
CVE-2012-5659 Important/Sec. abrt-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5660 Important/Sec. abrt-addon-ccpp-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5660 Important/Sec. abrt-addon-ccpp-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5659 Important/Sec. abrt-addon-ccpp-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5659 Important/Sec. abrt-addon-kerneloops-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5660 Important/Sec. abrt-addon-kerneloops-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5659 Important/Sec. abrt-addon-kerneloops-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5659 Important/Sec. abrt-addon-python-2.0.8-6.0.1.el6_3.2.x86_64
CVE-2012-5660 Important/Sec. abrt-addon-python-2.0.8-6.0.1.el6_3.2.x86_64
```

Similarly, the keywords bugfix, enhancement, and security filter the list for all bug fixes, enhancements, and security errata.

You can use the --cve option to display the errata that correspond to a specified CVE, for example:

```
# yum updateinfo list --cve CVE-2012-2677
Loaded plugins: refresh-packagekit, rhnplugin, security
ELSA-2013-0668 Moderate/Sec. boost-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-date-time-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-devel-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-filesystem-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-graph-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-iostreams-1.41.0-15.el6_4.x86_64
ELSA-2013-0668 Moderate/Sec. boost-program-options-1.41.0-15.el6_4.x86_64

updateinfo list done
```

To display more information, specify info instead of list, for example:

```
# yum updateinfo info --cve CVE-2012-2677
Loaded plugins: refresh-packagekit, rhnplugin, security
boost security update
Update ID : ELSA-2013-0668
   Release : Oracle Linux 6
     Type : security
   Status : final
   Issued : 2013-03-21
     CVEs : CVE-2012-2677
Description : [1.41.0-15]
         : - Add in explicit dependences between some boost
         :
            subpackages
         : [1.41.0-14]
         : - Build with -fno-strict-aliasing
         : [1.41.0-13]
         : - In Boost.Pool, be careful not to overflow
         :
            allocated chunk size (boost-1.41.0-pool.patch)
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring Access to Network Services

```
:

: [1.41.0-12]

: - Add an upstream patch that fixes computation of

: CRC in zlib streams.

: - Resolves: #707624

Severity : Moderate

updateinfo info done
```

To update all packages for which security-related errata are available to the latest versions of the packages, even if those packages include bug fixes or new features but not security errata, enter:

```
# yum --security update
```

To update all packages to the latest versions that contain security errata, ignoring any newer packages that do not contain security errata, enter:

```
# yum --security update-minimal
```

To update all kernel packages to the latest versions that contain security errata, enter:

yum --security update-minimal kernel*

You can also update only those packages that correspond to a CVE or erratum, for example:

```
# yum update --cve CVE-2012-3954
```

```
# yum update --advisory ELSA-2012-1141
```

Note

Some updates might require you to reboot the system. By default, the boot manager will automatically enable the most recent kernel version.

For more information, see the yum-security(8) manual page.

3.12 Configuring Access to Network Services

As networks are usually the primary point of entry point into IT systems, you can use network intrusion prevention and detection tools to help avert or uncover a security breach. You can then take steps such as disabling unused network services and configure a packet-filtering firewall and TCP wrappers.

There are several open-source tools for performing packet logging and analysis. For example, tcpdump and Snort capture TCP traffic and analyze it for suspicious usage patterns, such as those that typically occur with port scans or network DoS attacks. Sguil incorporates tcpdump, Snort, and the Wireshark protocol analyzer to provide a network intrusion and detection system that simplifies log analysis and reporting.

You can check what services are running on a system by using port scanning utilities. The following examples show the information that the netstat, lsof, and nmap commands return about open TCP ports and the associated services:

# netstat -tulp									
Active I	Active Internet connections (only servers)								
Proto Re	cv-Q Se	nd-Q	Local Address	Foreign Address	State	PID/Program name			
tcp	0	0	localhost:ipp	*:*	LISTEN	1657/cupsd			
tcp	0	0	localhost:29754	*:*	LISTEN	2072/vpnagentd			
tcp	0	0	*:amqp	*:*	LISTEN	2030/qpidd			
tcp	0	0	*:56652	*:*	LISTEN	1605/rpc.statd			

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Packet-filtering Firewalls

For more information, see the lsof(8), netstat(8), and nmap(1) manual pages.

Caution

Before installing or using the nmap command, check the local legislation relating to port scanning software. In some jurisdictions, the possession or use of port scanning software is considered as unlawful criminal activity. Some ISPs might also have acceptable use policies that forbid using such software outside of your private networks.

3.12.1 Configuring and Using Packet-filtering Firewalls

A packet filtering firewall filters incoming and outgoing network packets based on the packet header information. You can create packet filter rules that determine whether packets are accepted or rejected. For example, if you create a rule to block a port, any request is made to that port that is blocked by the firewall, and the request is ignored. Any service that is listening on a blocked port is effectively disabled.

The Oracle Linux kernel uses the Netfilter feature to provide packet filtering functionality for IPv4 and IPv6 packets respectively.

Netfilter consist of two components:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Packet-filtering Firewalls

- A netfilter kernel component consisting of a set of tables in memory for the rules that the kernel uses to control network packet filtering.
- The iptables and ip6tables utilities to create, maintain, and display the rules that netfilter stores.

To implement a simple, general-purpose firewall, you can use the Firewall Configuration GUI (systemconfig-firewall) to create basic Netfilter rules. To create a more complex firewall configuration, use the iptables and ip6tables utilities to configure the packet filtering rules.

Netfilter records the packet filtering rules in the /etc/sysconfig/iptables and /etc/sysconfig/ ip6tables files, which netfilter reads when it is initialized.

The netfilter tables include:

Filter	The default table, which is mainly used to drop or accept packets based on their content.
Mangle	This table is used to alter certain fields in a packet.
NAT	The Network Address Translation table is used to route packets that create new connections.

The kernel uses the rules stored in these tables to make decisions about network packet filtering. Each rule consists of one or more criteria and a single action. If a criterion in a rule matches the information in a network packet header, the kernel applies the action to the packet. Examples of actions include:

ACCEPT	Continue processing the packet.
DROP	End the packet's life without notice.
REJECT	As DROP, and additionally notify the sending system that the packet was blocked.

Rules are stored in chains, where each chain is composed of a default policy plus zero or more rules. The kernel applies each rule in a chain to a packet until a match is found. If there is no matching rule, the kernel applies the chain's default action (policy) to the packet.

Each netfilter table has several predefined chains. The filter table contains the following chains:

FORWARD	Packets that are not addressed to the local system pass through this chain.
INPUT	Inbound packets to the local system pass through this chain.
OUTPUT	Locally created packets pass through this chain.

The chains are permanent and you cannot delete them. However, you can create additional chains in the filter table.

For more information, see the iptables(8) and ip6tables(8) manual pages.

3.12.1.1 Listing Firewall Rules

Use the iptables -L command to list firewall rules for the chains of the filter table. The following example shows the default rules for a newly installed system:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Packet-filtering Firewalls

# iptables	5 -L			
Chain INPU	JT (policy	ACCEPT)		
target	prot opt	source	destination	
ACCEPT	all	anywhere	anywhere	state RELATED, ESTABLISHED
ACCEPT	icmp	anywhere	anywhere	
ACCEPT	all	anywhere	anywhere	
ACCEPT	tcp	anywhere	anywhere	state NEW tcp dpt:ssh
ACCEPT	udp	anywhere	anywhere	state NEW udp dpt:ipp
ACCEPT	udp	anywhere	224.0.0.251	state NEW udp dpt:mdns
ACCEPT	tcp	anywhere	anywhere	state NEW tcp dpt:ipp
ACCEPT	udp	anywhere	anywhere	state NEW udp dpt:ipp
REJECT	all	anywhere	anywhere	reject-with icmp-host-prohibited
Chain FORV	NARD (poli	cy ACCEPT)		
target	prot opt	source	destination	
REJECT	all	anywhere	anywhere	reject-with icmp-host-prohibited
Chain OUTE	PUT (polic	Y ACCEPT)		
target	prot opt	source	destination	

In this example, the default policy for each chain is ACCEPT. A more secure system could have a default policy of DROP, and the additional rules would only allow specific packets on a case-by-case basis.

If you want to modify the chains, specify the --line-numbers option to see how the rules are numbered.

Chain INPUT (policy ACCEPT) num target prot opt source destination 1 ACCEPT all anywhere anywhere state RELATED,ESTABLISHED 2 ACCEPT icmp anywhere anywhere 3 ACCEPT all anywhere anywhere 4 ACCEPT tcp anywhere anywhere state NEW tcp dpt:ssh 5 ACCEPT udp anywhere anywhere state NEW udp dpt:ipp 6 ACCEPT udp anywhere 224.0.0.251 state NEW udp dpt:mdns 7 ACCEPT tcp anywhere anywhere state NEW tcp dpt:spp 8 ACCEPT udp anywhere anywhere state NEW tcp dpt:ipp 9 REJECT all anywhere anywhere reject-with icmp-host-prohibited Chain FORWARD (policy ACCEPT) num target prot opt source destination 1 REJECT all anywhere anywhere reject-with icmp-host-prohibited	#	# iptables -Lline-numbers

6 ACCEPT udp anywhere 224.0.0.251 state NEW udp dpt:mdns 7 ACCEPT tcp anywhere anywhere state NEW udp dpt:ipp 8 ACCEPT udp anywhere anywhere state NEW udp dpt:ipp 9 REJECT all anywhere reject-with icmp-host-prohibited Chain FORWARD (policy ACCEPT) num target prot opt source destination	4	ACCEPT	tcp anywhere	anywhere	state NEW tcp dpt:ssh	
7ACCEPTtcpanywhereanywherestateNEWtcpdpt:ipp8ACCEPTudpanywhereanywherestateNEWudpdpt:ipp9REJECTallanywhereanywherereject-withicmp-host-prohibitedChainFORWARD (policyACCEPT)numtargetprotoptsourcedestination	5	ACCEPT	udp anywhere	anywhere	state NEW udp dpt:ipp	
8 ACCEPT udp anywhere anywhere state NEW udp dpt:ipp 9 REJECT all anywhere anywhere reject-with icmp-host-prohibited Chain FORWARD (policy ACCEPT) num target prot opt source destination	б	ACCEPT	udp anywhere	224.0.0.251	state NEW udp dpt:mdns	
9 REJECT all anywhere anywhere reject-with icmp-host-prohibited Chain FORWARD (policy ACCEPT) num target prot opt source destination	7	ACCEPT	tcp anywhere	anywhere	state NEW tcp dpt:ipp	
Chain FORWARD (policy ACCEPT) num target prot opt source destination	8	ACCEPT	udp anywhere	anywhere	state NEW udp dpt:ipp	
num target prot opt source destination	9	REJECT	all anywhere	anywhere	reject-with icmp-host-prohibited	
num target prot opt source destination						
	Ch	ain FORWARD	(policy ACCEPT)			
1 REJECT all anywhere anywhere reject-with icmp-host-prohibited	nu	m target	prot opt source	destination		
	1	REJECT	all anywhere	anywhere	reject-with icmp-host-prohibited	
Chain OUTPUT (policy ACCEPT)	Ch	ain OUTPUT	(policy ACCEPT)			
num target prot opt source destination	nu	m target	prot opt source	destination		

3.12.1.2 Inserting Rules in a Chain

Use the iptables -I command to insert a rule in a chain. For example, the following command inserts a rule in the INPUT chain to allow access by TCP on port 80:

# ij	# iptables -I INPUT 4 -p tcp -m tcpdport 80 -j ACCEPT					
# i	# iptables -Lline-numbers					
Cha	in INPUT (p	policy A	CCEI	PT)		
num	target	prot d	opt	source	destination	
1	ACCEPT	all ·		anywhere	anywhere	state RELATED, ESTABLISHED
2	ACCEPT	icmp		anywhere	anywhere	
3	ACCEPT	all ·		anywhere	anywhere	
4	ACCEPT	tcp ·		anywhere	anywhere	tcp dpt:http
5	ACCEPT	tcp ·		anywhere	anywhere	state NEW tcp dpt:ssh
6	ACCEPT	udp ·		anywhere	anywhere	state NEW udp dpt:ipp
7	ACCEPT	udp ·		anywhere	224.0.0.251	state NEW udp dpt:mdns
8	ACCEPT	tcp ·		anywhere	anywhere	state NEW tcp dpt:ipp
9	ACCEPT	udp ·		anywhere	anywhere	state NEW udp dpt:ipp
10	REJECT	all ·		anywhere	anywhere	reject-with icmp-host-prohibited
10	REJECT	all ·		anywhere	anywhere	reject-with icmp-host-prohibited

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using TCP Wrappers

The output from iptables -L shows that the new entry has been inserted as rule 4, and the old rules 4 through 9 are pushed down to positions 5 through 10. The TCP destination port of 80 is represented as http, which corresponds to the following definition in the /etc/services file (the HTTP daemon listens for client requests on port 80):

http 80/tcp www.www-http # WorldWideWeb HTTP

3.12.1.3 Deleting Rules in a Chain

Use the iptables -D command to delete a rule in a chain. For example, the following command deletes rule 4 from the INPUT chain:

iptables -D INPUT 4

3.12.2 Configuring and Using TCP Wrappers

TCP wrappers provide basic filtering of incoming network traffic. You can allow or deny access from other systems to certain *wrapped* network services running on a Linux server. A wrapped network service is one that has been compiled against the <code>libwrap.a</code> library. You can use the <code>ldd</code> command to determine if a network service has been wrapped as shown in the following example for the <code>sshd</code> daemon:

```
# ldd /usr/sbin/sshd | grep libwrap
libwrap.so.0 => /lib64/libwrap.so.0 (0x00007f877de07000)
```

When a remote client attempts to connect to a network service on the system, the wrapper consults the rules in the configuration files /etc/hosts.allow and /etc/hosts.deny files to determine if access is permitted.

The wrapper for a service first reads /etc/hosts.allow from top to bottom. If the daemon and client combination matches an entry in the file, access is allowed. If the wrapper does not find a match in /etc/hosts.allow, it reads /etc/hosts.deny from top to bottom. If the daemon and client combination matches and entry in the file, access is denied. If no rules for the daemon and client combination are found in either file, or if neither file exists, access to the service is allowed.

The wrapper first applies the rules specified in /etc/hosts.allow, so these rules take precedence over the rules specified in /etc/hosts.deny. If a rule defined in /etc/hosts.allow permits access to a service, any rule in /etc/hosts.deny that forbids access to the same service is ignored.

The rules take the following form:

daemon_list : client_list [: command] [: deny]

where *daemon_list* and *client_list* are comma-separated lists of daemons and clients, and the optional *command* is run when a client tries to access a daemon. You can use the keyword ALL to represent all daemons or all clients. Subnets can be represented by using the * wildcard, for example 192.168.2.*. Domains can be represented by prefixing the domain name with a period (.), for example .mydomain.com. The optional deny keyword causes a connection to be denied even for rules specified in the /etc/hosts.allow file. The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Chroot Jails

The following are some sample rules.

Match all clients for scp, sftp, and ssh access (sshd).

sshd : ALL

Match all clients on the 192.168.2 subnet for FTP access (vsftpd).

vsftpd : 192.168.2.*

Match all clients in the mydomain.com domain for access to all wrapped services.

ALL : .mydomain.com

Match all clients for FTP access, and displays the contents of the banner file /etc/banners/vsftpd (the banner file must have the same name as the daemon).

vsftpd : ALL : banners /etc/banners/

Match all clients on the 200.182.68 subnet for all wrapped services, and logs all such events. The %c and %d tokens are expanded to the names of the client and the daemon.

ALL : 200.182.68.* : spawn /bin/echo `date` "Attempt by %c to connect to %d" >> /var/log/tcpwr.log

Match all clients for scp, sftp, and ssh access, and logs the event as an emerg message, which is displayed on the console.

sshd : ALL : severity emerg

Match all clients in the forbid.com domain for scp, sftp, and ssh access, logs the event, and deny access (even if the rule appears in /etc/hosts.allow).

sshd : .forbid.com : spawn /bin/echo `date` "sshd access denied for %c" >>/var/log/sshd.log : deny

For more information, see the hosts_access(5) manual page.

3.13 Configuring and Using Chroot Jails

A chroot operation changes the apparent root directory for a running process and its children. It allows you to run a program with a root directory other than /. The program cannot see or access files outside the designated directory tree. Such an artificial root directory is called a *chroot jail*, and its purpose is to limit the directory access of a potential attacker. The chroot jail locks down a given process and any user ID that it is using so that all they see is the directory in which the process is running. To the process, it appears that the directory in which it is running is the root directory.

Note

The chroot mechanism cannot defend against intentional tampering or low-level access to system devices by privileged users. For example, a chroot root user could create device nodes and mount file systems on them. A program can also break out of a chroot jail if it can gain root privilege and use chroot() to change its current working directory to the real root directory. For this reason, you should ensure that a chroot jail does not contain any setuid or setgid executables that are owned by root.

For a chroot process to be able to start successfully, you must populate the chroot directory with all required program files, configuration files, device nodes, and shared libraries at their expected locations relative to the level of the chroot directory.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Running DNS and FTP Services in a Chroot Jail

3.13.1 Running DNS and FTP Services in a Chroot Jail

If the DNS name service daemon (named) runs in a chroot jail, any hacker that enters your system via a BIND exploit is isolated to the files under the chroot jail directory. Installing the bind-chroot package creates the /var/named/chroot directory, which becomes the chroot jail for all BIND files.

You can configure the vsftpd FTP server to automatically start chroot jails for clients. By default, anonymous users are placed in a chroot jail. However, local users that access an vsftpd FTP server are placed in their home directory. Specify the chroot_local_user=YES option in the /etc/vsftpd/vsftpd.conf file to place local users in a chroot jail based on their home directory.

3.13.2 Creating a Chroot Jail

To create a chroot jail:

1. Create the directory that will become the root directory of the chroot jail, for example:

mkdir /home/oracle/jail

2. Use the ldd command to find out which libraries are required by the command that you intend to run in the chroot jail, for example /bin/bash:

```
# ldd /bin/bash
linux-vdso.so.1 => (0x00007fff56fcc000)
libtinfo.so.5 => /lib64/libtinfo.so.5 (0x000003ad1200000)
libdl.so.2 => /lib64/libdl.so.2 (0x000003abe600000)
libc.so.6 => /lib64/libc.so.6 (0x000003abe200000)
/lib64/ld-linux-x86-64.so.2 (0x000003abe00000)
```

3. Create subdirectories of the chroot jail's root directory that have the same relative paths as the command binary and its required libraries have to the real root directory, for example:

```
# mkdir /home/oracle/jail/bin
# mkdir /home/oracle/jail/lib64
```

4. Copy the binary and the shared libraries to the directories under the chroot jail's root directory, for example:

```
# cp /bin/bash /home/oracle/jail/bin
# cp /lib64/{libtinfo.so.5,libdl.so.2,libc.so.6,ld-linux-x86-64.so.2} \
    /home/oracle/jail/lib64
```

3.13.3 Using a Chroot Jail

To run a command in a chroot jail in an existing directory (chroot_jail), use the following command:

chroot chroot_jail command

If you do not specify a command argument, chroot runs the value of the SHELL environment variable or / bin/sh if SHELL is not set.

For example, to run /bin/bash in a chroot jail (having previously set it up as described in Section 3.13.2, "Creating a Chroot Jail"):

```
# chroot /home/oracle/jail
bash-4.1# pwd
/
bash-4.1# ls
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring and Using Linux Containers

```
bash: ls: command not found
bash-4.1# exit
exit
#
```

You can run built-in shell commands such as pwd in this shell, but not other commands unless you have copied their binaries and any required shared libraries to the chroot jail.

For more information, see the chroot(1) manual page.

3.14 Configuring and Using Linux Containers

Note

Linux Containers (LXC) are available in Oracle Linux 6 with the Unbreakable Enterprise Kernel (2.6.29 or above). LXC is a Technology Preview feature that is made available for testing and evaluation purposes, but is not recommended for production systems.

The LXC feature provides a way to isolate a group of processes from other processes that are running on an Oracle Linux system. LXC is a lightweight operating system virtualization technology that uses the control group (cgroup) feature to provide resource management and namespace isolation in a similar manner to chroot. Within a container, processes can have their own private view of the operating system with its own process ID space, file system structure, and network interfaces.

See Oracle® Linux 6: Administrator's Solutions Guide for more information on how to configure and use Linux Containers.

3.15 Configuring and Using Kernel Security Mechanisms

The Linux kernel features some additional security mechanisms that you can use to enhance the security of a system. These mechanisms randomize the layout of a process's address space or prevent code from being executed in non-executable memory.

3.15.1 Address Space Layout Randomization

Address Space Layout Randomization (ASLR) can help defeat certain types of buffer overflow attacks. ASLR can locate the base, libraries, heap, and stack at random positions in a process's address space, which makes it difficult for an attacking program to predict the memory address of the next instruction. ASLR is built into the Linux kernel and is controlled by the parameter /proc/sys/kernel/ randomize_va_space. The randomize_va_space parameter can take the following values:

0	Disable ASLR. This setting is applied if the kernel is booted with the norandmaps boot parameter.
1	Randomize the positions of the stack, virtual dynamic shared object (VDSO) page, and shared memory regions. The base address of the data segment is located immediately after the end of the executable code segment.
2	Randomize the positions of the stack, VDSO page, shared memory regions, and the data segment. This is the default setting.

You can change the setting temporarily by writing a new value to /proc/sys/kernel/ randomize_va_space, for example: The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Data Execution Prevention

echo value > /proc/sys/kernel/randomize_va_space

To change the value permanently, add the setting to /etc/sysctl.conf, for example:

kernel.randomize_va_space = value

and run the sysctl -p command.

If you change the value of randomize_va_space, you should test your application stack to ensure that it is compatible with the new setting.

If necessary, you can disable ASLR for a specific program and its child processes by using the following command:

% setarch `uname -m` -R program [args ...]

3.15.2 Data Execution Prevention

The Data Execution Prevention (DEP) feature prevents an application or service from executing code in a non-executable memory region. Hardware-enforced DEP works in conjunction with the NX (Never eXecute) bit on compatible CPUs. Oracle Linux does not emulate the NX bit in software for CPUs that do not implement the NX bit in hardware.

You cannot disable the DEP feature.

3.15.3 Position Independent Executables

The Position Independent Executables (PIE) feature loads executable binaries at random memory addresses so that the kernel can disallow text relocation. To generate a position-independent binary:

- Specify the -fpie option to gcc when compiling.
- Specify the -pie option to 1d when linking.

To test whether a binary or library is relocatable, use the following command:

readelf -d elfname | grep TEXTREL

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible.

Chapter 4 Security Considerations for Developers

Table of Contents

4.1 Design Principles for Secure Coding	53
4.2 General Guidelines for Secure Coding	54
4.3 General Guidelines for Network Programs	55

This chapter provides information for developers about how to create secure applications for Oracle Linux, and how to extend Oracle Linux to access external systems without compromising security.

4.1 Design Principles for Secure Coding

The following well-established design principles are recommended for secure coding:

Least privilege	A process or user should be given only those privileges that are necessary to complete a task. User privileges should be assigned according to their role, but not otherwise. To create a minimal protection domain, assign rights when a process or thread requires them and remove them afterwards. This principle limits the potential damage that can result from attacks and user errors.
Economy of mechanism	Keep the design simple. There is less to go wrong, fewer inconsistencies are possible, and the code is easier to understand and debug.
Complete mediation	Check every attempt to access to a resource, not just the first. For example, Linux checks access permissions when a process opens a file but not thereafter. If a file's permissions change while a process has the file open, unauthorized access can result. Ideally, one could argue that the permissions should be checked whenever an open file is accessed. In practise, such checking is considered to be an unnecessary overhead given the circumstances under which access was first obtained.
Open design	Security should not depend on the secrecy of the code's design or implementation, sometimes referred to as <i>security through obscurity</i> . For example, an open back door to a system is only as secure as the knowledge of its existence. Of course, this principle does not apply to information such as passwords or cryptographic keys, knowledge of which should also be shared among as few people as possible. For this reason, many secure authentication schemes also rely on biometric identification or the possession of a physical artifact such a hardware token or smart card, in addition to knowledge of a PIN code or password.
Separation of privilege	Divide the code into modules, where each module requires a specific, limited set of privileges to perform a specific task. Typically, multiple privileges should be required to grant access to a sensitive operation. This principle ensures separation of duty and provides defense in depth. For example, a main thread that has no privileges can generate a privileged thread to perform a task. A successful attack against the main thread thus gains minimal access to the system.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. General Guidelines for Secure Coding

Least common mechanism	A system should isolate users and their activities from each other. Users should not share processes or threads and information channels should not be shared between users.
Fail-safe defaults	The default action should be to deny access to an operation. Should an attempt to perform an operation be denied, the system is as secure as it was before the operation started.
Accountability	Log the user and their privileges for each action that he or she attempts to perform. Any logs should be capable of being rotated and archived to avoid filling up a file system.
Psychological acceptability	Security mechanisms should be easy to install, configure, and use so that a user is less tempted to try to bypass them.

4.2 General Guidelines for Secure Coding

The following coding practices are recommended:

- Check that input data is what the program expects by performing type, length, and bound checking. Inputs include command-line arguments and environment variables in addition to data that a user enters.
- Check input data for the inclusion of constructs such as shell commands, SQL statements, and XML and HTML code that might be used in an injection attack.
- Check the type, length, and bounds of arguments to system calls and library routines. If possible, use library routines that guard against buffer overflows.
- Use full pathnames for file-name arguments, do not use files in world-writable directories, verify that a file being written to is not actually a symbolic link, and protect against the unintended overwriting of existing files.
- Check the type, length, and bounds of values returned by system calls and library routines. Make the code respond appropriately to any error codes that system calls and library functions set or return.
- Do not assume the state of the shell environment. Check any settings that a program inherits from the shell, such as the user file-creation mask, signal handling, file descriptors, current working directory, and environment variables, especially PATH and IFS. Reset the settings if necessary.
- · Perform assert checking on variables that can take a finite set of values.
- Log information about privileged actions and error conditions. Do not allow the program to dump a core file on an end-user system.
- Do not echo passwords to the screen, or transmit or store them as clear text. Before transmitting or storing a password, combine it with a salt value and use a secure one-way algorithm such as SHA-512 to create a hash.
- If your program uses a pseudo-random number generating routine, verify that the numbers that it generates are sufficiently random for your requirements. You should also use a good random seed that a potential attacker should not be able to predict. See RFC 4086, *Randomness Requirements for Security*, for more information.
- It is recommended that Address Space Layout Randomization (ASLR) is enabled on the host system as this feature can help defeat certain types of buffer overflow attacks. See Section 3.15.1, "Address Space Layout Randomization".

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. General Guidelines for Network Programs

- When compiling and linking your program, use the Position Independent Executables (PIE) feature to generate a position-independent binary. See Section 3.15.3, "Position Independent Executables".
- Consider using chroot() to confine the operating boundary of your program to a specified location within a file system.
- Do not execute a shell command by calling popen() or syscall() from within a program, especially from a setuid or setgid program.

The following guidelines apply if your program has its setuid or setgid bit set so that it can perform privileged actions on behalf of a user who does not possess those privileges:

- Do not set the setuid or setgid bit on shell scripts. However, if you use Perl scripts that are setuid or setgid, perl runs in *taint mode*, which is claimed to be more secure than using the equivalent C code. See the perlsec(1) manual page for details.
- Restrict the use of the privilege that setuid or setgid grants to the functionality that requires it, and then return the effective UID or GID to that of the user. If possible, perform the privileged functionality in a separate, closely-monitored thread or process.
- Do not allow a setuid or setgid program to execute child processes using execlp() or execvp(), which use the PATH environment variable.

4.3 General Guidelines for Network Programs

The following coding practices are recommended for network programs:

- Perform a reverse lookup on an IP address to obtain the fully qualified domain name, and then use that domain name look up the IP address. The two IP addresses should be identical.
- Protect a service against Denial of Service (DoS) attacks by allowing it to stop processing requests if it becomes overloaded.
- Set timeouts on read and write requests over the network.
- Check the content, bounds, value, and type of data received over the network, and reject any data that does not conform to what the program expects.
- Use certificates or preshared keys to authenticate the local and remote ends of the network connection.
- Use a well-established technology such as TLS or SSL to encrypt data sent over the network connection.
- Wherever possible, use existing networking protocols and technologies whose security characteristics are well known.
- Log information about successful and unsuccessful connection attempts, data reception and transmission errors, and changes to the service state.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible.

Chapter 5 Secure Deployment Checklist

Table of Contents

5.1 Minimizing the Software Footprint	57
5.2 Configuring System Logging	
5.3 Disabling Core Dumps	59
5.4 Minimizing Active Services	59
5.5 Locking Down Network Services	
5.6 Configuring a Packet-filtering Firewall	63
5.7 Configuring TCP Wrappers	63
5.8 Configuring Kernel Parameters	
5.9 Restricting Access to SSH Connections	
5.10 Configuring File System Mounts, File Permissions, and File Ownerships	
5.11 Checking User Accounts and Privileges	66

The sections in this chapter provide guidelines that help secure your Oracle Linux system.

For information about using OpenSCAP to scan a system for vulnerabilities, see Chapter 6, Using OpenSCAP to Scan for Vulnerabilities.

5.1 Minimizing the Software Footprint

On systems on which Oracle Linux has been installed, remove unneeded RPMs to minimize the software footprint. For example, you could uninstall the X Windows package (xorg-x11-server-Xorg) if it is not required on a server system.

To discover which package provides a given command or file, use the yum provides command as shown in the following example:

```
# yum provides /usr/sbin/sestatus
...
policycoreutils-2.0.83-19.24.0.1.el6.x86_64 : SELinux policy core utilities
Repo : installed
Matched from:
Other : Provides-match: /usr/sbin/sestatus
```

To display the files that a package provides, use the repoquery utility, which is included in the yumutils package. For example, the following command lists the files that the btrfs-progs package provides.

```
# repoquery -1 btrfs-progs
/sbin/btrfs
/sbin/btrfs-convert
/sbin/btrfs-debug-tree
.
.
.
```

To uninstall a package, use the yum remove command, as shown in this example:

```
# yum remove xinetd
Loaded plugins: refresh-packagekit, security
Setting up Remove Process
Resolving Dependencies
--> Running transaction check
---> Package xinetd.x86_64 2:2.3.14-35.el6_3 will be erased
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring System Logging

> Finished	Dependency Re	esolution		
Dependencies	Resolved

veritying	· Z·AINetu-z	.3.14-35.010_3.800_04		1/1
Removed:				
xinetd.x86	_64 2:2.3.14-3	35.el6_3		

Complete!

The following table lists packages that you should not install or that you should remove using yum remove if they are already installed.

of ftp, rcp, rlogin, rsh and telnet. If I instead.
Irsh use unencrypted communication that Jse SSH instead.
used by Samba. Remove this package if the ng as an Active Directory server, a domain domain member, and it does not provide s file and print sharing functionality.
d obsolete.
ncrypted communication that can be H instead.
rypted communication that can be snooped. d to support legacy hardware. If possible, secure protocol instead.
el used by the Internet listener daemon is
el used by NIS is inherently flawed. Use an

5.2 Configuring System Logging

Verify that the system logging service rsyslog is running:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Disabling Core Dumps

```
# service rsyslog status
rsyslogd (pid 1632) is running...
```

If the service is not running, start it and enable it to start when the system is rebooted:

service rsyslog start
chkconfig rsyslog on

Ensure that each log file referenced in /etc/rsyslog.conf exists and is owned and only readable by root:

```
# touch logfile
# chown root:root logfile
# chmod 0600 logfile
```

It is also recommended that you use a central log server and that you configure Logwatch on that server. See Section 3.9, "Configuring and Using System Logging".

5.3 Disabling Core Dumps

Core dumps can contain information that an attacker might be able to exploit and they take up a large amount of disk space. To prevent the system creating core dumps when the operating system terminates a program due to a segment violation or other unexpected error, add the following line to /etc/security/ limits.conf:

* hard core 0

You can restrict access to core dumps to certain users or groups, as described in the limits.conf(5) manual page.

By default, the system prevents setuid and setgid programs, programs that have changed credentials, and programs whose binaries do not have read permission from dumping core. To ensure that the setting is permanently recorded, add the following lines to /etc/sysctl.conf:

```
# Disallow core dumping by setuid and setgid programs
fs.suid_dumpable = 0
```

and then run the sysctl -p command.

Note

A value of 1 permits core dumps that are readable by the owner of the dumping process. A value of 2 permits core dumps that are readable only by root for debugging purposes.

5.4 Minimizing Active Services

Restrict services to only those that a server requires. The default installation for an Oracle Linux server configures a minimal set of services:

cupsd and lpd (print services)

sendmail (email delivery service)

sshd (openSSH services)

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Minimizing Active Services

If possible, configure one type of service per physical machine, virtual machine, or Linux Container. This technique limits exposure if a system is compromised.

If a service is not used, remove the software packages that are associated with the service. If it is not possible to remove a service because of software dependencies, use the chkconfig and service commands to disable the service.

For services that are in use, apply the latest Oracle support patches and security updates to keep software packages up to date. To protect against unauthorized changes, ensure that the /etc/services file is owned by root and writable only by root.

ls -Z /etc/services

-rw-r--r-. root root system_u:object_r:etc_t:SystemLow /etc/services

Unless specifically stated otherwise, consider disabling the services in the following table if they are not used on your system:

Service	Description		
anacron	Executes commands periodically. Primarily intended for use on laptop and user desktop machines that do not run continuously.		
apmd	(Advanced Power Management Daemon) Provides information on power management and battery status, and allows programmed response to power management events. Primarily intended for use on laptop machines.		
automount	Manages mount points for the automatic file-system mounter. Disable this service on servers that do not require automounter functionality.		
bluetooth	Supports the connections of Bluetooth devices. Primarily intended for use on laptop and user desktop machines. Bluetooth provides an additional potential attack surface. Disable this service on servers that do not require Bluetooth functionality.		
firstboot	Configures a system when you first log in after installation. Controlled by the /etc/rc.d/init.d/firstboot script. firstboot does not run unless RUN_FIRSTBOOT=YES is set in /etc/sysconfig/firstboot. If /etc/ reconfigSys exists or if you specify reconfig in the kernel boot arguments, firstboot runs in reconfiguration mode. Disable this service on servers following successful installation.		
gpm	(General Purpose Mouse) Provides support for the mouse pointer in a text console.		
haldaemon (Hardware Abstraction Layer Daemon) Maintains a real-time da devices that are connected to a system. Applications can use th discover and interact with newly attached devices. Primarily interact on laptop and user desktop machines to support hot-plug devices.			
	Caution		
	Do not disable this service. Many applications rely on this functionality.		
hidd	(Bluetooth Human Interface Device daemon) Provides support for Bluetooth input devices such as a keyboard or mouse. Primarily intended for use on laptop and user desktop machines. Bluetooth provides an additional potential attack surface. Disable this service on servers that do not require Bluetooth functionality.		

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Minimizing Active Services

Service	Description		
irqbalance	Distributes hardware interrupts across processors on a multiprocessor system. Disable this service on servers that do not require this functionality.		
iscsi	Controls logging in to iSCSI targets and scanning of iSCSI devices. Disable this service on servers that do not access iSCSI devices.		
iscsid	Implements control and management for the iSCSI protocol. Disable this service on servers that do not access iSCSI devices.		
kdump	Allows a kdump kernel to be loaded into memory at boot time or a kernel dump to be saved if the system panics. Disable this service on servers that you do not use for debugging or testing.		
mcstrans	Controls the SELinux Context Translation System service.		
mdmonitor	Checks the status of all software RAID arrays on the system. Disable this service on servers that do not use software RAID.		
messagebus	Broadcasts notifications of system events and other messages relating to hardware events via the system-wide D-BUS message bus.		
	Do not disable this service. Many applications rely on this functionality.		
microcode_ctl	Runs microcode that is required for IA32 processors only. Disable this service on servers that do not have such processors.		
pcscd	(PC/SC Smart Card Daemon) Supports communication with smart-card readers. Primarily intended for use on laptop and user desktop machines to support smart-card authentication. Disable this service on servers that do not use smart-card authentication.		
sandbox	Sets up /tmp, /var/tmp, and home directories to be used with the pam_namespace, sandbox, and xguest application confinement utilities. Disable this service if you do not use these programs.		
setroubleshoot	Controls the SELinux Troubleshooting service, which provides information about SELinux Access Vector Cache (AVC) denials to the sealert tool.		
smartd	Communicates with the Self-Monitoring, Analysis and Reporting Technology (SMART) systems that are integrated into many ATA-3 and later, and SCSI-3 disk drives. SMART systems monitor disk drives to measure reliability, predict disk degradation and failure, and perform drive testing.		
xfs	Caches fonts in memory to improve the performance of X Window System applications.		

You should consider disabling the following network services if they are not used on your system:

Service	Description		
avahi-daemon	Implements Apple's Zero configuration networking (also known as Rendezvous or Bonjour). Primarily intended for use on laptop and user desktop machines to support music and file sharing. Disable this service on servers that do not require this functionality.		
cups	Implements the Common UNIX Printing System. Disable this service on servers that do not need to provide this functionality.		

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Locking Down Network Services

Service	Description		
hplip	Implements HP Linux Imaging and Printing to support faxing, printing, and scanning operations on HP inkjet and laser printers. Disable this service on servers that do not require this functionality.		
isdn	(Integrated Services Digital Network) Provides support for network connection over ISDN devices. Disable this service on servers that do not directly control ISDN devices.		
netfs	Mounts and unmounts network file systems, including NCP, NFS, and SMB. Disable this service on servers that do not require this functionality.		
network	Activates all network interfaces that are configured to start at boot time.		
NetworkManager	Switches network connections automatically to use the best connection that is available.		
nfslock	Implements the Network Status Monitor (NSM) used by NFS. Disable this service on servers that do not require this functionality.		
nmb	Provides NetBIOS name services used by Samba. Disable this service and remove the samba package if the system is not acting as an Active Directory server, a domain controller, or as a domain member, and it does not provide Microsoft Windows file and print sharing functionality.		
portmap	Implements Remote Procedure Call (RPC) support for NFS. Disable this service on servers that do not require this functionality.		
rhnsd	Queries the Unbreakable Linux Network (ULN) for updates and information.		
rpcgssd	Used by NFS. Disable this service on servers that do not require this functionality.		
rpcidmapd	Used by NFS. Disable this service on servers that do not require this functionality.		
smb	Provides SMB network services used by Samba. Disable this service and remove the samba package if the system is not acting as an Active Director server, a domain controller, or as a domain member, and it does not provide Microsoft Windows file and print sharing functionality.		

To stop a service and prevent it from starting when you reboot the system, used the following commands:

service service_name stop
chkconfig service_name off

Alternatively, use the Service Configuration GUI (system-config-services) to configure services.

5.5 Locking Down Network Services

Note

It is recommended that you do not install the xinetd Internet listener daemon. If you do not need this service, remove the package altogether by using the yum remove xinetd command.

If you must enable xinetd on your system, minimize the network services that xinetd can launch by disabling those services that are defined in the configuration files in /etc/xinetd.d and which are not needed.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring a Packet-filtering Firewall

To counter potential Denial of Service (DoS) attacks, you can configure the resource limits for such services by editing /etc/xinetd.conf and related configuration files. For example, you can set limits for the connection rate, the number of connection instances to a service, and the number of connections from an IP address:

```
# Maximum number of connections per second and
# number of seconds for which a service is disabled
# if the maximum number of connections is exceeded
cps = 50 10
# Maximum number of connections to a service
instances = 50
# Maximum number of connections from an IP address
per_source = 10
```

For more information, see the xinetd(8) and xinetd.conf(5) manual pages.

5.6 Configuring a Packet-filtering Firewall

You can configure the Netfilter feature to act as a packet-filtering firewall that uses rules to determine whether network packets are received, dropped, or forwarded.

The primary interfaces for configuring the packet-filter rules are the iptables and ip6tables utilities and the Firewall Configuration Tool GUI (system-config-firewall). By default, the rules should drop any packets that are not destined for a service that the server hosts or that originate from networks other than those to which you want to allow access.

In addition, Netfilter provides Network Address Translation (NAT) to hide IP addresses behind a public IP address, and IP masquerading to alter IP header information for routed packets. You can also set rule-based packet logging and define a dedicated log file in /etc/syslog.conf.

For more information, see Section 3.12.1, "Configuring and Using Packet-filtering Firewalls".

5.7 Configuring TCP Wrappers

The TCP wrappers feature mediates requests from clients to services, and control access based on rules that you define in the /etc/hosts.deny and /etc/hosts.allow files. You can restrict and permit service access for specific hosts or whole networks. A common way of using TCP wrappers is to detect intrusion attempts. For example, if a known malicious host or network attempts to access a service, you can deny access and send a warning message about the event to a log file or to the system console.

For more information, see Section 3.12.2, "Configuring and Using TCP Wrappers".

5.8 Configuring Kernel Parameters

You can use several kernel parameters to counteract various kinds of attack.

kernel.randomize_va_space controls Address Space Layout Randomization (ASLR), which can help defeat certain types of buffer overflow attacks. A value of 0 disables ASLR, 1 randomizes the positions of the stack, virtual dynamic shared object (VDSO) page, and shared memory regions, and 2 randomizes the positions of the stack, VDSO page, shared memory regions, and the data segment. The default and recommended setting is 2.

net.ipv4.conf.all.accept_source_route controls the handling of source-routed packets, which might have been generated outside the local network. A value of 0 rejects such packets, and 1 accepts them. The default and recommended setting is 0.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Restricting Access to SSH Connections

net.ipv4.conf.all.rp_filter controls reversed-path filtering of received packets to counter IP address spoofing. A value of 0 disables source validation, 1 causes packets to be dropped if the routing table entry for their source address does not match the network interface on which they arrive, and 2 causes packets to be dropped if source validation by reversed path fails (see RFC 1812). The default setting is 0. A value of 2 can cause otherwise valid packets to be dropped if the local network topology is complex and RIP or static routes are used.

net.ipv4.icmp_echo_ignore_broadcasts controls whether ICMP broadcasts are ignored to protect against Smurf DoS attacks. A value of 1 ignores such broadcasts, and 0 accepts them. The default and recommended setting is 1.

net.ipv4.icmp_ignore_bogus_error_message controls whether ICMP bogus error message responses are ignored. A value of 1 ignores such messages, and 0 accepts them. The default and recommended setting is 1.

To change the value of a kernel parameter, add the setting to /etc/sysctl.conf, for example:

kernel.randomize_va_space = 1

and then run the sysctl -p command.

5.9 Restricting Access to SSH Connections

The Secure Shell (SSH) allows protected, encrypted communication with other systems. As SSH is an entry point into the system, disable it if it is not required, or alternatively, edit the /etc/ssh/sshd_config file to restrict its use.

For example, the following setting does not allow root to log in using SSH:

PermitRootLogin no

You can restrict remote access to certain users and groups by specifying the AllowUsers, AllowGroups, DenyUsers, and DenyGroups settings, for example:

```
DenyUsers carol dan
AllowUsers alice bob
```

The ClientAliveInterval and ClientAliveCountMax settings cause the SSH client to time out automatically after a period of inactivity, for example:

```
# Disconnect client after 300 seconds of inactivity
ClientAliveCountMax 0
ClientAliveInterval 300
```

After making changes to the configuration file, restart the sshd service for your changes to take effect.

For more information, see the sshd_config(5) manual page.

5.10 Configuring File System Mounts, File Permissions, and File Ownerships

Use separate disk partitions for operating system and user data to prevent a *file system full* issue from impacting the operation of a server. For example, you might create separate partitions for /home, /tmp, p, /oracle, and so on.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Configuring File System Mounts, File Permissions, and File Ownerships

Establish disk quotas to prevent a user from accidentally or intentionally filling up a file system and denying access to other users.

To prevent the operating system files and utilities from being altered during an attack, mount the /usr file system read-only. If you need to update any RPMs on the file system, use the -o remount, rw option with the mount command to remount /usr for both read and write access. After performing the update, use the -o remount, ro option to return the /usr file system to read-only mode.

To limit user access to non-root local file systems such as /tmp or removable storage partitions, specify the -o noexec, nosuid, nodev options to mount. These option prevent the execution of binaries (but not scripts), prevent the setuid bit from having any effect, and prevent the use of device files.

Use the find command to check for unowned files and directories on each file system, for example:

find mount_point -mount -type f -nouser -o -nogroup -exec ls -l {} \;
find mount_point -mount -type d -nouser -o -nogroup -exec ls -l {} \;

Unowned files and directories might be associated with a deleted user account, they might indicate an error with software installation or deleting, or they might a sign of an intrusion on the system. Correct the permissions and ownership of the files and directories that you find, or remove them. If possible, investigate and correct the problem that led to their creation.

Use the find command to check for world-writable directories on each file system, for example:

find mount_point -mount -type d -perm /o+w -exec ls -l {} \;

Investigate any world-writable directory that is owned by a user other than a system user. The user can remove or change any file that other users write to the directory. Correct the permissions and ownership of the directories that you find, or remove them.

You can also use find to check for setuid and setgid executables.

find path -type f \(-perm -4000 -o -perm -2000 \) -exec ls -l {} \;

If the setuid and setgid bits are set, an executable can perform a task that requires other rights, such as root privileges. However, buffer overrun attacks can exploit such executables to run unauthorized code with the rights of the exploited process.

If you want to stop a setuid and setgid executable from being used by non-root users, you can use the following commands to unset the setuid or setgid bit:

```
# chmod u-s file
# chmod g-s file
```

For example, you could use the chmod command to unset the setuid bit for the /bin/ping6 command:

```
# ls -al /bin/ping6
-rwsr-xr-x. 1 root root 36488 May 20 2011 /bin/ping6
# chmod u-s /bin/ping6
# ls -al /bin/ping6
-rwxr-xr-x. 1 root root 36488 May 20 2011 /bin/ping6
```

The following table lists programs for which you might want to consider unsetting setuid and setgid:

Program File	Bit Set	Description of Usage
/bin/ping	setuid	Sends an ICMP ECHO_REQUEST to a network host.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Checking User Accounts and Privileges

Program File	Bit Set	Description of Usage
/bin/ping6	setuid	Sends an ICMPv6 ECHO_REQUEST to a network host.
/bin/cgexec	setgid	Runs a task in a control group.
/sbin/mount.nfs	setuid	Mounts an NFS file system.
		Note /sbin/mount.nfs4,/sbin/ umount.nfs, and /sbin/ umount.nfs4 are symbolic links to this file.
/sbin/netreport	setgid	Requests notification of changes to network interfaces.
/usr/bin/chage	setuid	Finds out password aging information (via the -1 option).
/usr/bin/chfn	setuid	Changes finger information.
/usr/bin/chsh	setuid	Changes the login shell.
/usr/bin/crontab	setuid	Edits, lists, or removes a crontab file.
/usr/bin/wall	setgid	Sends a system-wide message.
/usr/bin/write	setgid	Sends a message to another user.
/usr/bin/Xorg	setuid	Invokes the X Windows server.
/usr/libexec/openssh/ ssh-keysign	setuid	Runs the SSH helper program for host-based authentication.
/usr/sbin/suexec	setuid	Switches user before executing external CGI and SSI programs. This program is intended to be used by the Apache HTTP server. For more information, see http:// httpd.apache.org/docs/2.2/suexec.html.
/usr/sbin/usernetctl	setuid	Controls network interfaces. Permission for a user to alter the state of a network inerface also requires USERCTL=yes to be set in the interface file. You can also grant users and groups the privilege to run the ip command by creating a suitable entry in the /etc/sudoers file.

Note

This list is not exhaustive as many optional packages contain setuid and setgid programs.

5.11 Checking User Accounts and Privileges

Check the system for unlocked user accounts on a regular basis, for example using a command such as the following:

```
# for u in `cat /etc/passwd | cut -d: -f1 | sort`; do passwd -S $u; done
abrt LK 2012-06-28 0 99999 7 -1 (Password locked.)
adm LK 2011-10-13 0 99999 7 -1 (Alternate authentication scheme in use.)
apache LK 2012-06-28 0 99999 7 -1 (Password locked.)
avahi LK 2012-06-28 0 99999 7 -1 (Password locked.)
avahi-autoipd LK 2012-06-28 0 99999 7 -1 (Password locked.)
bin LK 2011-10-13 0 99999 7 -1 (Alternate authentication scheme in use.)
...
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Checking User Accounts and Privileges

In the output from this command, the second field shows if a user account is locked (LK), does not have a password (NP), or has a valid password (PS). The third field shows the date on which the user last changed their password. The remaining fields show the minimum age, maximum age, warning period, and inactivity period for the password and additional information about the password's status. The unit of time is days.

Use the passwd command to set passwords on any accounts that are not protected.

Use passwd -1 to lock unused accounts. Alternatively, use userdel to remove the accounts entirely.

For more information, see the passwd(1) and userdel(8) manual pages.

To specify how users' passwords are aged, edit the following settings in the /etc/login.defs file:

Setting	Description
PASS_MAX_DAYS	Maximum number of days for which a password can be used before it must be changed. The default value is 99,999 days.
PASS_MIN_DAYS	Minimum number of days that is allowed between password changes. The default value is 0 days.
PASS_WARN_AGE	Number of days warning that is given before a password expires. The default value is 7 days.

For more information, see the login.defs(5) manual page.

To change how long a user's account can be inactive before it is locked, use the usermod command. For example, to set the inactivity period to 30 days:

usermod -f 30 username

To change the default inactivity period for new user accounts, use the useradd command:

useradd -D -f 30

A value of -1 specifies that user accounts are not locked due to inactivity.

For more information, see the useradd(8) and usermod(8) manual pages.

Verify that no user accounts other than root have a user ID of 0.

awk -F":" '\$3 == 0 { print \$1 }' /etc/passwd
root

If you install software that creates a default user account and password, change the vendor's default password immediately. Centralized user authentication using an LDAP implementation such as OpenLDAP can help to simplify user authentication and management tasks, and also reduces the risk arising from unused accounts or accounts without a password.

By default, an Oracle Linux system is configured so that you cannot log in directly as root. You must log in as a named user before using either su or sudo to perform tasks as root. This configuration allows system accounting to trace the original login name of any user who performs a privileged administrative action. If you want to grant certain users authority to be able to perform specific administrative tasks via sudo, use the visudo command to modify the /etc/sudoers file. For example, the following entry grants the user erin the same privileges as root when using sudo, but defines a limited set of privileges to frank so that he can run commands such as chkconfig, service, rpm, and yum:

erin ALL=(ALL) ALL

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Checking User Accounts and Privileges

frank ALL= SERVICES, SOFTWARE

Oracle Linux supports the pluggable authentication modules (PAM) feature, which makes it easier to enforce strong user authentication and password policies, including rules for password complexity, length, age, expiration and the reuse of previous passwords. You can configure PAM to block user access after too many failed login attempts, after normal working hours, or if too many concurrent sessions are opened.

PAM is highly customizable by its use of different modules with customisable parameters. For example, the default password integrity checking module pam_cracklib.so tests password strength. The PAM configuration file (/etc/pam.d/system-auth) contains the following default entries for testing a password's strength:

password requisite pam_cracklib.so try_first_pass retry=3 type= password sufficient pam_unix.so sha512 shadow nullok try_first_pass use_authtok password required pam_deny.so

The line for pam_cracklib.so defines that a user gets three attempts to choose a good password. From the module's default settings, the password length must a minimum of six characters, of which three characters must be different from the previous password.

The line for pam_unix.so specifies that the module is not to perform password checking (pam_cracklib will already have performed such checks), to use SHA-512 password hashing, to allow access if the existing password is null, and to use the /etc/shadow file.

You can modify the control flags and module parameters to change the checking that is performed when a user changes his or her password, for example:

password required pam_cracklib.so retry=3 minlen=8 difok=5 minclass=-1 password required pam_unix.so use_authtok sha512 shadow remember=5 password required pam_deny.so

The line for pam_cracklib.so defines that a user gets three attempts to choose a good password with a minimum of eight characters, of which five characters must be different from the previous password, and which must contain at least one upper case letter, one lower case letter, one numeric digit, and one non-alphanumeric character.

The line for pam_unix.so specifies that the module is not to perform password checking, to use SHA-512 password hashing, to use the /etc/shadow file, and to save information about the previous five passwords for each user in the /etc/security/opasswd file. As nullok is not specified, a user cannot change his or her password if the existing password is null.

The omission of the try_first_pass keyword means that the user is always asked for their existing password, even if he or she entered it for the same module or for a previous module in the stack.

Alternative modules are available for password checking, such as pam_passwdqc.so.

For more information, see Section 3.5, "Configuring and Using Pluggable Authentication Modules" and the pam_cracklib(8), pam_deny(8), pam_passwdqc(8), and pam_unix(8) manual pages.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible.

Chapter 6 Using OpenSCAP to Scan for Vulnerabilities

Table of Contents

6.1 About SCAP	
6.2 Installing the SCAP Packages	
6.3 About the oscap Command	
6.4 Displaying the Available SCAP Information	
6.5 Displaying Information About a SCAP File	
6.6 Displaying Available Profiles	
6.7 Validating OVAL and XCCDF Files	
6.8 Running a Scan Against a Profile	
6.9 Generating a Full Security Guide	
6.10 Running an OVAL Auditing Scan	

This chapter describes how to use OpenSCAP to scan your Oracle Linux system for security vulnerabilities.

6.1 About SCAP

The Security Content Automation Protocol (SCAP) provides an automated, standardized methodology for managing system security, including measuring and managing system vulnerability, and evaluating policy compliance against security standards such as the Federal Information Security Management Act (FISMA). The U.S. government content repository for SCAP standards is the National Vulnerability Database (NVD), which is managed by the National Institute of Standards and Technology (NIST).

Oracle Linux provides the following SCAP packages for Oracle Linux 6:

openscap-utils	The openscap-utils package contains command-line tools that use the OpenSCAP library. This package previously included the oscap command-line configuration and vulnerability scanner, but this is now made available separately in the openscap-scanner package. The openscap-scanner package is installed as a dependency when you install the openscap-utils package.
openscap-scanner	Provides the oscap command-line configuration and vulnerability scanner, which can perform compliance checking against SCAP content including the SCAP Security Guide. This is a dependency of the openscap-utils package.
openscap	Provides the OpenSCAP open-source libraries for generating SCAP- compliance documentation. OpenSCAP received SCAP 1.2 certification from NIST in April 2014.
scap-security-guide	Provides system-hardening guidance in SCAP format, including links to government requirements. The guide provides security profiles that you can modify to comply with the security policies that you have established for your site.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Installing the SCAP Packages

6.2 Installing the SCAP Packages

Use yum to install the SCAP packages from the $ol6_x86_64_latest$ channel on ULN or the $ol6_latest$ repository on the Oracle Linux Yum Server:

yum install scap-security-guide

6.3 About the oscap Command

The oscap command has the following general syntax:

oscap [options] module operation [operation_options_and_arguments]

oscap supports the following module types:

сре	Performs operations using a Common Platform Enumeration (CPE) file.
cve	Performs operations using a Common Vulnerabilities and Exposures (CVE) file.
CVSS	Performs operations using a Common Vulnerability Scoring System (CVSS) file.
ds	Performs operations using a SCAP Data Stream (DS).
info	Determines a file's type and prints information about the file.
oval	Performs operations using an Open Vulnerability and Assessment Language (OVAL) file.
xccdf	Performs operations using a file in eXtensible Configuration Checklist Description Format (XCCDF).

The info, oval, and xccdf modules are the most generally useful for scanning Oracle Linux systems.

The operations that oscap can perform depend on the module type. The following operations are the most generally useful with the oval and xccdf modules on Oracle Linux systems:

eval	For an OVAL file, Oscap probes the system, evaluates each definition in the file, and prints the results to the standard output.
	For a specified profile in an XCCDF file, oscap tests the system against each rule in the file and prints the results to the standard output.
generate	For an OVAL XML results file, generate report converts the specified file to an HTML report.
	For an XCCDF file, generate guide outputs a full security guide for a specified profile.
validate	Validates an OVAL or XCCDF file against an XML schema to check for errors.

For more information, see the oscap(8) manual page.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Displaying the Available SCAP Information

6.4 Displaying the Available SCAP Information

To display the supported SCAP specifications, any loaded plug-in capabilities, the locations of schema, Common Platform Enumeration (CPE), and probe files, inbuilt CPE names, and supported Open Vulnerability and Assessment Language (OVAL) objects and associated SCAP probes, use the oscap -v command, for example:

```
# oscap -V

6.5 Displaying Information About a SCAP File

To display information about a SCAP file, use the oscap info command, for example:

```
# oscap info com.oracle.elsa-2017.xml
Document type: OVAL Definitions
OVAL version: 5.3
Generated: 2017-06-01T00:00:00
Imported: 2017-06-13T23:12:06
```

This output shows that the file com.oracle.elsa-2017.xml is an OVAL definitions file.

6.6 Displaying Available Profiles

You can use the oscap info command to display the profiles that are supported by a checklist file such as the SCAP Security Guide, for example:

```
# oscap info "/usr/share/xml/scap/ssg/content/ssg-rhel6-xccdf.xml"
Document type: XCCDF Checklist
Checklist version: 1.1
Imported: 2017-02-22T14:53:20
Status: draft
```

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Validating OVAL and XCCDF Files

```
Generated: 2017-02-22
Resolved: true
Profiles:
        standard
        CS2
        common
        server
        stig-rhel6-server-upstream
        usgcb-rhel6-server
        rht-ccp
        CSCF-RHEL6-MLS
        C2S
        pci-dss
       nist-cl-il-al
Referenced check files:
        ssg-rhel6-oval.xml
                system: http://oval.mitre.org/XMLSchema/oval-definitions-5
```

This output shows that ssg-rhel6-xccdf.xml provides several different profiles. Each profile contains generic security recommendations that apply to all Oracle Linux installations and additional security recommendations that are specific to the intended usage of a system.

Note

The provided profiles might or might not be appropriate to your system. However, you can use them to create new profiles that test compliance with your site's security policies.

6.7 Validating OVAL and XCCDF Files

To validate an OVAL or XCCDF file against its schema, use the oscap validate command and examine the exit code, for example:

```
# oscap oval validate com.oracle.elsa-2017.xml \
    && echo "ok" || echo "exit code = $? not ok"
    ok
# oscap xccdf validate /usr/share/xml/scap/ssg/content/ssg-rhel6-xccdf.xml \
    && echo "ok" || echo "exit code = $? not ok"
    ok
```

An exit code of 0 indicates that the file is valid, 1 indicates an error prevented validation, and 2 indicates that the file is invalid. Error messages are written to the standard error output.

6.8 Running a Scan Against a Profile

To scan a system against an XCCDF profile, use the oscap xccdf eval command, for example:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Running a Scan Against a Profile

Ident CCE-26639-5 Result fail Title Ensure /var/log Located On Separate Partition Rule partition_for_var_log Ident CCE-26215-4 Result fail . . . Title Mount Remote Filesystems with nosuid Rule use_nosuid_option_on_nfs_mounts Ident CCE-26972-0 Result pass Title Require Client SMB Packet Signing, if using smbclient Rule require_smb_client_signing Ident CCE-26328-5 Result fail Title Require Client SMB Packet Signing, if using mount.cifs Rule require_smb_client_signing_mount.cifs Ident CCE-26792-2 Result pass

This example scan performs the scan against the server profile of the ssg-rhel6-xccdf.xml checklist using the ssg-rhel6-cpe-dictionary.xml CPE dictionary, and outputs the XML results and HTML report files to /tmp and /var/www/html respectively. Any rule in a profile that results in a fail potentially requires the system to be reconfigured.

You can view the HTML report in a browser as shown in Figure 6.1.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Generating a Full Security Guide

6.9 Generating a Full Security Guide

To create a full security guide for a system based on an XCCDF profile, use the oscap xccdf generate guide command, for example:

You can view the security guide in a browser as shown in Figure 6.2.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Running an OVAL Auditing Scan

6.10 Running an OVAL Auditing Scan

Oracle provides OVAL definitions for all errata on ULN. You can use these definitions to ensure that all applicable errata are installed on an Oracle Linux system. For example, Spacewalk allows you to schedule regular auditing scans.

The following OVAL definition files are available:

com.oracle.elsa- <i>cve</i> .xml	OVAL definition file for a single ELSA security patch. For example, com.oracle.elsa-20150377.xml relates to ELSA-2015-0377.
com.oracle.elsa-year.xml.	Compressed archive of OVAL definition files for all ELSA patches released in a given <i>year</i> .

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Running an OVAL Auditing Scan

com.oracle.else-
all.xml.bz2Compressed archive of all applicable OVAL definition files for all
available ELSA patches.

To download an OVAL definitions file and perform an audit on a system:

1. Use wget or a similar command to download a definitions file from https://linux.oracle.com/security, for example:

wget https://linux.oracle.com/security/oval/com.oracle.elsa-2017.xml.bz2

2. In the definitions file is a compressed bz_2 archive, use bz_{1p2} to extract the OVAL definitions file:

bzip2 -d com.oracle.elsa-2017.xml.bz2

3. Use oscap oval eval to audit a system using an OVAL definitions file, for example:

```
# oscap oval eval --results /tmp/elsa-results-oval.xml \
  --report /var/www/html/elsa-report-oval.html \
  /tmp/com.oracle.elsa-2017.xml
Definition oval:com.oracle.elsa:def:20173580: false
Definition oval:com.oracle.elsa:def:20173579: true
Definition oval:com.oracle.elsa:def:20173576: false
Definition oval:com.oracle.elsa:def:20173575: false
Definition oval:com.oracle.elsa:def:20173574: true
Definition oval:com.oracle.elsa:def:20173567: false
Definition oval:com.oracle.elsa:def:20173566: false
Definition oval:com.oracle.elsa:def:20173565: true
Definition oval:com.oracle.elsa:def:20173539: true
Definition oval:com.oracle.elsa:def:20173538: false
Definition oval:com.oracle.elsa:def:20173537: false
Definition oval:com.oracle.elsa:def:20173535: false
Evaluation done.
```

This example scan uses the OVAL definitions in com.oracle.elsa-2017.xml and outputs the XML results and HTML report files to /tmp and /var/www/html respectively. A result of true for a patch means that it has not been applied to a system; a result of false means that it has been applied.

If you generate an XML results file but not the HTML report, you can use oscap oval generate report to convert the results file to an HTML report, for example:

You can view the HTML report in a browser as shown in Figure 6.3.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Running an OVAL Auditing Scan

Chapter 7 FIPS 140-2 Compliance in Oracle Linux

Table of Contents

validation

7.1 FIPS Validated Cryptographic Modules for Oracle Linux	. 79
7.2 Enabling FIPS Mode on Oracle Linux	
7.3 Installing FIPS Validated Cryptographic Modules for Oracle Linux	. 82
7.4 Installing and Using the OpenSSL FIPS Object Module	. 82
7.4.1 Installing the OpenSSL FIPS Object Module	. 83
7.4.2 Using the OpenSSL FIPS Object Module	. 83

Oracle Linux provides a set of cryptographic libraries, services, and user-level cryptographic applications that are validated at the Federal Information Processing Standard (FIPS) Publication 140-2.

FIPS Publication 140-2, Security Requirements for Cryptographic Modules, specifies the security requirements that must be satisfied by a cryptographic module that is used within a security system to protect sensitive, but unclassified information. The NIST/CSE Cryptographic Module Validation Program (CMVP) validates cryptographic modules to FIPS 140-2. Validated products are accepted by the Federal agencies of both the USA and Canada for the protection of sensitive or designated information.

7.1 FIPS Validated Cryptographic Modules for Oracle Linux

Oracle has completed FIPS 140-2 Level 1 certifications for cryptographic components that reside within Oracle Linux 6.9.

Completed certifications include those that are listed in the following table.

Cryptographic Module Name	Package Versions	Certificate Number
Oracle Linux OpenSSL Cryptographic Module	openssl-1.0.1e-57.0.1.el6.x86_64	3017
Oracle Linux 6 OpenSSH Client Cryptographic Module	openssh- clients-5.3p1-122.el6.x86_64	3030
Oracle Linux 6 OpenSSH Server Cryptographic Module	openssh- server-5.3p1-122.el6.x86_64	3031
Oracle Linux 6 NSS Cryptographic Module	nss- softokn-3.14.3-23.3.0.1.el6_8.x86_	3111 _64
Oracle Linux 6 Libreswan Cryptographic Module	libreswan-3.15-7.5.0.1.el6_9.x86_6	4 3170
Oracle Linux 6 Unbreakable Enterprise Kernel	kernel- uek-4.1.12-124.16.4.el6uek.x86_64	3348
Oracle Linux 6 Kernel Crypto API Cryptographic Module	kernel-2.6.32-754.3.5.0.1.el6.x86_	6 3142 1pm
List of modules that are currently in FIPS 140-2	The site provides the following informatio	n for each module:

79

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Enabling FIPS Mode on Oracle Linux

- Name and description of the module.
- Package version or versions for the module.
- Status of the FIPS 140-2 validation process.

Important

To achieve compliance with FIPS Publication 140-2, you must use the package version that the *Security Policy* document specifies for each respective module *only*. You cannot install and use other versions of the cryptographic modules.

• Instructions on how to configure the module for FIPS mode. You should refer to *Section 10* of the *Security Policy* document when you install the module to verify that the package was FIPS 140-2 validated and to ensure that you correctly enable the module for FIPS mode.

7.2 Enabling FIPS Mode on Oracle Linux

You must enable FIPS mode on Oracle Linux prior to using FIPS validated cryptographic modules. The following procedure describes how to configure Oracle Linux to use only cryptographic algorithms that are FIPS-validated.

- 1. Depending on the type of FIPS module that you plan to install, do one of the following:
 - If you plan to install FIPS validated cryptographic modules for Oracle Linux, ensure that the system is running Oracle Linux 6 Update 9 or later.
 - If you plan to install the OpenSSL FIPS object module, ensure that the system is Oracle Linux 6 Update 5 or later.
- 2. Ensure that your system is registered with the Unbreakable Linux Network (ULN) and that you are subscribed to the ol6_x86_64_security_validation and ol6_x86_64_latest channels.

If you are using the Oracle Linux yum server, enable the ol6_security_validation and ol6_latest repositories as follows:

yum-config-manager --enable ol6_security_validation ol6_latest

3. Install the dracut-fips package.

yum install dracut-fips

The dracut-fips package provides the modules to build a dracut initramfs file system that performs an integrity check.

- 4. If the system CPU supports AES New Instructions (AES-NI), install the package.
 - Run the following command to check whether the system supports AES-NI:

grep aes /proc/cpuinfo

• To install the package:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Enabling FIPS Mode on Oracle Linux

yum install dracut-fips-aesni

5. Recreate the initramfs file system.

dracut -f

- 6. Perform the following steps to configure the kernel command line in the grub.conf file so that the system boots into FIPS mode:
 - a. Identify the boot partition and the UUID of the partition, for example:

```
# df /boot
Filesystem 1K-blocks Used Available Use% Mounted on
/dev/sda1 508588 294476 214112 58% /boot
# blkid /dev/sda1
/dev/sda1: UUID="a305c68f-3e04-4c53-a566-9d67c12ff293" TYPE="xfs"
```

- b. As the root user, edit the /etc/grub.conf file as follows:
 - i. Add the fips=1 option to the boot loader configuration.

```
GRUB_CMDLINE_LINUX="vconsole.font=latarcyrheb-sun16
rd.lvm.lv=ol/swap rd.lvm.lv=ol/root crashkernel=auto
vconsole.keymap=uk rhgb quiet fips=1"
```

ii. If the contents of /boot reside on a partition other than the root partition, you must use the boot=UUID=boot_UUID line to the boot loader configuration to specify that the device be mounted on /boot when the kernel loads.

```
GRUB_CMDLINE_LINUX="vconsole.font=latarcyrheb-sun16
  rd.lvm.lv=ol/swap rd.lvm.lv=ol/root crashkernel=auto
  vconsole.keymap=uk rhgb quiet
  boot=UUID=6046308a-75fc-418e-b284-72d8bfad34ba fips=1"
```

iii. Save the changes.

These steps are required for FIPS to perform kernel validation checks, where it verifies the kernel against the provided HMAC file in the /boot directory.

Note

On systems that are configured to boot with UEFI, /boot/efi is located on a dedicated partition, as it is formatted specifically to meet UEFI requirements, which does not automatically mean that /boot is located on a dedicated partition.

Only use the boot = parameter if /boot is located on a dedicated partition. If the parameter is specified incorrectly or points to a non-existent device, the system might not boot.

If your system is no longer able to boot, you can try to modify the kernel boot options in grub to specify an alternate device for the boot=UUID=boot_UUID parameter, or remove the parameter entirely.

- 7. Rebuild the GRUB configuration as follows:
 - a. On BIOS-based systems, run the following command:

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Installing FIPS Validated Cryptographic Modules for Oracle Linux

grub2-mkconfig -o /boot/grub2/grub.cfg

· On UEFI-based systems, run the following command:

grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg

b. To ensure proper operation of the in-module integrity verification, prelinking must be disabled on all system files.

By default, the prelink package is not installed on the system. However, if it is installed, disable prelinking on all libraries and binaries as follows:

- i. Set PRELINKING=no in the /etc/sysconfig/prelink configuration file.
- ii. If the libraries were already prelinked, undo the prelink on all of the system files as follows:

prelink -u -a

8. Reboot the system, then run the following command to verify that FIPS is enabled:

```
# cat /proc/sys/crypto/fips_enabled
1
```

A response of 1 indicates that FIPS is enabled.

7.3 Installing FIPS Validated Cryptographic Modules for Oracle Linux

After you enable FIPS mode on Oracle Linux, you can install FIPS validated cryptographic modules, as required.

To install FIPS validated cryptographic modules, refer to Section 10 of the Security Policy document for the module that you plan to install.

The Security Policy document explains how to verify that the package was FIPS 140-2 validated as well as how to configure the module for FIPS mode. See Section 7.1, "FIPS Validated Cryptographic Modules for Oracle Linux". The certificate number provides a link to the NIST FIPS 140 validation page. This page provides details about FIPS certification and the Security Policy document.

Note

The OpenSSL FIPS object module is separate to the FIPS cryptographic modules for Oracle Linux. The *Security Policy* document for this module is not specific to Oracle Linux. For instructions on installing and using this module, see Section 7.4, "Installing and Using the OpenSSL FIPS Object Module".

7.4 Installing and Using the OpenSSL FIPS Object Module

The OpenSSL FIPS object module is a software library that provides a C-language application program interface (API) that other processes can use for cryptographic functionality.

You can install and use the following package for the OpenSSL FIPS object module on an Oracle Linux 6 Update 5 or later system with the x86-64 architecture:

• /usr/lib64/libcrypto.so.1.0.1* (64-bit library)

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Installing the OpenSSL FIPS Object Module

• /usr/lib64/libssl.so.1.0.1* (64-bit library)

7.4.1 Installing the OpenSSL FIPS Object Module

To install the OpenSSL FIPS object module, do the following:

1. If your system is registered with ULN, log in to ULN and enable the ol6_x86_64_addons channel for the system.

Alternatively, if you are using the Oracle Linux yum server, you can enable the ol6_addons repository. For example:

```
# yum-config-manager --enable ol6_addons
```

2. Remove the existing openssl package and install the openssl-fips-1.0.1* package. You can use yum shell to perform these transactions as follows:

```
# yum -y shell <<EOF
remove openss1
install openss1-fips-1.0.1*
run
EOF</pre>
```

You cannot use separate yum remove and yum install commands as yum itself depends on the OpenSSL library being available.

Alternatively, download the openssl-fips-1.0.1* package and use the rpm command instead:

```
# rpm -e --nodeps openssl
# rpm -ivh openssl-fips-1.0.1*.rpm
```

3. Remove the existing SSH host keys:

rm /etc/ssh/ssh_host*

OpenSSH uses the FIPS-validated OpenSSL library modules to generate new, FIPS-approved keys when the system is next rebooted. (Under FIPS mode, ssh-keygen can create new RSA host keys in /etc/ssh, but not DSA keys, and it displays key fingerprints as SHA1 hashes instead of as MD5 hashes.)

4. Reboot the system.

Note

While the system is rebooting, generate input events by pressing keys at random or by moving the mouse. You should create at least 256 such events to ensure that the system has sufficient entropy available for key generation.

7.4.2 Using the OpenSSL FIPS Object Module

If the kernel command line specifies a fips=1 entry, the value of /proc/sys/crypto/fips_enabled is set to 1, which causes the OpenSSL library module to initialize the FIPS-approved mode of operation automatically. To handle automatic initialization, an application that uses the module must call one of the following routines:

void Calls OPENSSL_init() implicitly and adds all approved algorithms to OPENSSL_add_all_algorithmstheceVP API in FIPS-approved mode.

The software described in this documentation is either in Extended Support or Sustaining Support. See https://www.oracle.com/us/support/library/enterprise-linux-support-policies-069172.pdf for more information. Oracle recommends that you upgrade the software described by this documentation as soon as possible. Using the OpenSSL FIPS Object Module

void Performs basic initialization of the library and initialize FIPS-approved OPENSSL_init_library(void)mode without setting up the EVP API with supported algorithms.

voidCalls OPENSSL_init() implicitly, adds algorithms that are necessarySSL_library_init(void)for TLS protocol support and initializes the SSL library.

To put the library into FIPS-approved mode explicitly, an application can call the int FIPS_mode_set(int on) function. If the value of on is set to 1, the library switches from non-approved to approved mode. If any self tests or integrity verification tests fail, the library is put into the error state and the function returns 0. If the tests succeed, the function returns 1. If the value of on is set to 0, the library switches to non-approved mode. Alternatively, the application can call OPENSSL_conf(const char *config_name) to enable FIPS mode by reading the alg_section that is defined for the config_name entry in the standard configuration file (openss1.conf), for example:

```
[ config_name ]
alg_section = algsec
...
[ algsec ]
fips_mode = yes
```

OPENSSL_config() does not return a value. If there is an error in the configuration, the function writes a message to the standard error and forces the application to exit. To provide better error control, an application can call the CONF_modules_load_file() function instead.

An application can use the following functions to query the OpenSSL library module:

int FIPS_mode(void) Returns 1 if the module is in FIPS-approved mode; otherwise it returns
0.

Returns 1 if the module is in the error state; otherwise it returns 0.

FIPS_selftest_failed(void)

To set the FIPS random number generator key and internal state to zero, an application can call the void RAND_cleanup(void) function.

int

Note

If you set the value of the OPENSSL_FIPS environment variable to 1, the openssl binary that is included in the openssl-fips-1.0.1* package, and which has been built using the FIPS-compliant OpenSSL library, uses only FIPS 140-2 approved algorithms. The value of OPENSSL_FIPS has no effect on the FIPS mode of the system. Do not assume that the value of OPENSSL_FIPS has any effect on other applications that use the FIPS-compliant OpenSSL library.

For more information about using the OpenSSL library with FIPS, see https://www.openssl.org/docs/fips/ UserGuide-2.0.pdf.
